RESULTS: In HFD vs LFD rats, GU of insulin-stimulated single fibers was decreased in all fiber types ($P<0.05$) except type I. Insulin-independent GU in single fibers of each fiber type was increased IPEX ($P<0.05$). Glycogen content decreased in all fiber types IPEX ($P<0.01$). In HFD rats insulin-stimulated GU 3.5hPEX was increased in all fiber types ($P<0.05$) except type I. GLUT4 content was unchanged by diet or exercise in each fiber type.
CONCLUSIONS: Greater insulin-independent GU and decreased glycogen IPEX provides compelling evidence that each fiber type, including type I fibers, was recruited. Neither diet nor exercise effects on GU were attributable to altered GLUT4 abundance regardless of fiber type. Earlier research using whole muscles from normal rats demonstrated that exercise causes greater GLUT4 translocation concomitant with greater phosphorylation of AS160 protein, a key regulator of GLUT4 translocation. Our working hypothesis is that fiber type-selective improvement in insulin-stimulated GU at 3hPEX in insulin resistant rats is attributable to fiber type-selective increases of AS160 phosphorylation that facilitates greater GLUT4 translocation.

C-08   Thematic Poster - **Mental Health and Exercise**

Acute Exercise Effects Among Young Adults with Subclinical Generalized Anxiety Disorder: Replication and Expansion

Matthew P. Herring[1], Derek C. Monroe[2], Brett R. Gordon[1], Mark J. Campbell[1]. *[1]University of Limerick, Limerick, Ireland. [2]University of California Irvine, Irvine, CA.*

(No relevant relationships reported)

Little is known about the effects of acute exercise among individuals with subclinical Generalized Anxiety Disorder (GAD), a disorder marked by persistent worry, elevated anxiety, and low energy and fatigue. Recent findings supported the positive effects of acute exercise on worry, state anxiety, and feelings of energy and fatigue among young women with subclinical GAD. However, exercise effects among young men with subclinical GAD are unstudied. **PURPOSE**: To replicate initial findings, to compare acute responses to aerobic exercise and quiet rest among young men with subclinical GAD, and to explore potential sex-related differences. **METHODS:** Thirty-five young adults (21.4±2.3y; 19M; 16F) with Penn State Worry Questionnaire scores ≥45 (60±8) completed 30-min treadmill running at ~71.2±0.04 percent heart rate reserve and 30-min seated quiet rest in counterbalanced order. Outcomes included worry, worry engagement, absence of worry, state anxiety, and feelings of energy and fatigue. RM-ANOVA examined differences across condition and time. Sex-related differences were

explored with RM-ANOVA and paired samples *t*-tests stratified by sex. Hedges' *d* effect sizes were calculated to quantify and compare magnitude of change in the full sample, men, and women. **RESULTS:** There were no significant baseline differences between sexes. Compared to quiet rest, exercise significantly improved state anxiety ($p<0.04$; $d=0.27$) and feelings of energy ($p<0.001$; $d=1.09$). Small improvements were found for worry ($d=0.22$), worry engagement ($d=0.18$), and feelings of fatigue ($d=0.21$). Although RM-ANOVA did not support significant differences between sexes, exercise effects on worry, worry engagement, absence of worry, and feelings of energy were stronger among females. Moderate-to-large improvements in worry ($d=0.53$), absence of worry ($d=0.38$), and feelings of energy ($d=1.35$) were found among women. Among men, moderate-to-large improvements in state anxiety ($d=0.37$) and feelings of energy ($d=0.92$) and fatigue ($d=0.40$) were found. **CONCLUSION:** Findings support initial reports of positive effects of acute aerobic exercise on worry, state anxiety, and feelings of energy and fatigue among young women with subclinical GAD. Findings also provide initial support for these positive effects among young men with subclinical GAD.

Working It Out: Acute Exercise to Combat Anxiety and Depression in Individuals Living with PTSD

Daniel R. Greene[1], Steven J. Petruzzello, FACSM[2]. *[1]Augusta University, Augusta, GA. [2]University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

Mental health problems are increasingly prevalent in today's society. Exercise interventions have been shown to significantly reduce symptoms of many mental health problems, but often overlooked is the potential for exercise to reduce symptoms of Post-Traumatic Stress Disorder (PTSD) and comorbid psychological conditions (e.g., anxiety & depression). **Purpose:** Examine the acute effects of a bout of moderate intensity continuous aerobic exercise (MICE) and a bout of high-intensity interval exercise (HIIE), relative to a no-exercise inactive control (SED), in participants with subsyndromal PTSD. **Methods:** Participants [N= 24, 9 males; age ($M \pm SD$); 25.9 ± 9.2 yrs; Estimated VO$_{2peak}$ ($M \pm SD$); 34.6 ± 10.2 ml·kg^{-1}·min^{-1}] completed three randomly ordered 35-min conditions (HIIE, MICE, SED) following a within subjects design. All participants met the criteria for subsyndromal PTSD (i.e., having at least one symptom in each of the major DSM-5 clusters), with an average PCL-5 score of 47.64 which exceeded the cut point for probable PTSD of 33. State Anxiety, and Depression were assessed before (Pre), immediate after (Post0), 20-minutes after (Post20), and 40-minutes after (Post40) each condition. **Results:** Anxiety and Depression were significantly reduced following all conditions. Anxiety Post40 was significantly less than Pre for HIIE [Cohen's $d = 1.05$], MICE [Cohen's $d = 0.78$], and SED [Cohen's $d = 0.53$]. Depression Post40 was significantly less than Pre for HIIE [Cohen's $d = 0.76$], MICE [Cohen's $d = 0.84$], and SED [Cohen's $d = 0.32$]. **Conclusion:** Exercise significantly reduced Anxiety and Depression to a greater extent than SED. This study provides evidence for exercise-induced short-term improvements in comorbid psychological conditions associated with PTSD. Future studies need to apply these benefits to a longitudinal program.

The Interrelationship Between Depression and Hemoglobin: Men Are Affected More Than Women

Tina Bhateja[1], Jonathan M. Saxe[2], Lewis E. Jacobson[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.*

(No relevant relationships reported)

There are 16.1 million Americans with major depressive disorder (MDD) and 3.4 million Americans with anemia. Low hemoglobin (Hb) is known to predict depressive symptoms, but seldom is the inverse examined: how does MDD affect Hb? There may be a cyclic relationship in which depression reduces engagement in physical activity and reduced activity lowers Hb. This presents possible implications for young athletes owing to higher depression scores on average than age-matched controls. **PURPOSE:** To investigate MDD as a predictor of serum Hb levels. **METHODS:** We analyzed 2,206 patients who were treated at a major hospital. All patients had Glascow Coma Scale scores ≥14, received a complete blood count with differential, and were screened for MDD. Differences in Hb between depressed and non-depressed groups were assessed with independent samples t-tests; multiple linear regression measured the effect of MDD on Hb, controlling for confounding variables. **RESULTS:** Among depressed patients, Hb was 12.16 ± 1.86 g/dL; among non-depressed patients, Hb was 13.52 ± 1.93 g/dL ($p<0.001$). This difference was more pronounced among men (14.24 vs. 12.36; $p=0.001$) than women (12.62 vs. 12.02; $p=0.165$). Across the total sample, holding constant age, sex, oximetry, blood pressure, use of dialysis, and diagnoses of diabetes, bleeding disorder, cirrhosis, cancer, and respiratory disease, depression associated with a 5.7% reduction in Hb ($p=0.035$; 95% CI: -1.38 to -0.50 g/dL). The overall model was significant ($r^2=0.299$; $p<0.001$). Among men,

the model retained significance (r^2=0.226; p<0.001) and a diagnosis of depression associated with a reduction in Hb of 1.56 g/dL (p=0.002; 95% CI: -2.56 to -0.56 g/dL). **CONCLUSIONS:** The relationship between Hb and depression may be cyclic. In our population, depression had a greater effect on Hb than diabetes and respiratory diseases, and it had the same effect as bleeding disorders. Depression, via endocrine changes and reductions in physical activity, may lower oxygen-carrying capacity of the blood, and in turn affect endurance performance. Exercise-induced oxidative stress promotes Hb synthesis. For the anemic patient, exercise may enhance mood; for the moody, exercise may enhance oxygen-carrying capacity. For the athlete and the sport psychologist, there may be further implications.

1081   Board #4   May 31 8:00 AM - 10:00 AM

Prevalence of Depression and Low Self-Esteem among Collegiate Female Track and Field Athletes

Samantha Weber, Toni M. Torres-McGehee, Eva Monsma, Allison Smith. *University of South Carolina, Columbia, SC.*
(No relevant relationships reported)

Track and field athletes are under extreme amounts of pressure to be successful as student-athletes. Their academics and demands for their events may predispose them to having low self-esteem (LSE) and mental health disorders like depression (DEP). **PURPOSE:** To examine the prevalence of LSE and DEP in collegiate, NCAA Division I track and field athletes; and to investigate differences between academic status (i.e., freshman, senior, etc.) and event type (e.g., sprinter, distance, lean events etc.). **METHODS:** Collegiate female track and field athletes (n=387) were recruited from 25 NCAA Division I Institutions to participate in an online study. Demographic information, Center for Epidemiologic Studies Depression Scale (CESD) to estimate the risk for DEP and the Rosenburg Self-Esteem Scale for LSE were completed. **RESULTS:** The prevalence of DEP risk was estimated to be 65.1% (n=252). No significant differences were found between academic status; however the highest DEP risk was freshman (19.4%) then sophomores (17.3%). Significant differences were found between event type and DEP within sprinters, middle distance runners, and distance runners (11.4% - 19.6%, $p = \leq 0.01$). Overall, LSE was 10.9% (n=42), with LSE found highest among sophomores (4.1%) then freshman (3.9%). No significant differences were found for event type and LSE; however, distance runners were at the highest risk for LSE with 4.4%. **CONCLUSIONS:** Female track and field athletes demonstrated a high risk of DEP and a lower risk for LSE. Freshman and sophomores demonstrated the highest risk for DEP and LSE, potentially due to the new academic and collegiate sport demands placed upon them. Overall, it is perceived the more acclimated (upper classman) a student-athlete is, the lower risk they have for DEP and LSE. Additionally, distance runners were found to have a higher risk of DEP and LSE; therefore, further examination is needed to draw conclusions to what additional pressures they may have. With a risk of DEP and LSE being most prevalent among younger collegiate athletes, universities need to focus on establishing a support system or mentoring program for incoming student-athletes.

1082   Board #5   May 31 8:00 AM - 10:00 AM

Associations Between Physical Activity and Depression: Results from The Irish Longitudinal Study on Ageing

Cillian P. McDowell[1], Rodney K. Dishman, FACSM[2], Mats Hallgren[3], Ciaran MacDonncha[1], Matthew Herring[1]. *[1]University of Limerick, Limerick, Ireland. [2]University of Georgia, Athens, GA. [3]Karolinska Institutet, Stockholm, Sweden.*
(No relevant relationships reported)

Physical activity (PA) can protect against depression. However, few studies have assessed the influence of dose, including whether meeting PA guidelines is sufficient or if greater benefits can be derived from greater volumes of PA. **PURPOSE**: To examine associations between different volumes of MVPA and walking and prevalence and incidence of depressive symptoms and depression status using data from The Irish Longitudinal Study on Ageing. **METHODS**: Participants (N=4,556; 56.7% female) aged ≥50 years completed the International PA Questionnaire (IPAQ) at baseline, and the Center for Epidemiological Studies Depression Scale at baseline and two years later. Participants were classified as meeting World Health Organisation PA guidelines or not, divided into IPAQ categories, and divided into tertiles based on weekly minutes of walking. Prospective analyses included 4,146 non-depressed respondents. **RESULTS**: After adjustment for age, sex, waist circumference, social class, and smoking, odds of prevalent depression were 45.2% (OR=0.55, 95%CI: 0.44-0.69; p<0.001) lower among those meeting PA guidelines, 40.3% (OR=0.60, 0.47-0.76; p<0.001) and 53.2% (OR=0.47, 0.66-0.61; p<0.001) lower among those in minimally-active and very-active IPAQ categories, respectively, and 24.9% (OR=0.75, 0.59-0.96; p≤0.02) and 44.1% (OR=0.56, 0.43-0.73; p<0.001) lower among those in moderate and high walking tertiles, respectively. Odds of incident depression were 24.4% (OR=0.76, 0.56-1.01; p≤0.06) lower among those meeting PA guidelines, 34.7% (OR=0.65, 0.46-0.93; p≤0.02) and 24.5% (OR=0.75, 0.77-1.07; p>0.10) lower among those in minimally-active and very-active IPAQ categories, respectively, and 22.7%

(OR=0.77, 0.54-1.09; p>0.13) and 25.6% (OR=0.74, 0.52-1.06; p>0.10) lower among those in moderate and high walking tertiles, respectively. **CONCLUSION**: Among a large, nationally representative sample of older adults, moderate and high volumes of MVPA were significantly associated with lower odds of concurrent depression and significantly and non-significantly associated with lower odds of incident depression, respectively. Meeting PA recommendations and walking were associated with significantly lower odds of concurrent depression and non-significantly lower odds of incident depression.

1083   Board #6   May 31 8:00 AM - 10:00 AM

Influence Of Omega-3 Status On Depression And Anxiety In Young Women With Obesity

Helen T. O'Connor[1], Rebecca L. Cook[1], Helen M. Parker[1], Cheyne Donges[2], Janet Franklin[3], Kate S. Steinbeck[4], Hoi Lun Cheng[4], Manohar Garg[5], Nicholas J. O'Dwyer[1]. *[1]The University of Sydney, Sydney, Australia. [2]Charles Sturt University, Bathurst, Australia. [3]Royal Prince Alfred Hospital, Sydney, Australia. [4]The Children's Hospital Westmead, Sydney, Australia. [5]The University of Newcastle, Newcastle, Australia.* (Sponsor: Melinda Manore, FACSM)
(No relevant relationships reported)

PURPOSE: Obesity is associated with an increased risk of depression and anxiety. Higher omega-3 polyunsaturated fatty acid (n-3PUFA) status may help to reduce negative consequences of obesity on mental health outcomes. This cross-sectional study aimed to investigate the relationship of obesity and n-3PUFA with depression and anxiety in young women with a normal (N) or obese (O) body mass index (BMI). **METHODS:** Healthy, young (18-35y) women (N: 18.5-24.9kg/m^2 O: >30.0kg/m^2) with no history of treatment (counselling or medication) for depression or anxiety completed the Depression, Anxiety and Stress Scale (DASS). Status of n-3PUFA was assessed using the red cell Omega-3 Index (low<4%; safe 4-8%; optimal >8%). Data were analysed via repeated measures ANOVA, ANCOVA (controlling for n-3PUFA). DASS components are reported as mean ± SD z-scores (normal <0.5, mild 0.5-1, moderate >1-2, severe >2-3, extremely severe >3). Cohen's d effect size (ES) between BMI, depression and anxiety was also determined. **RESULTS:** 299 women (N: n=157, 24.9±4.6y; O: n=142, 26.9±5.4y) completed the study. Although mean DASS scores were in the normal range, the O group had higher depression (N: -0.33±0.71, O: 0.11±0.98, p<0.001) and anxiety (N: -0.08±0.97, O: 0.29±1.23, p=0.004) scores and lower n-3PUFA status (low; safe, optimal: N: 1%, 83%, 16%, O: 8%, 85%, 8%; p<0.001) than the N group. Medium or small strengths of association were observed between obesity and depression (ES=0.52), anxiety (ES=0.34) and stress (ES=0.21). Adjusting for n-3PUFA attenuated the significance of the depression (p=0.001) and anxiety (p=0.033) scores but they still remained significantly higher for the O group. **CONCLUSIONS:** Young women with obesity had significantly higher scores for depression and anxiety. The status of n-3PUFA had a minimal impact on these scores. This study reinforces the pervasive, negative impact of obesity on mental health in young women.

1084   Board #7   May 31 8:00 AM - 10:00 AM

An Examination of Affective Change in the Absence of Physical Sensation

Kathryn M. Rougeau[1], Stephen R. Koziel[2], Steven J. Petruzzello, FACSM[2]. *[1]Oakland University, Rochester, MI. [2]University of Illinois, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)
(No relevant relationships reported)

Examination of affective responses to acute exercise has been plagued by the inability to find an appropriate control condition, as a true placebo has been elusive. This has resulted in various "control" conditions (e.g., quiet rest, reading, sitting in a chair on a treadmill, stretching). A potential option involves passive cycling. This would also provide a unique methodology for studying affective responses to activity in spinal cord injured (SCI) individuals. **PURPOSE**: To examine the psychological and physiological effects of Passive (PaC) versus Placebo cycling (PLC), both compared to Rest, in SCI individuals. **METHODS**: Heart rate (HR), Rating of Perceived Exertion (RPE), and affect (Calmness, Tension, Energy, Tiredness, State Anxiety) were recorded in 21 (11 male; 27 ± 6.52 yrs; $M \pm SD$) participants before, during and after each Rest, PaC, and PLC 25-min bout. Each cycling session consisted of identically paced warm-ups (5-min @ 35 r·min⁻¹), movement bout (15-min @ 60 r·min⁻¹), and cool-down (5-min @ 35 r·min⁻¹). **RESULTS:** PaC elicited psychological changes that varied significantly with respect to perceptions of Energy and Calmness, but not valenced (i.e., positive, negative) affect. Energy increased from Pre to Post-0 exercise (P= 0.024), then decreased Post-0 to Post-10 (P= 0.002). Enjoyment was greater following PaC relative to PLC (M_{diff}= 8.29, P= 0.06) and Rest (M_{diff}= 9.33, P=0.001). RPE was significantly higher during the PaC (M= 7.05±0.70) compared to both Rest (M= 6.11±0.08; P< 0.001) and PLC (M= 6.32±0.05; P< 0.001). There were no significant effects on physiological factors such as HR or Temperature across conditions. **CONCLUSION**: These results provide support for this methodological technique as a

THURSDAY, MAY 31, 2018

way of examining potential placebo effects of activity on affective outcomes. This also provides insights into how activity may influence affective responses in individuals with a SCI.

1085   Board #8   May 31 8:00 AM - 10:00 AM
Acute Effects of Resistance Exercise in Depressed Black/African American People Living with HIV

Sanaz Nosrat, James W. Whitworth, Nicholas J. SantaBarbara, Mark E. Louie, Joseph T. Ciccolo. *Teachers College, Columbia University, New York, NY.*
(No relevant relationships reported)

In the US, Blacks/African Americans (AA) comprise the largest proportion of People Living with HIV (PLWH). Depressive symptoms and fatigue are highly prevalent among PLWH. Depressive symptoms are linked to progression of HIV disease, and fatigue is linked to severity of depressive symptoms. Resistance exercise (RE) is shown to have psychological benefits in non-HIV depressed populations, and these benefits are hypothesized to be intensity-dependent. To date, no study has examined the use of a single bout of RE for management of affect and fatigue with depressed PLWH. **PURPOSE**: To test the acute effects of RE intensity on affect, arousal, and distress among sedentary AA PLWH who screen positive for depression. **METHODS**: Twenty-five men and 17 women ages 24-66 (47.5±11.2) with a Center for Epidemiologic Studies Depression Scale score of ≥10 completed a battery of questionnaires and 10 repetition maximum (10RM) muscular strength tests. Participants were randomized into: moderate intensity RE (MRE) (i.e., 70% of 10RM), n=21, or vigorous intensity RE (VRE) (i.e., 100% of 10RM), n=21. They had to complete 3 sets of 10 repetitions for 5 exercises. Affect, arousal, and distress were measured with the Feeling Scale, Felt Arousal Scale, and Subjective Units of Distress Scale, respectively. Measures were administered at PRE, MID, POST, at 15-minute DELAY, and at 30-minute DELAY. Changes were analyzed using ANOVAs, with Bonferroni adjustments. **RESULTS**: There were significant group x time interactions for affect (p<.05), and distress (p<.01), and main effect of time for arousal (p<.01). With MRE, affect improved PRE to POST (p<.01), PRE to DELAY15 (p<.01), and PRE to DELAY30 (p<.01), and arousal increased PRE to MID, and PRE to POST (p's<.01). In addition, distress reduced PRE to all time points (p's<.01). With VRE, affect decreased PRE to MID (p<.01), while arousal increased PRE to MID, and PRE to POST (p's<.01). In addition, distress reduced PRE to Delay15 (p<.01), and PRE to DELAY30 (p<.01). **CONCLUSIONS**: Results suggest that an acute bout of MRE is more effective than VRE in improving affect, increasing energy, and reducing distress in depressed AA PLWH. However, VRE also appears to have distress-reducing benefits. These findings should be considered when prescribing exercise for symptom management in this population.

C-09   Thematic Poster - Performance after ACL Reconstruction

Thursday, May 31, 2018, 8:00 AM - 10:00 AM
Room: CC-Lower level L100F

1086   Chair: Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*

1087   Board #1   May 31 8:00 AM - 10:00 AM
Peak and Rapid Force Deficits during Countermovement Jump Persist Longer than Reduced Jump Height post-ACL Reconstruction

Daniel G. Cobian, Demitra R. Philosophos, Jennifer L. Sanfilippo, Mikel R. Stiffler-Joachim, Bryan C. Heiderscheit. *University of Wisconsin-Madison, Madison, WI.*
(No relevant relationships reported)

Following anterior cruciate ligament reconstruction (ACLR) athletes often demonstrate persistent lower extremity biomechanical abnormalities which may inhibit return to sports and/or contribute to increased risk of re-injury. Countermovement jump (CMJ) height is an indicator of lower extremity explosiveness and athletic ability. Phase-specific CMJ ground reaction force-time curve variables provide detailed information on jump performance, and have not yet been examined in collegiate athletes post-ACLR. **PURPOSE**: To assess eccentric (ECC) and concentric (CONC) phase CMJ maximal and rapid ground reaction force (GRF) variables in collegiate athletes post-ACLR and compare with healthy controls. **METHODS**: 18 Division I athletes (12 males) post-ACLR and 18 controls matched by sport, gender, year, and position performed maximal CMJs on force plates (800

Hz) 5.7 ± 1.8 (EARLY) and 9.8 ± 1.8 months post-surgery (LATE). ECC and CONC phase peak force, rate of force development (RFD), and rate of force unloading (RFU) were computed. Variables were analyzed by 3-way mixed ANOVAs (group x limb x interval). **RESULTS**: Jump height was significantly lower in the ACLR group EARLY (ACLR: 29.7 ± 7.5 cm, CONTROL: 35.7 ± 11.3 cm), but not LATE (33.8 ± 7.6 cm). ACLR group involved (INV) limb peak and rapid force variables were significantly reduced compared to the uninvolved limb at both intervals (Limb symmetry indices: peak ECC force - EARLY: 84.1%, LATE: 96.9%; peak CONC force - EARLY: 83.8%, LATE: 90.1%; ECC RFD - EARLY: 83.3%, LATE: 82.4%, CONC RFU - EARLY: 80.3%, LATE: 90.0%). LATE post-surgery, ACLR group INV limb peak ECC force (deficit: 10.8%), peak CONC force (7.6%), ECC RFD (41.8%), and CONC RFU (22.5%) were significantly lower compared to CONTROL athletes.
CONCLUSIONS: Although CMJ height was not significantly reduced compared to healthy controls 10 months post-surgery, collegiate athletes post-ACLR present with CMJ maximal and rapid force deficits between limbs and when compared to healthy controls. These findings indicate that kinetic abnormalities persist despite minimal limitation in jump height, the most common CMJ performance metric. Deficits in rapid GRF capacity are greater than deficits in maximal GRF capacity and have practical relevance, as sports activities have limited time available for force development.

1088   Board #2   May 31 8:00 AM - 10:00 AM
Neuromuscular Training improves Sagittal Plane Hip and Knee landing Kinematics and Kinetics In Acl-reconstructed athletes

Christopher Nagelli[1], Samuel Wordeman[2], Stephanie Di Stasi[2], Joshua Hoffman[2], Tiffany Marulli[2], Timothy E. Hewett, FACSM[1]. [1]*Mayo Clinic, Rochoester, MN.* [2]*The Ohio State University, Columbus, OH.*
(No relevant relationships reported)

Deficits in hip and knee biomechanical and neuromuscular control are commonly observed in anterior cruciate ligament (ACL) reconstructed (ACLR) athletes and are associated with an elevated risk of future ACL injury. The efficacy of neuromuscular training (NMT) programs to improve hip and knee biomechanical deficits in ACLR athletes is currently unknown.**PURPOSE:** To quantify the effect of a NMT program in ACL-reconstructed athletes to improve sagittal plane landing biomechanics. The primary hypothesis tested was that sagittal plane hip and knee biomechanics associated with greater risk of ACL injury would be significantly reduced in ACLR athletes after participation in an NMT program. It was further hypothesized that following training hip and knee sagittal plane biomechanics in the ACLR cohort would not differ from a control cohort who also completed the training program.
METHODS: Eighteen ACLR and ten control athletes were recruited and completed a 12 session NMT program. Both groups of athletes participated in three-dimensional motion analysis prior to and after completion of the NMT program to evaluate hip and knee kinematics and kinetics during a drop vertical jump. Repeated measures ANOVA was conducted to determine the effect of training on kinematic and kinetic measures in ACLR athletes. In addition, a two-way ANOVA was conducted to compare post-training differences between the ACLR and control group. **RESULTS**: The ACLR athletes demonstrated significantly greater hip and knee flexion angle at initial contact and lower hip and knee flexion moment at initial contact after participation in the NMT program (p<0.05). Post-training comparison between the ACLR and control group showed no significant differences (p>0.05) in hip and knee flexion moment at initial contact and knee flexion angle at initial contact. The ACLR group landed with significantly greater (p>0.05) hip flexion angle at initial contact than the control group after training.
CONCLUSIONS: Hip and knee sagittal plane biomechanical and neuromuscular measures of ACL injury risk demonstrate significant improvements after completion of a NMT program in ACLR athletes. In addition, comparison of post-training hip and knee biomechanics between ACLR athletes and controls demonstrate recovery of biomechanical control.

1089   Board #3   May 31 8:00 AM - 10:00 AM
Biomechanical Adaptations After Exercise in Healthy and ACL Reconstructed Individuals

Lindsay V. Slater[1], Silvia Blemker[2], Jay Hertel, FACSM[2], Sue Saliba[2], Art Weltman, FACSM[2], Joe Hart, FACSM[2]. [1]*Northwestern University, Chicago, IL.* [2]*Univeristy of Virginia, Charlottesville, VA.* (Sponsor: Joe Hart, FACSM)
(No relevant relationships reported)

Athletes with history of anterior cruciate ligament (ACL) reconstruction (ACLR) who return to high level of sport are at increased risk of another ACL injury during a game. Neuromuscular fatigue during sport may result in adaptive movement patterns that increase risk of injury. **Purpose:** Compare changes in an ACLR limb and a healthy limb based on fitness level after exercise. **Methods:** Thirty-three individuals with history of ACLR (22F/11M, 22.7±23.3 months post-surgery) and 29 healthy

individuals (18F/11M) were divided into two groups based on VO$_2$max (higher fit and lower fit). Sagittal, frontal, and transverse knee, hip, and trunk kinematics and triplanar knee and hip internal moments were measured on the involved limb before and after exercise. Data were reduced to 101 points for 0-100% of the gait cycle for kinematics and reduced to 41 points for 0-40% of the gait cycle (stance phase) for kinetics. Change scores were calculated for each 1% with 90% confidence intervals. Significant differences between groups were determined when confidence intervals did not overlap for three or more consecutive points. Mean differences were calculated for all significant differences. **Results:** Higher fit ACLR demonstrated decreased knee (-3.13°) and hip flexion (-2.14°) and increased trunk flexion (1.59°) and knee abduction (2.79°) compared to healthy individuals after exercise. Higher fit ACLR also demonstrated increased knee flexion moment (0.18Nm/kg) and hip extension moment (0.21Nm/kg) after exercise. Lower fit ACLR demonstrated increased hip adduction (1.48°), knee external rotation (3.57°), hip external rotation (2.87°), and trunk rotation (3.61°) compared to healthy individuals after exercise. **Conclusions:** Higher fit ACLR demonstrated more sagittal plane changes while lower fit ACLR demonstrated increased transverse plane motion after exercise, suggesting that fitness level should be a consideration when making return to activity decisions after ACLR.

Influence of Lower Extremity Muscle Activation on Altered Landing Biomechanics in ACL Reconstructed Individuals

Elisabeth Holt[1], Anh-Dung Nguyen[1], David R. Bell[2], Stephanie M. Trigsted[1]. *[1]High Point University, High Point, NC. [2]University of Wisconsin Madison, Madison, WI.* (Sponsor: Kevin R. Ford, FACSM)

(No relevant relationships reported)

While altered landing biomechanics contribute to secondary ACL injury following reconstruction (ACLR), neuromuscular contributions to altered landings are unknown. Understanding this relationship may lead to more effective rehabilitation programs and mitigate re-injury risk. **PURPOSE:** To determine differences in landing biomechanics between ACLR and healthy controls and how muscle activation predicts altered landing biomechanics. **METHODS:** Thirty-six females with ACLR and 14 controls (19.4±1.7yrs, 168.5±6.7cm, 66.9±9.4kg) participated. 3D biomechanics of the reconstructed (ACLR) or dominant (Control) limb were collected during 5 jump landings (JL). The average peak root mean square amplitude (RMS) of 6 muscles [gluteus medius (GMED), gluteus maximus (GMAX), biceps femoris (BF), semitendinosis (ST), vastus lateralis, rectus femoris (RF)] was calculated 50ms prior to initial contact (PRE) and during landing (LAND), normalized to peak RMS. ANOVAs determined differences (P<0.05) in landing biomechanics between groups, and separate step-wise regressions examined whether muscle activation predicted altered landing biomechanics in ACLR individuals. **RESULTS:** ACLR individuals landed (ACLR, control) with greater peak knee external rotation (ER) (-10.4±7.4°, -5.0±5.1°, P=0.016), peak hip flexion (FLX) (-89.4±15.8°, -75.6±21.8°, P=0.017), hip FLX excursion (-51.2±12.5°, -40.2±16.1°, P=0.013), peak knee abduction (ABD) moment (-0.8±1.1, 0.1±0.2, P=0.035), less peak hip adduction (ADD) (-1.3±5.5°, 2.5±6.8°, P=0.046) and less peak knee internal rotation (4.8±7.8°, 9.5±6.1°, P=0.049) compared to controls. In the ACLR: less BF and GMAX LAND predicted greater peak hip FLX (R^2=0.320, P=0.002); less BF LAND, RF PRE, GMAX LAND, and greater ST PRE EMG predicted greater hip FLX excursion (R^2=0.475, P=0.001); greater RF PRE EMG predicted greater peak hip ADD (R^2=0.142, P=0.026); greater BF PRE EMG predicted greater peak knee ER (R^2=0.161, P=0.017); and less GMED PRE predicted greater knee ABD moment (R^2=0.122, P=0.040). **CONCLUSIONS:** ACLR individuals adopt altered landing strategies that increase the risk of re-injury. Muscle activation patterns that mediate altered landings provide valuable information toward developing targeted neuromuscular interventions and decreasing ACL re-injury risk.

Fear of Reinjury is Associated with Knee Biomechanics During Single Limb Landing after ACL Reconstruction

Julie P. Burland, Lindsey K. Lepley, Lindsay J. DiStefano, Steven. M. Davi, Adam S. Lepley. *University of Connecticut, Storrs, CT.*

(No relevant relationships reported)

Biomechanical alterations after anterior cruciate ligament reconstruction (ACLR) are thought to predict reinjury and are common at return to play. These aberrant movement patterns are highlighted by lower sagittal plane knee angles and moments, and greater asymmetry between limbs. Emerging data suggest that fear of reinjury can hinder rehabilitative success. Identifying whether a patient's fear of reinjury is associated with biomechanical alterations is critical to understanding the role of psychological factors after ACLR on movement control. **PURPOSE:** To evaluate the relationship between knee biomechanics during a single limb hop and a patient's fear of reinjury. **METHODS:** Ten participants with a history of unilateral ACLR

(age 22±2y; height 166.4±7.1cm; mass 65.6±12.1kg; years from surgery, 6±2) volunteered. Lower extremity biomechanics were recorded using 3D motion analysis during a single limb forward hop task. For the injured limb, area under the curve (AUC) during the first 50% of stance for knee flexion angle and internal extension moment was used for analysis. Limb symmetry indices (LSIs) were derived by normalizing to the contralateral limb. Fear of reinjury was measured using the Tampa Scale of Kinesiophobia (TSK), which uses a high score to indicate greater fear of reinjury. Initial Spearman correlations and linear regressions were used to determine the association between biomechanical measures and TSK. **RESULTS:** Knee flexion angle (rho=-0.75, p=0.01) and extension moment (rho=0.67, p=0.03) AUC values for the ACLR limb were negatively associated with TSK scores, predicting 56.4% (p=0.01) and 44.5% (p=0.03) of variance in TSK scores, respectively. Knee flexion angle (rho=0.03, p=0.92) and extension moment (rho=0.01, p=0.96) AUC LSIs were not associated with TSK. **CONCLUSIONS:** Greater knee flexion angle and extension moment AUC of the ACLR limb were associated with less fear of reinjury, indicating those who have lower fear completed the hopping task with more optimal biomechanics. LSIs were not associated with fear of reinjury indicating that biomechanical symmetry may not be the best predictor of fear of reinjury after ACLR. Fear of reinjury and optimization of movement control in the ACLR limb during rehabilitation, rather than limb symmetry, may help to improve ACLR outcomes at return to play.

Functional Knee Bracing Improves Loading Symmetry Following ACL Reconstruction

Robin Queen, FACSM[1], Kristen Renner[1], Alex Pebebles[1], Thomas Miller[2]. *[1]Virginia Tech, Blacksburg, VA. [2]Virginia Tech Carilion School of Medicine, Roanoke, VA.*

Reported Relationships: *R. Queen: Contracted Research - Including Principle Investigator; Don Joy Orthopaedics.*

Previous work has revealed significant between limb asymmetry following anterior cruciate ligament reconstruction (ACLR). Current clinical return to sport testing utilizes single-limb hop distance symmetry (limb symmetry index (LSI) > 90%) and time since surgery to determine readiness to return to sport (RTS). Loading metrics could provide new insights on readiness to RTS. Functional knee braces are recommended by clinicians following ACLR. The impact of bracing on hop symmetry is not well understood. **Purpose**: To evaluate the effect of knee bracing and time since surgery on loading symmetry during hop testing (single hop (SH), triple hop (TH) and crossover hop (CH)). **Methods**: 25 ACLR (6 male/19 female, age: 18.7, height: 1.73 m, weight: 709.7 N) completed hop testing after being RTS (29.8 weeks post-op) by the orthopedic surgeon and again 3 months later (RTS +3), while wearing the loadsol (100Hz) (Novel Electronics, St. Paul, MN). Hopping tasks (SH, TH and CH) were collected twice per task. Testing (testing order was randomized) was completed with and without a custom extension constraint knee brace (DonJoy Orthopaedics). Peak vertical ground reaction force (vGRF), loading rate (LR), and impulse (Imp) were calculated using a custom Matlab program. The LSI was calculated as the ratio of the Sx/NSx*100%. The effect of time (RTS, RTS +3) and condition (Braced, Non-Braced) was assessed using a repeated measures ANOVA for all tasks. **Results**: No significant interactions or main effects for time were found. Bracing resulted in improved LSI's for vGRF during TH (p<0.039) and CH (p<0.013) and for Imp during the TH (p<0.039) (Table 1). **Conclusion**: These results reveal that loading symmetry is improved while wearing a functional knee brace and loading symmetry (LSI>90%) was achieved during most hopping tasks. Future work needs to examine additional functional measures (eg. bilateral landings, running) to determine the impact of functional knee bracing and time on loading LSI.

Table 1

	Single Hop			Triple Hop			Cross-over Hop		
	vGRF	LR	Imp	vGRF	LR	Imp	vGRF	LR	Imp
RTS	93.24 (4.177)	89.05 (6.772)	92.897 (2.673)	87.362 (2.792)	89.478 (4.564)	90.992 (2.134)	91.807 (3.770)	92.611 (5.133)	94.835 (2.576)
RTS +3	97.791 (1.984)	107.937 (6.711)	95.264 (1.397)	92.124 (2.615)	93.340 (5.151)	92.908 (1.974)	93.179 (1.508)	95.375 (3.780)	92.820 (1.369)
Braced	97.107 (2.938)	99.122 (6.942)	93.505 (2.493)	**91.921 (2.133)***	92.063 (4.374)	**93.256 (1.887)***	**96.042 (2.406)***	96.319 (3.186)	93.593 (1.647)
Non-braced	93.928 (2.676)	97.865 (6.635)	94.656 (1.762)	**87.565 (2.463)***	90.754 (4.493)	**90.643 (1.762)***	**88.944 (2.124)***	91.666 (3.497)	94.062 (1.815)

Effects of Localized Vibration on Knee Joint Position Sense in Individuals with ACL-Reconstruction

Takashi Nagai, Nathan D. Schilaty, Nathaniel A. Bates, Timothy E. Hewett, FACSM. *Mayo Clinic, Rochester, MN.* (Sponsor: Timothy E. Hewett, PhD, FACSM, FACSM)
(No relevant relationships reported)

Anterior cruciate ligament (ACL) injury can disrupt one's proprioception such as joint position sense (JPS) and ultimately motor function. The application of localized vibration has been used to investigate the integrity of the sensorimotor system and the mechanisms of quadriceps weakness after ACL injury and ACLR-reconstruction (ACLR). However, effects of localized vibration on knee JPS in ACLR subjects are largely unknown. **PURPOSE:** To evaluate JPS with and without vibration and compare among ACLR, contralateral, and control limbs. **METHODS:** Fourteen subjects with ACLR (8 males and 6 females) and fourteen control subjects (7 males and 7 females) participated. Subjects sat on an isokinetic dynamometer chair with vibration strapped on the quadriceps tendon while visual and auditory cues were removed. Subjects were asked to remember target position and replicate that position. The absolute difference between the target and replicated trial was used as JPS. There were three trials at three target positions (15, 45, and 75 degrees of knee flexion) with and without vibration. The JPS differences between vibration and no-vibration conditions were calculated by subtraction. The average JPS was used for analyses. The order of testing conditions was randomized. One-way analysis of variance (ANOVA) or nonparametric (Kruskal-Wallis) was used to compare among limbs. Significance was at $p<0.05$ a priori. **RESULTS:** There were no significant JPS differences among ACLR, contralateral, and control limbs ($p=0.207$-0.914) in vibration and no-vibration conditions. Similarly, when the JPS differences between vibration and no-vibration conditions were used to compare the limbs, there were no significant JPS differences among ACLR, contralateral, and control limbs ($p=0.288$-0.755). **CONCLUSION:** The current investigation found minimal effects of localized vibration on JPS in the ACLR, contralateral, and control limbs. There are several potential reasons such as vibration-induced post effect, locations of vibration, types of vibration, and rehabilitation status. Despite the current results and limitations, continued effort to develop and refine a means to examine one's sensorimotor system is warranted.

1094   Board #8   May 31 8:00 AM - 10:00 AM
Quantifying Whole Body Compensations in Ground Reaction Forces During Gait in Individuals Post-ACLr

Paige E. Lin, Neama H. Neamat Allah, Stephanie M. Yano, Andrea L. Alsalahat, Susan M. Sigward. *University of Southern California, Los Angeles, CA.*
(No relevant relationships reported)

Individuals 3 months post-ACL reconstruction (ACLr) decrease vertical (vGRF) and posterior (pGRF) ground reaction forces during loading response (LR) of gait. At this time of double limb support (DLS), decreased loading may result from modifications by the trailing limb. **PURPOSE:** To compare GRFs between limbs during DLS in individuals post-ACLr and controls. **METHODS:** 17 individuals (11F, 24±11yrs) 114±17days post-ACLr and 17 healthy controls (CTRL; 11F, 23±8yrs) walked 1.4 m/s. DLS of stance was divided into initial (iDLS) and terminal (tDLS). Maximum vGRF and pGRF during iDLS and maximum vGRF and anterior GRF (aGRF) during tDLS were identified for ACLr, non-surgical (NS) and CTRL limbs. vGRF and anteroposterior (AP) GRF ratios were calculated: (Reference limb GRF in iDLS)/(Contralateral limb GRF in tDLS). One-way ANOVAs were used to compare variables among limbs; α=0.05, post hoc: paired and independent t-tests. **RESULTS:** Vertical (p=0.007, ACLr:0.92±.02, NS:1.00±0.02; p=.02, CTRL:0.99±0.02) and AP GRF ratios (p<0.001, ACLr:0.83±0.03, NS:0.97±0.03; p=0.001, CTRL:1.00±0.04) were reduced in ACLr compared to NS and CTRL limbs. vGRF (p=0.02, ACLr:1.01±0.01, NS:1.06±0.01; p=0.04, CTRL:1.05±0.01BW) and pGRF (p=0.001, ACLr:0.19±0.01, NS:0.22±0.01; p=.03, CTRL:0.22±0.01BW) during iDLS were reduced in ACLr compared to NS and CTRL limbs. vGRF of the contralateral limb in tDLS was greater when the ACLr limb was in iDLS compared to NS and CTRL (p=0.006, ACLr:1.10±0.01, NS:1.05±0.01; p=0.10, ES:0.56, CTRL:1.07±0.02BW). No differences were observed in aGRF between limbs (p=0.81, ACLr:0.23±0.01, NS:0.23±0.01, CTRL:0.22±0.01BW). **CONCLUSIONS:** Altered GRF ratios suggest differences among limbs in the distribution of forces between the leading and trailing limbs during LR. Reduced vGRF in the surgical limb during iDLS along with greater vGRF in the contralateral limb in tDLS limb may reflect an interlimb compensation that shifts the load to the non-surgical limb. However, no alterations in aGRF were observed suggesting reduced pGRF in the surgical limb during LR is not compensated for by the trailing limb.

Does PhysicalActivity Reduce Cancer Risk? Latest Resultsfrom the WCRF/AICR Third Expert Report.

Nigel T. Brockton[1], Kate Allen[2], Rachel L. Thompson[2], Martin J. Wiseman[2], Giota Mitrou[2], Teresa Norat[3], Michael Leitzmann[4], Anne McTiernan[5]. *[1]American Institute for Cancer Research, Arlington, VA. [2]World Cancer Research Fund, London, United Kingdom. [3]Imperial College London, London, United Kingdom. [4]Regensburg University, Regensburg, Germany. [5]Fred Hutchinson Cancer Research Centre, Seattle, WA.*
(No relevant relationships reported)

Purpose World Cancer Research Fund (WCRF) and American Institute for Cancer Research (AICR) routinely review, synthesize and interpret the scientific literature on the links between physical activity, nutrition, and cancer through the Continuous Update Project (CUP). The WCRF/AICR Third Expert Report, to be published in 2018, will present the latest synthesis of the strength of the evidence linking physical activity to 17 cancer sites and to outcomes in breast cancer survivors. These assessments inform the update of the WCRF/AICR Recommendations for Cancer Prevention and Survival. **Methods** The research team at Imperial College London searched PubMed for relevant prospective studies and extracted literature according to the CUP Systematic Literature Review Protocol for each cancer site. Meta-analyses were conducted comparing the highest versus the lowest categories of physical activity. Where possible, dose-response meta-analyses were conducted and summary relative risks (RR) were calculated using a random effects model. The CUP Expert Panel graded the evidence as: Convincing/probable (strong evidence); Limited-suggestive (limited evidence); 3) Limited-no conclusion (limited evidence); 4) Substantial effect on risk unlikely (strong evidence). **Results** The Panel determined that strong evidence supports that physical activity decreases the risk of postmenopausal breast cancer by 13% (RR: 0.87; 0.79-0.96), premenopausal breast cancer by 17% (RR:0.83; 0.73-0.98, vigorous activity), colon cancer by 20% (RR:0.80; 0.72-0.88) and endometrial cancers by 21-27% (RR:0.79; 0.71-0.88, occupational; RR:0.73: 0.58-0.93, recreational). Studies with compatible measurements were too few to allow dose-response analysis in endometrial and colon cancer; dose-response analyses were statistically non-significant for breast cancer. Limited-suggestive evidence was found for decreased risk of liver and esophageal cancer and all-cause mortality in breast cancer survivors with highest vs. lowest physical activity levels. **Conclusions** There is strong evidence that physical activity reduces the risk of cancer at specific sites. Research is needed to determine the duration, intensity, frequency and timing of physical activity for optimal cancer risk reduction and to improve prognosis in cancer survivors.

Breast Cancer and Physical Activity Level (BC-PAL) Trial: Findings on Cardiorespiratory Fitness and Body Composition

Jessica McNeil[1], Darren R. Brenner[1], Chelsea R. Stone[1], Rachel O'Reilly[1], Jeffrey K. Vallance[2], Kerry S. Courneya[3], Kevin E. Thorpe[4], Douglas J. Klein[3], Christine M. Friedenreich[1]. *[1]Alberta Health Services, Calgary, AB, Canada. [2]Athabasca University, Athabasca, AB, Canada. [3]University of Alberta, Edmonton, AB, Canada. [4]University of Toronto, Toronto, ON, Canada.*
(No relevant relationships reported)

Regular physical activity (PA) participation can improve recovery and survival following a breast cancer diagnosis. Current guidelines focus on moderate-vigorous intensity PA participation (50-85% heart rate reserve; HRR). However, approximately 85% of breast cancer survivors do not meet PA guidelines and may prefer lighter-intensity PA (≈40-60% HRR). **PURPOSE:** We assessed the effects of prescribing different PA intensities, compared to no additional PA, on cardiorespiratory fitness (VO_{2peak}), anthropometry and body composition in breast cancer survivors. **METHODS:** The Breast Cancer and Physical Activity Level (BC-PAL) Trial is a three-arm, 12-week randomized controlled trial. Forty-five inactive (≤60 minutes of moderate-vigorous PA/wk and ≤10,000 steps/day) breast cancer survivors recruited

for pilot data collection were randomized to one of three groups: no additional PA prescribed (CON), 300 min/wk of lighter-intensity PA (LIPA; 40-60% HRR) and 150 min/wk of higher-intensity PA (HIPA; 60-80% HRR). VO_{2peak} (maximal Balke protocol), anthropometric measures (height, weight, waist and hip circumferences) and body composition (DXA) were assessed at baseline and end of study. Participants in both PA groups received written resources on PA, an activity tracker (Polar A360®) to record heart rate and PA time, and a diary to record PA goals, facilitators and barriers throughout the intervention. In-person/telephone meetings occurred every three weeks to review activity tracker data, reinforce adherence and discuss barriers to achieving the prescribed PA goals.

RESULTS: Statistical differences in VO_{2peak} between groups were noted. Specifically, increases in VO_{2peak} were noted in HIPA vs. CON (5.9±6.4 vs. 0.5±3.0 ml/kg/min; $P = 0.01$) and LIPA vs. CON (4.2±4.9 vs. 0.5±3.0 ml/kg/min; $P = 0.03$). No significant changes in BMI (0.3±0.9, -0.1±0.8, -0.0±1.4 kg/m²; $P = 0.6$), waist (1.2±4.2, -1.1±3.3, -1.1±3.8 cm; $P = 0.2$) and hip (0.8±1.7, -0.2±2.7, -0.2±2.1 cm; $P = 0.4$) circumferences, body fat (0.1±1.4, -0.4±1.9, -1.1±2.3 kg; $P = 0.3$) and lean (0.4±0.8, -0.1±1.4, 0.7±1.5 kg; $P = 0.3$) mass were observed between CON, LIPA and HIPA, respectively.

CONCLUSIONS: Pilot results indicate that improvements in cardiorespiratory fitness can be achieved with both higher- and lower-intensity PA in breast cancer survivors.

Self-reported Physical Activity Is Associated With Angiogenesis- And Inflammation-related Biomarkers In Colorectal Cancer Patients: Results From The Colocare Cohort

Caroline Himbert[1], Biljana Gigic[2], Christy A. Warby[1], Tengda Lin[1], Petra Schrotz-King[3], Clare Abbenhardt-Martin[3], Stephanie Skender[3], Nina Habermann[4], Lin Zielske[2], Alexis Ulrich[2], Juergen Boehm[1], Jennifer Ose[1], Cornelia Ulrich, FACSM[1]. [1]Huntsman Cancer Instiute, Salt Lake City, UT. [2]University Clinic of Heidelberg, Heidelberg, Germany. [3]National Center for Tumor Diseases, Heidelberg, Germany. [4]European Molecular Biology Laboratory, Heidelberg, Germany. (Sponsor: Jim Martin, FACSM)

(No relevant relationships reported)

Background: Increased physical activity among cancer patients is associated with decreased cancer-related deaths and improved quality of life. The underlying mechanisms of this association are under investigation. We examined the association between biomarkers of angiogenesis and inflammatory pathways and physical activity in colorectal cancer patients.

Materials/Methods: Pre-surgery (baseline) serum samples were collected from 222 colorectal cancer patients in the ColoCare cohort. Levels of CRP, SAA, IL-6, IL-8, MCP-1, sICAM-1, sVCAM-1, TNFα, VEGFA, and VEGFD were measured with the Meso Scale Discovery platform. Self-reported physical activity levels were assessed at baseline by using the VITAL questionnaire from the VITamins And Lifestyle cohort study and calculated into metabolic equivalent (MET) hours/week (h/wk). Patients were classified into ≤10 METs versus >10 METs hours/week based on the American Cancer Society (ACS) cancer prevention recommendations. Partial correlations, t-test, and multinomial linear regression adjusted for age, gender, and body mass index were used to quantify the associations between biomarker and physical activity levels.

Results: A total of 132 patients (59%) reported weekly physical activity levels below cancer prevention recommendations. Lower METs h/wk were significantly correlated with increased IL-8, sICAM-1, and VEGFD serum levels (r=-0.14, p=0.046, r=-0.15, p=0.047; r=-0.20, p=0.006, respectively). sVCAM-1 and VEGFD also significantly differed by METs h/wk groups, where increased physical activity was associated with decreased biomarker levels (≤10 METs h/wk vs. >10 METs h/wk, sVCAM-1: 0.6 ± 0.2 vs. 0.6 ± 0.2, p=0.03; VEGFD: 926 ± 308 vs. 791 ± 240, p=0.002).

Discussion: For the first time, we report an association between not only inflammation-related, but also angiogenesis-related biomarkers among patients diagnosed with colorectal cancer. This research contributes to our understanding regarding potential mechanisms of physical activity in relation to cancer development, and prognosis.

Pennsylvania Cancer Survivors And Their Adherence To The ACSM Physical Activity Guideline

Joachim Wiskemann, Wayne Foo, Renate M. WInkels, Shirley M. Bluthmann, Scherezade K. Mama, William Calo, Eugene Lengerich, Joel Segel, Kathryn H. Schmitz, FACSM. *The Pennsylvania State University, Hershey, PA.* (Sponsor: Kathryn Schmitz, FACSM)

(No relevant relationships reported)

PURPOSE: To investigate whether Pennsylvania cancer survivors adhere to the ACSM exercise and cancer roundtable guidelines recommending to perform either 75 min of vigorous aerobic exercise per week or, 150 min of moderate aerobic exercise per week, or an equivalent combination, and to performed muscle-strengthening exercises at least two times weekly.**METHODS**: We analyzed data from cancer survivors (n=585), identified using the Pennsylvania Cancer Registry, who were mailed a BRFSS-based questionnaire. We created four guideline-related groups (meeting aerobic guideline, meeting strength guideline, meeting both guideline and not meeting any guideline aspects). We evaluated whether demographic factors (e.g. age, gender, education), health aspects (e.g. smoking, comorbidities, general health status) or disease-related factors (e.g. cancer type, time since diagnosis) were associated with meeting the PA guideline.

RESULTS: Out of 585 respondents 449 (77%) provided sufficient PA data to be included in the analysis. Overall 84 (18.7%) of participants met both, 144 (32.1%) met the aerobic and 28 (6.2%) met the strength guideline. However, 192 (43%) did not meet any aspects of the guideline. Participants with higher education (p=.01) and unemployed/retired participants (p=.04) were more adherent to PA guidelines (main differences for the subcategory meeting both guideline aspects). Having more than two comorbidities (p<.01), being a smoker (p=.04) or being overweight/obese (p<.01) and having a lower general health perception (p<.01) was associated with lower adherence rates for PA guidelines. With regard to disease-related factors no significant differences were found. However, cancer type was borderline non-significant (p=.055) showing lower adherence rates for lung and gynecologic (other than breast) cancer patients.

CONCLUSIONS:More than 50% of Pennsylvania cancer survivors were meeting at least one component of the ACSM PA guideline for cancer patients. Various factors were found to be associated with adherence to the guideline. Identifying predictors for low guideline adherence can help to identify patient groups that may benefit from increased support to achieve a physically active lifestyle.

Differences In Physical Activity Patterns Between Adults With And Without Cancer History

Amal A. Wanigatunga[1], Gillian K. Gresham[2], Pei-Lun Kuo[1], Pablo Martinez-Amezcua[1], Vadim Zipunnikov[1], Sydney M. Dy[1], Eleanor M. Simonsick[3], Jennifer A. Schrack[1]. [1]Johns Hopkins University, Baltimore, MD. [2]Cedars-Sinai Medical Center, Los Angeles, CA. [3]National Institute on Aging, Baltimore, MD. (Sponsor: Todd M. Manini, FACSM)

(No relevant relationships reported)

ABSTRACT

Purpose: Patterns of activity and rest in a typical day may provide insight into functional capacity and reserve in older cancer survivors that may not be apparent in examining total physical activity alone. Using objectively collected PA data from the Baltimore Longitudinal Study of Aging, we assessed differences in the accumulation of daily PA among older adults by cancer history.

Methods: 663 participants (mean age 71 +/- 10 years, 51% women) wore a chest-fitted accelerometer for 7 consecutive days. Participants self-reported cancer history via questionnaire. Accelerometer data were summarized into two continuous metrics: 1) log-transformed total daily PA volume defined as mean counts/day and 2) a fragmentation index defined as the total number of PA bouts (consecutive minutes registering at 10+ counts/min)/total PA minutes. Volume and fragmentation were also each dichotomized into low and high categories using their medians. Participants were categorized into four groups: high PA/low fragmentation, low PA/low fragmentation, high PA/high fragmentation, and low PA/high fragmentation to assess patterns of daily PA accumulation. Multivariable regression models were used to estimate PA pattern differences by cancer history, adjusting for demographics, behavioral factors and number of morbid conditions.

Results: Participants reporting cancer history averaged 0.12 (SE=0.05, p=0.02) fewer log-transformed activity counts per day compared to those reporting no cancer history. Although no significant fragmentation differences were detected between cancer groups (p=0.15) in the continuous model, cancer history was associated with a 78% (odds ratio (OR): 1.78, 95% confidence interval (CI): 1.11-2.82) higher odds of being in a high (versus low) fragmentation group and a 93% (OR: 1.98, 95% CI: 1.13-3.32) higher odds of being in a low PA/high fragmentation group (versus high PA/low fragmentation group) when compared to no cancer history.

Discussion: These results suggest that cancer survivors engage in lower total daily PA and that this activity is performed in a more fragmented manner, compared to those with no cancer history. Collectively, these results may be attributable to lower reserve capacity and greater fatigue burden among older cancer survivors that warrant further investigation.

Exercise Is More Effective Than Health Education In Reducing Fatigue In Fatigued Cancer Survivors

Patricia Sheehan, Suzanne Denieffe, Michael Harrison, FACSM. *Waterford Institute of Technology, Waterford, Ireland.*
(No relevant relationships reported)

Cancer-related fatigue is the most debilitating side effect reported by cancer survivors, often lasting years following treatment. **PURPOSE**: To determine the effects of a 10 wk exercise intervention compared to a health education intervention on fatigue, psychological health outcomes and physical fitness in cancer survivors with documented fatigue. **METHODS**: This quasi experimental study allocated 37 post-treatment cancer survivors (33 female, 30 breast cancer, aged 55±2 yr, body mass index 28.5±1.3, time since treatment 2.3±0.3 yr; mean±SEM) to an exercise group (ExG, n=19) or health education comparison group (HEG, n=18). The intervention, with 2 min increments weekly, was tailored to fatigued individuals and emphasized brisk walking, stretching, exercise education and self-efficacy enhancement. Participants were evaluated at 0, 4, 8 and 10 weeks with the ExG evaluated again at 26 weeks. **RESULTS**: The intervention effect on fatigue (FACT-F) in ExG was greater (p<0.05) than in HEG, the difference between groups at 10 weeks being 4 times the recognised clinical important difference. The intervention also increased (p<0.05) cognitive function, global quality of life, 6 min walk test and 30 sec sit to stand scores. It reduced (p<0.05) insomnia and fear of physical activity. There was no intervention effect on C-reactive protein, total leukoytes, lymphocytes, monocytes or granulocytes, or on pulse wave velocity. The intervention effect on fatigue in ExG was largely achieved by wk 4 and maintained to 26 weeks. There was 100% retention rate at 10 weeks in both experimental groups and no adverse events reported. **CONCLUSIONS**: In survivors with documented fatigue, progressive exercise training has beneficial and sustained effects of considerable magnitude on fatigue, physical fitness and other quality of life outcomes beyond those attributable to peer support and investigator attention. These effects do not appear to be mediated by inflammatory factors.

Fatigue and fitness changes following an exercise intervention in fatigued cancer survivors				
.	Exercise		Health Education	
Outcome	Pre-	Post	Pre-	Post
‡ Fatigue (FACT-F)	19.3±2.2	40.3±2.4 *	21.9±2.2	29.6±2.5 *

Effects of a Lifestyle Intervention on Change in Body Composition in Prostate Cancer Patients Undergoing Androgen Deprivation Therapy

Zachary L. Chaplow[1], Brian C. Focht, FACSM[1], Alexander R. Lucas[2], Elizabeth Grainger[1], Christina Simpson[1], Ciaran M. Fairman[1], Jennifer M. Thomas-Ahner[1], Victoria R. DeScenza[1], Jessica Bowman[1], Jackie Buell[1], Steven K. Clinton[1]. [1]*The Ohio State University, Columbus, OH.* [2]*Wake Forest University, Winston Salem, NC.* (Sponsor: Brian C. Focht, FACSM)
(No relevant relationships reported)

Androgen deprivation therapy (ADT) is a foundation of treatment for a many prostate cancer (PCa) patients. However, the adverse effect of ADT on body composition place PCa patients at increased risk for sarcopenic obesity, cardiovascular disease, and metabolic syndrome. The synergistic benefits of promoting concomitant change in both exercise and dietary behavior (EX+D) could represent an optimal lifestyle intervention approach for offsetting the adverse effects of ADT on body composition. Nonetheless, knowledge of the effects of lifestyle EX+D interventions on change in body composition remains relatively limited. **PURPOSE**: The purpose of the single-blind, randomized controlled Individualized Diet and Exercise Adherence-

Pilot (IDEA-P) trial is to evaluate the preliminary efficacy of an EX+D intervention, implementing a group-mediated cognitive behavioral (GMCB) approach, relative to standard of care (SC) treatment among PCa patients undergoing ADT. In the current study, we evaluated the effects of the EX+D intervention on select body composition outcomes. **METHODS**: A total of 32 PC patients (*M* age = 65 years) on ADT were randomly assigned to the EX+D (n = 16) or SC (n = 16) interventions. Measures of body composition were obtained via Dual x-ray absorptiometry (DEXA) at baseline and 3-month follow-up assessments. **RESULTS**: Results of intention to treat 2 (Intervention) x 2 (Time) ANOVA analysis yielded significant Intervention x Time interactions for android, gynoid, and total body fat (p<0.05). Post hoc analysis revealed that the EX+D intervention resulted in significant reduction in android, gynoid, and total body fat while no change in any body composition outcomes were observed with the SC intervention across 3 months. **CONCLUSIONS**: Findings from the IDEA-P trial suggest that an EX+D intervention, implementing a GMCB approach designed to promote adoption and adherence to lifestyle behavior change, resulted in superior improvements in key body composition outcomes relative to SC approach. Given the meaningful impact favorable body composition changes may have on chronic disease risk, these results underscore the utility of including EX+D intervention in the adjuvant treatment of PCa patients undergoing ADT.

Breast Cancer Survivors Maintain Exercise after Breast Cancer Survivors Maintain Exercise after Team Triathlon Training

Linda B. Piacentine[1], Judy A. Tjoe[2], Leslie J. Waltke[2], Aidan M. Flanagan[1], Elizabeth M. DePauw[1], Julia A. Hilbert[1], Lauren Opielinski[1], Alexander V. Ng, FACSM[1]. [1]*Marquette University, Milwaukee, WI.* [2]*Aurora Health Care, Milwaukee, WI.*
(No relevant relationships reported)

Breast Cancer Survivors (BCS) often do not exercise at recommended levels. Estimates are that only 21% exercise at recommended levels 10 years after treatment. Interventional exercise programs examining exercise maintenance have found 49% to 58% maintain exercise at 6 months, and less then 50% of BCS can be expected to maintain exercise levels at 1 year or longer. Our previous studies have shown improvement in physical and psychosocial function with a 14-week training program. The 14-week triathlon training was comprised of two supervised group sessions and three home-based sessions per week. The training program culminated with participation in a sprint distance triathlon (0.25-0.5 mi swim, 12-15 mi bike, 3.1 mi run). **PURPOSE**: To determine if BCS who participate in a triathlon training program maintain high exercise levels after training. **METHODS**: Female BCS (n=156) were asked to complete a mailed survey about their leisure time activity 1-6 years after completing a triathlon training program. A Leisure Score Index (LSI) was derived from the Godin Leisure-Time Activity Questionnaire in the survey. Those completing the survey who reported the highest and lowest LSI scores were invited to participate in testing which included weight, BMI, body fat and circumference measurements as well as a 6-minute walk test and the FACIT-fatigue scale. **RESULTS**: Eighty (75%) reported LSI of 24 or greater. A subset of BCS with high (H) scores (n=6) and low (L) scores (n=5) were tested. No significant group differences (p>.05) were noted in age (H=62.3(5.1), L=56.6(5.7)yrs), time since training (H=3.2(1.7), L=3.2(1.3) yrs), and 6MWT (H=593.2(60.6), L=553.4(29.6) min p>0.1). Group differences were found in hip circumferences (H=96.2(6.9) L=116(11.5) cm, p<.01), waist circumferences (H=79.8(11.2) L=97.5(9.1) cm, p<.05), weight (H= 61.0(9.9) L=86.2(12.9)kg, p<.01), BMI (H=23.2(3.2), L=39.2(13.7) p<.05), body fat % (H=36.7(2.4) L=46.8(5.1), p<.01) and fatigue (H=49.3(2.1), L=34.8 (14.8) p≤.05). Data are mean (sd). **CONCLUSIONS**: Structured training for BCS can lead to higher levels of activity maintenance at 1-6 years after training. Thus, triathlon training could lead to continued exercise, less fatigue, and better health in breast cancer survivors.

The Influences of Acute and Chronic Sleep Duration on Endurance Performance in Female Youth Athletes

Andrew Watson, Kristin Haraldsdottir, Stacey Brickson. *University of Wisconsin-Madison, Madison, WI.*

(No relevant relationships reported)

Prior research has evaluated the influence of sleep deprivation on endurance performance, but the influence of real-world variation in acute and chronic sleep in youth athletes is unknown. **Purpose:** To determine the relationship between acute, chronic, and acute:chronic sleep on aerobic performance in female youth soccer athletes. **Methods**: 59 female soccer players (13-18 years) underwent cycle ergometer testing to determine maximal aerobic capacity (VO_{2max}), time to exhaustion (T_{max}) and ventilatory threshold (VT). Subjects were asked to report prior night sleep duration and average sleep duration during the previous calendar month. Acute:chronic sleep was calculated as the ratio of prior night and prior month sleep. Variables were grouped by prior night and prior month sleep duration (<8 hours, ≥8 hours) as well as acute:chronic sleep (<1, ≥1). VO_{2max}, T_{max}, and VT were compared between groups using least square means from age-adjusted linear models. Effect size was calculated as Cohen's d. **Results:** No statistically significant differences were identified between those subjects who slept ≥8 the prior night and those who slept <8 hours, with respect to VO_{2max} (50.3 ± 2.4 v 47.6 ± 2.0 ml/kg/min, p=0.10, d=0.45), T_{max} (15.7 ± 0.7 v 14.9 ± 0.9 min, p=0.17, d=0.37), or VT (43.2 ± 1.9 v 40.7 ± 2.2 ml/kg/min, p=0.09, d=0.46). Subjects who averaged ≥8 hours of sleep in the prior month demonstrated significantly greater VO_{2max} (50.4 ± 3.2 v 45.2 ± 1.7 ml/kg/min, p=0.011, d=0.83) and VT (43.0 ± 1.5 v 39.0 ± 2.9 ml/kg/min, p=0.016, d=0.78), but not T_{max} (15.6 ± 0.6 v 14.8 ± 1.2 min, p=0.24, d=0.37). On the other hand, subjects who slept more the previous night than over the previous month (acute: chronic ≥1) demonstrated greater T_{max} (16.4 ± 1.0 v 14.9 ± 0.7 min, p=0.012, d=0.73), but not VO_{2max} (50.1 ± 2.8 v 48.7 ± 1.3 ml/kg/min, p=0.38, d=0.25) or VT (42.7 ± 2.5 v 41.9 ± 1.7 ml/kg/min, p=0.60, d=0.15). **Conclusion:** Among female adolescent athletes, greater sleep duration over the prior month is associated with increased VO_{2max} and VT, while increased prior night sleep relative to the preceding month was associated with increased T_{max}. This suggests that chronic sleep may facilitate physiologic adaptation to increase aerobic capacity, while acute:chronic sleep may exert a greater influence on perceived exertion that impacts overall performance.

Effects of 36 h of Sleep Deprivation on Physical Performance

Edward F. Coyle, FACSM, Michael R. Casner, Steve Kornguth. *University of Texas at Austin, Austin, TX.*

(No relevant relationships reported)

Acute sleep deprivation is often experienced in military operations. **PURPOSE:** To determine if 36h of sleep deprivation influences physical and cognitive performance. **METHODS:** Twenty-seven physically fit college age men and women, mostly from the U.S. Military Academy at West Point, were evaluated on Day 1 (baseline) and then again on Day 2 after missing a night's sleep and being awake for 36h. Peak oxygen consumption while cycling (VO_2peak) was measured breath by breath using a mass spectrometer, and time to fatigue was determined. Deoxygenated hemoglobin of the vastus lateralis was measured with near infrared spectroscopy. Maximal neuromuscular power was measured using the inertial load ergometer. Cognitive performance was assessed from the two-back test and reaction time. **RESULTS:** The differences between Day 1 and Day 2 were small or non-existent. Peak HR was reduced slightly from 193.6 ± 8.4 bpm to 191.7 ± 8.6 bpm (p < 0.05). Furthermore, during the first stage of submaximal exercise the oxygen cost of cycling increased from 44.7 ± 8.7% to 48.0 ± 7.4% VO_2peak ; p < 0.01). VO_2peak was 3,619 ± 1,026 mL/min vs. 3,671 ± 1,038 mL/kg, respectively; (p = 0.274). Time to fatigue was not different between the two trials (347 ± 168 seconds vs. 347 ± 186 seconds (p = 0.954) and deoxygenated hemoglobin of the vastus lateralis increased similarly. Maximal neuromuscular power was not different on the two days (1,188±268 watts vs. 1,173±215 watts). Cognitive performance was similar on Days 1 and 2, although it did decline during exercise due to divided attention. **CONCLUSION**: Missing a night's sleep and being awake for 36h has little influence on aerobic performance or maximal neuromuscular power although it does appear to slightly reduce peak heart rate and increase the oxygen cost of low intensity exercise.

The Effect Of Sleep Duration On Sleep Quality In Elite Soccer Athletes

Ryan M. Curtis[1], William M. Adams[2], Courteney L. Benjamin[1], Yasuki Sekiguchi[1], Douglas J. Casa, FACSM[1]. *[1]University of Connecticut, Storrs, CT. [2]University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Douglas Casa, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the effect of sleep duration on sleep quality in elite soccer athletes. **METHODS**: Twenty-two male collegiate soccer players (mean±SD; age, 20±1y; height, 181.2±6.5cm; body mass, 79.4±6.9kg; VO_{2max}, 50.9±4.4 ml•kg⁻¹•min⁻¹) participated in this study. Participant sleep observations were recorded via wrist-worn actigraphy throughout the complete 2016 competitive season from August to November (1450 files). Sleep was categorized according to sleep duration: <6 hours (580 files), 6-8 hours (643 files), and >8 hours of sleep (227 files). Percentage of time in bed spent in wake time (WT%), light sleep time (LS%), slow wave sleep time (SWS%), and rapid eye movement time (REM%) were used to assess sleep quality. Significant differences between sleep groupings and effect of sleep duration ($Sleep_{Hours}$) on sleep quality was assessed via linear mixed effects models and subsequent tukey post hoc testing (p<0.05). Results are presented as Mean±SE, mean difference (MD) and 95% confidence intervals (95%CI). **RESULTS**: Athletes who slept <6 hours had significantly more WT% (Mean±SE, 15.2%±0.6%) than athletes who slept between 6-8 hours (MD [95%CI], -1.9% [-0.9%, -2.8%], p<0.01) and >8 hours (-1.7% [-0.4%, -3.1%], p<0.01). Athletes who slept >8 hours had significantly more REM% (15.4%±1.1%) than athletes who slept between 6-8 hours (-1.4% [-0.1%, -2.8%], p<0.05) and <6 hours (-1.7% [-0.3%, -3.1%], p<0.05). There were no significant relationships found between sleep duration, LS% and SWS% (p>0.05). For every one hour increase in $Sleep_{Hours}$ athletes decreased WT% by 0.5% [0.3%-0.8%] and increased REM% by 0.4% [0.1%-0.6%]. **CONCLUSIONS**: Increased sleep duration positively impacted aspects of sleep quality by decreasing WT% and increasing REM%, which may allow increases in neuronal and memory formation and decreases in non-functional sleep. Further investigation is warranted to elucidate facilitators of other aspects of sleep quality, such as restorative sleep (SWS), and to examine the extent to which training stress may influence sleep and recovery and vice versa.

1108   Board #4   May 31 8:00 AM - 10:00 AM

In-season Examination Of Sleep Quality, Hormone Function, Strength And Affective State Of Division-i Volleyball Athletes

Randy L. Aldret, Michael J. McDermott, Alanna G. Hoffpauir, Hannah Corley, Aimee Mattox, Stephanie Aldret, David M. Bellar. *University of Louisiana at Lafayette, Lafayette, LA.*

(No relevant relationships reported)

PURPOSE: Over the course of the 2017 competitive season, the researchers collected data from 20 Division 1 volleyball players. Beginning with the initial team meeting of the season, measures of sleep quality, hormone regulation and affective state were collected from each member of the team. **METHODS**: Sleep quality measures were gathered using wrist-worn actigraph device. Hormone regulation was measured via passive drool sample collection. Affective and emotional states data was collected digitally using an email link to two reliable and validated psychological surveys: Positive and Negative Affect Survey (PANAS); and the Depression, Anxiety, and Stress Survey (DASS-21). **RESULTS**: Repeated measure Anova did not reveal a main effect for week over the course of the season (F=1.31, p=0.38, range from 93.3% to 95.9%). Similar analysis did reveal a main effect for time for salivary cortisol (F=3.76, p=0.04), with post hoc testing revealing that week 6 significantly elevated over baseline (1.77 µg/dl± 1.08)and week 8 (0.42 µg/dl± 0.33), 9 (0.40 µg/dl± 0.26) and 10 (0.53µg/dl± 0.45) significantly reduced compared to baseline. Analysis of testosterone did not reveal a significant main effect for time (F=2.72, p=0.11). When testosterone to cortisol ratio was examined a significant main effect for time was revealed (F=8.89, p<0.01) with week 1,2,3,10,11 significantly elevated over baseline and week 6 significantly reduced compared to baseline. Analysis of DASS 21 data did not reveal main effects for time for Depression (F=0.70, p=0.72), Anxiety (F=1.00, p=0.60) or Stress (F=2.43, p=0.32). Analysis for PANAS positive scores revealed a significant main effect for time (F=3.78, p=0.032). For the PANAS positive all time points (weeks 1-11: average 32.0±10.8) were significantly lower than baseline (38.7±5.7). Analysis for PANAS negative score did not reveal a significant main effect for time (F=0.69, p=0.76).

CONCLUSIONS: While being a competitive scholarship athlete is stressful and time consuming, it is not all that defines the participants. Further examination of other factors, such as academic demands, along with social and family commitments should be studied to better understand their effects on the hormone and psychometric scores.

1109   Board #5   May 31 8:00 AM - 10:00 AM

Self-Reported, Current and Ideal Sleep Habits of Adolescent Athletes

Melissa L. Anderson, Kortney J. Dalrymple, Timothy J. Roberts. *GSSI, Bradenton, FL.*

Reported Relationships: M.L. Anderson: *Salary; This study was funded by the Gatorade Sports Science Institute. The views expressed in this abstract are those of the authors and do not necessarily reflect the position or policy of PepsiCo, Inc..*

BACKGROUND: Leading health organizations recommend adolescents obtain 8 to 10 hours of sleep each day. There is a growing body of literature that suggests many adolescents, including athletes, are not meeting these recommendations; however, barriers to obtaining adequate sleep are still largely unknown. **PURPOSE**: To quantify sleep habits in a group of athletes and to understand how their current habits compare with their self-reported ideal sleep durations. **METHODS**: One hundred seventy three adolescent team- and individual-sport athletes (16 ± 2 y; male: n=139, female: n=34) from 10 different sports completed both Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale (ESS) surveys during a laboratory visit. The PSQI was analyzed to determine self-reported habitual bedtime, wake time, and sleep duration, as well as sleep quality over the previous month. The ESS was analyzed to determine self-reported ideal bedtime, wake time, and sleep duration. Data are presented as mean $\pm$ SD. A paired t-test was used to compare current and desired sleep durations. **RESULTS**: Habitual bedtime (n=171) was $22:37 \pm 0:46$. Habitual wake time (n=167) was $06:47 \pm 0:58$. Self-reported actual sleep duration was 7.6 ± 1.0 h with 54% of athletes obtaining less than the recommendation of 8 h of sleep per night. To feel their best, ideal self-reported bedtime (n=162) was $21:57 \pm 0:41$ and self-reported wake time (n=159) was $07:49 \pm 1:18$. Calculated ideal total sleep duration (n=158) was 9.9 ± 1.4 h, which was significantly longer than actual sleep duration (n=155; p<0.001). Habitual sleep quality, assessed as the mean Global PSQI score, (n=159) was 4.3 ± 2.2; however, 63 athletes (39.6%) had a score ≥ 5, which is the PSQI cutoff indicative of poor sleep quality. **CONCLUSIONS**: Self-reported habitual sleep duration in a group of adolescent athletes suggests the majority do not meet the minimum sleep duration recommendations and many have poor sleep quality. However, when reporting their ideal sleep habits, most athletes would prefer to obtain significantly more sleep, desiring durations at the top end of the recommendations even. This suggests lack of desire is not the main reason for sub-optimal sleep duration in this group. Therefore, researchers and practitioners should focus on identifying and creating solutions to overcome barriers to sleep.

1110   Board #6   May 31 8:00 AM - 10:00 AM

Sleep Coaching Augments the Physiological Benefits of Exercise Training

Eric V. Neufeld, Brett A. Dolezal, David M. Boland, Jennifer L. Martin, Christopher B. Cooper, FACSM. *David Geffen School of Medicine at UCLA, Los Angeles, CA.*

(No relevant relationships reported)

Exercise and quality sleep exert positive effects on each other. The practice of healthy sleep habits also enhances sleep quality and duration.
PURPOSE: To examine whether a multicomponent sleep coaching intervention (SC) combined with aerobic and resistance training programs would improve fitness and health measures more than the training program alone. **METHODS:** Thirty-eight healthy fitness club patrons (22 men) were randomized to receive SC (n = 19), consisting of twelve, 10-min education sessions between the trainer and participant to discuss sleep-related topics coupled with weekly, individualized sleep improvement assignments or equal-attention (EA) (n =19), consisting of identical training and education time, with education sessions discussing general wellness topics. All participants engaged in one hour of coached resistance training and remotely guided aerobic exercise thrice weekly for 12 weeks. Fitness measures (aerobic performance, body composition, muscle strength and endurance, lower-body power), sleep characteristics, heart rate variability (HRV), and biochemical assays were obtained at baseline and after the 12-week program. **RESULTS:** SC demonstrated greater improvements in aerobic performance measures [maximum oxygen uptake (0.44 ± 0.12 vs. $0.23+0.08$ L/min, $P < 0.001$), metabolic (lactate) threshold (0.64 ± 0.13 vs. 0.34 ± 0.13 L/min, $P < 0.001$) and ventilatory threshold (0.36 ± 0.13 vs. 0.05 ± 0.71 L/min, $P = 0.003$)], peak and average lower-body power (524 ± 190 vs. 300 ± 208 W, $P = 0.006$ and 212 ± 79 vs. 137 ± 58 W, $P = 0.005$, respectively), and body composition [decreased body fat percentage (-3.6 ± 2.6 vs. $-1.4\pm1.9\%$, $P = 0.011$) and fat mass (-2.7 ± 1.7 vs. -1.3 ± 1.6 kg, $P = 0.021$)]. Additionally, SC positively influenced the parasympathetic tone (HF-HRV: 2.6 ± 3.3vs. 0.3 ± 2.2 ms^2, $P = 0.036$) and glucose metabolism [fasting insulin (-1.6 ± 1.7 vs. 0.2 ± 1.2 mIU/L, $P = 0.004$) and fasting glucose (-8.4 ± 9.9 vs.

6.1 ± 8.8 mg/dL, $P < 0.001$)]. **CONCLUSION:** SC resulted in greater improvements in fitness measures, body composition, and HRV compared with an equal-attention control group. These findings have intriguing implications regarding the role of SC in maximizing health and physical performance.

1111   Board #7   May 31 8:00 AM - 10:00 AM

Effects Of Continuous Versus Interval Exercise On Sleep Profile In Young Healthy Males

Jorge Fernando Tavares de Souza, Solange Prado São José, Hanna Karen Moreira Antunes. *Universidade Federal de São Paulo, São Paulo, Brazil.*

(No relevant relationships reported)

The total sleep time of the population is decreasing every year and, in addition, the number of people complaining of poor sleep or sleep disorders is increasing. On the other hand, regular exercise is known as one of the tools that help to promote sleep hygiene. However, it is not known which type of exercise is best.
Purpose: To evaluate the effects of continuous running and interval running on the sleep profile of healthy young males.
Methods: 12 healthy males were recruited, all physically active, aged 23.6 ± 1.9 years and BMI of 24.9 ± 2.7 kg/m². The volunteers were all submitted to 3 different conditions: Baseline (BL), Continuous Running (CR) and Interval Running (IR). In the BL condition, no physical exercise was performed for 24h. In the CR condition, they were submitted to continuous running (5 minutes of warm-up, 30 minutes run at intensity 12-14 according to the Borg Scale, and 5 minutes of cool down). In the IR condition, they were submitted to interval running (5 minutes of warm-up, 6 bouts of 2.5 minutes at intensity 15-17 on the Borg Scale separated by 2.5 minutes recovery intervals, followed by 5 minutes of cool down). In the morning soon after waking up, volunteers completed 4 records: Sleep Diary, Visual Analog Pain Scale, Scale of Overall Quality of Recovery and STAI-state. The data analysis performed was one-way ANOVA with Duncan test and a significance level at $P < 0.05$. The study was approved by UNIFESP Ethics Committee (#1686/08).
Results: In the sleep diary, a decrease was observed in the scores in CR condition when compared to the BL (BL= 28.00 ± 3.19, CR= 23.36 ± 4.59, p= 0.01). In the waking sensation, a decrease was observed in CR condition when compared to the BL (BL= 8.13 ± 1.13, CR= 6.68 ± 1.82, p= 0.02). In the Visual Pain Scale, the CR condition presented higher scores when compared to the BL condition (BL= 1.12 ± 1.11, CR= 3.18 ± 2.48, p= 0.01). Finally, in the Overall Quality of Recovery Scale, the BL condition presented higher scores when compared to CR and IR conditions (BL= 17.08 ± 2.50, CR= 14.64 ± 2.94, IR= 14.58 ± 2.11, p= 0.02). No significant differences were found regarding STAI-state.
Conclusions: After more intense exercise volunteers had a more restful sleep when compared to continuous running. Thus, we concluded that interval exercise can be used in training to also improve sleep quality.

The Effect of Total Sleep Time on Ultra-Endurance Triathlon Performance

Jacob N. Kisiolek[1], Kyle A. Smith[1], Daniel A. Baur[2], Brandon D. Willingham[1], Margaret C. Morrissey[1], Samantha M. Leyh[1], Patrick G. Saracino[1], Michael J. Ormsbee, FACSM[1]. *[1]Florida State University, Tallahassee, FL. [2]Elon University, Elon, NC.* (Sponsor: Dr. Michael Ormsbee, FACSM)

(No relevant relationships reported)

PURPOSE: The primary purpose was to determine the effect of sleep time on performance during a 3-day multistage ultra-endurance triathlon (stage 1: 10km swim, 144.8km bike; stage 2: 275.8 km bike; stage 3: 84.4km run). Secondarily, we determined if performance time predicts sleep time. **METHODS:** Eighteen triathletes (age: 37 ± 7.9y; height: 175 ± 7cm; weight: 70 ± 9kg) partook in sleep analysis pre, during, and post triathlon using an actigraphy wrist band. Participants wore the band to record sleep time for five days (1-2 days pre-race, 3 race days, 1-day post-race), except during racing. Bands were collected before each stage to download the previous night's data, then re-distributed after each stage. Performance times were recorded after each stage, and following total completion of the race. The data was analyzed via linear regression. **RESULTS:** Total sleep time (mean$\pm$SD; pre-race: 393.9 ± 81.1 min, pre-stage 1: 342 ± 90.2min, pre-stage 2: 347.5 ± 54.6min, pre-stage 3: 299.7 ± 107.0min, post-race: 308.8 ± 86.3min) significantly decreased over time (P<0.05). Sleep time predicted performance in multiple stages. Specifically, pre-stage 3 sleep time explained 30% and 43% of the variation in stage 3 performance (R^2=0.30, p=0.035), and total finishing time (R^2=0.43, p=0.008). Performance time also predicted sleep time. Specifically, stage 1 performance explained 37% and 47% of the variation in pre-stage 2 sleep time (R^2=0.37, p=0.010), and pre-stage 3 sleep time (R^2=0.47, p=0.005). Stage 2 performance explained 39% the variation in pre-stage 3 sleep time (R^2=0.39, p=0.014). Total race sleep time (Pre-stage 1, 2, and 3) was averaged; 33% of the variation in total finishing time can be predicted by average total racing sleep

time (R^2=0.33, p=0.015). No additional relationships were seen. A cutoff value was found at 401.6 min of average total race-night sleep time, indicating the top 25% of race finishers slept for ≥401.6 min. **CONCLUSIONS:** During a multistage ultra-endurance triathlon, performance time can be predicted by sleep time the night before. In addition, faster performance times during each stage predicts more sleep time. Based on our results, average total race-night sleep time of roughly 402 min (6.7h/night) leads to faster finishing time in the Ultraman Florida. This study was supported by FSU and FatigueScience.

C-12   Free Communication/Slide - **New Insights in Measurement of Physical Activity and Sedentary Behavior**

Measuring Change in Physical Activity Across a Technology-Based Intervention
Whitney A. Welch, Bonnie Spring, Siobhan M. Phillips, Juned Siddique. *Northwestern University Feinberg School of Medicine, Chicago, IL.* (Sponsor: Ann M Swartz, FACSM)
(No relevant relationships reported)

PURPOSE: To characterize and compare the change in moderate to vigorous physical activity (MVPA) between an accelerometer and smart phone-based physical activity log across a three-week physical activity intervention. **METHODS**: Participants (N=204, 77% female, age=33±11y, BMI=28.2±7.1 kg/m²) in the Make Better Choices 1 (MBC1) Study were randomized to one of two activity-related intervention arms: 1) increase MVPA arm or 2) decrease sedentary active control arm. Participants wore an accelerometer while simultaneously completing a smart phone-based physical activity log for five weeks: a two-week baseline assessment phase and a three-week intervention follow-up phase. Linear mixed effects models were used to characterize the difference in MVPA between measurement methods across baseline and intervention. **RESULTS**: Physical activity logs show a 43.5 min/day (95% CI: 31.9, 55.1) difference in means between the two groups at follow-up and accelerometer results indicate a 12.3-min/day (95% CI: 9.5, 15.2) difference in means between the two groups at follow-up, with the increase MVPA group recording more minutes per day of MVPA. Correlations between the two measurement methods for the physical activity group increased from baseline (r=0.58, p<0.001) to intervention follow-up (r=0.68, p<0.001) and no change was seen in the active control group from baseline (r=0.59, p<0.001) to intervention follow-up(r=0.55, p<0.001). Intervention effect size when using the physical activity log was 0.48 and 0.54 when capturing change in MVPA using the accelerometer. **CONCLUSIONS:** Treatment effects measured in minutes per day were very different between measurement method, however, the standard deviations were similar. Similar effect sizes suggest smart phone-based activity logs may provide similar results to accelerometers for estimating intervention effects.

1115   May 31 8:15 AM - 8:30 AM
Validation Of A Research-grade Accelerometer In Estimating Free-living Sedentary Time
Albert Mendoza[1], Kate Lyden[2], John Sirard[3], John Staudenmayer[3], Catrine Tudor-Locke, FACSM[3], Patty Freedson, FACSM[3]. [1]*California State University, East Bay, Hayward, CA.* [2]*KAL Research|Consulting LLC, Denver, CO.* [3]*University of Massachusetts-Amherst, Amherst, MA.* (Sponsor: Patty Freedson, FACSM)
(No relevant relationships reported)

Research-grade accelerometers (RGA) are valuable tools to monitor sedentary behavior. Despite the broad appeal of RGA for researchers and clinicians, there is limited evidence of how well they estimate sedentary time (ST) in free-living settings. **PURPOSE:** To examine the accuracy and precision of ST estimates from an RGA worn on the hip and wrist in free-living settings. **METHODS:**Thirty-two participants were directly observed while completing three, 2-hour sessions on different days and wearing commonly used hip- and wrist-worn RGA's. A validated video-taped direct observation (DO) system was used to determine ST. For the RGA, ST was estimated using (1) the 100 counts/min cutpoint (hip RGA) and (2) random forest model using 15-sec raw acceleration data (Staudenmayer et al., 2015) (wrist RGA). Linear mixed models were used to compare the accuracy and precision of ST estimates from the hip- and wrist-worn RGA to DO measured ST. Pearson correlation coefficients were used to determine the association between DO measured and RGA estimated ST. **RESULTS:**

	Mean min (SD)	Bias	95% CI	r
DO (Criterion)	42.8 (42.3)			
RGA hip	93.4* (24.0)	50.7	43.3,58.1	0.59
RGA wrist	63.1* (25.2)	20.3	13.3,27.3	0.77

*, significantly different than criterion (p<0.05).

The hip- and wrist-worn RGA estimates of ST were significantly overestimated compared with DO. Precision, assessed as the 95% CI for the bias, was similar between the RGA hip and RGA wrist. The RGA ST min was moderately (RGA hip) to highly (RGA wrist) correlated with DO. **CONCLUSION:** The accuracy of ST estimates from RGA were affected by wear location and data processing technique. These results demonstrate the need for more research to elucidate how these factors influence estimates of ST from RGA in free-living settings. Funded by: NIH: 1F31HL129802-01

1116   May 31 8:30 AM - 8:45 AM
Validation of Activity Monitor Methods in Classifying Sedentary Behavior in Distinct Activity Domains
Julian Martinez, Mami M. Takeda, Sarah K. Keadle. *California Polytechnic State University San Luis Obispo, San Luis Obispo, CA.* (Sponsor: Todd Hagobian, FACSM)
(No relevant relationships reported)

PURPOSE: The present study compared sedentary time estimates from a thigh-worn monitor (AP) to a wrist and hip-worn AG monitor across five different activity domains in a free-living environment.
METHODS: Participants (n=16, mean age=26.9yrs, 69% female) wore two AG monitors (right hip, non-dominant wrist), and one AP accelerometer (thigh) for two, 2-hour sessions. Each participant completed 2 out of 5 activity domains that represent daily life: household (H, N=5), active leisure (AL, N=8), sedentary leisure (SL, N=6), work (W, N=7), and transportation/errands (TE, N=4).Sedentary time was estimated from the AG-hip data using: Sojourn 3x (S3x), 100 vertical count cut-point (V100), 200 vector magnitude cut-point (VM200), and the Crouter two-regression (C2) method. A random forest machine learning method (RF) was used to classify AG wrist data. Relationship between AG and AP methods were examined with Pearson correlations. A paired t-test was used to examine mean differences in overall sedentary time estimates, and a linear mixed effects model was used to test for any significant interaction between accuracy of AG methods by activity domain. P-values < 0.05 are considered statistically significant.
RESULTS: Compared to AP, correlations for AG methods were: S3x (R=0.82), VM200 (R=0.81), C2 (R=0.71), V100 (R=0.61) and wrist RF (R=0.68), (all p<0.05). Compared to AP, estimates were significantly higher for the S3x (mean diff [95%CI)] 9.4 (0.57, 18.3)min (p=0.02) and V100 (18.9[5.3, 32.4]min, p=0.003). The RF (-4.6 [-17.4, 8.2]min, 200VM (-1.2 [-10.8, 8.4] min), and C2 (2.2 [-9.8, 14.2]min), were not statistically different than AP. The accuracy of S3x did not differ by domain (0.05), while the accuracy of the 200VM, C2, 100V and RF estimates significantly differed by domain (p<0.05). VM200, C2 and RF overestimated sedentary time in the TE and H domains and underestimated in AL and SL.
CONCLUSIONS: The S3x method overestimated sedentary time compared to AP, but was the most precise and consistent across domains. These data highlight the importance of ensuring a range of activity domains in free-living validation studies. Future research should expand the sample and include direct observation measures of sedentary time compared to AP and AG.

Video-Recorded Validation of Wearable Step Counters Under Free-living Conditions
Lindsay Toth. *University of Tennessee, Knoxville, TN.* (Sponsor: David R. Bassett, Jr., PhD, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the accuracy of 14 step counting methods under free-living conditions during all waking hours of one day. **METHODS**: Twelve adults (mean±SD, age: 35±13 yrs) wore a chest harness that held a GoPro video camera angled down towards the feet. The GoPro continuously recorded video of all steps taken throughout the day. Simultaneously, participants wore two StepWatch [SW] devices on each ankle (each programmed with different settings), one activPAL [AP] on each thigh, four devices at the waist (Fitbit Zip [FZ], Yamax Digi-Walker SW-200 [DW], New Lifestyles NL-2000 [NL], and ActiGraph GT9X

[AG]), and two devices on the dominant and non-dominant wrists (Fitbit Charge [FC] and AG). The GoPro videos were downloaded to a computer and two researchers independently counted steps using a hand tally device, which served as the criterion method.
RESULTS: The SW devices captured between 95.3% and 102.8% of actual steps taken throughout the day (P>0.05). Seven step counting methods estimated less than 100% of actual steps; FZ, NL, AG with the Moving Average Vector Magnitude algorithm (MAVM) and without the low frequency extension (LFE), both worn on the hip, the FC worn the non-dominant wrist, and the AP on both the left and right thighs, capturing 69% to 81% of actual steps (P<0.05). Three methods estimated more than 100% of actual steps; AG with LFE worn on the hip and both wrists, capturing 128% to 220% of actual steps (P<0.05). Estimated steps from SW (with all settings), DW, FC on the dominant wrist, and AG (with LFE and MAVM) on both wrists did not significantly differ from actual steps (P>0.05).
CONCLUSIONS: Across all waking hours of one day, step counts differ between methods. Compared to hand counted steps, the SW device, regardless of settings, was highly accurate for counting all free-living steps.

Use of Consumer Monitors for Estimating Energy Expenditure in Youth

Andrew S. Kaplan, Samuel R. Lamunion, Paul R. Hibbing, Scott E. Crouter, FACSM. *University of Tennessee- Knoxville, Knoxville, TN.*

(No relevant relationships reported)

Consumer-grade physical activity monitors (PAMs) have been extensively examined for estimating energy expenditure (EE) in adults; however, few studies have examined their ability to estimate EE in youth. **PURPOSE:** The purpose of this study was to examine equivalence between predicted EE (consumer-grade PAMs) and measured EE (indirect calorimetry) in youth. **METHODS:** Ninety-five youth (mean(SD); age, 12.2(3.5) yr; 49% male) performed 30 min of supine rest and 16 structured activities ranging from sedentary behaviors to vigorous intensities. Each structured activity was performed twice: once for 60-90 s and once for 4-5 min. During all testing, participants wore an Apple Watch 2 (AW, left wrist) and Mymo Activity Tracker (MT, right hip). Subsamples wore two Misfit Shine 2 devices (MSH, right hip; MSS, right shoe, n = 27), a Samsung Gear Fit 2 (SG, right wrist, n = 44), and/or a Fitbit Charge 2 (FC, right wrist, n = 53). A Cosmed K4b^2 was used as the criterion measure of EE. Oxygen consumption was converted to EE in kilocalories (kcal), then summed over the whole trial to obtain gross EE. Net EE was calculated by subtracting the estimated basal EE (Schofield's equation) from the measured gross EE. For all PAMS, EE was recorded at the start and end of the trial, and the difference was used for analysis. 95% equivalence testing with ±10% equivalence zone was used to assess equivalence between the estimated (PAM) and measured (K4b^2) EE. All PAMs estimated gross EE, except for AW which estimated net EE, thus separate equivalence test was performed for the AW. Mean absolute percent error (MAPE) was used to assess individual-level error. **RESULTS:** Equivalence testing results and MAPE are summarized in Table 1.
CONCLUSION: Only the MT was equivalent to the K4b^2, however it also had the largest individual error. Caution is warranted when using consumer-grade PAMs in youth for tracking EE as there is a high degree of variability in device output.

Table 1. Mean EE±SD (kcal) and MAPE for six PAMs in youth.

	K4b^2 EE	Apple Watch
Net EE		
EE (kcal)	160±59 (143.9-175.9)#	75±42
MAPE	---	56.4

	K4b^2 EE	Mymo Tracker	Misfit Shine Hip	Misfit Shine Shoe	Samsung Gearfit 2	Fitbit Charge 2
Gross EE						
EE (kcal)	232±71 (209.1-255.6)#	236±108*	208±77	208±76	177±65	281±113
MAPE	---	42.1	17.6	21.8	33.9	39.1

*significantly equivalent to K4b^2 (p<0.05); #values in parentheses are equivalence zone

Validity and Reliability of the Exercise Vital Signs Questionnaire in a Diverse Urban Population

Norberto Quiles[1], Lin Piao[1], Aston K. McCullough[2]. [1]*Queens College, Flushing, NY.* [2]*Teachers College, Columbia University, New York, NY.*

(No relevant relationships reported)

The Exercise Vital Signs (EVS) is a new brief (<30 seconds) physical activity (PA) questionnaire used by the Exercise is Medicine initiative within the American College of Sports Medicine. While the criterion validity of the EVS has been evaluated in a select number of ethnic groups, research on the validity and reliability of the EVS questionnaire in a diverse, urban sample is lacking. **PURPOSE**: To determine the validity and reliability of the EVS in a diverse, urban sample.
METHODS: An ethnically-diverse sample (White 33%, Latino 31%, Asian 21%, Black 15%) of N=39 participants [age *31*(10.4)] were asked to wear an accelerometer at the hip for 9 days and to complete the EVS at the beginning (T1) and end (T2) of the wear period. The criterion validity of the EVS-estimated minutes of weekly moderate-vigorous PA (MVPA) was determined against accelerometer-derived estimates of the total time spent in ≥10min bouts of MVPA using Spearman's correlations. EVS responses were used to predict subjects who were confirmed to meet current PA guidelines of ≥150 MVPA min/week via accelerometry using logistic regression. The EVS receiver operating characteristic area under the curve (AUC), sensitivity, and specificity were calculated. The concurrent validity of the EVS MVPA estimates was tested against accelerometer-derived steps/day using Spearman's correlations. The intraclass correlation coefficient (ICC) was calculated between the EVS responses at T1 and T2 in order to evaluate questionnaire test-retest reliability.
RESULTS: Reliability for the EVS questionnaire was strong (ICC= .98). There was a moderate correlation (*rho*= .58 at T2, *p*= <.01) between the EVS-estimated PA minutes/week and the accelerometer-derived MVPA minutes/week. There was also a moderate correlation (*rho*= .43 at T2, *p*= .006) between EVS-determined PA minutes/ week and the accelerometer-derived steps/day. The T2 EVS specificity and sensitivity were 56% and 78%, respectively, and the AUC was 0.74.
CONCLUSIONS: In a diverse, urban sample, the EVS questionnaire has acceptable validity and high test-retest reliability. The EVS may be a useful tool for identifying ethnically-diverse individuals not meeting current PA guidelines. Further research in larger ethnically-diverse samples is needed.

1120   May 31 9:30 AM - 9:45 AM

Validity of a Novel Objective Screening Test for Risk of Physical Inactivity in Toddlers

Aston K. McCullough, Carol Ewing Garber, FACSM. *Columbia University Teachers College, New York, NY.* (Sponsor: Carol Ewing Garber, FACSM)

(No relevant relationships reported)

PURPOSE. To evaluate the accuracy of the Objective Physical Inactivity Risk Assessment for Toddlers (OPIRA-T), a brief (15-60min) screening test for physical inactivity.
METHODS. Families (N=119) with children 24-35 months-old were recruited from an urban Early Head Start (EHS). Children's physical activity (PA) was measured for 7 days via hip-worn triaxial accelerometers. Cliff (2009) wear time criteria were applied to children's 15s epoch PA data, and Trost (2012) cut points were applied. Children not meeting respective moderate-vigorous PA (MVPA) and total PA (TPA) guidelines of 60min/day and 180min/day were determined using 7-day wear time data. Brief raw accelerometer data segments [15, 30, 45, 60min] were randomly extracted from the full 7-day wear data from periods when children were in the EHS. The raw signals were scored using our novel signal analysis algorithm (OPIRA-T). A classification tree (CART) was used to fit OPIRA-T scores as a predictor of children not meeting PA guidelines during the 7-day wear period. CART algorithm ROC area under the curve (AUC) and bootstrapped 95% CI were evaluated. OPIRA-T scores were also used to classify children at risk of physical inactivity using a custom cascaded 2-step algorithm (OPIRA-T screening test). The bootstrapped sensitivity, specificity, positive and negative predictive values for the OPIRA-T screening test were calculated. Descriptive statistics are presented as Mean(SD) and Frequencies (%).
RESULTS. Children [n=60; F: 53%; age: 29(4) months] with valid 7-day wear time data were included. Respectively, 75% and 32% of toddlers did not meet MVPA and TPA guidelines. OPIRA-T score and OPIRA-T screening test validation results appear in Table 1.
CONCLUSION. Within the EHS setting, OPIRA-T accurately identified toddlers at risk of physical inactivity from a brief period (15min) of objectively measured PA. Further research is needed on which classroom periods are the most reliable testing times for using OPIRA-T.

THURSDAY, MAY 31, 2018

Table 1. Accuracy of OPIRA-T scores and screening test in identifying toddlers at risk of insufficient daily activity according to current physical activity recommendations

Accuracy Indices	Observation Length			
	15min	30min	45min	60min
	n = 53	n = 60	n = 58	n = 55
OPIRA-T Scores (AUC [95% C.I.])				
Not Meeting MVPA[a]	0.96 [0.89, 0.99]	0.97 [0.91, 0.99]	0.92 [0.77, 0.99]	0.95 [0.86, 0.99]
Not Meeting TPA[b]	0.95 [0.87, 0.98]	0.94 [0.84, 0.98]	0.92 [0.81, 0.97]	0.90 [0.78, 0.97]
OPIRA-T Screening Test (%)				
Sensitivity	90%	93%	96%	96%
Specificity	92%	93%	92%	70%
Positive Predictive Value	94%	96%	96%	86%
Negative Predictive Value	86%	88%	92%	90%

Sensitivity of a Consumer Activity Tracker to Detect Changes In Lab-based and Free-living Activity Settings

Greg J. Petrucci, Jr., Patty S. Freedson, FACSM, Brittany R. Masteller, Melanna F. Cox, John W. Staudenmayer, John R. Sirard. *UMass Amherst, Amherst, MA.* (Sponsor: Patty S. Freedson, FACSM)

Reported Relationships: G.J. Petrucci: *Contracted Research - Including Principle Investigator; Misfit Shine™ Wearables (Fossil Group, Richardson, TX, USA).*

PURPOSE: Determine the sensitivity of a consumer activity tracker (CAT) to detect changes in physical activity (PA) measures during laboratory (LAB) and free-living (FL) conditions. **METHODS**: Twenty-one participants wore the CAT and ActiGraph GT3X+ accelerometer (AG) at the hip and dominant wrist during three, 1-hour LAB sessions: sedentary (SS), sedentary plus walking (SW), and sedentary plus jogging (SJ). For SW and SJ, participants performed 30-minutes of sitting, then 30-minutes of walking or jogging at 5.15 or 8.0 kph, respectively. Direct observation (DO) of steps served as the criterion measure for SW and SJ sessions. Devices were also worn during two FL conditions: 1) active week where participants met activity guidelines (ACT); 2) sedentary week, absent of purposeful activity (SED). The PA measures were: CAT and AG steps and kCals, CAT "points", and AG vertical axes counts. For LAB and FL, significant differences were examined by comparing non-overlapping 95% confidence intervals (C.I.'s) and linear mixed effects models, respectively. Linear mixed effects models were fit for differences (bias; absolute and percent) between CAT device estimated steps and DO step ($\alpha \le 0.05$). **RESULTS**: For all hip-worn CAT measures there was a significant step-wise increase (p < 0.05) from SS to SJ. For the wrist-worn CAT, there was a significant step-wise increase in steps and "points" from SS to SJ (p < 0.05). However, the wrist CAT kCal estimates were greater for SJ, compared to SS and SW, which were similar to each other [95% C.I.'s (95.5, 152.8) and (141.1, 378.9), respectively]. Compared with DO, CAT hip significantly underestimated steps by 3.5%, while CAT wrist significantly overestimated steps by 4.2%. AG estimates of kCals and counts showed a significant step-wise increase from SS to SJ (p < 0.05), however estimates of steps were greater for SJ, compared to SS and SW, which were similar to each other [95% C.I.'s hip: (2861, 3542) and (3433, 4789), wrist: (2068, 2803) and (1908, 2647)]. During FL conditions, all CAT and AG outcomes were sensitive to changes between ACT and SED (p < 0.0001). **CONCLUSIONS**: The hip-worn CAT was sensitive to changes during LAB and FL. CAT may be a useful tool for interventions where PA measures are used as exposure and/or outcome measures. **FUNDING:** UMass Institute of Applies Life Sciences and Fossil GroupTM

Fitness And Age-related Associations: Is VO$_{2peak}$ A Valid Measure For Older Adults?

Ryan J. Dougherty, Jacob B. Lindheimer, Aaron J. Stegner, Stephanie Van Riper, Jacob V. Ninneman, Ozioma C. Okonkwo, Dane B. Cook, FACSM. *University of Wisconsin - Madison, Madison, WI.* (Sponsor: Dane B. Cook, FACSM)

(No relevant relationships reported)

Cardiorespiratory fitness (CRF) is routinely investigated in older adults; however, the most appropriate CRF measure to use for this population has received little attention. **Purpose:** To (i) evaluate the reliability and validity of the oxygen uptake efficiency slope (OUES) as a sub-maximal measurement of CRF, (ii) examine demographic, risk-factor, and exercise testing differences in older adults who satisfied standardized criteria for a peak oxygen consumption (VO$_{2peak}$) test compared to those who did not and (iii) determine the difference between directly measured VO$_{2peak}$ values and OUES-predicted VO$_{2peak}$ values. **Methods:** One hundred ten enrollees from the Wisconsin Registry for Alzheimer's Prevention participated in this study. Participants performed a graded maximal exercise test and wore an accelerometer for 7 days. For each participant, the OUES was calculated at 75, 90 and 100% of exercise duration. VO$_{2peak}$ was recorded at peak effort, and one week of physical activity behavior was measured. **Statistical analyses:** Intraclass correlation coefficients (ICC), bivariate Pearson correlations and a one-way repeated-measures ANOVA examined the reliability and criterion validity. Independent samples t-tests and Cohen's effect sizes examined between group differences and linear regression was used to obtain the formula for OUES-predicted VO$_{2peak}$. **Results:** OUES values calculated at separate relative exercise durations displayed excellent reliability (ICC = .995; $p < .001$), and were strongly correlated with VO$_{2peak}$ (r_{range} = .801 - .909; $p < .001$). As hypothesized, participants who did not satisfy VO$_{2peak}$ criteria were significantly older than those who satisfied criteria ($p = .049$) and attained a directly measured VO$_{2peak}$ that was 2.31 mL·kg·min^{-1} less than their OUES-predicted VO$_{2peak}$ value ($d = .72; p = .003$). **Conclusions:** Older adults are less likely to satisfy VO$_{2peak}$ criteria, which results in an underestimation of their CRF. Without adhering to standardized criteria, VO$_{2peak}$ measurement error may lead to misinterpretation of CRF and age-related associations. Here, we conclude that OUES is a reliable, valid measurement of CRF which does not require consideration of standardized criteria.

1124　　May 31 8:15 AM - 8:30 AM

Evaluating The Influence Of Methodological Variables On The Determination Of Vo$_{2max}$ And The Lactate Threshold.

Nicholas Jamnick[1], Javier Botella[1], David Pyne, FACSM[2], David Pyne, FACSM[3], David Bishop, FACSM[1], David Bishop, FACSM[4]. [1]*Victoria University, Melbourne, Australia.* [2]*Australian Institute of Sport, Canberra, Australia.* [3]*University of Canberra, Canberra, Australia.* [4]*Edith Cowan University, Joondalup, Australia.* (Sponsor: Professor David Bishop, FACSM)

(No relevant relationships reported)

Graded exercise tests (GXTs) can be used to determine peak oxygen uptake (VO$_{2peak}$) and the lactate threshold (LT), and are commonly employed by sport scientists and coaches to evaluate and prescribe exercise training. Two critical methodological choices that influence these indices are GXT stage length (for VO$_{2max}$ and the LT), and the method used to calculate the LT. However, there has been little investigation of the effects of these choices on the validity of the derived indices. **PURPOSE:** To determine the influence of GXT stage length and method of calculation on the estimation of LT and VO$_{2peak}$. **METHODS:** Trained male cyclists (n=17) completed five GXTs of varying stage length (1, 3, 4, 7 and 10 min) on different days, each followed by a verification exhaustive bout (VEB) to confirm VO$_{2peak}$, and a series of 30-min constant power bouts to establish the maximal lactate steady state (MLSS). All tests except GXT$_1$ (which was performed first) were performed in a randomized order. VO$_2$ was assessed during each GXT and VEB, and 15 different LTs were calculated from four of the GXTs (3, 4, 7 and 10 min) - yielding a total 60 LTs. Agreement was assessed between the highest VO$_2$ measured during each GXT (VO$_{2peak}$), and between each GXT and subsequent VEB. Validity of the LTs derived from the GXTs was assessed using the MLSS as the criterion measure. VO$_{2peak}$ and LT data were analyzed

THURSDAY, MAY 31, 2018

using mean difference (MD), effect size (ES), intraclass correlation (ICC), and the coefficient of variation (CV). **RESULTS:** The VO_{2peak} value from GXT_1 was 61.0 ± 5.3 mL/kg/min and the peak power 420 ± 55 W (mean $\pm$ SD). The MLSS power was 264 ± 39 W. VO_{2peak} from $GXT_{3, 4, 7, 10}$ underestimated VO_{2peak} from GXT_1 (MD = -1.2, -2.1, -3.7 and -4.8 mL/kg/min; ES = 0.23, 0.36, 0.69 and 0.88; ICC = 0.82, 0.75, 0.63 and 0.77; GXT_1 vs. $GXT_{3, 4, 7, 10}$, respectively). The VO_{2peak} values from the GXT and VEB during GXT_1 and GXT_4 were within the error of the measurement (CV<3%). The Modified Dmax method (log-poly-MD_{max}) derived from GXT_4, with an alternate initial data point calculated using the log-log method, provided the most valid estimate of the MLSS (MD = 1.1 W; ES = 0.03; ICC = 0.96). **CONCLUSION:** The log-poly-MD_{max} derived from GXT_4 yielded the most valid estimate of the MLSS; however, the VO_{2peak} from the four longest GXTs (3, 4, 7 and 10 min) underestimated the VO_{2peak} from GXT_1.

Evaluation of VO²ᵖᵉᵃᵏ Calculations for the Boer 2 Through 5 Protocols

Nicholas F. Boer, Josh Johann, Gregory Heath, FACSM. *Univ. of Tennessee, Chatanooga, TN.*

(No relevant relationships reported)

PURPOSE: The purpose of this investigation was to determine whether individuals of varying fitness levels would self-select an appropriate exercise test from the Boer 1 - 5 graded (maximal) exercise testing protocols. The protocols were developed to be discreet for each of five fitness levels (1 - Clinical, 2- Moderately Fit, 3 - Fit, 4 - Highly Fit and 5 - Elite). It is hypothesized that calculated VO_{2peak} in each group will be different, while testing time will be statistically the same.
METHODS: Students from an exercise prescription lab course completed one of the five Boer protocols as a class assignment. Subjects completed a short survey and listened to a lecture regarding protocol selection. Subjects completed the grade exercise test and stopped the test when volitional fatigue was achieved. Treadmill testing time and calculated VO_{2peak} (from the intensity reached during the last two minutes) was recorded. A one-way ANOVA was completed with treadmill time and calculated VO_{2peak} as dependent variables and protocol selection as the independent variable.
RESULTS: N=83 (33 Male, 50 Female) Age 21.8 years (1.3), BMI 24.9 (4.3) There were no statistical difference between male and female results. Therefore, all subjects were pooled into the respective protocol. (No subjects completed Boer 1.)

	Boer 2 (N=9)	Boer 3 (N=50)	Boer 4 (N=20)	Boer 5 (N=4)
VO2Peak (ml/kg/min)	36.5 (2.2)*	43.3 (3.8)*	54.1 (4.5)*	64.0 (5.2)*
Time (min)	14.9 (2.6)	13.9 (2.1)	13.5 (2.2)	12.8 (1.5)

* (p<0.0001 compared to each of the other groups) Total time includes a three minute warm up. **CONCLUSIONS**: Subjects were able to determine an appropriate Boer 1 - 5 protocol and calculated VO_{2peak} was discreet between participants in each protocol. Treadmill time remained similar in each group, which does not occur when existing maximal protocols are used to determine aerobic fitness in subjects of varying fitness levels. Preliminary evidence would suggest that this is a viable method to test aerobic fitness in the population.

1126   May 31 8:45 AM - 9:00 AM

Change In VO₂max And Time Trial Performance To Interval Training Prescribed According To Ventilatory Threshold

Todd A. Astorino, Jamie DeRevere, Theodore Anderson, Patrick Holstrom, Erin Kellogg, Sebastian Ring, Nicholas Ghasb, Anders Rosland Nordstrand. *California State University--San Marcos, San Marcos, CA.*

(No relevant relationships reported)

Research shows that about 20 % of participants demonstrate no change in maximal oxygen uptake (VO_2max) in response to moderate intensity continuous training (MICT) (Bouchard et al 1999) or high intensity interval training (HIIT, Astorino & Schubert 2014). Approximately 50 % of this non-response is hereditary (Bouchard et al 1999) although the other 50 % is unexplored (Mann et al. 2015) and likely related to participants' habitual physical activity and dietary patterns, sleep, and traits of the training regime. In unfit adults, Wolpern et al. (2015) showed that MICT prescribed according to Ventilatory Threshold (VT) led to lower onset of individual non-response than when prescribed using HR. **PURPOSE:** To prescribe HIIT according to VT to monitor aggregate and individual responses in both VO_2max and time trial (TT) performance. **METHODS:** Eleven active (age and VO_2max = 28.9 ± 7.9 yr and 38.4 ± 4.5 mL/kg/min) men and women performed baseline testing including a VO_2max test on a cycle ergometer to determine peak power output (PPO) and ventilatory threshold (Caiozzo et al. 1986). Each subject also performed a 8.2 km cycling TT over three separate trials. Over a 3 wk period, they underwent 9 d of HIIT consisting of 8 – 10 60

---

s bouts at work rate of 130% VT with a 75 s active recovery period. Training elicited an intensity = 89.2 ± 5.7 %PPO. VO_2max and TT were assessed within 96 h after training. Controls (CON) (n=6, age and VO_2max = 22.7 ± 2.3 yr and 40.4 ± 8.7 mL/kg/min) consisted of active individuals who completed two sessions of baseline testing separated by 3 wk. **RESULTS:** Data showed a significant groupXtime interaction for VO_2max (38.4 ± 4.5 mL/kg/min to 40.7 ± 4.8 mL/kg/min vs. 40.4 ± 8.7 mL/kg/min to 40.6 ± 8.7 mL/kg/min, p=0.017) and TT (923.1 ± 78.2 s to 899.4 ± 67.2 s vs. 921.2 ± 115.0 s to 924.3 114.4 s, p=0.007) between HIIT and CON. With 2Xtypical error = 0.11 L/min for VO_2max and 18.0 s for TT, 63 % of participants showed meaningful increases in VO_2max and TT in response to this low dose of HIIT. Two of 11 participants exhibited non-response in both variables. **CONCLUSION:** These preliminary data show that 9 d of HIIT at 130 %VT significantly increases VO_2max and TT performance, but these responses do not occur in everyone. It is possible that the volume or duration of HIIT used is inadequate to promote greater responses in habitually active individuals.

1127   May 31 9:00 AM - 9:15 AM

The Impact Of An Interval Training Program On Muscle And Cerebral Oxygenation Responses To Incremental Ramp Exercise.

Jan Boone, Kevin Caen, Kobe Vermeire, Jan Bourgois. *Ghent University, Ghent, Belgium.*

(No relevant relationships reported)

PURPOSE: To study the effects of interval training on cerebral and muscle (de) oxygenation and their relationship to improvements in VO_2peak obtained from incremental ramp cycle exercise.
METHODS: Ten male subjects performed incremental ramp exercise tests (50 Watt + 25 Watt.min⁻¹) prior to and following a six week training intervention. During the tests, muscle (M. Vastus Lateralis) and cerebral (de)oxygenation (O_2Hb and HHb) was recorded with Near-Infrared Spectroscopy (NIRO 200, Hamamatsu, Japan). The training sessions were performed 3 times a week and consisted of 6 bouts of 4 min cycling at the critical power, interspersed by 3 min recovery a work rate corresponding to the gas exchange threshold. The changes in the tissue oxygenation responses (muscle HHb and totHb, cerebral O_2Hb and totHb) was calculated by expressing these responses obtained from the posttest relative to those obtained in the pretest in which the amplitude was set to 100%.
RESULTS: Following the training intervention, the VO_2peak had increased from 52.4±3.5 ml.min⁻¹.kg⁻¹ to 56.4±3.8 ml.min⁻¹.kg⁻¹ (P<0.001) and peak power output from 384±36 Watt to 415±40 Watt (P<0.001). Muscle HHb amplitude had increased (P<0.01) with 64±50%, whereas also the muscle HHb/work rate slope had increased (P<0.01) from 0.52±0.14%.Watt⁻¹ to 0.99±0.57%.Watt⁻¹. The change in muscle HHb amplitude was correlated to the increase in VO_2peak (r=0.75, P=0.03). Muscle totHb amplitude increased with 85±79%, although this was not correlated to VO_2peak increase (r=0.22, P>0.05). Cerebral O_2Hb amplitude had increased (P=0.019) by 50±57% with no change in cerebral O_2Hb/work rate slope (0.89±0.47%.Watt⁻¹ vs. 1.00±0.42%.Watt⁻¹, P=0.58). Cerebral totHb did not show a change in amplitude (28±46%, P=0.24) nor in slope (0.67±0.15%.Watt⁻¹ vs. 0.73±0.27%.Watt⁻¹, P=0.58).
CONCLUSIONS: This study showed that the improvement in VO_2peak was predominantly related to an improved fractional O_2 extraction (i.e, amplitude of muscle HHb). However, interval training also induced an enhanced O_2 diffusive capacity (i.e., amplitude of muscle totHb) and cerebral oxygenation which might also affect maximal exercise performance.

1128   May 31 9:15 AM - 9:30 AM

Relationships Between Vo₂max And Blood Lactate During Exercise Across Different Populations

Inigo San-Millán[1], Jared Berg[2], Janel Martinez[1], Ryan Kohler[2], Charles Van Atta[2]. *[1]University of Colorado School of Medicine, Aurora, CO. [2]CU Sports Medicine and Performance Center; Boulder, Colorado, CO.*

Reported Relationships: I. San-Millán: *Consulting Fee; Ascent Nutrition, Institute of Motion Analysis (IMA). Contracted Research - Including Principle Investigator; Leomo, LLC. Ownership Interest (Stocks, Bonds); MuscleSound, Inc.*

BACKGROUND: Maximal oxygen consumption ($VO2_{max}$) has been considered for decades the gold standard to measure cardiorespiratory fitness. The field of exercise physiology has experienced an important shift towards cellular and exercise metabolism in the past decade. The measurement of blood lactate ($[La^-]_b$) as a biomarker of cellular metabolism reflecting the metabolic response to exercise is widely used nowadays to assess performance. While many laboratories around the world still use VO2 and $VO2_{max}$ to assess human performance, many others use $[La^-]_b$. The debate of weather $VO2_{max}$ or $[La^-]_b$ is the best approach to assess fitness and performance has escalated over the past decade. However, there is neither consensus nor studies showing which method is more appropriate to assess fitness and performance. **PURPOSE:** To show the relationships between $VO2_{max}$ and $[La^-]_b$ during

exercise across different populations. **METHODS:** 232 male subjects divided in 24 international-level professional cyclists (PC), 77 US domestic competitive cyclists (DC), 107 recreational cyclists (REC) and 24 sedentary men (SM) performed an incremental cycling test starting at 1.0 W·kg^{-1} with increments of 0.5 W·kg^{-1} every 5 min until volitional exhaustion. VO$_2$ and VO2$_{max}$ (ml·kg^{-1}) and [La$^-$]$_b$ (mmol·L^{-1}) were measured at the end of each step. Comparisons were done for each group by means a Student t-test. Pearson correlation coefficient was used to verify the relationships between the different variables studied. Statistical significance was set at $p<0.05$. **RESULTS:** The average correlations between the VO2 and the [La$^-$]$_b$ at each step of the cycling test were weak for PC ($r = 0.05 \pm 0.02$, $p<0.001$), DC ($r = -0.11 \pm 0.12$, $p<0.001$), REC ($r = 0.17 \pm 0.14$, $p<0.001$) and SM ($r = 0.13 \pm 0.21$, $p<0.001$). The average correlations between VO2$_{max}$ and the [La$^-$]$_b$ at each step of the incremental test was moderate for PC ($r = -0.50 \pm 0.14$, $p<0.001$) while weak for DC ($r = -0.36 \pm 0.15$, $p<0.001$), REC ($r = -0.27 \pm 0.26$, $p<0.001$) and SM ($r = -0.32 \pm 0.28$, $p<0.001$). **CONCLUSION:** Our study shows weak to moderate correlations between VO2, VO2$_{max}$ and [La$^-$]$_b$ across different populations. Since lactate is a more descriptive parameter of the metabolic responses to exercise, measuring [La$^-$]$_b$ over VO2 and VO2$_{max}$ is a more appropriate parameter to assess metabolic fitness and performance.

1129   May 31 9:30 AM - 9:45 AM

The Effect Of Stride Frequency Variations On Running Performance At The Velocity Of Vo$_2$Max

Boram Lim, Boe Burrus, Justus Ortega, Young Sub Kwon. *Humboldt State University, Arcata, CA.*

(No relevant relationships reported)

Running economy (RE) is considered to be a critical factor to improve running performance. Stride frequency (SF) is an important variable for determining RE. The importance of SF has gained more attention in recent years, especially for recreational runners. However, no previous research has investigated the interaction between running performance at the velocity of VO2max and SF. **PURPOSE**: To investigate the effect of five different SF conditions on running performance at the velocity of VO$_2$max. **METHODS**: Twelve male recreational runners (Age=25 ± 4.2yr, Height=1.70 ± 0.6m, Body Mass=70.9 ± 8kg) measured VO$_2$max (53.1 ± 5.4 ml/kg/min) and preferred stride frequency (PSF; 89.5 ± 4 / min) through a graded exercise test (GXT) and running session, respectively. Running speed was determined based on each individual's GXT results by using ACSM estimation equations for exercise metabolism. Participants ran on the treadmill at this constant speed (0% grade) with different SF conditions (PSF, ±5%, ±10%) until time to exhaustion. Data were analyzed using a one way ANOVA with repeated measures. **RESULTS**: The total running distance was statistically significant among SF variations ($p<0.05$). Specifically, A Tukey post hoc revealed that the total distance at four SF conditions (90%, 95%, 100%, 110% of PSF) was statistically significant compared to 105% of PSF ($p<0.05$). Additionally, the respiratory exchange ratio (RER) was no statistically significant among SF variations ($p=0.37$). **CONCLUSIONS**: The SF variations have a significant influence on running performance. The relationship between SF variations and RER were possibly related to the central governor theory to delay the onset of fatigue. These results suggest that recreational runners could use a 105% of PSF to improve performance with the better RE.

Table 1. The relationship between SF, Distance, and RER					
SF variations	90%	95%	100% (PSF)	105%	110%
Distance(mile)	1.00 ± 0.5 *Ψ	1.04 ± 0.5 *	1.32 ± 0.6*	1.64 ± 0.7	1.15 ± 0.7 *
RER	1.05 ± 0.05	1.05 ± 0.03	1.03 ± 0.03	1.01 ± 0.02	1.02 ± 0.03

Note. Results reported in mean ± SD. * $p < 0.05$, vs. 105% SF conditions. Ψ $p < 0.05$, vs. 100% PSF conditions.

1130   May 31 9:45 AM - 10:00 AM

Predictability Of VO$_{2max}$ From Three Commercially Available Devices

Luke D. McCormick. *Eastern Michigan University, Ypsilanti, MI.* (Sponsor: Dr. Karin Pfeiffer, FACSM)

(No relevant relationships reported)

Sports watches have been developed with a feature that predicts VO$_{2max}$ from a submaximal effort. **PURPOSE**: To examine the predictability of VO2max from two heart rate monitors (Device A and V) and a global positioning system (GPS) watch compared to measured VO2max. **METHODS**: Twenty-seven participants, 15 males and 12 females ages 18 to 55, came to the Running Science Laboratory at Eastern Michigan University on two occasions. During visit 1, participants arrived in a semi-fasted state (without caffeine or caloric consumption for 3 hours) and completed a maximal graded exercise test (GXT) to determine VO$_{2max}$. The participant determined a self-selected speed which remained constant throughout the test while only grade increased by 2% every 2 minutes until volitional exhaustion. A VO$_{2max}$ (ml/kg/min) was

reached if heart rate was ≥95% of age predicted max, RER was ≥1.05, and there was a plateau in VO$_2$ (< 2 ml/kg/min). During visit 2, participants first wore two heart rate monitors simultaneously (Device A and V) and were instructed to lie still for 6 minutes to allow for the devices to estimate VO$_{2max}$. After these values were obtained, these two devices were replaced by a GPS watch. Participants then completed a 15-minute submaximal outdoor run, and the GPS watch estimated VO$_{2max}$. Pearson correlations and a Repeated Measures ANOVA were utilized to compare estimated VO$_{2max}$ values from the three devices to measured VO$_{2max}$ from the GXT ($p<0.05$). **RESULTS**: Six participants were excluded due to having a VO2max less than 35ml/kg/min, not returning for the second visit, or a device malfunctioning. Device A (r=0.66; $p<0.001$), Device V (r=0.80; $p<0.001$), and the GPS watch (r=0.72; $p<0.001$) were associated with measured VO2max. A significant main effect was found among VO2max values (F (2.0, 39.6) = 14.0; $p<0.05$). There was a significant difference ($p<0.01$) between measured VO2max (51.0±9.1 ml/kg/min) compared to Device A (44.0±5.5), Device V (45.3±5.6), and the GPS watch (45.7±5.3). **CONCLUSIONS**: Even though there were moderate to strong relationships, all three watches underestimated VO2max compared to measured VO2max. However, the difference between measured VO2max and all three devices may fall within daily variation of VO2max. The three devices may serve as an appropriate measure of cardiorespiratory fitness from a submaximal effort.

C-14   Clinical Case Slide - **Cardiovascular II**

Thursday, May 31, 2018, 8:00 AM - 10:00 AM

Left Arm Cramping and Prominent Veins in a 19 year-old Women's Collegiate Soccer Player

Andrew Schleihauf, Kimberly Kaiser, Robert Hosey, FACSM. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

History: 19-year old female collegiate soccer goalie with PMHx iron-deficiency anemia due to heavy menses presents with left arm cramping, numbness, and purple discoloration. She was doing an overhead weightlifting workout and felt numbness and a cramping sensation in her left arm while performing front squats. She then noticed a purple discoloration of her left arm along with prominent veins and presented to the training room. After being examined, she was sent to the emergency department. She denies having any previous episodes similar to this. She was on oral contraceptives due to heavy menses but has no personal or family history of clotting disorders.
Physical Exam: Constitutional: 5'9, 173 lb. BP 123/71, pulse 63, RR 14. Athletic build. *Extremities*: Left forearm pallid and mottled with engorged basilic and cephalic veins. Mild generalized edema and diffuse tenderness from forearm to upper arm. Radial pulse 2+ bounding, brachial and carotid pulse 2+
Differential Dx: Neurogenic thoracic outlet syndrome, vascular thoracic outlet syndrome, complex regional pain syndrome
Test and results: *Left UE Venous Doppler*: Occlusive DVT in mid subclavian vein near the clavicle extending to the axillary, proximal basilic and proximal brachial veins. There is thrombus in the proximal cephalic vein. The jugular, radial and ulnar veins were patent with normal augmentation, compressibility, and flow
Left UE Arterial Doppler: Normal flow and waveforms throughout
Final working diagnosis: Paget-Schroetter syndrome
Treatment and Outcome: She was placed on a heparin drip and underwent thrombolysis with catheter directed tPA. A balloon angioplasty was done of the left subclavian vein for a 3 cm occlusion and then she underwent a first rib resection 6 weeks after initial presentation. Upon arrival to school for the fall semester, she continued to have pressure, mild pain, and discoloration of her left arm with minimal exertion. Repeat ultrasound and angiogram showed no evidence of acute thrombus one-month post surgery. After continuing to get discoloration of her arm walking across campus, she underwent a venogram two months after surgery that showed a well-adhered thrombus in her subclavian vein. She is scheduled for a repeat angioplasty and has been unable to return to full soccer activity after 5 months.

Abstracts were prepared by the authors and printed as submitted.

1135   May 31 8:20 AM - 8:40 AM
Cardiovascular Football

Stephen Carek[1], Timothy Durkin[1], Michael Dillon[2], Floyd Burke[1], Katherine Edenfield[1], Guy Nicolette[1], James Clugston[1]. [1]University of Florida, Gainesville, FL. [2]Heart and Vascular Institute of Florida, Gainesville, FL.
(No relevant relationships reported)

History: A 19 year old male freshman football defensive lineman presented for his pre-participation examination. He denied any cardiac symptoms or family history of sudden cardiac death. Screening ECG did not demonstrate pathological electrocardiographic abnormalities for athletes. Screening echocardiogram was significant for moderate concentric left ventricular hypertrophy and an interventricular septal diameter of 1.41 cm. Physical Exam: African-American Male. Height 76.5 in, Weight 349.4 lbs, BMI 42.4, Arm span: height ratio 1.06, Cardiac exam without murmurs, rubs or gallops. No physical findings consistent with Marfan's Syndrome. Differential Diagnosis: Physiologic Left Ventricular Hypertrophy (Athlete's Heart), Hypertrophic Cardiomyopathy, Hypertensive Cardiomegaly Tests and Results 1. Cardiac MR (1)Moderate to borderline severe symmetric hypertrophy. Hyperdynamic left ventricular systolic function. Ejection fraction of 75%. (2) No evidence of hyper-enhancement with gadolinium. (3) Maximal interventricular septum thickness of 17 mm. (4) Left Ventricular End Diastolic Volume Index (LVEDVI)/Left Ventricular End Diastolic Mass Index (LVEDMI) ratio of 0.75 (less than 1.2 is more consistent with HCM). (5) Wall thickness to LVEDVI ratio is 0.23 (less than 0.15 suggests HCM). (6) Findings equivocal for the assessment of hypertrophic cardiomyopathy versus athlete's heart. 2. Transthoracic Echocardiogram with Color Flow Doppler and Spectral Doppler (1) Normal left ventricular size, structure, systolic function. (2) Mild LV asymmetric septal hypertrophy, septal thickness 1.6 cm, posterior wall thickness 1.3 cm. (3) No evidence of left ventricular outflow tract obstruction. (4) Normal global longitudinal strain imaging with normal strain-derived left ventricular systolic function. 3. Exercise Stress Test (1) No ischemic ECG changes or arrhythmia with stress. Final Diagnosis: Physiologic Left Ventricular Hypertrophy (Athlete's Heart) Treatment and Outcomes: After being withheld from football during this evaluation, he has since been cleared for participation and has not demonstrated any unusual symptoms, including lightheadedness, dizziness, syncope, chest pain or shortness of breath. He is scheduled for follow-up in 6 months with a repeat echocardiogram.

1136   May 31 8:40 AM - 9:00 AM
Chest Pain, Palpitations and Heart Murmur In A Basketball Player

Colin L. Conner[1], John Stock[2], Mitchell Cohen[1]. [1]Arizona Pediatric Cardiology, Phoenix, AZ. [2]Pediatric Cardiac Care of Arizona, Phoenix, AZ.
(No relevant relationships reported)

HISTORY: A 16 year old male competitive basketball player referred for a 3 month history of intermittent palpitations associated with chest pain at rest. Initially the symptoms were occurring once or twice a week, then once every 2 days, then occurring almost daily. The episodes are characterized by irregular heartbeat, followed by chest pain, with occasional shortness of breath. There is also chest pain associated with exercise. Characterized as burning which lasts 15-20 seconds. It does not change with activity level. He can usually play through the pain. He denies dizziness, presyncope or syncope. Also denies effort intolerance.
PHYSICAL EXAMINATION: Well developed in no distress. No thyromegaly. No pallor. Lungs clear. Regular rate and rhythm. Normal S1 and S2. I-II/VI nonspecific SEM heard at LUSB and RUSB in the supine position. Pulses 2+ and equal. Abdomen soft and non-tender.
DIFFERENTIAL DIAGNOSIS:
1. Musculoskeletal chest pain
2. Palpitations-probably benign
3. Innocent murmur
TESTS AND RESULTS:
ECG: sinus bradycardia, LVH, ST elevation right precordial leads, T wave inversion inferior leads
ECHOCARDIOGRAM: LVH with notable hypertrophy of left posterior wall (14 mm). Borderline LAE.
HOLTER MONITOR: rare PVC's and PAC's. One polymorphic couplet
CARDIAC MRI: borderline concentric LVH (max 12.8 mm: Z score 2.2), borderline LV wall mass. Borderline LAE. No regional wall motion abnormalities or delayed gadolinium enhancement
METABOLIC STRESS: peak VO2 93% predicted. Ventricular ectopy at rest, with exercise and in recovery: suppressed at max HR. PFT (post exercise): FVC decreased 15%; FEV1 decreased 14%; FEF 25-75% decreased 39%
CARDIAC CATHETERIZATION: normal LV end diastolic pressures. No myocardial bridge
GENE DX: negative
FINAL/WORKING DIAGNOSIS:
1. Left Ventricular Hypertrophy

2. Premature Ventricular Contractions
3. Exercise Induced Bronchospasm
TREATMENT AND OUTCOMES:
1. Implantable loop recorder
2. Allowed to return to play with AED on site
3. Albuterol MDI prior to exercise
4. Repeat Metabolic Stress in 6 months

1137   May 31 9:00 AM - 9:20 AM
New Heart Murmur in a Male Basketball Player

Emily Miller, Dena Florczyk. UCLA, Los Angeles, CA.
(No relevant relationships reported)

HISTORY: 20 year old African American male presents for his pre-participation examination. Upon reaching the cardiovascular screening questions answers yes to both "have you ever been told you have a heart murmur" and "sudden death before the age of 50 in a relative." At a visit two days prior he was told he had a heart murmur. His estranged father, with whom he had no relationship, passed away in his forties secondary to unknown heart disease. His father was reportedly born with "blue heart disease with a hole in his heart." The etiology behind his father's passing was unknown but he had a history of incarceration, alcohol and substance abuse. No other family history of cardiac disease. The athlete himself specifically denies any personal history of pre-syncope, syncope, chest pain with exercise, dyspnea on exertion, palpitations.
PHYSICAL EXAMINATION:
BP: 130/70 General: alert and oriented, no stigmata of Marfan's Cardiac: regular rate and rhythm, S1 S2, 1/6 systolic murmur when supine, resolved when standing or sitting, no increase with valsalva. Normal radial and femoral pulses Respiratory: clear to auscultation bilaterally
DIFFERENTIAL DIAGNOSIS: 1. Cardiomyopathy - hypertrophic vs restrictive vs dilated vs other 2. Hypertensive heart disease 3. Benign systolic ejection murmur - Still's vs VSD vs mitral valve prolapse 4. Athletic heart
TEST AND RESULTS: EKG: Normal sinus rhythm. Echocardiogram: Normal EF 55-60%, no valvular stenosis or regurgitation. No outflow tract obstruction. Apical portion of the LV with findings consistent with apical localized non-compaction of the myocardium. Normal LV wall motion and wall thickness.
FINAL WORKING DIAGNOSIS: Non-compaction of the left ventricle
TREATMENT AND OUTCOMES:
Clinically asymptomatic. Increased trabeculations noted on echo consistent with non-compaction of the LV but with preserved ejection fraction and without evidence of dilation. CAM monitor for 1 week - no evidence of arrhythmias. Treadmill stress test with stress echocardiogram - no evidence of ischemia or exercise induced arrhythmias; normal cardiac response to exercise. ASA 81 mg daily to reduce risk of stroke associated with LV non-compaction. Reassurance provided that while being physical active this risk is minimal. Cleared to participate in athletics. Repeat echocardiogram in one year.

1138   May 31 9:20 AM - 9:40 AM
Misleading Congenital Brain and Heart Abnormalities in a Syncopal Soccer Player

Michael E. Pitzer[1], Heather Bauby[2]. [1]Virginia Commonwealth University, Richmond, VA. [2]Randolph-Macon College, Ashland, VA.
(No relevant relationships reported)

HISTORY: A 19-yr-old female collegiate soccer player reported recurrent fainting episodes during a pre-participation physical examination after transferring from another school. She reported sustaining a sports-related concussion in December 2014 and subsequently developed frequent fainting spells, headaches, and recurrent numbness in her arms and legs. Fainting spells are not provoked by Valsalva-like circumstances. Fainting spells are not associated with chest pain, palpitations, racing heart, shortness of breath, or diaphoresis. During fainting spells altered cognition may last only a few seconds or up to thirty minutes. Fainting spells are not associated with tonic-clonic movements, tongue biting, bowel incontinence, or bladder incontinence. She had already undergone evaluation for these symptoms including a Neurology evaluation that included a normal electroencephalogram and a Cardiology evaluation that included an electrocardiogram and echocardiogram. Echocardiogram revealed an atrial septal defect (ASD) which was subsequently closed and fainting spells became less frequent after ASD closure. Prior clearance to participate in soccer was provided by all evaluating providers including Cardiologist, Neurologist, and Primary Care Physician.
PHYSICAL EXAMINATION: Normal cardiac and neurologic examination.
DIFFERENTIAL DIAGNOSIS: Vasovagal syncope, postural orthostatic tachycardia syndrome, migraine variant, postconcussion disorder, psychogenic seizures, and somatization disorder.
TEST AND RESULTS: **Brain MRI:** The cerebellar tonsils descend below the foramen magnum, consistent with a Chiari I malformation. No upper cervical cord syrinx. **Brain MRI with CSF flow sequences:** The ventral foramen magnum

remains patent and the ventricles are normal. There is decreased flow across the foramen magnum at the fourth ventricular outflow and posterior to the cerebellar tonsils. **Cervical spine MRI:** No syrinx. **Neurosurgical evaluation:** Asymptomatic Chiari 1 malformation. **FINAL WORKING DIAGNOSIS**: 1. Vasovagal syncope.2. ASD status post closure.3. Asymptomatic Chiari 1 malformation. **TREATMENT AND OUTCOMES**: The athlete was allowed to participate when she expressed understanding of the associated risks. Episodes of syncope continued to occur.

1139   May 31 9:40 AM - 10:00 AM

Evaluation And Management Of Recurrent Symptomatic, Exercise-induced Tachyarrhythmia

Michael Fitzgerald. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

HISTORY: A 15-year-old high school sophomore presented to the ED with palpitations, chest pain, and lightheadedness that began during volleyball conditioning. She reported one similar episode several months earlier and was seen by pediatric cardiology for outpatient evaluation, which included resting ECG, 24-hour Holter monitor, and echocardiogram. While participating in consecutive scrimmages, she felt her heart racing and experienced dull, non-radiating substernal chest pain. Her symptoms prevented further participation and did not resolve with rest. Her heart rate was recorded as 195bpm at home.
PHYSICAL EXAMINATION: HR 186, RR 22, BP 107/68. Patient was diaphoretic but generally well appearing and in no acute distress. Cardiovascular exam revealed rapid heart rate with regular rhythm and identifiable S1 and S2 heart sounds without murmurs or clicks. Peripheral pulses were 2+ and symmetric, no JVD. Chest pain was not reproducible. Lungs were clear to auscultation bilaterally. Abdomen was soft and non-distended. Thyroid was symmetric and without nodules.
DIFFERNTIAL DIAGNOSIS:
1. Supraventricular tachyarrhythmia (SVT)
— AVNRT
— MAT
2. Sinus tachycardia
— hyperthyroidism
3. WPW syndrome
4. Ventricular tachycardia
5. Atrial fibrillation
TESTS AND RESULTS:
1. ECG
— narrow complex tachycardia with rate 184, QTc 441, and indeterminate PR
2. CMP
— creatinine 1.09
3. Troponins
— T0 <0.010
FINAL/WORKING DIAGNOSIS:
Exercise-induced SVT likely secondary to AVNRT
TREATMENT AND OUTCOME:
1. 1L IV fluid bolus
2. Vagal maneuvers - modified Valsalva technique (strain followed by passive leg raise for 15 seconds at 45 degrees)
— synchronized cardioversion was considered unnecessary with stable vital signs
— normal sinus rhythm (NSR) was achieved after 3 attempts
3. Outpatient referral to pediatric cardiology before return to activity
— previous outpatient testing was reviewed and within normal limits
— patient was given the option for antiarrhythmic management vs. catheter ablation - opted for catheter ablation
— cleared for activity with vagal maneuver education and return precautions for refractory SVT
4. Interim ED visit for refractory SVT
— vagal maneuvers were unsuccessful - adenosine was required to achieve NSR
— patient was ultimately trialed on metoprolol while awaiting EPS and ablation

---

C-15   Clinical Case Slide - **Knee II**

Thursday, May 31, 2018, 8:00 AM - 10:00 AM
Room: CC-200F

1140   **Chair:** Aaron Rubin, FACSM. *Kaiser Permanente Sports Medicine Program, Fontana, CA.*

(No relevant relationships reported)

1141   **Discussant:** Anthony E. Annan. *Home, London, United Kingdom.*

(No relevant relationships reported)

1142   **Discussant:** Cindy Y. Lin. *University of Washington Medical Center, Seattle, WA.*

(No relevant relationships reported)

1143   May 31 8:00 AM - 8:20 AM

Knee Pain - Exercise

Samuel T. Dona, Dean Padavan, Robert Monaco, Steven Sclafani. *Atlantic Sports Health, Morristown, NJ.*

(No relevant relationships reported)

HISTORY: A 58-year-old male presented with a 4-week history of spontaneous knee pain. One year prior to presentation, he had bariatric surgery and increased his exercise regimen resulting in a 100 lb weight loss. He denies trauma or inciting injury. His pain localized to the posterolateral knee and is described as a 5/10 cramping pain. He describes a popping sensation and experiences a snapping moment in the lateral knee with deep squatting. He denies swelling and ecchymosis. He has tried ice, physical therapy and ibuprofen without relief.
PHYSICAL EXAMINATION: Focused left knee exam revealed a palpable cystic structure in the lateral popliteal fossa. There is tenderness over the lateral joint line with no instability of the proximal tibiofibular joint or biceps femoris tendon. Range of motion was 0-140° with pain greater than 120° of flexion. When the knee is brought into deep flexion, there is an audible pop over the lateral aspect of the knee. When the knee is then brought into extension, there is reproduction of an audible pop and snapping moment of the lateral knee at end range extension. Flexion McMurray's test is positive. Strength, reflexes, sensation, and pulses are normal throughout.
DIFFERENTIAL DIAGNOSIS:
1. Snapping biceps femoris tendon
2. Snapping popliteus tendon
3. Lateral meniscus tear
4. Iliotibial band friction syndrome
5. Proximal tibiofibular joint instability
TEST AND RESULTS:
Three view x-rays of left knee:
— Medial joint space narrowing. No acute fracture.
Dynamic ultrasound of the left knee:
— Normal biceps femoris tendon. Popliteal cyst noted.
MRI of left knee without contrast:
— Incomplete discoid lateral meniscus and small multiseptated popliteal cyst noted.
FINAL WORKING DIAGNOSIS: Left knee discoid lateral meniscus with subluxation of the meniscus
TREATMENT AND OUTCOMES:
1. Patient counseled on activity modification.
2. Dynamic ultrasound revealed no evidence of hamstring irregularities.
3. Unsuccessful ultrasound-guided aspiration of popliteal cyst attempted followed by an intra-articular corticosteroid injection.
4. After MRI evaluation, orthopedic surgery performed an arthroscopic partial meniscectomy of subluxing torn posterior horn and midbody saucerization of lateral meniscus.
5. He tolerated surgery well with no further subluxation of his meniscus in physical therapy.

1144   May 31 8:20 AM - 8:40 AM

Knee Effusion-gymnast

Reno Ravindran. *Nationwide Childrens Hospital, Columbus, OH.*

(No relevant relationships reported)

HISTORY: 12 y/o gymnast comes into the office complaining of right knee swelling with minimal pain for 3 days after a gymnastics competition. She does not recall a specific injury during the competition but noticed discomfort as the day went on. The swelling worsened later that evening. They were seen by their primary care provider

---

Abstracts were prepared by the authors and printed as submitted.

who referred them in to sports medicine clinic. She does endorse similar swelling and pain 6 weeks ago that responded to ibuprofen and ice and resolved in 2-3 days. Denies locking, catching, popping or instability episodes in knee. Family history: unknown; adopted

PHYSICAL EXAMINATION: Inspection: Moderate sized effusion, no erythema. Range of motion full in flexion and extension with mild discomfort in full flexion. Palpation: Mild tenderness around patellar facets, mild medial joint line tenderness. Special Tests: Negative Lachmans, Negative McMurray's, Negative patellar apprehension, Mild pain with valgus stress at 30degrees. Proprioception: Engaged Hip exam normal

DIFFERENTIAL DIAGNOSIS: 1.Patellofemoral Syndrome. 2.MCL sprain. 3.Inflammatory process: JIA, Synovitis. 4.Patellar instability

TEST AND RESULTS: X-rays 4 view Within normal limits. MRI with and without contrast: Findings consistent with an inflammatory synovitis with a moderate knee effusion and moderate synovitis.2. Signal abnormality both deep and superficial to the medial collateral ligament may be secondary to strain. Labs: ESR 20mm/h, CBC normal, CRP: normal, ANA positive, Lyme serology positive

FINAL WORKING DIAGNOSIS: 1.Lyme Synovitis 2.Grade I MCL sprain

TREATMENT AND OUTCOMES: Currently undergoing antibiotic treatment with doxycycline 75mg BID for 4 weeks. Is also going through physical therapy in regards to MCL sprain.

1145 May 31 8:40 AM - 9:00 AM

Acute Knee Pain in Adolescent Basketball Player

Kristopher Paultre. *JMH/UM, Miami, FL.*

(No relevant relationships reported)

History:

14 y/o male basketball player presents to ED after sustaining an injury to his left lower extremity. This occurred during a school basketball game while landing from a jump shot. Patient stated he felt a pop in his left knee upon landing and rated pain a 9/10 severity. Immediately after, he had swelling with decreased ROM and was unable to flex/extend his knee due to pain.

PE:

Left Knee:

Edema was present with mild discoloration over the anterior of knee and severe tenderness upon palpation over anterior patellar tendon. Patient unable to perform active ROM. Passive ROM limited secondary to pain. Full scope of exam, including assessment of ligaments, menisci, and ROM also limited secondary to pain.

Bilateral Ankles:

No deformity noted b/l. Non-tender on palpation. Neurovascularly intact.

Differential Diagnosis:

Patellar dislocation

ACL tear Patellar tendon rupture Proximal tibia fractureDistal femur fracture Meniscal tear

Tests and Results:

X-rays of left femur (3 view), left knee (AP/ lateral), and left tibia/fibula (3 view): Findings showed a displaced type-3a tibial tuberosity avulsion fracture, displaced 1.5 cm with an associated knee effusion and intra-articular extension. No additional fractures noted on left femur, knee, tibia, or fibula.

Final/Working Diagnosis:

Closed left tibial tubercle avulsion fracture, displaced type-3A with avulsion of left quadriceps infrapatellar tendon.

Treatment and Outcome:

1.Open reduction and internal screw fixation of tibial tuberosity with repair of infrapatteller tendon

2.long leg walker cast placed

3.At 6 week follow-up visit, repeat x-rays showed anatomic alignment of the fracture site,good positioning of 2 fixation screws, and articular surface which was realigned. Knee immobilizer was discontinued and he was given walker for stability. Instructed to d/c use of walker once left knee felt stable and remain out of athletic activities until further evaluation. Referred to PT for Quad strengthening and ROM exercises.

4. At 5 month post injury visit, patient showed favorable progress. He had full ROM, improved strength, and was cleared to resume sports starting at a low level intensity. He was advised to gradually increase the duration and intensity of his training. Patient advised to continue knee mobility exercises and to f/u with PCP for routine Health care.

1146 May 31 9:00 AM - 9:20 AM

Soccer Knee Injury

Kameron Bazmi[1], Caitlin Cicone[1], Richard G. Chang[2]. *[1]SUNY Downstate, Brooklyn, NY. [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

(No relevant relationships reported)

HISTORY: 19 year old male presented with right thigh weakness and difficulty walking for 2 years following a soccer injury that resulted in a right patellar dislocation. Patient was managed non-operatively for 1 year after the injury before

proceeding to surgical intervention. Subsequently, the patient underwent medial patellofemoral ligament reconstruction. Since the injury, patient reported weakness and atrophy of his right quadriceps, with no improvement after surgery. He denied numbness or pain, but did complain of intermittent right lower extremity buckling.

PHYSICAL EXAMINATION: Examination in the clinic revealed right quadriceps atrophy with mild right knee effusion. There was no tenderness to palpation along right quadriceps, knee joint line, patella or patellar tendon. There was limited active range of motion secondary to weakness, with passive range of motion through 0 to 90 degrees limited by pain. Manual muscle testing was 1/5 for right knee extension, 4-/5 for right hip abduction, all else 5/5. Lower extremity reflexes were 2+ and symmetrical, bilateral. There was right knee buckling during ambulation.

DIFFERENTIAL DIAGNOSIS: 1.Disuse atrophy 2.Lumbar plexopathy 3.Lumbar radiculopathy 4.Quadriceps muscle avulsion 5.Polymyositis 6.Diabetic polyneuropathy

TEST AND RESULTS: Electrodiagnostics

-Right femoral nerve showed prolonged onset latency

-The right sural nerve showed prolonged peak latency and slowed conduction velocity

-The right superficial peroneal nerve showed prolonged peak latency and mild slowed conduction velocity

-The right saphenous showed decreased amplitude

-Right vastus lateralis, rectus femoris, and vastus medialis showed decreased insertional activity, minimal to no recruitment; vastus lateralis most affected -Right demyelinating and axonal femoral neuropathy with the lesion at or distal to the right inguinal ligament & right sural and superficial peroneal sensory neuropathies

FINAL WORKING DIAGNOSIS: Primarily axonal femoral neuropathy

TREATMENT AND OUTCOMES:

1. Patient started physical therapy with a focus of strengthening quadriceps, hip abductors and core 2. Patient prescribed Meloxicam 7.5 mg to be used as needed 3. Patient was non-compliant with therapy for over 6 months, did not return to sport and eventually lost to follow up

---

1147 May 31 9:20 AM - 9:40 AM

Chronic Medial Knee Pain in a Collegiate Basketball Player and Marching Band Member

Nicholas E. Anastasio, David Hryvniak. *University of Virginia, Charlottesville, VA.* (Sponsor: Robert Wilder, MD, FACSM)

(No relevant relationships reported)

History:

Patient 1:

A 17 year-old female collegiate basketball player presented with insidious onset right medial knee pain for the last 8 months. Pain waxed and waned with activity. No history of swelling, instability or locking. No numbness or weakness. Pain located diffusely over the medial knee and proximal medial tibia. Symptoms refractory to PT, patellofemoral kinesiotaping, medial arch support orthotics and NSAIDs. No relief following Medrol dose pack, intraarticular corticosteroid injection, or pes anserine bursa corticosteroid injection.

Patient 2:

A 19 year-old female collegiate marching band member presented with insidious onset right medial knee pain present for 4 years. Patient reported intermittent swelling but denied instability or locking. Symptoms were worse with walking and marching. Previous Rheumatologic consult unrevealing. Symptoms refractory to PT, knee sleeve, and patellar straps. No relief following right pes anserine bursa corticosteroid injection.

Physical Examination:

Patient 1 - Knee without effusion. Diffuse tenderness to palpation over the medial knee at and below mid medial joint line. ROM and strength normal. No laxity. Neurovascular intact.

Patient 2 - Knee without effusion. Tenderness to palpation over the medial joint line and distally over pes anserine. Tinel's sign positive over the medial femoral condyle. ROM and strength normal. No laxity. Neurovascular intact.

Differential Diagnosis:

1. Pes anserine bursitis

2. MCL bursitis

3. Patellofemoral syndrome

4. Medial meniscal tear

5. Medial patellar plica

6. Saphenous neuralgia

Test and Results:

Patient 1:

XR Knee - No fracture or joint effusion.

MRI knee - No meniscus tear. No internal derangement. Mild increased T2 signal within the superior lateral aspect of Hoffa's fat.

Diagnostic saphenous nerve block - 0.5% bupivacaine injected 2 inches cephalad to the medial joint line - 24 hours of relief.

Patient 2:

XR Knee - No fracture or malalignment.

MRI knee - Unremarkable MRI of the knee.

Labs - ESR 8, TSH 1.7

Final/Working Diagnosis:

Saphenous Neuralgia

Treatment and Outcomes:
Patient 1:
Saphenous nerve injection - 40 mg triamcinolone/0.5% bupivacaine - 5 months of relief.
US guided hydrodissection saphenous nerve - Full resolution for 1.5 years.
Patient 2:
US guided hydrodissection saphenous nerve - 6 months of relief.

1148   May 31 9:40 AM - 10:00 AM
Lingering Right Knee Pain - Mountain Biking

Andrew McBride. *University of Colorado - Denver, Aurora, CO.*
(Sponsor: John Hill, FACSM)
(No relevant relationships reported)

Title: Lingering right knee pain - mountain biking Authors: Andrew McBride, John Hill, FACSM, Michelle Wolcott Sponsor: John Hill, FACSM Institutions: University of Colorado - School of Medicine History: Patient is a 32 y/o previously healthy male who presented to sports medicine clinic with one month of right anterior knee pain. Pain began after he swerved to avoid dogs while mountain biking. He fell from his bike and directly struck his anterior right knee on a rock. He had immediate pain and swelling but continued riding. His pain did not resolve with ice and ibuprofen, if fact it gradually worsened especially with deep knee bending and mountain biking. He felt the knee was unstable but denied locking or catching. Physical Exam: Right knee: Neutral alignment; Normal gait; No effusion; Patellar apprehension with medial facet tenderness and patellofemoral crepitus; swelling of patellar tendon; Lachman with soft endpoint; slight Anterior drawer; medial joint line pain; Normal neurovascular exam Differential Diagnosis: ACL sprain/tear, Patellar tendonitis, Medial meniscus tear, Patellofemoral syndrome, Fat pad impingement Tests and Results: X-ray of right knee showing soft tissue edema with small osseous fragment around distal patella; MRI right knee showing severe patellar tendinosis with no internal knee derangement; Diagnostic U/S showing severely thickened (1.2 cm) patellar tendon with near complete disorganized fiber pattern with only mild neovascularity seen. Final Diagnosis: Traumatic patellar tendonitis Treatment and Outcomes: The patient initially tried rest, ice and ibuprofen with minimal relief. He later tried 4 visits with PT but pain worsened during these sessions.. He was referred to U/S clinic for possible percutaneous tenotomy. At this visit the tendon appeared so disorganized that it was recommended he follow-up with our knee surgeon to discuss surgical management options. He is currently in the surgical planning process, complete follow-up will be available in May 2018.

C-16   Clinical Case Slide - **Medical Issues II**

Thursday, May 31, 2018, 8:00 AM - 10:00 AM
Room: CC-200E

1149   **Chair:** William W. Dexter, FACSM. *Maine Medical Center, Portland, ME.*
(No relevant relationships reported)

1150   **Discussant:** Andrea Stracciolini, FACSM. *Children's Hospital Boston, Boston, MA.*
(No relevant relationships reported)

1151   **Discussant:** Francis G. O'Connor, FACSM. *Uniformed Services University, Bethesda, MD.*
(No relevant relationships reported)

1152   May 31 8:00 AM - 8:20 AM
Abdominal Pain - Professional Singer

Tamara Rial-Rebullido[1], Fernanda Gonzalez[2], Iván Chuli-Medrano[3]. *[1]International Hypopressive and Physical Therapy Institute, Vigo, Spain. [2]Universidad Autónoma de Durango, Durango, Mexico. [3]University of Alicante, Alicante, Spain.*
(Sponsor: Avery D. Faigenbaum, FACSM)
(No relevant relationships reported)

HISTORY: A 24-year-old male singer presented symptoms of trunk and abdominal pain, reduced breathing capacity and limited trunk mobility after six months of a laparoscopic Nissen fundoplication due to gastric volvulus associated with a paraesofagic hiatal hernia. His pain made it difficult to sing and perform sustained quality notes. He was referred to respiratory physical therapy. He was a non-smoker and not taking any medications. **PHYSICAL EXAMINATION:** Height 173 cm, weight 76 kg, body mass index 25.3 kg/m². Abdominal and thoracic examination revealed limited thoracic amplitude, diaphragmatic hypertonicity, altered sensitivity from T7 to T10, limited range of motion and pain during right and left trunk rotations and trunk extensions. Mild epigastric tenderness. Hemodynamically stable. **DIFFERENTIAL DIAGNOSIS**: 1. Dyspnea 2. Respiratory disease 3. Hernia **TEST AND RESULTS**: Visual Analog Scale revealed pain 7 under ribcage and xiphoid process. Cough hyperpressure test negative. Positive toe touch test. Breath-holding test positive. Negative thoracic amplitude test. **FINAL WORKING DIAGNOSIS**: Dysfunctional breathing and muskuloskeletal pain. **TREATMENT AND OUTCOMES**: 1. Progressive breathing exercises. 2. Diaphragm stretching exercises. 3. Hypopressive exercises. 4. Returned to singing after 10 weeks (3 sessions per week) when he had full trunk motion, no abdominal pain and was able to meet the demands of vocal performance.

1153   May 31 8:20 AM - 8:40 AM
Abnormal Weight Gain in a Collegiate Athlete - Swimming

Roberta Dennison. *Boston Children's Hospital, Boston, MA.*
(Sponsor: Kathryn E. Ackerman, MD, MPH, FACSM)
(No relevant relationships reported)

HISTORY: 21 year-old-female Division III collegiate swimmer presenting for evaluation of significant weight gain and declining performance. Patient reports 20 lb weight gain over 18 months without change in diet or exercise routine. She endorses 15+ hrs/wk of training between pool and dryland exercise. Over prior 6 months, she continued to gain weight despite diligent dietary adjustments and nutrition consultation. Patient was diagnosed with PCOS in high school. She reports long-standing issues with irregular menses, acne, and facial hair, which were previously managed with spironolactone, OCP, and metformin. Medications were discontinued 2 months prior to presentation, as they were no longer effective. Simultaneously, patient was started on bupropion as an appetite suppressant, but has not noticed any weight change since initiation.
PHYSICAL EXAMINATION:
Orthostatic Vitals:
Lying: BP: 115/75, HR: 58
Standing: BP: 110/70, HR: 64
Weight: 75.3 kg; Height: 165 cm; Body Mass Index: 27.7 kg/m²
GEN: Well-appearing young female in no acute distress. Alert and oriented x3.
HEENT: Normocephalic, atraumatic, with round facies. Significant coarse facial hair. EOMI. Thyroid is nontender without nodules. +Dorsocervical fat pad.
CV: RRR, no M/R/G
Resp: CTAB
Ext: Warm and well-perfused, no edema, moving all 4 extremities, gait stable.
Skin: Thin purple striae on breasts, abdomen, and inner thighs. + facial acne.
DIFFERENTIAL DIAGNOSIS:
1) PCOS
2) Hypothyroidism
3) Caloric surplus
4) Acromegaly
5) Hypercortisolism
TESTS AND RESULTS:
Labs:
Chemistry panel WNL
TSH 1.59 uIU/mL
Free T4 0.87 ng/mL
17-hydroxyprogesterone: 69 ng/dL
DHEAS: 559.3 mcg/dL (H)
LH: 11.8 IU/L
FSH: 4.36 IU/L
Testosterone: 53 ng/dL
Free testosterone: 11.3 pg/mL (H)
Sex hormone binding globulin: 25 nmol/L (L)
Free Androgen Index: 7.36 (H)
IGF-1: 275 ng/mL
Prolactin 19.92 ng/mL
24 hour urine cortisol: 65.5 mcg (H)
AM Cortisol following 1mg dexamethasone suppression test 8.5 ug/dL
FINAL/WORKING DIAGNOSIS:
Hypercortisolism
TREATMENT AND OUTCOMES:
Currently awaiting results of high dose dexamethasone suppression test to further determine pituitary vs. adrenal vs. ectopic origin of Cushing Syndrome.

1154   May 31 8:40 AM - 9:00 AM

Syncopal Episode in a College Football Player

Bjorn A. Jacobson, Richard A. Okragly. *TriHealth Bethesda Primary Care Sports Medicine Fellowship, Cincinnati, OH.* (Sponsor: Henry Stiene, FACSM)

(No relevant relationships reported)

HISTORY: A 20 year old African American college football player started to feel faint, walk slowly and then collapse during the end of a fitness session. Immediately triaged by his AT he was unresponsive to verbal or noxious stimuli, demonstrating brief decorticate posturing, tachypneic, with palpable pulses. The episode lasted 90 seconds. I arrived to find an alert and oriented male in no distress. Initially resistant, he did eventually agree to go to the ED. He stated he had taken 5 decongestant pills in the preceding 24 hours. He denied any preceding chest pain or palpitations, but did feel short of breath and light headed prior to collapsing. He said that he had a previous syncopal episode during exercise years ago that was reportedly secondary to dehydration.
PHYSICAL EXAMINATION: Initial exam on the field showed an alert, fully coherent and oriented well appearing male in no distress; pupils equal/reactive to light; no foaming of the mouth or tongue bite wounds; a regular rate and rhythm with no murmurs/gallops; lungs clear to auscultation; overall a benign physical exam. VS - BP 133/69, HR 63, RR 18, T 97.9F, SpO2 98%
DIFFERENTIAL DIAGNOSIS: 1) Vasovagal syncope or other reflex (neurally) mediated syncope 2) Cardiovascular syncope 3) Hypertrophic Cardiomyopathy 4) Metabolic (drug induced) syncope 5) Volume depletion orthostatic syncope 6) Seizure
TEST AND RESULTS: BMP, CBC, Cardiac Enzymes - Normal; Chest XR AP and Lateral - Normal; EKG - Sinus Rhythm, Normal Axis, ST elevation in leads V1-V5 followed by T wave inversions, Prominent QRS complexes (unchanged on 4 EKGs over 3 weeks); 2D Echo - LVEF 55-60%, mild concentric LVH, bicuspid aortic valve; Cardiac MRI - LVEF 55%, no LVH (wall thickness less than 11 mm), tricuspid aortic valve; Stress EKG (GXT) - Baseline EKG abnormalities normalized, negative for ischemia, Duke treadmill score 14 (low risk)
FINAL WORKING DIAGNOSIS: Vasovagal syncope/possibly related to pseudoephedrine
TREATMENT AND OUTCOMES: After extensive cardiac work up, baseline EKG repolarization abnormalities normalized with exercise testing. Given his normal cardiac MRI and normal stress testing he was cleared by cardiology for full athletic participation. He was advised to immediately notify us if he develops any recurrent symptoms. He is now completing his college football season without incident.

1155   May 31 9:00 AM - 9:20 AM

Headache and Near Syncope in a Soldier After Training

Robert H. Lutz. *Duke Sports Science Institute, Durham, NC.* (Sponsor: Shawn F. Kane, FACSM)

(No relevant relationships reported)

HISTORY: A 34 y/o male active duty Soldier presented to an Army clinic with headache, nausea and lightheadedness around 1000 in the morning. Symptoms started indoors in a classroom environment, two hours after conducting a challenging obstacle course. On a bathroom break he felt like he was going to pass out after urinating and knelt to the ground. He denied falling off an obstacle, striking his head or sustaining any injuries on the morning obstacle course. He was weak, nauseous, and dizzy, with a 4/10 headache. He had been previously well and reported no history of head injury, fever, or neck stiffness. He denied peri-oral tingling or numbness. During the evaluation, his headache increased in severity. Past medical history significant for radio frequency ablation for SVT 2007. The course medic verified there was no injury and reported the Soldier had recently been drinking a lot of water and protein shakes. Training for the three days prior to presentation included several prolonged, physically demanding events.
PHYSICAL EXAMINATION: Initial vitals: Pulse- 112, B/P- 115/69, respirations-28, SPO2- 99%, GCS- 15
General: Pt on gurney with eyes closed, responding appropriately to questions. Respiratory rate rapid and deep. The physical exam to include a complete neurologic exam was only remarkable for mild photophobia and a lack of carpal pedal spasms.
DIFFERENTIAL DIAGNOSIS:
1. Hyperventilation
2. Hyponatremia
3. Hypoglycemia
4. Arrhythmia
5. Migraine Headache
6. Micturition Syncope
7. Sub-acrachnoid Hemorrhage
8. Panic Attack
TESTS AND RESULTS:
-Glucose: 90, CMP and CBC normal, UA: 2+ ketones, myoglobin negative.
-ECG: sinus tachycardia, normal axis, normal intervals, no ischemic changes.
-Head CT: right-sided 2.8 cm epidural hematoma with 8mm of midline shift. No skull fracture identified.

FINAL/WORKING DIAGNOSIS:
Epidural Hematoma
TREATMENT AND OUTCOME:
1. Transfer to a tertiary care center for craniotomy and hematoma evacuation of the hematoma. There was a fine, non-displaced fracture of the temporal bone discovered at time of surgery.
2. No neurologic sequelae.
3. Cleared to return to training after 6 months of healing.
4. Investigation after the injury revealed the Soldier had sustained minor blow to the right side of the head 3 days prior to presentation.

1156   May 31 9:20 AM - 9:40 AM

Going the Distance Makes Me Tired: Seizure in a Cross Country Runner

Caitlin G. Waters, James Broadhurst, John H. Stevenson. *UMass Memorial Medical Center, Worcester, MA.* (Sponsor: Pierre Rouzier, FACSM)

(No relevant relationships reported)

HISTORY: 21 y/o M collegiate cross country runner presents to team doctor with hand shaking and body cramping after a strenuous 12 mile run. Complained of generalized weakness, abdominal and leg cramping, nausea, diarrhea, slight shaking of his hands, and thirst. Felt well prior to the run. Endorsed increased thirst this week and had been drinking water. Sent to the ER for IV hydration. On his way to the ER, he suddenly became unresponsive with stiffness, shaking, and frothing at the mouth.
PHYSICAL EXAMINATION: Temp: 36.9 Celsius, BP: 140/80, HR: 90-110, RR:21-27, SpO2: 100% on RA, GEN: Responsive, staring. Pale. NAD. Photosensitive. No rigidity. Clear speech. PSYCH: Answers "Yup." to most questions. Occ. confused. Alert. Oriented x3. HEENT: PERRL. EOMI. No LAD. Neck supple. No JVD. CARDIOPULM: CTA B/L. S1, S2, RRR, no MRG, ABD: Soft, NT, ND, no HSM, BS+ , EXT: No edema, capillary refill <2, SKIN: No rash, NEURO: CN II-XII testing limited, but grossly intact. Would not stick out tongue. Opens eyes on request. Normal grasp. Reflexes 2+ DTR's b/l.
DIFFERENTIAL DIAGNOSIS:Metabolic Derangement, Hyponatremia, Hypercalcemia, Hypoglycemia; Rhabdomyolysis/Dehydration; Toxic Encephalopathy; Drug Withdrawal; Intracranial Mass; CNS Infection; Epilepsy
TEST AND RESULTS:Initial Na 118, Anion Gap 17, Bicarbonate 15, Magnesium 1.5, initial CPK 917, CK rose to greater than 60,000 despite IV hydration, Toxicology Negative, CT head: questionable hypodensities in the medial temporal lobe, MRI Brain: normal, EEG: negative
FINAL WORKING DIAGNOSIS: Seizure induced by Hyponatremia Secondary to Psychogenic Polydipsia; Hyponatremia Induced Myopathy
TREATMENT AND OUTCOMES:Sodium corrected in the ICU over a few days. Patient drank a total of 48 oz prior to his run, and 160 oz post-run. Despite hydration and gentle correction of sodium, CK continued to rise. Rhabdomyolysis thought initially due to seizure and muscle breakdown in the setting of aggressive exercise; however, the delayed clearance of CPK raised concerns for glycogen storage deficiency vs genetic dysfunction. Referred to Genetics for a muscle biopsy to rule out glycogen storage deficiency, biopsy pending. Returned to cross country running with strict instructions regarding hydration, runs 5-8 miles without any issues.

1157   May 31 9:40 AM - 10:00 AM

Cotton Mouth In A Cross Country Runner.

Jason A. Kirkbride, Siobhan Statuta. *University of Virginia, Charlottesville, VA.* (Sponsor: John MacKnight, FACSM)

(No relevant relationships reported)

HISTORY: A 21-year-old Division I cross-country runner presented to the athletic training room the day he was to leave for ACC championships, concerned about his intolerable dry mouth, leg heaviness and worsening fatigue. He had an unintended weight loss of 15 pounds despite working with Sports Nutrition over the summer due to a baseline BMI of 17.9 and a history of a sacral stress fracture the prior year. He endorsed normal eating pattern, but often felt full secondary to increased fluid intake from his dry mouth. Over the past few days, he also noted the onset of blurry vision. His only medication was an Omega-3 supplement and he denied a family history of autoimmune diseases, but did have an uncle with Type II diabetes mellitus.
PHYSICAL EXAMINATION: Temp: 36.9 °C (Oral) HR: 54 beats per minute Orthostatic blood pressure: Supine: 112/72 Standing: 108/65 Weight: 61.3 kg BMI: 17.36 kg/m2 GEN: No acute distress, Thin. Cachectic appearing. HEENT: Eyes prominent where conjunctiva is visible around entire iris, no thyromegaly. Tongue and uvula covered with white scrapable film, no cervical lymphadenopathy. CV: Normal S1, S2, normal rhythm. No murmurs. Bradycardic (baseline for patient). NEURO: Alert, oriented x3, speech fluent, sensation intact. PSYCH: Quiet, slower to respond compared to baseline. "Spacey," but logical thinking. No tangentiality.
DIFFERENTIAL DIAGNOSIS: Relative energy deficiency in sport Overtraining syndrome Thyroid disease Anemia Viral illness/ Mononoculeosis Diabetes Mellitus Type 1 Malignancy Diabetes Insipidus

TEST AND RESULTS: Urinalysis: Color yellow, Appearance Clear, Specific Gravity 1.035, pH 6.5, Protein Neg., Glucose 3+, Ketone Moderate, Bilirubin Neg., Blood Neg., Nitrite Neg., Leukocyte esterase neg. CBC: WBC 7.3, Hgb. 16.6, Hct. 46, Plt. 268 CMP: Na 130, K+ 5.6, Cl. 88, Bicarb. 27, BUN. 39, Cr. 0.8, Glc. 870, Alk phos. 183, ALT 67, AST 35, Anion Gap 15 TSH 0.27, Free T4 0.9, Free T3 1.5 CRP 0.2 ESR 7 Ferritin 224 HIV Non-reactive Hgb. A1c 13.6
FINAL WORKING DIAGNOSIS:New onset Diabetes Mellitus Type 1 in diabetic ketoacidosis
TREATMENT AND OUTCOMES:Urgent transport to the emergency department for DKA management including insulin and intravenous fluids with several day admission. Endocrinology work-up in process. Plan to follow weekly x 6 weeks and held from sport the remainder of the semester.

C-33   Free Communication/Poster - **Acute Exercise - Cardiorespiratory Physiology**

Thursday, May 31, 2018, 7:30 AM - 12:30 PM
Room: CC-Hall B

1193   Board #1   May 31 8:00 AM - 9:30 AM
Aerobic Exercise Reduces The Pro-thrombotic Potential Of Circulating Microparticles in Healthy Individuals

Patrick J. Highton[1], David J. Stensel[1], Fernanda R. Goltz[1], Naomi Martin[2], Nicolette C. Bishop[1]. [1]Loughborough University, Leicester, United Kingdom. [2]De Montfort University, Leicester, United Kingdom.

(No relevant relationships reported)

PURPOSE: Microparticles (MPs) are extracellular vesicles shed upon cellular activation or apoptosis that possess pro-thrombotic functions via Tissue Factor (TF) expression. Aerobic exercise (AE) may impact circulating MPs, though recent research is conflicting. Previous other results may also reflect underlying circadian variations. This study investigated the impact of AE or rest with a standardized meal on MP phenotypes and pro-thrombotic potential over a morning period.
METHODS: 15 healthy males (22.9 ± 3.3 years; 81.9 ± 11.4 kg; VO_2 max 54.9 ± 6.5 mL·kg·min^{-1}; mean ± SD) completed 1 hr of AE (70% VO_2max) at 9am, and consumed a standardised meal (1170 kcal, 43% CHO, 17% PRO, 40% fat) at 10:45am. Venous blood samples were taken at 9am, 10am and 11:30am. Control trials included no exercise. MP phenotypes (platelet, neutrophil, monocyte and endothelial cell) and TF expression were assessed by flow cytometry.
RESULTS: Data are presented as mean ± SEM**.** Effect sizes are presented as η^2 (0.2 = small, 0.5 = moderate, 0.8 = large; Statistical Power Analysis for the Behavioral Sciences, Cohen, 1988). Total numbers of MP increased from 9am to 10am (1.62 ± 0.59 to 1.74 ± 0.73 x10^{10}/L, p = .016, η^2 = .105) in both conditions, but was unaffected by trial. All other phenotype counts remained unaffected by trial or time. The % of TF+ platelet-derived MPs reduced from 9am to 10am (44.0 ± 5.5 to 21.5 ± 2.4%, p = .001, η^2 = .582) in the exercise trial, but remained unchanged in the control trial (36.8 ± 4.7 to 34.9 ± 3.9%, p = .972). %TF+ neutrophil-derived MPs reduced from 9am to 11:30am (42.3 ± 4.4 to 25.1 ± 3.8%, p = 0.48, η^2 = .801) in the exercise trial, but remained unchanged in the control trial (28.5 ± 4.1 to 32.2 ± 2.5%, p = .508).
CONCLUSION: The increase in total MP count was not affected by exercise and may be due to diurnal variation – this warrants further investigation over a 24h period. Moderate intensity AE with a standardized meal seem to have little effect on absolute circulating MP
phenotype counts in this population. However, AE induced a large reduction in the % of platelet and neutrophil MPs that express TF, suggesting a mechanism via which AE can reduce cardiovascular risk via reduced TF-stimulated coagulation and thrombosis. This effect requires more investigation in clinical populations at greater cardiovascular disease risk.

FURIN Variant Associations with Postexercise Hypotension are Ethnicity and Intensity Dependent

Burak T. Cilhoroz[1], Gregory A. Panza[2], Elizabeth D. Schifano[1], Garrett I. Ash[3], Lauren M.L. Corso[1], Ming-Hui Chen[1], Ved Deshpande[1], Amanda Zaleski[2], Paulo Farinatti[4], Beth A. Taylor, FACSM[2], Rachel J. O'Neill[1], Paul D. Thompson, FACSM[2], Linda S. Pescatello, FACSM[1]. [1]University of Connecticut, Storrs, CT. [2]Hartford Hospital, Hartford, CT. [3]Yale University, New Heaven, CT. [4]Rio de Janeiro State University, Rio de Janeiro, Brazil. (Sponsor: Linda S. Pescatello, FACSM)

(No relevant relationships reported)

Furin (paired basic amino acid cleaving enzyme) is a proprotein convertase subtilisin/kexin (PCSK) enzyme and important in pro renin receptor processing. *FURIN* variants have been identified to be involved in multiple aspects of blood pressure (BP) regulation, and targeting PCSKs is a promising future form of drug therapy.
PURPOSE: To examine the associations among *FURIN* variants and the immediate blood pressure (BP) response to bouts of acute exercise performed at different intensity, termed *postexercise hypotension* (PEH).
METHODS: Obese (30.9±3.6 kg m^{-2}) African American (n=14) (AF) and Caucasian (n=9) adults 42.0±9.8yr with hypertension (139.8±10.4/84.6±6.2mmHg) performed three random acute experiments: bouts of vigorous (VIGOROUS) and moderate (MODERATE) intensity cycling and control. Subjects were attached to an ambulatory BP monitor for 19 hr. We performed deep-targeted exon sequencing using with the Illumina TruSeq Custom Amplicon kit. Variant genotypes were coded as the number of minor alleles (#MA) and selected for additional statistical analysis based upon Bonferonni or Benjamini-Yekutieli multiple testing corrected p-values under time adjusted linear models for 12 hourly BP measurements, when all subjects were awake and ambulating; and for 19 hourly BP measurements, the total duration the BP monitor was worn.
RESULTS: After VIGOROUS over 19 hr, as *FURIN* #MA increased in rs12917264 (p=2.4E-04), rs6226 (p=2.4E-04), and rs75493298 (p=6.4E-04), systolic BP (SBP) decreased 30.4 to 33.7 mmHg; and in rs12917264 (p=1.6E-03), rs6226 (p=1.6E-03), and rs75493298 (p=9.7E-05), diastolic BP (DBP) decreased 17.6 to 20.3 mmHg among AF only. In addition, after MODERATE over 19 hr in *FURIN* rs74037507, as #MA increased, SBP increased 20.8 mmHg among AF only. Whereas, after MODERATE over the awake hours, as *FURIN* #MA increased in rs2071410 (p=6.1E-04), rs1573644 (p=6.1E-04), and rs6227 (p=6.1E-04), DBP decreased 12.5 mmHg among Caucasians only.
CONCLUSION: *FURIN* variants were associated with PEH after MODERATE and VIGOROUS over 19 hr among AF, and after MODERATE over the awake hours among Caucasians. *FURIN* appears to exhibit ethnicity and intensity dependent associations with PEH that merit further exploration among a larger, ethnically diverse sample of adults with hypertension.

1195   Board #3   May 31 8:00 AM - 9:30 AM
Repeatability of the Neurocardiovascular Responses to Isometric Handgrip in Young Adults

Gabrielle A. Dillon[1], Paul J. Fadel, FACSM[2], Lacy M. Alexander, FACSM[1], Jody L. Greaney[1]. [1]Pennsylvania State University, University Park, PA. [2]University of Texas Arlington, Arlington, TX. (Sponsor: Lacy Alexander, FACSM)

(No relevant relationships reported)

Blood pressure (BP) and muscle sympathetic nerve activity (MSNA) responses to isometric handgrip (HG) are primarily driven by the skeletal muscle metaboreflex. The magnitude of the pressor and sympathoexcitatory responses to isometric HG and isolation of the muscle metaboreflex with post exercise ischemia (PEI) are commonly used maneuvers to compare groups and assess aberrant neurocardiovascular regulation. However, the repeatability of these responses remains unclear. **PURPOSE:** Consistent with the NIH requirements for rigor and reproducibility in biomedical research, we sought to determine the intra-day repeatability of the neurocardiovascular responses to isometric HG and PEI in young adults. We tested the hypothesis that the increases in BP and MSNA during isometric HG and PEI would be repeatable within an individual. **METHODS**: Mean arterial pressure (MAP; finger photoplethysmography), heart rate (HR; ECG), and MSNA (peroneal microneurography) were measured in 8 (6 M; 24±1 yrs) healthy young adults at baseline and during isometric HG at 30% of maximum voluntary contraction followed by PEI to isolate the muscle metaboreflex. Subjects completed two trials separated by 15 min. Linn's repeatability coefficient (ρc) was used to assess repeatability. **RESULTS:** MAP and MSNA increased significantly during HG and PEI in all subjects during both trials (all P<0.05). The BP and HR responses to HG (MAP: Δ29±5 v. Δ32±4 mmHg, ρc= 0.68, 95%CI: 0.09 -0.92; HR: Δ14±3 v. Δ20±4 bpm, ρc= 0.56, 95%CI: 0.0-0.84) and PEI (MAP: Δ18±5 v. Δ18±5 mmHg, ρc= 0.62, 95%CI: 0.14-0.86; HR: Δ-1±1 v. Δ0±2 bpm, ρc= 0.74, 95%CI: 0.39-0.91) were repeatable. The increase in MSNA during HG (n=5; Δ14±3 v. Δ20±6 bursts/min, ρc= 0.44, 95%CI: -0.173-0.804) was only moderately repeatable; however, during

PEI better repeatability was found ($\Delta 12 \pm 3$ v. $\Delta 15 \pm 3$ bursts/min, $\rho c = 0.86$, 95%CI: 0.130 - 0.986). **CONCLUSIONS:** These preliminary data suggest that MAP and HR responses to isometric HG and PEI are repeatable within an individual. Likewise, the MSNA response to PEI was repeatable, however, there was less repeatability of the MSNA response to isometric HG. These initial findings have important implications for the assessment and interpretation of neurocardiovascular regulation during HG and PEI, particularly when group comparisons are being made.

1196   Board #4   May 31 8:00 AM - 9:30 AM

Ambulatory Blood Pressure Lower Following Aquatic Exercise than Land Treadmill Exercise

Dustin P. Joubert, Caitlin Hogan, Jessica Barnes, Taylor Todd, Joshua Warner. *Stephen F. Austin State University, Nacogdoches, TX.* (Sponsor: Stephen F Crouse, FACSM)

(No relevant relationships reported)

Blood pressure (BP) is an important marker of cardiovascular (CV) health. Aquatic (AQ) exercise training has been shown to reduce BP reactivity to exercise to a greater degree than land treadmill (LT) training. Furthermore, an acute bout of AQ exercise tended to elicit a greater post-exercise hypotensive response and augmentation in flow-mediated dilation (FMD). However, it is unclear how long the post-exercise hypotensive benefits last following an acute bout of AQ exercise. **Purpose:** To determine the effects of acute bouts of deep water aqua-jogging and land treadmill exercise on daytime ambulatory BP (AMBP) in pre-hypertensive, physically untrained men and women. **Methods:** Following resting BP screening, 12 subjects (9 male, 29 ± 13 years, 30.4 ± 6.1 kg·m^{-2}, $127 \pm 8/82 \pm 8$ mmHg) completed acute bouts of both AQ and LT exercise at 55% heart rate reserve for a duration of 30 minutes. Exercise sessions began at 0700 hours. Immediately following the exercise bout, subjects wore an AMBP device (Oscar 2, Suntech Medical), which was programmed to take measurements every 15 minutes throughout the day until 1600 hours. Sessions occurred on separate days with 2-7 days off between sessions. The order that the modes were performed was counterbalanced among the subjects. Subjects were required to abstain from alcohol, caffeine, nicotine, and exercise on the day of the session and 24 hours prior. Comparisons between modes were made by a dependent sample t-test. **Results:** All results are displayed in Table 1. **Conclusion:** Daytime AMBP was significantly lower following AQ than LT exercise. This is consistent with previous findings of a greater post-exercise hypotensive response in the 1-2 hours post AQ exercise. Previous research also demonstrated improved FMD and increased atrial natriuretic peptide levels following AQ exercise, which could potentially explain the reduced BP findings. These data further support the efficacy of AQ exercise for the promotion of CV health and BP regulation.

Table 1. Ambulatory Blood Pressure Response

Variable	Aquatic	Land	p-value
SBP (mmHg)	136 ± 9	140 ± 9	0.051
DBP (mmHg)	76 ± 6	81 ± 6	0.006*
MAP (mmHg)	96 ± 7	101 ± 6	0.007*
HR (bpm)	78 ± 12	78 ± 11	0.964
All values represent Mean ± SD. *p < 0.05

Effects of Different Exercise Modalities on Postprandial Hyperglycemia in Overweight and Obese Adults

Craig W. Berry, Conlan J. Varty, Kristina B. Arslain, Kevin D. Ballard. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)

(No relevant relationships reported)

Postprandial hyperglycemia (PPH) is directly associated with cardiovascular disease risk. A single bout of aerobic (AE) or resistance exercise (RE) lowers PPH the following morning in healthy adults. No studies have examined the extent to which prior exercise regulates PPH in overweight and obese adults, and whether differences exist between exercise modalities. **PURPOSE:** The purpose of this ongoing investigation is to determine the effects of different exercise modalities on PPH responses to an oral glucose tolerance test (OGTT) in overweight and obese adults. We hypothesize that a single bout of exercise performed 14-17 h prior to an OGTT will attenuate increases in blood glucose, independent of exercise modality. **METHODS:** Recruitment for the current study is ongoing. In a randomized, cross-over design, participants [n=6 (3 women); age=24.3 ± 5.1 y; BMI=32.4 ± 5.8 kg/m^2] completed three trials. For each trial, an OGTT (1 g/kg body weight) was preceded (14-17 h prior) by seated rest (control), a single bout of AE, or a single bout of RE. The AE bout consisted of 30 min of continuous moderate-intensity (~60% VO$_2$max) treadmill exercise. The whole-body RE bout consisted of 3 sets of 10 repetitions of the following exercises: leg press, chest press, seated leg extension, lat pulldown, shoulder press, and seated row. The weight used for each set was determined from the participant's previously determined 10-RM. Blood was obtained prior to and at 30 min intervals for

3 hours following glucose ingestion. Repeated-measures ANOVA and LSD post-hoc tests were used to evaluate differences within and between trials. **RESULTS:** Blood glucose did not differ between trials at baseline. A main effect due to time (P<0.001) was observed for glucose. Relative to baseline, blood glucose increased (P<0.05) by 26-53%, 18-45%, and 16-46% at 30-120 min post-ingestion in the control, AE, and RE trial, respectively. Glucose area under the curve did not differ between trials (P≥0.37). **CONCLUSION:** Preliminary findings from our ongoing study suggest that acute aerobic or resistance exercise performed the evening prior to an OGTT does not affect PPH responses in overweight and obese adults. **Supported by College of Education, Health, and Society Seed Grant and Miami University Committee on Faculty Research Grant.**

Autonomic Modulation After Acute Resistance Exercise in Resistance-Trained Individuals

Alexa DeBord, Alaina Glasgow, Kathryn Geither, Leslie Sensibello, Jason C. Parks, Erica M. Marshall, Yu Lun Tai, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*

(No relevant relationships reported)

Differences in autonomic modulation between free-weight and weight machines resistance exercise is unknown. **PURPOSE:** To investigate the effects of acute free-weight (FW) and weight machines (WM) resistance exercise on heart rate complexity (HRC) and variability (HRV) in resistance-trained individuals. **METHODS:** Resistance-trained individuals were assigned to either a FW (n = 25) or a WM (n = 16) group. Autonomic modulation was collected at rest, and 15 (Rec1) and 25 (Rec2) min following acute resistance exercise (ARE) or a control. Sample Entropy (SampEn), indicative of vagal modulation, was used as a measure of HRC. HRV measurements included vagal modulation (normalized high frequency (HFnu)), and sympathovagal balance (LF/HF ratio). ARE for the FW group consisted of 3 sets of 10 repetitions at 75% 1-repetition maximum (1RM) on the squat, bench press, and deadlift, while the WM group utilized of 3 sets of 10 repetitions at 75% 1RM on the leg press, lat pull down, leg extension, chest press, and leg curl. A 2x2x3 ANCOVA was used to examine groups (FW, WM) across conditions (ARE, control) and time (Rest, Rec1, Rec2), with load as a covariate. **RESULTS:** The groups were similar (p>0.05) for age, height, weight, BMI, and baseline autonomic modulation, but differed for years of training. There was a significant group by condition by time interaction (p=0.03) for SampEn such that in the FW group (Rest: 1.5 ± 0.3; Rec1: 1.1 ± 0.3; Rec2: 1.1 ± 0.4) it was attenuated during Rec1 and Rec2 after ARE compared to rest and the control. In the MW group, while there were no significant differences from rest to Rec1 or Rec2, there was a significant difference from Rec1 to Rec2 (Rest: 1.4 ± 0.5; Rec1: 1.0 ± 0.3; Rec2: 1.3 ± 0.3) such that it differed from the control. There was also a significant group by time interaction for HFnu (Rest: $62.5 \pm 15.0\%$; Rec1: $29.5 \pm 18.9\%$; Rec2: $29.2 \pm 19.9\%$, p=0.002) such that it was attenuated compared to rest, and the control, in both groups. The LF/HF ratio (Rest: 61.0 ± 52.1; Rec1: 420.0 ± 424.7; Rec2: 456.7 ± 390.2, p=0.007) was augmented such that it differed from rest, and the control, in both groups. **CONCLUSIONS:** Based on our data the use of free-weight resistance exercises results in significant reductions in vagal modulation that are immediate, and maintained, up to 30 min, which does not appear to occur when using weight machines.

1199   Board #7   May 31 8:00 AM - 9:30 AM

Daily exercise Compared To Exercise On Alternating Days On Post-exercise Hypotension In prehypertensive Men

Zachary Zeigler, Conner Dreos, Tabor Morse, Rebecca Lentz, Ezekial Morse, Lydia Durnil. *Grand Canyon University, mesa, AZ.*

(No relevant relationships reported)

Purpose: Acute exercise can result in post-exercise hypotension (PEH) lasting up to 24-h. Whether exercise performed on consecutive days would lead to an accumulating PEH effect has yet to be determined. The purpose of this study was to compare daily exercise (DE) to exercise performed on alternating days (AE) and a control (CON) on PEH. **Methods**: Sedentary, PHTN men 18-30yr participated in this three-arm randomized cross-over trial. The primary comparison was the magnitude of PEH between three groups (control (CON), alternating exercise (AE), and daily exercise (DE)) and within each group over time (day 1, 2, and 3). Both exercise groups were prescribed the same exercise intensity (70-75%HRmax), and total duration of exercise (90min) on a cycle ergometer. DE performed exercise on three consecutive days (three bouts of 30min). AE performed exercise on two alternating days (2 bouts of 45min). After exercise sessions subjects remained in the laboratory for 1-h while BP was taken every 5min. **Results**: Eight overweight (BMI=29 ± 4kg/m^2), young (22 ± 2years), moderately fit (VO$_2$peak=34 ± 6ml.kg.min), PHTN ($126 \pm 10/73 \pm 6$mmHg) male subjects completed the study. There was a significant SBP condition by day effect such that on day three SBP (CON 120 ± 9, AE 123 ± 13, DE 118 ± 12 mmHg), and DBP (CON 73 ± 6, AE 70 ± 9, DE 68 ± 7 mmHg) were lowest during the post-exercise DE condition

(P < 0.001). **Conclusion**: In conclusion, the PEH effect appeared to accumulate during DE such that day 3 was the lowest of all conditions and days. It has been suggested that the current recommendation on training frequency should be changed from accumulating 30 min on most, preferably all days of the week, to *all days* of the week. Our preliminary findings support this notion.

1200   Board #8   May 31 8:00 AM - 9:30 AM

Upper and Lower-body Resistance Exercise With and Without Blood Flow Restriction on Pulse Wave Reflection

Yu Lun Tai, Erica M. Marshall, Alaina Glasgow, Jason C. Parks, Kathryn Geither, Leslie Sensibello, Ramon Oliveira, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*
(No relevant relationships reported)

Acute resistance exercise (RE) with blood flow restriction (BFR) on pulse wave reflection is unclear. **PURPOSE**: To evaluate the differences between acute upper-body RE (URE) and lower-body RE (LRE) with and without BFR on pulse wave reflection in resistance-trained individuals. **METHODS**: Pulse wave reflection was assessed at rest, and during recovery at 10 (R10), 25 (R25), 40 (R40), and 55 (R55) minutes after either URE or LRE with or without BFR in twelve resistance-trained individuals. The URE consisted of the lat pulldown and chest press while the LRE consisted of knee extension and knee flexion. The BFR condition consisted of 4 set of 30, 15, 15, and 15 repetitions at 30% 1-repetition maximum (1RM) while the non-BFR condition consisted of 4 sets of 8 repetitions at 70% 1RM. A 2x2x3 repeated measures ANOVA was used to evaluate the effect of group across conditions and time on pulse wave reflection. **RESULTS**: There were no differences for any variable between conditions. There were significant group by time interactions for brachial systolic blood pressure (BSBP), brachial diastolic blood pressure (BDBP), aortic systolic blood pressure (ASBP), and aortic diastolic blood pressure (ADBP) such that BSBP (rest: 120±9mmHg, R10: URE: 115±12mmHg, LRE:126±8mmHg; p<0.001) and ASBP (rest: 104±8mmHg, R10: URE: 102±10mmHg, LRE:109±8mmHg; p=0.005) were increased at R10 from LRE compared to URE and rest, with no difference from rest to R25, R40, or R55. BDBP (rest: 64±7mmHg, R10: URE: 60±6mmHg, LRE:67±6mmHg, p=0.001; R25: URE: 62±5mmHg, LRE:67±7mmHg, p<0.001) and ADBP (rest: 65±7mmHg, R10: URE: 60±6mmHg, LRE:69±6mmHg, p≤0.001; R25: URE: 63±5mmHg, LRE:69±7mmHg, p<0.001) were elevated at R10 and R25 from LRE compared to URE and rest, and no difference at R40 or R55. There were significant group by time interactions for augmentation index (AIx) (rest: 13.3±9.8%, R10: URE: 26.4±10.5%, LRE: 15.7±8.4%; p<0.001) and AIx normalized to 75bpm (rest: 3.7±11.7%, R10: URE: 25.4±14.0%, LRE: 15.8±13.5%; p=0.001) such that they were increased at R10 from URE compared to LRE and rest, and were fully recovered by R25. **CONCLUSIONS**: These data suggest that LRE significantly elevated blood pressure more so than URE, and that URE significantly increased pulse wave reflection more than LRE, regardless of whether they were completed with or without BFR.

1201   Board #9   May 31 8:00 AM - 9:30 AM

Blood Pressure Reactivity During Short-term Water Restriction in Young Adults

Joseph C. Watso[1], Matthew C. Babcock[1], Austin T. Robinson[1], Kamila U. Migdal[1], Sean D. Stocker[2], Megan M. Wenner[1], William B. Farquhar, FACSM[1]. *[1]University of Delaware, Newark, DE. [2]University of Pittsburgh, Pittsburgh, PA.* (Sponsor: William B Farquhar, FACSM)
(No relevant relationships reported)

Dehydration reduces plasma volume and concentrates electrolytes, increasing plasma osmolality (pOsm). Water deprivation (WD) studies in animals demonstrate that elevated pOsm is associated with altered sympathetic outflow and blood pressure (BP) regulation. However, it remains unclear if WD augments BP responses to sympathoexcitatory stimuli in humans. **PURPOSE:** We tested the hypothesis that WD elevates pOsm and consequently augments BP reactivity. **METHODS:** Twenty healthy young adults were recruited (10M/10W; age: 24±1 yrs; BMI: 24±1 kg/m²; BP: 109±2/61±2 mmHg) to complete two hydration conditions, in random order. A normal hydration (NH) and WD visit were separated by at least one week. Daily water intake for the NH condition was 23mL H_2O/kg bodyweight/day for 3 days prior to testing. The WD condition included a stepwise reduction in water intake over 3 days then a 16hr water restriction prior to testing. Beat-by-beat BP was measured continuously with finger photoplethysmography throughout a 10-min baseline, handgrip exercise (HG), post-exercise ischemia (PEI), and a cold pressor test (CPT). Isometric HG was performed at 30% of maximal voluntary contraction for 2 mins and PEI immediately followed with rapid upper arm cuff inflation to 250mmHg for 3 mins (to isolate the metaboreflex). Following HG & PEI, participants rested quietly for 10 mins prior to a 2-min hand-in-ice H_2O CPT. Peak responses were calculated as the absolute change in BP during the final minute of each perturbation from the respective baseline. **RESULTS:** Plasma volume, estimated by changes in hemoglobin and hematocrit, declined 5.6±1.4% during WD. POsm (287.0±1.0 vs. 290.0 ±1.0 mOsm/kg H_2O), urine

osmolality (481±137 vs. 708±42 mOsm/kg H_2O), urine specific gravity (1.015±0.002 vs. 1.022±0.001), and thirst rating on a 0-10 scale (1.7±0.4 vs. 6.7±0.4) were higher for the WD condition (p<0.05 for all), suggesting mild dehydration. Mean BP responses were augmented following WD during HG (Δ12.8±1.7 vs. 18.7±2.0 mmHg, p<0.05), PEI (Δ8.8±1.0 vs. 14.7±2.4 mmHg, p<0.05), and CPT (Δ14.9±2.0 vs. 18.6±2.3 mmHg, p=0.05). **CONCLUSION:** These preliminary findings suggest that short-term WD increases pOsm and augments BP responses during moderate intensity isometric HG exercise, PEI, and CPT, suggesting enhanced BP reactivity.

Brachial Artery FMD Responses To Steady-State Moderate-Intensity And High-Intensity Interval Exercise In Mid-Spectrum Chronic Kidney Disease

Jeffrey S. Forsse[1], Matthew Peterson[1], Zacharias Papadakis[1], Fernando Gutierrez[1], Nicholas Schwedock[2], Burritt W. Hess[2], Jackson O. Griggs[2], D. Crawford Allison[3], Ron L. Wilson[3], Peter W. Grandjean, FACSM[1]. *[1]Baylor University, Waco, TX. [2]Family Health Center, Waco, TX. [3]Baylor Scott & White Health, Waco, TX.* (Sponsor: Dr. Peter W. Grandjean, FACSM)
(No relevant relationships reported)

Brachial artery flow-mediated dilation (FMD) is a nitric oxide-dependent measure of conduit artery endothelial function that is transiently potentiated by moderate-intensity steady-state exercise (SSE) in healthy adults. Whether exercise imparts similar effects in adults with Stage 3 or 4 chronic kidney disease (CKD) has not been reported. Moreover, a comparison of SSE and high-intensity interval exercise (HIIE) may add to clinically-relevant findings for improving vascular function in mid-spectrum CKD. **PURPOSE:** To determine the influence of SSE and a comparable amount of HIIE on post-exercise brachial artery FMD in patients diagnosed with secondary Stage 3 or 4 CKD. **METHODS:** Twenty participants (n = 6 men; n = 14 women; age 62.0 ± 9.9 yr; weight 80.9 ± 16.2 kg; body fat 37.3 ± 8.5% of weight; VO₂max 19.4 ± 4.7 ml/kg/min) completed 30 min of SSE at 65% VO₂reserve or HIIE by treadmill walking (90% and 20% of VO₂reserve in 3:2 min ratio) in a randomized crossover design. Both exercise conditions averaged ~ 65% VO₂reserve. Ultrasound measurements of brachial artery FMD were obtained by the same technician under standardized conditions just before, 1 hr and 24 hrs after exercise. FMD responses were analyzed using 2 (condition) by 3 (sample point) repeated measures ANOVAs. **RESULTS:** Brachial artery FMD responses were augmented 1 hr after exercise in both exercise conditions (p < 0.005 versus pre-exercise FMD). SSE (pre-exercise = 11.5 ± 1.3; 1 hr = 17.2* ± 1.8; 24 hr = 14.0* ± 1.1%) HIIE (pre-exercise = 12.5 ± 1.3; 1 hr = 15.6* ± 1.5; 24 hr = 15.8* ± 1.2%) **SUMMARY:** We report for the first time that brachial artery FMD can be augmented by a single episode of exercise in mid-spectrum CKD. SSE and HIIE, averaging ~65% of VO₂reserve, is equally effective at transiently improving conduit artery vascular function in this clinical population.

Pulmonary Responses During Exercise On Dryland Vs. Immersible Ergocycle

Mauricio Garzon[1], Mathieu Gayda[2], Anil Nigam[2], Alain-Steve Comtois[3], Martin Juneau[2]. *[1]University of Quebec in Montréal, Cardiovascular Prevention and Rehabilitation Centre (EPIC)., Montreal, QC, Canada. [2]Cardiovascular Prevention and Rehabilitation Centre (EPIC), Montreal Heart Institute, Montreal, QC, Canada. [3]University of Quebec in Montréal, Montreal, QC, Canada.*
(No relevant relationships reported)

Water immersion can affect respiratory responses during exercise relative to exercise on dry land. Exercise training in an aquatic environment has added benefits relative to training on land, improving central hemodynamic responses as stroke volume (SV), cardiac output (Q) and heart rate recovery (HRR) as well as increasing cerebrovascular blood flow, relative to land-based exercise of a similar intensity, in healthy humans. **PURPOSE:** We sought to compare pulmonary responses during an incremental exercise done on immersible ergocycle (IE) vs dryland ergocycle (DE) at the same external power output (P_{ext}). **METHODS:** Ten (10) young healthy subjects (Age: 31±9 years; BMI: 23.3±1.9 kg/m²) performed incremental exercise tests on IE at chest level immersion and DE at equal external power output (P_{ext}). Pulmonary responses were measured and P_{ext} on IE was calculated according to the general fluid equation $F_d = \frac{1}{2}\rho Av^2C_d$. Tangential speed of the pedaling mechanism was calculated by $2\pi r$ (rpm), $2\pi (r/2)(rpm)$ and $\omega 2\pi (r/2)/360°(rpm)$, for pedals, paddles-rods, and legs, respectively, as used in previous studies. **RESULTS:** VO₂ (p=0.0087) and VCO₂ (p=0.0138) were significantly lower during exercise on IE at every stage of the incremental test relative to DE. No differences were detected between IE and DE for respiratory exchange ratio (RER) ventilation (V_E), breathing frequency (f), tidal volume (V_T), fraction of expired O_2 and CO_2 (FetO₂ and FeCO₂, respectively), time of inspiration (Ti), time of expiration (Te), time of respiratory cycle (Ttot), duty cycle (Ti/Ttot), and partial pressure of end tidal O_2 and CO_2 (PetO₂ and PetCO₂, respectively). **CONCLUSIONS:**

Abstracts were prepared by the authors and printed as submitted.

Exercise during water immersion results in a significantly lower mean VO_2, relative to a land exercise of equivalent power output. No differences were detected in the respiratory parameters suggesting that the lower VO_2 reached with IE is not attributed to changes in ventilation, but rather to central or peripheral convection (cardiac output) or diffusion (capillary O_2 extraction) factors. We have previously shown that hemodynamic factors (convection) are modestly improved, but not sufficiently to explain the large gap in VO_2 between IE and DE. We hypothesize that diffusion is improved by an unknown mechanism that remains to be explained.

Blood Pressure Responses to Intermittent Physical Activity in Elementary School-Age Children

Emma Weston, Tiwa Ajibewa, Matt Nagy, Molly O'Sullivan, Shannon Block, Rebecca Hasson, FACSM. *University of Michigan, Ann Arbor, MI.*
(No relevant relationships reported)

PURPOSE: The purpose of this study was to compare the acute effects of prolonged sitting on resting blood pressure (BP) with a similar duration of sitting combined with intermittent physical activity (PA) performed at varying intensities in healthy weight (HW) and overweight/obese (OW/OB) preadolescent children.
METHODS: Thirty-nine children (18 males, 21 females; ages 7-11 years; 33% OW/OB; 59% non-white) completed four experimental conditions in random order: 8 hours of sitting interrupted with 20, 2-minute low-intensity, moderate-intensity, or high-intensity PA breaks, or 20, 2-minute sedentary screen-time breaks. Exercise intensity corresponded with 25%, 50% and 75% of heart rate reserve, respectively. Using a digital BP monitor, BP was measured during each experimental condition in the morning (0800 hrs), midday (1200 hrs), and end-of-day (1600 hrs).
RESULTS: Across all time points, there were no significant between-condition differences observed in systolic blood pressure (SBP) (sedentary:101±2 mmHg; low:105±2 mmHg; moderate:102±2 mmHg; high:105±2 mmHg; p>0.05). SBP did however decrease significantly throughout the day for all conditions (morning:106±1 mmHg; midday:101±2 mmHg; end-of-day:103±1 mmHg; p=0.01). OW/OB children displayed a greater decline in SBP throughout the day compared to HW children (p<0.01). Across all time points, no significant between-condition differences were observed in diastolic blood pressure (DBP) (sedentary:61±2 mmHg; low:63±2 mmHg; moderate: 61±2 mmHg; high: 65±2 mmHg; p>0.05). No significant effects of time were observed in DBP (morning:63±1 mmHg; midday:62±1 mmHg; end-of-day:62±1 mmHg; p>0.05). At all time points, higher DBP were observed in OW/OB compared to HW children (HW:60±1 mmHg; OW/OB:64±2 mmHg; p=0.03).
CONCLUSION: Contrary to previous findings in adults, both interrupted and uninterrupted sitting resulted in a similar decrease in SBP throughout the day. The decline in SBP was greater in OW/OB children compared to HW children. Future research should examine the long-term effects of interrupted and uninterrupted sitting on resting BP in preadolescent children.

Comparing the Changes in Cardiovascular Function After Acute Exposure to Tai Chi or Walking

Stephen A. Maris, Christa R. Winter, Vincent J. Paolone, FACSM, Samuel A.E. Headley, FACSM. *Springfield College, Springfield, MA.* (Sponsor: Samuel Headley, FACSM)
(No relevant relationships reported)

Hypertension is a major health concern throughout the United States and is a major cause of cardiovascular disease and recent research has indicated that central aortic pressures more accurately depict of pressure within the myocardium compared to commonly used brachial measures. **PURPOSE:** The purpose of this study was to compare the responses of Tai Chi and walking on measures of central and peripheral cardiac measurements when controlling for exercise intensity. **METHODS:** 15 pre-hypertensive subjects (2 males, 13 females; age = 20.7±3.77 years; body fat percentage = 24.26±10.27%) participated in Tai Chi (TC) and walking (WK) for 30 minutes on non-consecutive days. Central systolic (CSBP) and diastolic blood pressure (CDBP), augmentation index (Alx), pulse pressure (PP), heart rate (HR), and brachial systolic (BSBP) and diastolic blood pressure (BDBP) were measured prior to exercise and following exercise every 10 minutes for a total of 60 minutes in a seated position. A repeated measures ANOVA with two repeated measure factors was computed for each outcome measure. **RESULTS:** There were no significant differences between the two exercise forms. However, CSBP decreased 10 minutes after exercise in both exercise types (TC = 6.63±3.258 mmHG, p < .05; WK = 7±4.144 mmHG p < .05), and 40 minutes after exercise in both exercise types (TC = 6.07±3.33 mmHG, p < .05; WK = 8.2±3.15 mmHG, p < .05) compared to the before exercise measurement. BSBP also decreased in both exercise forms following 10 min of rest (TC=6.99±3.776 mmHG, p = .05; WK=8.8±3.20 mmHG p = .05), and 40 min (TC=8.46±3.07 mmHG, p = .05; WK=8.87±3.87 mmHG, p = .05) when compared to the initial resting measurement. A trend indicated that heart rate was lower during the Tai Chi rest periods when compared to walking during the 30th minute (TC= 73.73±12.31 bpm,

WK = 78.40±15.82 bpm, p = .051) and the 60th minute of rest (TC= 73.0±13.95 bpm, WK= 76.0±13.85 bpm p = .06). There were no significant changes in Alx, PP, or diastolic pressures. **CONCLUSIONS:** Central aortic pressure exhibits a post exercise hypotensive (PEH) effect similar to that of peripheral blood pressure. Both Tai Chi and walking elicited similar PEH effects on systolic blood pressure in prehypertensive individuals.

Metabolic Responses to a Battling Rope Protocol Performed in the Seated or Stance Positions

Dominisha Felder, Hannah Mitchell, 77030, Kasey Hogan, Reka Kovacs, Wayne Brewer, 77030. *Texas Woman's University, Houston, TX.* (Sponsor: Alexis Ortiz PT, PhD, FACSM, FACSM)
(No relevant relationships reported)

PURPOSE: To compare the levels of oxygen consumption (VO2) and heart rate (HR) responses elicited by a treadmill (TM) or bicycle (BK) VO2 max test with a standing or sitting battling rope protocol (BRP) (TM vs. standing BRP) (BK vs. seated BRP). To examine the associations between the peak HR and VO2 responses elicited from the two BRP with their respective VO2 max tests (TM vs. standing BRP) (BK vs. seated BRP).
METHODS: Forty healthy subjects, 24 females and 16 males, mean age 24.83 years, performed either a ramped VO2 max TM or BK test (respiratory exchange ratio > 1.0). At least 3 days later, the subjects who performed the ramped TM test did the standing BRP, and the subjects who performed the ramped BK test did the sitting BRP. Each BRP (standing and sitting) consisted of 15 seconds of double arm swings, followed by 45 seconds of rest for 10 rounds. The highest recorded VO2 and HR values (VO2 peak and HR peak, respectively) were recorded after each round.
RESULTS: Metabolic responses were significantly lower for the BRP in both sitting (VO2 peak and HR peak: p < .001) and standing (VO2 peak and HR peak: p < .001) as compared to the HR max and VO2 max values derived from the BK and TM tests. The BRP produced a VO2 peak that was 71.87% (sitting) and 68.37% (standing) of the subjects' VO2 max assessed via the BK and TM protocol, respectively. Moderate correlations were found between the VO2 during the seated (r = .61; p =.003) and standing (r=.43; p=.03) BRP and the BK and TM VO2 max tests, respectively. The HR peak elicited by the BRP done in sitting (r = .52; p = .009) and standing (r = .67; p = .001) had a moderate correlation with the HR max derived from the BK and TM tests. **CONCLUSIONS**: Both the seated and standing BRPs demonstrated the capacity to produce acute metabolic responses that may enhance aerobic capacity. Battling ropes may be a low cost, accessible option to improve cardiovascular endurance for individuals who cannot stand or move their lower extremities in a rhythmic manner to conduct aerobic exercise.

Longer vs. Shorter Intervals Elicit Similar Cardiovascular But Significantly Different Metabolic Responses During Interval Cycling

Andrew Scott, Christopher Bennett, Jasmine Lasslett, Daniel Reeves. *University of Portsmouth, Portsmouth, United Kingdom.*
(No relevant relationships reported)

PURPOSE: Interval training (IT) is utilised to optimise adaptations to exercise training with some recent research interest in whether low volume IT is efficacious. Therefore the purpose was to determine whether using shorter intervals would elicit similar acute cardiorespiratory responses to longer intervals.
METHODS: Nine low active participants (8 males, 1 female) performed an incremental cycle test and then two experimental IT trials on an electronically-braked cycle ergometer at least 48 hours apart in a counter-balanced repeated measures study. Ventilatory threshold (T_{vent}) and peak oxygen uptake (VO_{2peak}) were calculated from the incremental cycle test. The participants then completed the two IT trials which consisted of six blocks of work and recovery at a ratio of 2:3 minutes for LONG, and a ratio of 1:1 minutes for SHORT, for work and recovery, respectively. The 'work' intensity of each IT trial was calculated as 50% of the difference between V O_{2peak} and T_{vent} (Δ50%) and the 'recovery' intensity was calculated as 80% of Tvent. SHORT was 12 minutes and LONG was 30 minutes, plus 5 minutes warm-up and 2 minutes cool down. Oxygen uptake (VO_2), respiratory exchange ratio (RER), heart rate (HR) and power (W) were recorded continuously. Rating of perceived exertion (RPE) was collected at the end of each interval. Blood lactate [La-] and systolic blood pressure (SBP) were recorded pre and post-exercise. Rate-pressure product (RPP) and energy expenditure (EE) were calculated. Participants reported which was their preferred session. Paired samples analyses were applied to quantitative data.
RESULTS: Mean RPE during work (13 ± 2 vs. 13 ± 3; p=0.421), mean VO_2 (2234 ± 404 vs. 2258 ± 483 mL^{-1}·min^{-1}; p=0.471), RPP (25412 ± 2456 vs. 24234 ± 2363; p=0.346), SBP (150 ± 12 vs. 140 ± 13 mmHg; p=0.204) and [La-] (7.30 ± 1.86 vs. 6.46 ± 2.15 mmol·L^{-1}; p=0.416) were not significantly different between SHORT and

LONG. However, mean RER (1.02 ± 0.09 vs. 0.99 ± 0.04; p=0.002) was significantly lower and energy expenditure (287 ± 81 vs. 473 ± 93 kcal; p>0.001) was significantly greater following LONG. SHORT was preferred to LONG by all 9 participants. **CONCLUSIONS**: LONG elicited significantly different metabolic responses with similar cardiovascular responses to SHORT but was perceived as less enjoyable.

Oxygenation Characteristics during Knee Extension Exercise in Severe and Extreme Domain

Andrew M. Alexander, Kaylin D. Didier, Shane M. Hammer, Thomas J. Barstow, 66502, FACSM. *Kansas State University, Manhattan, KS.* (Sponsor: Thomas J Barstow, FACSM)

(No relevant relationships reported)

Near-infrared spectroscopy (NIRS) has been used to quantify oxygenation characteristics of skeletal muscle during exercise. Changes in total-[heme] and deoxy-[heme] have been used as an indices of diffusive and perfusive conductance, respectively. Total-[heme] and deoxy-[heme] have been shown to reach similar values at end exercise following exercise in the severe intensity domain It has further been suggested that time of exercise tolerance (T_{lim}) in the extreme domain (T_{lim} < 2 min) is too short for VO_2 kinetics to reach maximum values. It is unknown if total-[heme] and deoxy-[heme] characteristics reach similar values after exercise in the extreme domain as exercise in the severe domain. **PURPOSE**: We hypothesized that total-[heme] and deoxy-[heme] would be lower following exercise in the extreme domain than compared to exercise in the severe domain. **METHODS**: Six men (age 22 ± 3.1 yrs, 72.5 ± 6.5 kg; 178 ± 2 cm) performed 8 bi-lateral knee extension tests to task failure. First, one-repetition maximum (1RM) was determined by progressively increasing weight until a pre-determined range of motion could not be achieved. Subjects then performed 3 exercise tests in the severe intensity domain (T_{lim} = 2 - 15 min; S1 = 25.8 ± 2.7, S2 = 33.5 ± 4.3, S3 = 44.3 ± 6.9 % 1RM) and 4 in the extreme domain (60, 70, 80, 90% 1RM), in random order on non-consecutive days. A 1RM was performed 5 min before each exercise bout. Changes total-[heme], deoxy-[heme], and Sat% were measured on the L vastus lateralis. **RESULTS**: Total-[heme] at end exercise was not different between exercise intensities (p > 0.05). Total-[heme] at end exercise was not different (p > 0.05) than peak total-[heme] of the 1RM for the extreme domain exercise tests. However, total-[heme] at end exercise was greater than peak total-[heme] following severe intensity exercise (S1, p = 0.002; S2, p = 0.025, S3, p = 0.02). End exercise deoxy-[heme] and Sat% were not different (p > 0.05) compared to peak deoxy-[heme], and Sat%, respectively, of the 1RM. **CONCLUSIONS**: The current study showed that total-[heme], but not deoxy-[heme] or Sat%, is intensity- or time-dependent. These data suggest that diffusive O_2 conductance is compromised during extreme intensity exercise, whereas perfusive O_2 conductance is able to reach similar values regardless of intensity.

1209   Board #17   May 31 8:00 AM - 9:30 AM

Perceptual And Cardiovascular Responses To Very Low Load Exercise With And Without Blood Flow Restriction

Zachary W. Bell, Samuel L. Buckner, Matthew B. Jessee, J Grant Mouser, Kevin T. Mattocks, Scott J. Dankel, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

Low load (30% one repetition maximum (1RM)) exercise can produce growth if taken to failure. However, at very low loads, failure may not be possible. Applying blood flow restriction (BFR) may circumvent this by expediting fatigue and this effect may be pressure dependent. Although potentially efficacious, it is important to investigate the acute response in order to determine the utility of this stimulus. **PURPOSE**: To determine the cardiovascular and perceptual response to exercise with and without BFR. **METHODS**: Participants (n=21) completed high load (70% 1RM) and very low load (15% 1RM) exercise with (40% (15/40) and 80% (15/80) of arterial occlusion pressure (AOP)) and without BFR to failure (up to 90 reps) in the upper (biceps curl) and lower body (knee extension). AOP was determined pre and post exercise. Ratings of perceived exertion (RPE, 6-20) and discomfort (0-10+) were taken at pre and after each set. Significance was set at p ≤ 0.05. AOP presented as mean (SD) and perceptual responses presented as median (25th, 75th percentiles). **RESULTS**: There was no interaction for AOP in the upper body (p=.095) but there was a main effect of condition and time [change of 42 (16) mmHg]. The 15/80 condition [172 (23) mmHg] was greater than 15/40 [166 (22) mmHg] and 70% 1RM condition [162 (18) mmHg] but similar to 15%1RM [168 (19) mmHg]. There was an interaction for AOP in the lower body (p=.006). All conditions increased but at post the 15/40 [237 (30) mmHg] condition was greater than 15%1RM [218 (25) mmHg] and 70%1RM [200 (19)

mmHg] and the 15/80 [233 (24) mmHg] condition was greater than 70%1RM. RPE and discomfort in the upper body tended to be greatest with a high pressure. Within set 4, the RPE and discomfort were 17.5 (15, 20) and 7 (6, 8) for 15/80 which was greater than that observed with 15/40 [RPE: 15 (14, 19); discomfort: 6 (3, 8)]. In the lower body, RPE was higher for lower loads and discomfort tended to be greatest with higher pressure. Within set 4, the RPE and discomfort were 18 (15, 19) and 8 (6, 9) for 15/80 which was greater than that observed for 70%1RM [RPE: 16 (15, 17); discomfort: 4 (1, 6)]. **CONCLUSIONS**: Applying BFR with lower loads tends to augment the cardiovascular and perceptual response and often this appears greater for high pressure. These findings will need to be considered alongside any potential benefits of training with very low loads.

1210   Board #18   May 31 8:00 AM - 9:30 AM

Use of Compression Socks During a Marathon Does Not Mitigate Exercise-Associated Muscle Damage

Amanda L. Zaleski[1], Linda S. Pescatello, FACSM[2], Gregory Panza[1], Kevin Ballard[3], William Adams[4], Yuri Hosokawa[2], Pauld D. Thompson, FACSM[5], Beth A. Taylor, FACSM[1]. *[1]Hartford Hospital and University of Connecticut, Hartford, CT. [2]University of Connecticut, Storrs, CT. [3]Miami University, Oxford, OH. [4]University of North Carolina Greensboro, Greensboro, NC. [5]Hartford Hospital, Hartford, CT.* (Sponsor: Beth Taylor, FACSM)

(No relevant relationships reported)

Compression socks have become increasingly popular with athletes due to perceived enhancement of exercise performance and recovery. However, research examining the efficacy of compression socks to reduce exercise-associated muscle damage has been equivocal, with few direct measurements of markers of muscle damage. **PURPOSE**: We investigated the influence of wearing compression socks during a marathon run on creatine kinase (CK) levels in endurance athletes running the 2013 Hartford Marathon. **METHODS**: Adults (n=20) were randomized to compression sock (SOCK; n=10) and control (CONTROL; n=10) groups. SOCK was naïve to wearing compression socks, and wore them during the marathon only. Age, anthropometrics, vital signs, training mileage, and finishing time were collected. Venous blood samples were collected 1 d before, immediately after, and 1 d following the marathon for analysis of plasma CK, a marker of muscle damage. **RESULTS**: Baseline plasma CK levels did not differ between CONTROL (89.3±41.2 U/L) and SOCK (100.0±56.2 U/L; p=0.633), and were within normal reference ranges for males and females. Immediately following the marathon (≤1hr), CK increased 273% from baseline (p=0.000 for time), with no difference in exercise-induced changes in CK from baseline between CONTROL (+293.9±278.2 U/L) and SOCK (+233.1±225.3 U/L; p=0.598 for time x group). The day following the marathon (≤24hr), CK further increased 1094% from baseline (p=0.000 for time), with no difference in changes in CK from baseline between CONTROL (+1191.9±1194.8 U/L) and SOCK (+889.1±760.2 U/L; p=0.529 for time x group). These similar trends between CONTROL and SOCK persisted despite controlling for potential covariates such as age, body mass index, and race finishing time (ps>0.291), which was also similar between groups (CONTROL: 4:20:42±0:38:33 hr vs. SOCK: 4:02:33±0:38:39 hr; p=0.333). **CONCLUSIONS**: Our results suggest the use of compression socks during a marathon do not appear to mitigate objectively measured markers of muscle damage (i.e., exercise-induced increases in CK) immediately following and 24hr after a marathon.

1211   Board #19   May 31 8:00 AM - 9:30 AM

Influence of Acute Exercise and Insulin on the Akt/eNOS Pathway in Rodent Aortic Smooth Muscle.

Lea Haverbeck, Gavin Connolly, Brendan J. Farley, Roop C. Jayaraman, Naveen Sharma, Rachael K. Nelson. *Central Michigan University, Mount Pleasant, MI.*

(No relevant relationships reported)

Insulin resistance can contribute to endothelial dysfunction and subsequent cardiovascular disease. An acute bout of exercise has been shown to attenuate insulin resistance and enhance endothelial function, yet the underlying molecular mechanism(s) for this benefit in smooth muscle remains unclear. **PURPOSE**: To examine key proteins in the Akt/eNOS signaling pathway in response to an acute session of exercise with and without the presence of insulin. **METHODS**: Female Sprague-Dawley rats (n=25) were assigned to one of four groups: 1) sedentary control group without insulin injection (CON-ins), 2) control group with insulin injection (10mU/g; CON+ins), 3) exercise group without insulin injection (EX-ins), and 4) exercise group with insulin injection (EX+INS). Insulin or saline injections were administered 5-min prior to sacrifice. Under isoflurane anesthesia, blood and the descending aorta was harvested. Exercise cohorts were sacrifcied 3-hr after a 60-min swimming protocol. Plasma samples were analyzed for glucose, insulin concentrations, and markers of endothelial function (i.e., intracellular adhesion molecule, E-selectin, Von Willebrand factor, and adiponectin) using commercially available kits. Western immunobloting was used to determine total Akt (Akt), phosphorylated Akt (pAkt[Ser473]),

---

total eNOS (eNOS), and phosphorylated eNOS (p-eNOS^{Ser1177}). **RESULTS**: Akt, eNOS, plasma glucose, and markers of endothelial function were similar among all cohorts. As expected, plasma insulin concentration was significantly (p<0.05) higher under insulin stimulated compared to non-insulin stimulated conditions, however exercise blunted this increase (CON+ins > EX+ins; p<0.05). Similarly, pAkt^{Ser473} was significantly (p<0.05) higher under insulin stimulated compared to non-insulin stimulated conditions, this effect was also attenuated with exercise (CON+ins > EX+ins; p<0.05). Conversely, p-eNOS^{Ser1177} was only significantly (p<0.05) enhanced in the EX+ins versus the EX-ins group. **CONCLUSIONS**: Insulin and acute exercise resulted in the greatest enhancement of p-eNOS^{Ser1177}, signifying enhanced endothelial function. This response cannot be completely attributed to increased pAkt^{473} suggesting that other kinases are likely responsible for the improvement in p-eNOS^{Ser1177} in the aorta.

Effect of Aerobic Exercise on Artery Stiffness and Cerebrovascular Pulsatility in Hypertensive and Non-Hypertensive Adults

Wesley K. Lefferts, Jacob D. DeBlois, Girolamo L. Mammolito, Elizabeth A. Dressel, Candace N. Receno, Kevin S. Heffernan. *Syracuse University, Syracuse, NY.* (Sponsor: Bo Fernhall, FACSM)

(No relevant relationships reported)

Large elastic arteries (i.e. aorta, carotid) buffer pulsatile hemodynamics by dampening changes in pressure and flow. Stiffer central arteries, as seen in hypertension, transmit greater pulsatile hemodynamics into fragile cerebral vessels. Aerobic exercise is recommended for hypertensives (HTN), but its effects on artery stiffness and pulsatility in this group are unclear. **PURPOSE:** Investigate the effect of acute aerobic exercise on artery stiffness and cerebrovascular pulsatility in HTN and non-HTN adults. **METHODS:** 30 medicated HTN and 30 age, sex, and body mass index (BMI)-matched non-HTN adults (56±6 yrs, BMI 28.2±2.9 kg/m²; 32 men) underwent hemodynamic measures pre and 10 min post a 30-min cycling bout (55% peak oxygen consumption). Aortic stiffness was measured using carotid-femoral pulse wave velocity (cf PWV) and carotid artery (CA) stiffness was assessed with PWV-β via Ultrasound. Aortic mean (MP) and pulse pressure (PP; via radial generalized transfer function), and CA PP were measured by tonometry. CA and middle cerebral artery (MCA) blood velocity pulsatility index (PI) were measured using Doppler. **RESULTS:** cf PWV, MCA PI and CA PI increased and aortic PP decreased, post exercise compared to pre in both groups (p<0.05). Aortic MP and CA PP, PWV-β were unaltered post-exercise. Aortic MP was greater in HTN vs non-HTN. No other significant effects were detected. **CONCLUSION:** Acute aerobic exercise increases aortic stiffness and cerebrovascular hemodynamic pulsatility in both non-HTN and HTN individuals. These data suggest medicated-HTN have similar vascular responses to early recovery from acute aerobic exercise as non-HTN.

Supported by a Foundation Research Grant from ACSM and AHA Pre doctoral Fellowship

Table 1: Arterial stiffness and hemodynamic pulsatility pre/post acute exercise in non-HTN and HTN subjects.

Measure	non-HTN Pre	non-HTN Post	HTN Pre	HTN Post	Effects G	T	GxT
Aorta

Kinetics of High-Sensitivity Cardiac Troponin Release Following a Strenuous Swimming Test

Karen Schulz[1], Jorge Jorge Díaz-Garzón[2], Ricardo Navarro-Orocio[3], Luis E. Carranza-García[3], Alejandro Legaz-Arrese[4], Eloy Cardenas-Estrada[3], Fred Apple, FACSM[5]. [1]*Minneapolis Medical Reseach Foundation of Hennepin County Medical Center, Minneapolia, MN.* [2]*Hospital Universitario La Paz, Madrid, Spain.* [3]*Autonomous University of Nuevo Leon, Monterrey, Mexico.* [4]*University of Zaragoza, Zaragoza, Spain.* [5]*Hennepin County Medical Center, Minneapolis, MN.* (Sponsor: Fred Apple, FACSM)

(No relevant relationships reported)

PURPOSE: Athletes are susceptible to muscle injury during strenuous exercise. Exercise-induced release kinetics of high sensitivity cardiac troponin I (hs-cTnI) and hs-cTnT are unclear. We analysed hs-cTnI and hs-cTnT kinetics after a maximal swimming test and examined differences between age and gender. **METHODS**: Fifty adolescents (25 males, 25 females) and 16 adults (7 males, 9 females) participated in a 60-min maximal swimming test. hs-cTnT (Roche, 99th percentiles male=22, female=14 ng/L, and hs-cTnI (Beckman Coulter, 99th percentiles male=11, female=9 ng/L) were measured at rest, immediately post-exercise, and at 1, 3, 6, 12, and 24 h post-exercise. **RESULTS**: Mean baseline (0h) concentrations were: hs-cTnT male 3.4 ng/L, female 3.1 ng/L; hs-cTnI male 0.5 ng/L, female 0.5 ng/L. We observed a greater percentage of hs-TnI results > 99th percentile vs. hs-cTnT for genders. For males, this was at 6h (44% vs. 60%), 12h (20% vs. 44%) and 24 h (8% vs. 28%). For females this was at 6h (32% vs. 39%), 12h (3% vs. 19%) and 24h (0% vs. 10%). Until 3h both hs-cTnI and hs-cTnT presented similar percentages and no result over the 99th percentiles was observed for any hs-cTn value at rest. 13 subjects (10 males; 84.6%) had a maximum hs-cTnI over 50 ng/L. Medians were: hs-cTnI, 146 (IQ 89-247) ng/L and hs-cTnT, 77 (73-123) ng/L. There were no significant correlations between hs-cTn maximum concentration and age. However, significant differences (Mann-Whitney) in maximum concentration due to gender: hs-cTnT, (p=0.004) and hs-cTnI (p=0.018): hs-cTnT, (p=0.004) and hs-cTnI (p=0.018).**CONCLUSIONS**: We observed parallel increases, but different kinetics, between hs-cTnI and hs-cTnT in swimmers during maximal efforts. hs-cTnT appeared to increase earlier than hs-cTnI. Both assays peaked at 3h post-exercise, with higher hs-cTnI concentrations. Higher values were found in men, but no differences were found due to age. Clinicians need to be educated regarding these observations in healthy athletes.

The Effects of Caffeine Ingestion on the Hemostatic Response to Simulated Firefighting Activities.

Sierra D. Wassell, Elizabeth S. Edwards, Michael J. Saunders, FACSM, Christopher J. Womack, FACSM. *James Madison University, Harrisonburg, VA.*

(No relevant relationships reported)

PURPOSE: Sudden cardiac events are the leading cause of death among firefighters, a population that commonly overuses caffeine. The objective of this study was to examine the potential effects of caffeine on the hemostatic response to simulated firefighting activity.
METHODS: Twelve healthy male firefighters, wearing full personal protective equipment (PPE) and self-contained breathing apparatus (SCBA), completed two trials of a simulated firefighting activities course one hour after consuming either 6mg/kg body weight of caffeine or placebo. Blood samples and air levels from the SCBA were obtained pre-exercise and post-exercise. The effects of caffeine and simulated firefighting on outcome variables were assessed using repeated measures ANOVA.
RESULTS: Factor VIII increased more in the caffeine trial (Pre = 0.20 ± 0.13 IU/mL, Post = 0.43 ± 0.15 IU/mL) than the placebo trial (Pre = 0.21 ± 0.11 IU/mL, Post = 0.38 ± 0.15 IU/mL). tPA activity increased significantly ($P < 0.05$) by the same magnitude in both the placebo (Pre = 0.18 ± 0.18 IU/mL, Post = 3.23 ± 3.21 IU/mL) and caffeine (Pre = 0.18 ± 0.31 IU/mL, Post = 3.97 ± 3.53 IU/mL) conditions. PAI-1 activity significantly ($P < 0.05$) decreased from pre- to post-exercise in both the placebo (Pre = 33.86 ± 21.29 U/mL, Post = 28.77 ± 21.21 U/mL) and caffeine (Pre = 37.34 ± 28.81 U/mL, Post = 23.71 ± 19.42 U/mL) conditions. There was a trend (p = 0.05) for increased air consumption in the caffeine condition versus placebo condition.
CONCLUSIONS: Results from the present study suggest that caffeine elicits a higher coagulation response without concomitant increases in fibrinolysis during simulated firefighting.

1215   Board #23   May 31 8:00 AM - 9:30 AM

Exercise Duration Augments Inter-Arm Systolic Blood Pressure Difference

Sarah R. Allen, Melanie M. Clarke, Maureen A. Walsh, Daniel L. Komoroski, Brock T. Jensen, Michael E. Holmstrup. *Slippery Rock University, Slippery Rock, PA.*
(No relevant relationships reported)

Blood pressure is a universal measurement used to aid in appropriate clinical decision-making and monitor safe exercise participation. Inter-arm systolic blood pressure difference (ISBPD; difference of ≥10mmHg between arms) at rest is associated with vascular disease, arterial stiffness, and premature morbidity and mortality. The incidence ISBPD at rest is low (i.e. commonly reported as 10%), though the occurrence of ISBPD is known to increase with short-term (i.e. <5 min at 6 metabolic equivalents) moderate-intensity aerobic exercise. **PURPOSE**: To determine the exercise-induced ISBPD response during a prolonged steady-state bout of aerobic exercise. **METHODS:** Fifty-four individuals were studied on two separate occasions. On an initial visit, anthropometric measures and a VO_{2peak} test on a cycle ergometer were completed. On a subsequent visit, participants cycled at a workload equivalent to 50% of their VO_{2peak} for 30 min. Heart rate (HR) and systolic blood pressure difference (SBPD; measured sequentially using standard auscultation in both arms) were measured at rest, 5, 10, 20, and 30 minutes of exercise (EX-5, EX-10, EX-20, EX-30), and during an active recovery (AR). Descriptive and comparative (one-way ANOVA) statistics were generated. A binary logistic regression analysis was used to determine the change in the odds ratio (OR) of ISBPD given exposure to exercise. **RESULTS:** The incidence of ISBPD at rest was 19%. The occurrence of ISBPD increased to 35% at EX-5 and EX-10, and 46% at EX-20 and EX-30. Occurrence decreased to 20% during AR. Interestingly, each additional 1mmHg difference in SBPD at rest was associated with an increased OR of ISBPD at EX-5 (1.139), EX-10 (1.335), EX-20 (1.220), and EX-30 (1.196; p<0.05). Individuals in the highest tertile of systolic blood pressure (SBP) response during exercise presented with the greatest SBPD (10.7 mmHg) at EX-5. Finally, individuals identified as underweight and obese class II were more likely to present with ISBPD at rest and EX-20. **CONCLUSION:** The occurrence of ISBPD during moderate-intensity aerobic exercise increased with prolonged steady-state aerobic exercise. Body mass index and the magnitude of the SBP response to exercise may be linked to ISBPD incidence.

Effects of Acute Vibration Exercise on Endothelial Function and Inflammation in Healthy Males

Anthony Kaleth, FACSM[1], Kelsey Rupert[1], Bruce Neff[2], Yameena Jawed[2], Eleni Beli[2], Maria Grant[2], Keith March[2], Mary Loghmani[2]. *[1]Indiana University-Purdue University Indianapolis, Indianapolis, IN. [2]Indiana University, Indianapolis, Indianapolis, IN.*
(No relevant relationships reported)

Endothelial progenitor cells (EPCs) are thought to play a key role in vascular regeneration, endothelial repair, and restoration of endothelial function. While studies have confirmed a relationship between exercise and EPCs, the mechanisms by which exercise mobilizes EPCs into circulation remains unknown. **PURPOSE**: To evaluate the effects of vibration training (VT*)* on the mobilization of angiogenic circulating progenitor cells (CPCs) and hematopoietic progenitors. We hypothesized that VT would increase the acute mobilization of angiogenic CPCs and decrease inflammatory marker levels. **METHODS**: 11 healthy males [18-30 yr (n=6) and 50-65 yr (n=5)] performed each of the following in random order on separate days: 1) standing on a vibrating platform only; 2) dynamic leg squat exercise (without vibration); and 3) in combination, i.e. leg squat with vibration. Blood samples were taken pre-and post-activity. **RESULTS**: Angiogenic CPCs increased 33% with vibration alone (p=0.02), 21% with exercise alone (p=0.02), and 34% with exercise plus vibration (p=0.004). VEGF levels were higher with vibration alone (p<0.005); TNFα increased with vibration (p<0.01); interleukin-6 (IL-6) approached a significant drop during vibration (p=0.056); and higher levels of IL-10 were found with vibration alone (p<0.03) and exercise alone (p<0.05). A decrease in IL-10 level was found when exercise and vibration were combined.
CONCLUSIONS: Our findings suggest vibration alone may have a pro-angiogenic effect taken together with higher VEGF and TNFα levels; more than with exercise alone or in combination. Furthermore, vibration alone may have greater anti-inflammatory effects, evidenced by a trend toward decreased inflammatory marker (IL-6) and a significant increase in anti-inflammatory marker (IL-10). Curiously, the anti-inflammatory effect was dampened when vibration was combined with exercise in that the drop in IL-6 did not approach significance and IL-10 levels were actually lowered, suggesting there may be a threshold for the optimal dose and/or combination effects. VT may be a viable option to increase stem/progenitor cell circulation levels and decrease inflammation with possible health benefits in multiple health conditions.

Effects of Acute Resistance Exercise on Heart Rate Variability and Central Blood Pressure in Women

Kristen Dempsey, Brian Thompson, Christa Winter, Elizabeth O'Neill, Samuel Headley. *Springfield College, Springfield, MA.*
(No relevant relationships reported)

INTRODUCTION: Heart rate variability (HRV) is defined as the beat-to-beat fluctuations of R wave to R wave and is an indirect measure of autonomic nervous system function, whereas central blood pressure (CBP) is indicative of the pressure load faced centrally on the aortic, coronary and carotid arteries. Both factors relate to cardiac health and are two variables that can be altered by exercise. **PURPOSE:** To determine the effects of acute resistance exercise on HRV and CBP in overweight women. **METHODS:** Eight overweight, non-resistance trained young women (BMI 27.17 ± 1.76; age 23.75 ± 4.13 years) volunteered to participate in three study sessions. The first session served to familiarize the subjects with the resistance protocol and obtain demographics. Sessions two and three consisted of either a control session of supine rest, or a resistance exercise session (composed of two sets of six total body, compound resistance exercises including a trap-bar deadlift, split squat, bench press, pull-up, bent-over row and shoulder press at a 2-0-2 tempo) lasting 30 min. A metronome and perceived exertion scale were used during exercise. HRV and CBP were measured before, and for 60 min after rest and exercise conditions. Repeated measures ANOVA's were used to analyze the data. **RESULTS:** The main finding was significantly lower values for standard deviation of N-N's (SDNN; a component of HRV) during the exercise condition, when compared to pre-exercise values (61.18 ms ± 32.15; 28.30 ms ± 17.69 immediate post exercise, p < .05, until 20 min post, 32.06 ms ± 16.55, p < .05). Values returned close to baseline at 60 min post exercise (64.33 ms ± 31.66, p > .05) No significant differences existed for systolic or diastolic CBP, or brachial blood pressures. **CONCLUSION**: Acute, total body resistance exercise depressed the SDNN component of HRV for up to 20 min post exercise, when compared to baseline values in a group of non-resistance trained, overweight women. Central blood pressure values did not change significantly after resistance exercise. Acute, resistance exercise temporarily lowers HRV in a group of overweight, young women.

Cardiovascular Responses To Different Resistance Exercise Intensities In Young And Older Adults

Amanda V. Sardeli[1], Arthur F. G[aspari[1], Marina L.V. Ferreira[1], Lucas C. Santos[1], Alexander J. Rosenberg[2], Bo Fernhall, FACSM[2], Cláudia R. Cavaglieri[1], Mara Patrícia T. Chacon-Mikahil[1]. *[1]University of Campinas, Campinas, Brazil. [2]University of Illinois at Chicago, Chicago, IL.* (Sponsor: Bo Fernhall, FACSM)
(No relevant relationships reported)

Older individuals are at increased cardiovascular risk both during rest and during physical effort. Acute resistance exercise (RE) conducted at high intensity significantly increases heart rate (HR), blood pressure (BP), and arterial stiffness in young individuals. The effects of high (HI) and low intensity (LI) RE performed until failure on cardiovascular responses are likely different among populations of different ages. **PURPOSE:** Compare the effects of acute HI and LI between young (Y) and older adults (O) on cardiovascular recovery responses. **METHODS:** 9 Y and 9 O performed two experimental sessions in randomized sequence, using leg press, with 4 sets until failure for HI (80% 1RM) and for LI (30% 1RM). Pre, 3-min and 30-min post-RE beat-to-beat BP waveforms were recorded by finger photoplethysmography from which the hemodynamic variables (HR, stroke volume [SV], cardiac output [CO], total peripheral resistance [TPR]) were derived. Left common carotid artery images were acquired by ultrasound and carotid compliance (CC) were calculated. Two-way ANOVAs were performed on raw (mean BP, HR, CO) and normalized (SV, TPR, CC) data. Data is presented as mean ± standard deviation. **RESULTS:** Following HI RE there was an increase in HR in Y (56 ± 8 to 95 ± 23) with no changes in O (64 ± 8 to 81 ± 12) at 3-min post-RE (interaction, p < 0.05), with similar increases in HR in Y and O following LI RE (Y: 56 ± 8 to 94 ± 12 and O: 66 ± 10 to 90 ± 13; time, p < 0.05). Y increased CO (6.1 ± 0.8 to 10.9 ± 3.2) and reduced TPR (0.81 ± 0.14 to 0.45 ±0.16) 3-min post HI RE while O did not change (CO 5.6 ± 0.9 to 7.6 ± 2.0 and TPR 1.02 ± 0.23 to 0.79 ± 0.24) (interaction, p < 0.05). No interactions were seen for the other variables. **CONCLUSION:** Aging impacts the hemodynamic recovery following HI RE but aging does not impact hemodynamic recovery following LI RE. These data suggest that LI RE may be a more desirable form of RE for older individuals.

Heart Rate Variability During Submaximal Exercise And The Impact Of Gender And Race

Kate S. Early[1], Conrad P. Earnest, FACSM[2], Nathan P. Lemoine[3], Damon L. Swift[4], Neil M. Johannsen[3]. [1]Columbus State University, Columbus, GA. [2]Texas A&M, College Station, TX. [3]Louisiana State University, Baton Rouge, LA. [4]East Carolina University, Greenville, NC. (Sponsor: Conrad Earnest, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the effect of exercise duration on heart rate variability (HRV) and whether race or sex alters HRV during exercise. METHODS: Untrained participants (n=26, 46% male, 50% African-American [AA]) underwent fasting blood lipid and glucose tests and cardiovascular assessments (flow-mediated dilation [FMD], pulse wave analysis, and HRV). Maximal oxygen consumption (VO_{2max}) was used to prescribe a 30-min cycling bout at 50%VO_{2max}. Exercise intensity was similar across sex (Male 1.3±0.2L/min; Female 0.9±0.1L/min, P<0.001) and race (AA 1.1±0.3L/min; Cau 1.1±0.2L/min, P=0.23). HRV during exercise was assessed in 2 min increments before exercise (Pre-EX) and during steady-state submaximal exercise from 14-16 min (Mid-EX) and 28-30 min (End-EX). RESULTS: At rest, no race or sex differences were observed in blood lipids, fasting glucose, PWV or FMD (all P>0.05). VO_{2max} was significantly greater in males (29.9±6.7 vs. 25.3±4.4mL/kg/min; P<0.001). During exercise, heart rate was higher in females than males at Mid-Ex and Post-Ex (P<0.01). The natural logarithm of root mean square of successive differences (lnRMSSD) and high frequency (lnHF) significantly decreased from Pre-EX to Mid-Ex (P<0.001), and was similar from mid-EX to End-EX (lnRMSSD P=0.47; lnLF P=0.35). No race differences were observed in HRV during exercise (P>0.05). CONCLUSION: HRV was similar during exercise past 15 min, suggesting the time course of autonomic changes occurs early during exercise. No sex or race differences were observed in HRV during exercise, suggesting sex and race have similar cardiovascular responses during 30 min of submaximal exercise. However, it is plausible that intensity of exercise was not a sufficient stimulus for the sympathetic activity to observe differences between sex and race.

Graduated Compression Socks Does Not Improve Cardio-respiratory Responses To Maximal Exercise

Rodrigo Villar, Alison Stanlewicz, Victoria Vargas, Devin Neary, Nathaniel Presti, Stephanie Priest, Drew Bois, Robert Anzalone. Franklin Pierce University, Rindge, NH.

(No relevant relationships reported)

Cardiovascular and Respiratory Research Laboratory, Franklin Pierce University, Rindge, NH
PURPOSE: The purpose of this study was to determine if the use of graduated compression socks (GCS) would improve cardio-respiratory responses to maximal exercise. METHODS: Eight healthy young participants (4 men and 4 women; age = 20.50 ± 1.41 years; height = 1.71 ± 0.12 m; weight = 72.34 ± 12.53 kg; body mass index = 24.65 ± 3.15kg/m²) performed a Cardiopulmonary Maximal Exercise Test (CPET) on a treadmill that consisted of 3 minutes warm-up at a speed of 4 mph at 0° grade followed by an increase in speed to 6 mph for 1 minute and then increases of 1 mph every minute until 8 mph with maintained grade (0°). After that, the grade increased 2° every minute until exhaustion, but the speed of the treadmill was kept constant. Each participant visit the laboratory twice to perform the CPET test in two different conditions: (1) wearing graduated compression socks (GCS); and (2) not wearing the graduated compression socks (NGCS) in a randomized and counterbalanced order. Peak oxygen consumption (VO₂peak), peak carbon dioxide production (VCO₂peak), peak respiratory exchange ratio (RER$_{peak}$), peak Heart Rate (HRpeak), and exercise time to exhaustion (ETE) were collected via metabolic cart system. RESULTS: There were no statistical differences in VO₂peak (NGCS = 49.94 ± 8.34 mL.kg⁻¹.min⁻¹ and GCS = 50.55 ± 8.67 mL.kg⁻¹.min⁻¹); VCO₂peak (NGCS = 4.19 ± 1.17 L.min⁻¹ and GCS = 4.34 ± 1.38 L.min⁻¹); RERpeak (NGCS = 1.41 ± 0.17 and GCS = 1.45 ± 0.16); HRpeak (NGCS = 191.63 ± 7.25 bpm and GCS = 190.75 ± 7.63 bpm); and ETE (NGCS = 512.36 ± 149.48 s and GCS = 528.15 ± 165.17 s) between non-graduated compression socks and with graduated compression socks, respectively. CONCLUSIONS: Based on the results, there were no statistical significant difference in any variables indicating that there was no effect of the passive external compression on the cardio-respiratory responses during maximal exercise. The conclusions drawn from our data need to be analyzed with extremely caution due to small sample size (n = 8). Therefore, more research need to be done to support these initial findings. **Research supported by New Hampshire-INBRE through an Institutional Development Award (IDeA), P20GM103506, from the National Institute of General Medical Sciences of the NIH".**

Easy Breather Exercise Table: A Feasibility Evaluation of a Medical Device to Facilitate Gravity Powered Ventilation

David J. Giordano, Jared G. Kerr, Robert W. Boyce, FACSM, Justine J. Reel, Lisa K. Sprod, Susan M. Sinclair, Savannah L. Knight, Stephanie N. Spencer. University of North Carolina at Wilmington, Wilmington, NC. (Sponsor: Robert W. Boyce, FACSM)

(No relevant relationships reported)

Gravity powered ventilation is a concept that utilizes visceral pressure to facilitate pulmonary ventilation. Such a procedure may provide a form of complementary therapy for those with Chronic Obstructive Pulmonary Disease.
PURPOSE: Investigate if the Easy Breather Exercise Table (EBET) prototype is suitable for clinical studies in patients with Chronic Obstructive Pulmonary Disease (COPD). METHODS: The EBET bed uses arm power to tilt the supine subject from a Trendelenburg to a reverse-Trendelenburg position with the goal of assisting breathing. Healthy volunteers (N=40) operated the device for 15 minutes. Variables of interest: A body part discomfort scale (0 = no discomfort to 5 = very uncomfortable) administered at 0 and 13 minutes, a Borg scale rating of perceived exertion (0 to 10) at 14 minutes, and an end-of-session safety rating. RESULTS: Areas with the greatest discomfort at minute 13 and the associated percent reaching ≥ level 3 follow: Left elbow (5%), right elbow (5%), left wrist (23%), right wrist (28%), left hand (16%), and right hand (15%). Of these body parts, there was a significant (p ≤ 0.01) increase in discomfort from 0 to 13 minutes. Regarding exertion: 33% reported moderate to somewhat strong levels, while 13% reported strong levels. In terms of safety, 98% felt safe on the device, and 2% were undecided. CONCLUSION: Further clinical studies with the current EBET in COPD patients are not advised due to the discomfort and exertion in healthy volunteers. Safety data indicates tilting may be a viable means to achieve gravity powered ventilation, thus device modification is recommended.

Three Weeks of Respiratory Muscle EnduranceTraining Decrease the O₂ Cost of Walking In Obese Adolescents

Hailu K. Alemayehu[1], Desy Salvadego[1], Miriam Isola[1], Gabriella Tringali[2], Roberta De Micheli[2], Mara Caccavale[2], Alessandro Sartorio[2], Bruno Grassi, FACSM[1]. [1]University of Udine, Udine, Italy. [2]Istituto Auxologico Italiano, IRCCS, Milan and Piancavallo (VB), Italy.

(No relevant relationships reported)

Obese adolescents have an increased O₂ cost of exercise, attributable at least in part to an increased O₂ cost of breathing. In a previous work a short (3-wk) program of respiratory muscle endurance training (RMET) slightly reduced the O₂ cost of high-intensity cycling in these patients.
PURPOSE: We hypothesized that the effects of RMET would be more pronounced during walking on a treadmill compared to those described during cycling.
METHODS: Sixteen obese patients (age 16.0±0.8 yrs; height 1.80±0.05 m; body mass 127.7±14.2 kg; BMI 40.7±4.0 kg/m²) participated to the study. In the experimental group (RMET, n=8), subjects followed for 3 weeks a standard RMET protocol in addition to a multidisciplinary body mass reduction program, whereas controls (CTRL, n=8) did only the latter. Among other variables, heart rate (HR), and pulmonary O₂ uptake (VO₂) were measured during incremental exercise and 12-minute constant work rate (CWR) exercises at 60 (moderate-intensity) and 120% (high-intensity) of the gas exchange threshold (GET), determined before the interventions. The O₂ cost of walking (aerobic energy expenditure per unit of covered distance) was calculated as VO₂/walking velocity.
RESULTS: Body mass decreased both in CTRL (~4 kg) and in RMET (~5 kg). All subjects completed 12-minute CWR tests. VO₂ peak was not affected by both interventions. Both during moderate- and high-intensity walking, VO₂, the O₂ cost of walking and HR decreased in RMET, but not in CTRL. During heavy-intensity walking the positive slopes of the VO₂ and HR vs. time linear relationships from the 3rd to the 12th minute of exercise decreased in RMET, but not in CTRL.
CONCLUSIONS: In obese adolescents a short RMET program significantly lowered the O₂ cost of moderate- and high-intensity walking and improved exercise tolerance.

Individual Variability in the Leg Blood Flow Response to Expiratory and Inspiratory Resistive Loading

Tim A. Hardy, Marcelle P. Ribeiro, Bryan J. Taylor. *University of Leeds, Leeds, United Kingdom.* (Sponsor: Lee M. Romer, FACSM)
(No relevant relationships reported)

BACKGROUND. Fatiguing inspiratory muscle work initiates the inspiratory muscle metaboreflex causing a time-dependent increase in muscle sympathetic nerve activity (MSNA) and a decrease in leg blood flow (Q_L). Fatiguing contractions of the expiratory muscles also facilitates an increase in MSNA. However, the effect of fatiguing expiratory muscle work on Q_L is somewhat unknown. **PURPOSE.** To determine the effect of expiratory resistive loading (ERL) compared to inspiratory resistive loading (IRL) on Q_L in healthy humans. **METHODS.** Five healthy men ($n = 2$, 30 ± 6 y) and women ($n = 3$, 29 ± 5 y) performed ERL and IRL at 65% of maximal expiratory and maximal inspiratory mouth pressure (MEP; MIP) to task failure. Respiratory frequency was maintained at 15 breaths/min with an inspiratory duty cycle of 0.5. Q_L (via Doppler ultrasound) and mean arterial pressure (MAP) (via finger photoplethysmography) were measured before, during and up to 3 min after ERL and IRL. Expiratory and inspiratory muscle fatigue was assessed by measuring the reduction in MEP and MIP from pre- to post-ERL and IRL. EMG was measured in each leg to ensure no muscular contraction occurred. **RESULTS.** Task failure occurred at 10.6 ± 2.4 min for ERL and at 20.6 ± 8.8 min for IRL; each subject performed ≥ 7 min of ERL and IRL. There was a $21 \pm 4\%$ reduction in MEP and a $7 \pm 5\%$ reduction in MIP from before to after ERL and IRL, respectively ($P < 0.05$). Despite an increase in group mean MAP from rest to during ERL (14 ± 14 mmHg, $P = 0.035$) and IRL (12 ± 6 mmHg, $P = 0.021$), there was no change in group mean Q_L across time during either ERL or IRL ($P > 0.05$). There was, however, substantial individual subject variability in the Q_L response to loaded breathing. During ERL, Q_L decreased relative to baseline values at min 3 ($-29 \pm 20\%$) and min 7 ($-17 \pm 6\%$) in 2 of the 5 subjects; Q_L increased by $15 \pm 7\%$ from rest to min 7 in the remaining 3 subjects. Similarly, there was a reduction in Q_L from rest to min 3 ($-23 \pm 9\%$) and min 7 ($-16 \pm 3\%$) in 2 of the 5 subjects during IRL; Q_L increased by $60 \pm 26\%$ from baseline to min 7 in the remaining 3 subjects. There was no significant change in MAP or Q_L during ERL and IRL trials at 2% of MEP and MIP. **CONCLUSION.** Leg blood flow appears to decrease in some but not all healthy humans in response to ERL. Indeed, we report substantial individual variability in the leg blood flow response to both ERL and IRL.

Hypercapnic and Hypoxic Ventilatory Responses are Non-Normally Distributed: A Retrospective Analysis

Benjamin C. Skutnik, Joel T. Greenshields, Stephen R. Gagnon, Robert F. Chapman, FACSM, Joel M. Stager, FACSM. *Indiana University, Bloomington, IN.* (Sponsor: Joel M. Stager, FACSM)
(No relevant relationships reported)

Hypercapnic ventilatory response (HCVR) and hypoxic ventilatory response (HVR) are common procedures used to describe an individual's responsiveness to inhaled increases in CO_2 and decreases in O_2 respectively. To our knowledge there are no studies of HCVR or HVR of a grand enough scale to determine normative values or a 'typical' response. No description of the distribution of values, yet, is available in the literature such that little can currently be said about population-based differences. **PURPOSE:** To characterize the distribution of and establish reference values for ventilatory responses of the broad population using readily accessible sources. **METHODS:** Previously published dissertations and peer-reviewed manuscripts ($N=25$) were used to obtain subjects' responses ($N=312$, age = 29.4 ± 13.2 yrs). HCVR tests ($n=262$) were analyzed using the slope of the linear regression line relating P_ACO_2 to minute ventilation (V_E), $l*min^{-1}*mmHg^{-1}$. HVR was calculated using either the calculated slope of the linear regression relating V_E to oxyhemoglobin saturation, $l*min^{-1}*\%^{-1}$ ($n=105$) or using the hyperbolic shape parameter (A) of the curve relating V_E to P_AO_2 ($n=170$). Confidence intervals for mean and median values were calculated using bootstrapping procedures. **RESULTS:** Data are presented mean/median; ±95% CI width. HCVR values displayed a right skewed non-normal distribution (skew = 5.25, p <.05), mean 2.67; ±0.70 $l*min^{-1}*mmHg^{-1}$, median 2.00; ±0.51 $l*min^{-1}*mmHg^{-1}$ (IQR: 1.50). HVR A values showed a non-normal right skewed distribution (skew = 0.92, p <.05), mean 131.8; ±23.62 $l*min^{-1}*mmHg^{-1}$, median 112.50; ±58.25 $l*min^{-1}*mmHg^{-1}$ (IQR: 118.99). Linearized HVR values using %SaO2 was also a right skewed non-normal distribution (skew=1.33, p<.05), mean 0.35; ±0.10 $l*min^{-1}*\%^{-1}$, median 0.26; ±0.23 $l*min^{-1}*\%^{-1}$ (IQR: 31.00). **CONCLUSION:** This analysis allows researchers to better place into context assessments of HCVR and HVR by providing distribution parameters derived from the literature. However, as HVR measures contrast due to methodological differences, distribution parameters remain infirm. In an effort to strengthen these distributions, researchers should include individual responses when reporting results of studies.

Comparing Ventilatory Mechanics Between Face Mask and Mouthpiece During High-Intensity Exercise

Jessica Freemas. *Indiana University, Bloomington, IN.*
(No relevant relationships reported)

Purpose:
A snorkel-like mouthpiece and the Hans Rudolph mask are used interchangeably to collect ventilatory data. Since the mask has a greater amount of dead space (250ml vs. 41ml) it may affect operating lung volumes and mouth pressure. Therefore, the aim of this study was to compare ventilatory mechanics while breathing through the mouthpiece and the mask during high-intensity exercise.
Methods:
Seven recreationally active, healthy males [age (mean ± SD) = (27 ± 1 yr.); VO$_2$max = 53.4 ± 6.1 ml·kg⁻¹·min⁻¹] visited the laboratory on 3 separate occasions. Visit one consisted of a VO$_2$max test and familiarization of the maximal graded flow volume loop (MFVL) procedure. During visits two and three, participants performed two 5-min cycle bouts at 90% of their power output at VO$_2$max. During one bout participants breathed through the mouthpiece; during the other bout, they breathed through the mask. The initial order of the devices used was randomized between subjects and then reversed on the subsequent visit. Both visits included a pre- and post-MFVL procedure, and participants were instructed to perform an inspiratory capacity (IC) maneuver every 30 seconds of exercise. Minute ventilation (V_E), mouth pressure (Pm) (cmH20), and tidal volumes (V_t) (L/s) were collected in the last minute of exercise.
Results:
V_E was not significantly different ($p = 0.919$) between the mouthpiece (158.1 ± 18.4 L/min) and mask (158.9 ± 11.2). Furthermore, no significant differences were observed in P_m ($p = 0.542$), V_t ($p = 0.303$), and percent flow limitation (%FL) ($p = 0.98$) between the two breathing devices.
Conclusion:
The extra dead space in the Hans Rudolph mask does not significantly alter breathing mechanics. Therefore, the mask can be used as a more comfortable alternative to the mouthpiece during near maximal exercise.

Cycling Time Trial Performance with Addition of External Dead Space

Vincent P. Georgescu, Aaron B. McMichael, Jayvaughn T. Oliver, Erica M. Larson, Jonathon L. Stickford. *Appalachian State University, Boone, NC.*
(No relevant relationships reported)

When athletes have the ability to self-select their work rate, it is unknown how the addition of external dead space (DS), a potent ventilatory stimulus, will influence cycling power and ventilatory dynamics. **PURPOSE:** To examine mechanical power, ventilatory dynamics, and perceptual responses during a fixed-work cycling time trial (TT) in trained male cyclists under a condition of increased DS. **METHODS:** Eleven trained cyclists completed pulmonary function testing and a peak aerobic capacity (VO$_{2peak}$) test on a cycle ergometer during the initial visit. During the second visit, subjects completed a familiarization TT. During visits three and four, subjects completed TTs with (TT$_{DS}$) or without (TT$_C$) the addition of DS. Mechanical power, elapsed time, metabolic and ventilatory parameters, and perceptual responses were measured throughout each TT. Statistical differences between TT$_{DS}$ and TT$_C$ were tested each 20% interval of the TT using Student's paired t-tests. Data are expressed as means ± SD. **RESULTS:** Subjects displayed normal pulmonary function upon study entry. Time to completion was greater in TT$_{DS}$ compared with TT$_C$ (536 ± 34 vs. 489 ± 34 s, p<0.05) as a result of reduced power at 40-100% of TT$_{DS}$ completion compared with TT$_C$ (Δ=-10.2±8.7%). Additionally, minute ventilation (V_E) was similar at 40-100% of TT$_{DS}$ completion compared with TT$_C$ (Δ=0.9±11.0%). However, integrated inspiratory mouth pressure ($\int P_m$) was greater throughout TT$_{DS}$ compared with TT$_C$ (p<0.05), and arterial pulse saturation (SpO$_2$) fell at a greater rate throughout TT$_{DS}$ compared with TT$_C$ (-2.2±0.8 vs. -1.3±0.4 % per interval, p<0.01). Rating of perceived breathlessness (RPB) was significantly greater at 20% and 40% of TT$_{DS}$ compared with TT$_C$, but was not different during the remaining intervals. **CONCLUSION:** Power output during a cycling time trial is reduced in response to increased ventilatory stress in an effort to balance the additional ventilatory work and potential impact to blood gas tensions. Additionally, the fact that V_E and RPB were largely similar between conditions suggests that these parameters may play an important role in the determination of self-selected work rates. Supported by the Office of Student Research and Graduate Student Association Senate at Appalachian State University.

Characterizing The Mechanics Of Breathing In Swimmers

Michael G. Leahy, Mckenzie N. Summers, Carli M. Peters, Yannick Molgat-Seon, Caitlin M. Geary, A. William Sheel, FACSM. *University of British Columbia, Vancouver, BC, Canada.* (Sponsor: Dr. A. William Sheel, FACSM)

(No relevant relationships reported)

During freestyle swimming, the hydrostatic pressure of water limits expansion of the lungs and chest wall, and narrows airways >2 mm in diameter. Moreover, the horizontal body position causes blood to shift from the extremities to the chest, which reduces lung compliance. Thus, during freestyle swimming, the mechanics of breathing are altered, which likely increases the work of breathing (W_b). However, no previous studies have quantified W_b during freestyle swimming.
PURPOSE: To compare W_b during freestyle swimming relative to cycling, and to characterize the differences in the cardiorespiratory responses to swimming relative to cycling in the same individuals. **METHODS:** Seven collegiate swimmers (n=4 male, n=3 female; age= 22±2 y) performed a graded swim test while tethered to a resistance apparatus. On a separate day subjects performed a graded cycle test. During swimming and cycling, metabolic and ventilatory parameters were measured using a customized metabolic cart, and inspired W_b was quantified using an esophageal balloon catheter. **RESULTS:** Swimming and cycling elicited statistically similar maximal oxygen uptakes (3.87±0.92 vs. 4.20±0.83 l·min^{-1}, p=0.143). However, minute ventilation (V_E)(118±3 vs. 154±25 l·min^{-1}) and heart rate (164±19 vs. 183±8 beats·min^{-1}) were significantly lower during swimming relative to cycling (both p<0.05). Total inspired W_b was higher at a V_E of 50 l·min^{-1} (+27±16 J·min^{-1}) and a V_E of 100 l·min^{-1} (+53±22 J·min^{-1}) during swimming compared to cycling (both p<0.05). Periods of inter-breath apnea were observed at lower ventilations while swimming, resulting in decreased breathing frequency (V_E=50 l·min^{-1}, 19±6 vs. 22±4 breaths·min^{-1}, p<0.05), and were not observed at higher ventilations (V_E=100 l·min^{-1}, 37±11 vs. 35±7, p>0.05). Peak inspired flow was greater while swimming, when matched for V_E (+0.26±0.73 l·sec^{-1}, p<0.05). **CONCLUSION:** We found that swimming resulted in a higher inspired W_b, at a V_E of 50 and 100 l·min^{-1} compared to cycling. We interpret our findings to mean that the horizontal body position and hydrostatic pressure on the chest wall requires swimmers to generate greater inspiratory pressures to sustain adequate V_E during exercise.

Effect of Growth and Changes in Body Composition on Cycling Efficiency in Normal Weight and Obese Children

Dharini M. Bhammar[1], Vipa Bernhardt[2], Rubria Marines-Price[3], Tony G. Babb, FACSM[3]. *[1]University of Nevada, Las Vegas, NV. [2]Texas A&M University-Commerce, Commerce, TX. [3]Institute for Exercise and Environmental Medicine, Dallas, TX.*
(No relevant relationships reported)

PURPOSE: Efficiency refers to the amount of work performed for a given energy consumption. Excess body weight is known to increase resting oxygen uptake, but not net oxygen uptake or mechanical efficiency during non-weight bearing exercise such as cycling in prepubertal children. We examined whether the VO_2/WR slopes during incremental exercise were affected by changes in body composition after 1 year in normal weight and obese 10-12 year-old children.
METHODS: 17 children (9 obese) underwent an incremental exercise test on a cycle ergometer and dual energy x-ray absorptiometry at baseline and at 1-year follow-up. A VO_2/WR slope was calculated from measured VO_2 and WR (r^2 = 0.97 ± 0.1). No intervention was prescribed during the year between testing.
RESULTS: There were no mean differences in the VO_2/WR slope between normal weight and obese children during the incremental exercise test at baseline or 1-year follow-up (P=0.715). Over 1 year, obese children gained 8.1±4.6kg and normal weight children gained 4.3±1.9kg of body mass (P=0.048). Obese children gained 2.6kg more lean body mass than normal weight children (P=0.018), with no differences in percent fat or fat weight gained over 1 year. There were no significant associations between changes in body mass, percent fat, fat mass, or lean body mass and changes in VO_2/WR slope in normal weight or obese children.
CONCLUSIONS: Muscular efficiency (VO_2/WR slope) during cycling exercise is similar between normal weight and obese children and does not appear to be related to relatively short-term changes in body composition.
Supported by funds from NIH R01HL136643, Texas Health Presbyterian Hospital Dallas, Dr. Pepper Snapple, and King Charitable Foundation Trust
Figure 1: $\dot{V}O_2$/WR slope was not different between normal weight and obese children at baseline or at 1-yr follow-up.

Blunted Sympathetic Vasomotor Outflow To Inspiratory Resistive Breathing During Exercise In Women Compared to Men

Keisho Katayama[1], Joshua R. Smith[2], Kanako Goto[1], Kaori Shimizu[1], Mitsuru Saito[3], Koji Ishida[1], Teruhiko Koike[1], Satoshi Iwase[4], Craig A. Harms, FACSM[5]. *[1]Nagoya University, Nagoya, Japan. [2]Mayo Clinic, Rochester, MN. [3]Toyota Technological Institute, Nagoya, Japan. [4]Aichi Medical University, Nagakute, Japan. [5]Kansas State University, Manhattan, KS.* (Sponsor: Craig Harms, FACSM)
(No relevant relationships reported)

It has been reported that in young men high inspiratory muscle work at rest and during exercise reflexively increases muscle sympathetic nerve activity (MSNA), with corresponding increases in arterial blood pressure (ABP). This sympathoexcitation occurs through an inspiratory muscle-induced metaboreflex. Young women have attenuated inspiratory muscle metaboreflex-induced increases in ABP compared to age-matched men. One potential mechanism is less sympathetic vasomotor output in women compared to men. **PURPOSE:** We compared changes in MSNA and cardiovascular variables during leg cycle exercise with increased inspiratory muscle resistance in men and women. **METHODS:** Eight young women (19.5±0.2) and seven men (20.3±0.3) completed the study. The subjects performed two 10-min submaximal cycle ergometer exercises in a semirecumbent position. The first 5-min was spontaneous breathing, and latter 5-min half was voluntary hyperventilation with or without inspiratory resistive breathing. Mean arterial blood pressure (MAP) was measured using finger photoplethysmography and MSNA was recorded via microneurography of the arm at the elbow. **RESULTS:** During exercise with inspiratory resistive breathing, MSNA burst frequency was significantly increased accompanied by an increase (p<0.05) in MAP in both men and women. Women had significantly less of an increase in MSNA (Women: +9.6±1.0 vs. Men: +14.6±2.4 bursts/min) and MAP (Women: +22.8±5.7 vs. Men: +32.2±2.0 mmHg) as compared to men. **CONCLUSION:** These results suggest that lesser sympathetic vasomotor outflow partially contributes the attenuated inspiratory muscle-induced metaboreflex during exercise in young women. Spirometry Values In Recreational Runners Are Acutely Lower After Prolonged Exercise

Gerald S. Zavorsky, FACSM[1], Ralph D. Zimmerman[1], Derek G. Shendell[2], Lynda T. Goodfellow[1]. *[1]Georgia State University, Atlanta, GA. [2]Rutgers University, Piscataway, NJ.*
(No relevant relationships reported)

PURPOSE: Prolonged endurance running may acutely reduce spirometric lung function. This study examined changes in spirometric lung function before and immediately after prolonged endurance exercise (running/walking) in a large sample. This study also examined if presence or absence of exercise-induced bronchoconstriction (EIB) was related to finishing time.
METHODS: Recruitment was obtained at the pre-race expo, where an informed consent form was signed. Pre- and post-race spirometry measurements were obtained in seventy-nine participants who participated in the 2008 ING (Internationale Nederlanden Groep) Georgia half-marathon (n = 66) or marathon (n = 13). Mean ambient temperature was 47ºF (range 43-50ºF); mean ambient relative humidity was 88% (range 76-100%). Spirometry was performed 24 hours before the marathon or half-marathon and then again about 25 minutes (SD 7) after finishing it.

RESULTS: The post-race forced expiratory volume in 1 second (FEV_1) and forced vital capacity (FVC) were statistically lower by ~10% compared to pre-race, and peak expiratory flow decreased by ~8% compared to pre-race. About 30% of the participants, regardless of sex, demonstrated a post-exercise reduction in FEV_1 by at least 10% compared to pre-race. EIB was the most probable explanation for the reduction in FEV_1 post-race. There was no difference in spirometric lung function changes between men and women, nor between participants completing the marathon versus half-marathon. Presence or absence of a 10% reduction in FEV_1 (i.e., EIB) did not predict finishing time, only the distance run, age, body mass index, and sex affected finishing time (adjusted R^2 = 0.82).
CONCLUSIONS: Prolonged endurance exercise reduced spirometric lung function by about 10%, but did not affect finishing times among recreational runners/walkers.

Exercise-Induced Diaphragmatic Fatigue Is Determined By The Work Of Breathing In Healthy Men

Bruno Archiza[1], Joseph F. Welch[2], Caitlin M. Geary[2], Grayson P. Allen[2], Audrey Borghi-Silva[1], A. William Sheel, FACSM[2].
[1]*Federal University of Sao Carlos, Sao Carlos, Brazil.*
[2]*University of British Columbia, Vancouver, BC, Canada.*
(Sponsor: A. William Sheel, FACSM)
(No relevant relationships reported)

It has been purported that diaphragmatic fatigue (DF) may occur relatively early during high-intensity exercise. However, studies examining the temporal characteristics of exercise-induced DF are limited by incongruent methodology. **PURPOSE**: To determine the time-course of exercise-induced DF during high-intensity exercise. **METHODS**: Eight healthy adult males (25 ± 5 yrs, 182 ± 8 cm, 74.5 ± 5.8 kg) performed a maximal incremental exercise test on a cycle ergometer on Day 1. A constant load time-to-exhaustion (TTE) exercise test was conducted on Day 2 at 60% delta between the calculated gas exchange threshold and peak work rate (85-90% of maximal oxygen consumption). On Days 3 and 4, constant load exercise tests were performed at the same intensity to either 50 or 75% TTE in random order. Assessment of DF was made by measurements of transdiaphragmatic twitch pressure ($P_{di,tw}$) using cervical magnetic stimulation. **RESULTS**: DF ($\geq$ 20% decrease in $P_{di,tw}$) was present in 2/8 subjects after 50% TTE, 6/8 subjects after 75% TTE and all subjects after 100% TTE. The magnitude of fatigue at 100% TTE (35.0 ± 12.1%) was significantly greater than 75 (23.6 ± 6.4%) and 50% TTE (15.5 ± 5.7%) (both P < 0.01), and 75 to 50% TTE (P < 0.01). Ventilation, the mechanical work of breathing (WOB), and pressure-time products responded similarly between trials (P > 0.05). The accumulated WOB was significantly greater after 100 (3,420 ± 1,093 J) compared to 75 (1,792 ± 611 J) and 50% (877 ± 427 J) TTE (both P < 0.01), and after 75 compared to 50% TTE (P < 0.01). A significant relationship was found between the magnitude of DF and cumulative diaphragmatic force output (r = 0.785; P < 0.001). **CONCLUSION**: Our data indicate that exercise-induced DF is proportional to the cumulative WOB; thus, the ability of the diaphragm to generate pressure progressively declines throughout exercise.

Prevalence of Exercise Induced Bronchoconstriction in Recreational Adult Hockey Players as determined by Sport Specific Field Exercise Challenge Test

Kaleigh Suhs[1], Luke Stephens[2]. [1]*Advocate Lutheran General, Park Ridge, IL.* [2]*University of Missouri, Columbia, MO.*
(No relevant relationships reported)

BACKGROUND: Exercise induced bronchoconstriction (EIB) is provoked by exercise and results in narrowing of the airways. Studies have shown an EIB prevalence of 11-50% in athletic populations. The diagnosis of EIB is dependent upon objective measurement of respiratory function, as respiratory symptoms are unreliable. Cold and dry ambient conditions contribute to the severity of EIB. The environmental conditions and manner of exertion an athlete is exposed to in ice hockey are significantly different than any current standardized laboratory test to evaluate for EIB. In a prior study of elite women hockey players, 39.5% presented symptoms of asthma and 21% demonstrated EIB. Sport-specific field exercise challenge tests (SSFECT) have been validated for the assessment of EIB, and are more sensitive than laboratory challenges in elite winter athletes.**PURPOSE**: To use a SSFECT to determine the prevalence of EIB in adult recreational ice hockey players, and the correlation between reported symptoms and diagnosis by this method.
METHODS: Participants were 18 males and 2 females (mean age of 34.7 yrs, mean height of 1.78 m); who participated in 1 of 2 recreational ice hockey leagues in Chicago, IL. Using a Piko-1 portable spirometer, FEV1 was measured prior to the hockey game and immediately following periods 1, 2, and 3. All respiratory measurements occurred with hockey equipment adorned. Airway response was expressed as the percent fall in FEV1 from the baseline value. Diagnosis of EIB was given if athletes had a greater than 10% decrease in FEV1 from baseline measured at any time point. Athletes also completed an intake questionnaire prior to testing which included clinical symptoms, exercise history, and past medical history.
RESULTS: EIB was diagnosed in 3/20(15%) athletes. A prior diagnosis of asthma or exercise induced asthma was reported in 5/20 (25%) athletes, yet only one of these had a decrease of > 10 % of FEV1 as measured by this test. Of the three EIB+, two were symptomatic (67%); and of the EIB-, 9/17 (53%) reported respiratory symptoms. Diagnosis of EIB was consistent for all three periods in all but one athlete. Mean FEV1 for the three periods was 4.08, 4.07, and 4.07 respectively.
CONCLUSIONS: Symptoms remain unreliable for diagnosis of EIB. SSFECT can be utilized for diagnosis of EIB in ice hockey athletes.

Improving The Accuracy Of A Turbine Spirometer At Low Flow Rates

Troy J. Cross, Jennifer M.J. Isautier, Briana L. Ziegler, Bradley S. Cierzan, Robert Wentz, Alex Carlson, Bruce D. Johnson. *Mayo Clinic, Rochester, MN.*
(No relevant relationships reported)

The turbine spirometer is a popular laboratory device used to measure respiratory volumes and flows during exercise, and while performing gross, voluntary respiratory manoeuvres (i.e., inspiratory capacity efforts). Indeed, these devices have been incorporated into many commercially-available pulmonary function and metabolic systems. Yet, while the turbine spirometer may provide accurate/reliable measurements of respiratory volumes at modest-to-high flows, these devices perform poorly at low flow rates. **PURPOSE:** To improve the accuracy of a turbine spirometer over an extended range of low flows using the "weighted averaging technique" described by Yeh *et al.* (*J Appl Physiol*, 53(1): p280, 1982). **METHODS:** A commercially-available turbine spirometer was interfaced with a custom-designed microcontroller unit (MCU). The MCU recorded discrete rotations of the turbine rotor, and the corresponding rotational frequency (*f*rot). Repeated 5-fold cross-validation was used to determine the optimal number of bins in *f*rot and iterations used in the Weighted Averaging algorithm. This method yielded a discrete array of calibration constants (*K*) across a relevant range of *f*rot (<1-1800 Hz). The accuracy of this "nonlinear" calibration curve was compared to that obtained by assuming a constant *K* across all frequencies (i.e., flows). Over 200 calibrations strokes were recorded using a 3 L syringe. **RESULTS:** By assuming a constant *K* (15.6 mL·pulse^{-1}), the turbine spirometer exhibited an average volume error of +94 mL (+3.1%) over a 95% confidence interval ($CI_{95\%}$) of -856 to +375 mL (-28.5 to 12.5%). Conversely, applying the nonlinear *K* curve resulted in an average volume error of <0.001 mL (<0.001%) and a $CI_{95\%}$ ranging from -60 to +60 mL (-2.0 to 2.0%). Importantly, the nonlinear *K* curve provided accurate (within ±3%) volume measurements down to 0.33 Hz (~7 mL·s^{-1}). **CONCLUSIONS:** The "weighted averaging technique" improved the accuracy/reliability the turbine spirometer to within ±3% across an interval of flows ranging between ~0.01 to 20 L·s^{-1}.

Baseline Ventilatory Thresholds Determine Cardiorespiratory Adaptations to High-Intensity Interval Training in Obese Participants

Juan F. Ortega, María del Valle Guío-de-Prada, Miguel Ramirez-Jimenez, Félix Morales-Palomo, Jesús G. Pallarés, Ricardo Mora-Rodríguez. *University of Castilla-La Mancha, Toledo, Spain.*
(No relevant relationships reported)

PURPOSE: To study if cardiorespiratory fitness (CRF) evolution after high intensity interval training (HIIT) depends on training intensity relative to ventilatory thresholds (VTs).
METHODS: A sample (n=134) of sedentary participants with obesity (54±9 years, BMI 31.6±5.6 kg·m^{-2}, 42% female) trained for 16 weeks, 3 days·week^{-1} alternating bouts of 70-90% of peak heart rate (HR). CRF was evaluated before and after training using a graded cycle-ergometer exercise tests (GXT) until exhaustion. Starting at rest, oxygen consumption (VO_2), power output (PO), and HR, were determined at ventilatory threshold (VT_1), respiratory compensation threshold (VT_2) and at maximal values ($_{PEAK}$). Participants were separated in two groups according to the relationship between the training intensity (target-HR based) and the VTs location. One group (BelowVTs) was composed for those who trained below their VTs (n=74), whereas the other group (AboveVTs) for those who trained above their VTs (n=60).
RESULTS: Before intervention, age and body composition were similar in both groups. While at baseline, VO_2 at $_{PEAK}$ was higher in AboveVTs (P=0.005), at VT_1, and VT_2, was similar in both groups. After training, both groups improved their VO_{2PEAK} by 11-12% (P<0.001) without differences between groups (P=0.880). However, in BelowVTs group, 54% of the VO_2 improvement occurred below VT_1, 12% between VTs and 33% above VT_2, whereas for AboveVTs, 96% of the VO_2 improvement occurred below VT_1, 0% between VTs and 4% above VT_2.

CONCLUSIONS: Target-HR based HIIT improves VO_{2PEAK} in middle-aged individuals with obesity independently of the VTs location. However, the extent of the widening of exercise workloads tolerated after the onset of metabolic acidosis (i.e., improvements above VT_2) and exercise workloads supplied solely with oxidative metabolism (i.e., improvements at VT_1) depends if the workload chosen for training fall above or below the workload at both VTs.

The Impact Of An Eight Week Apnea Training Program On Spleen Volume And Hematological Values

Janne Bouten, Kevin Caen, Jan Stautemas, Filip Lefevere, Wim Derave, Leen Lootens, Peter Van Eenoo, Jan G. Bourgois, Jan Boone. *Ghent University, Gent, Belgium.*

(No relevant relationships reported)

PURPOSE: Apnea training has recently been proposed as a simple and cheap method to stimulate erythropoietin (EPO) production and increase hemoglobin (Hb) concentration and hematocrit (Hct). This study aimed to investigate both acute and chronic effects of apnea on spleen volume and hematological values through an 8-week apnea training program.
METHODS: Thirteen subjects daily performed five static apneas. Before, halfway through and after the apnea training period, subjects performed five maximal breath-holds at the laboratory. Baseline values for and changes in splenic volume, [Hb], Hct, reticulocyte count (RET%) and EPO were assessed.
RESULTS: A strong spleen contraction in response to acute apnea was observed with volume reductions of $50 \pm 10\%$ (p<0.001). An acute increase in [Hb] from 156 ± 11 g L^{-1} to 159 ± 9 g L^{-1} (+2%, p<0.05) was seen immediately after the last apnea. Apnea training did not improve acute effects for neither spleen volume (p=0.868), [Hb] (p=0.358) nor Hct (p=0.421). Although no differences in baseline Hct, RET% and EPO were found (p>0.05), the apnea training program did increase baseline spleen volume by $24 \pm 27\%$ (p<0.05) and baseline [Hb] by $3.3 \pm 5\%$ (p<0.05).
CONCLUSIONS: Our results show an apnea-specific training effect, as it was demonstrated that both baseline spleen volume and [Hb] had increased after eight weeks of apnea training. These increases suggest improved oxygen storage and transport capacity which might be beneficial for both elite athletes and anemic patients. In contrast, acute spleen contraction and temporarily increases in Hb remained unaltered after training.

Sex Differences in Diaphragmatic Fatigue: Implications for Performance

Joseph F. Welch, Bruno Archiza, Jordan A. Guenette, Christopher R. West, A. William Sheel, FACSM. *University of British Columbia, Vancouver, BC, Canada.* (Sponsor: William Sheel, FACSM)

(No relevant relationships reported)

Inspiratory muscle fatigue (IMF) is associated with a sympathetically mediated metaboreflex, resulting in time-dependent sympathoexcitation, including increased heart rate, mean arterial pressure and limb vascular resistance that impairs tolerance to exercise. Women may be more resistant to IMF relative to men and therefore, may experience an attenuated inspiratory muscle metaboreflex. **PURPOSE**: To examine sex-based differences in *a*) the cardiovascular response to inspiratory pressure-threshold loading (PTL) and *b*) the effect of prior-induced IMF on subsequent exercise performance. **METHODS**: Healthy men ($n = 9$) and women ($n = 9$) completed a maximal incremental cycle test on day 1. On day 2, subjects performed PTL to task failure followed by a constant load submaximal time-to-exhaustion (TTE) exercise test (85% peak work rate). On day 3, subjects performed the same exercise test without prior-induced IMF. Diaphragmatic fatigue was assessed by measuring transdiaphragmatic twitch pressure ($P_{di,tw}$) in response to cervical magnetic stimulation. Heart rate (HR) and mean arterial pressure (MAP) were measured beat-by-beat throughout PTL via photoplethysmography, and low-frequency systolic pressure (LF_{SBP}, surrogate for sympathetic vasomotor tone) calculated from arterial waveforms using power spectrum analysis. **RESULTS**: At task failure of PTL, the severity of IMF was similar between sexes (W = $23 \pm 6\%$, M = $24 \pm 8\%$ reduction in $P_{di,tw}$, $p = 0.33$). However, time to task failure was significantly longer in women than men (27 ± 11 vs. 16 ± 11 min, $p = 0.02$) and consequently, women tended to produce greater cumulative diaphragmatic pressure ($46,805 \pm 16,723$ vs. $32,288 \pm 20,752$ cmH$_2$O $\cdot$ s^{-1}; $p = 0.06$). Furthermore, women exhibited less of an increase in HR (13 ± 8 vs. 19 ± 12 bpm, $p = 0.01$) and MAP (10 ± 8 vs. 14 ± 9 mmHg, $p = 0.02$) during PTL, and significantly lower LF_{SBP} (27 ± 12 vs. 38 ± 7 mmHg², $p = 0.04$) compared to men. Prior-induced IMF resulted in the premature termination of exercise that did not differ on the basis of sex (W = $15 \pm 19\%$, M = $16 \pm 19\%$ decrease in TTE, $p = 0.89$). **CONCLUSIONS**: Inspiratory muscle endurance time is significantly longer in women than men. Fatiguing contractions of the diaphragm elicit a blunted cardiovascular response in women, whilst IMF contributes to exercise impairment independent of sex.

C-35   Free Communication/Poster - **Blood Flow Restriction**

Corticomotor Function During Blood Flow Restricted Arm Crank Ergometry

Mikaela L. Frechette[1], Ann-Maree Vallence[2], Brendan R. Scott[2], Summer B. Cook, FACSM[1]. *[1]University of New Hampshire, Durham, NH. [2]Murdoch University, Perth, Australia.* (Sponsor: Summer B. Cook, FACSM)

(No relevant relationships reported)

Low-intensity exercise with blood flow restriction (BFR-LI) may be used as an alternative to high-intensity (HI) exercise. The underlying neurophysiological mechanisms of adaptation remain elusive. **PURPOSE:** To examine corticomotor and metabolic function during HI and BFR-LI arm ergometry. **METHODS:** Twelve males (age: 23.9 ± 3.75 yrs, BMI: 25.3 ± 4.26 kg•m^{-2}) completed three 15-minute arm ergometry conditions: HI, low-intensity (LI), and BFR-LI. HI was completed at 60% of maximal power output, while LI and BFR-LI were completed at 30% of maximal power output. In the BFR-LI condition, cuff pressure to the proximal biceps brachii was set to 70% of occlusion pressure. Single-pulse transcranial magnetic stimulation was delivered to the left primary motor cortex to measure motor evoked potentials (MEPs) in the right biceps brachii at baseline, 1, 10, and 15 minutes post-exercise. Blood lactate (BL) was measured at baseline, immediately and 5-minutes post-exercise. Relative VO_2 and HR were recorded at 2 minute intervals during the exercise protocol. Each dependent variable was analyzed using within-subject repeated-measures ANOVA to evaluate condition x time interactions. **RESULTS:** MEP amplitudes throughout exercise were not different between conditions ($p = 0.883$). A significant main effect of time indicated an overall elevation in all conditions in MEP compared to baseline (0.80 ± 0.51 mV), 10 minutes (1.16 ± 0.74 mV), and 15 minutes (1.04 ± 0.47 mV; $p < 0.001$). BL following HI was 45% greater ($p = 0.03$) and 50% greater ($p < 0.001$) than the BFR-LI and LI conditions, respectively. A similar trend was seen at 5-minutes post-exercise. The HI condition resulted in HR values of (162 bpm±4 bpm) at the completion of exercise. This was higher than LI (117 ± 5 bpm) and BFR-LI (125 ± 5 bpm; $p < 0.001$). VO_2 values were significantly higher with HI (24.0 ± 1.1 ml•kg•min^{-1}) when compared to LI (11.4 ± 1.2ml•kg^{-1}•min^{-1}) and BFR-LI (13.7 ± 0.8ml•kg^{-1}•min^{-1}) ($p < 0.001$). **CONCLUSION:** High intensity arm ergometry elicited the highest VO_2, HR, and BL values, suggesting greater metabolic demands. Despite higher physical demands, MEP amplitudes increased for all conditions, suggesting similar responses in corticospinal excitability. Supported by: 2017 International Research Opportunities Program from the University of New Hampshire.

Acute Muscle Fatigue In Men And Women Following Upper-limb Low-intensity Blood-flow Restricted Exercise

Afonso Borges[1], Carolina Teodósio[1], Pedro Matos[1], Pedro Pezarat Correia[1], Pedro Mil-Homens[1], Pedro Fatela[2], Goncalo V. Mendonca[1]. *[1]Faculdade de Motricidade Humana, Lisboa, Portugal. [2]Universidade Europeia, Lisboa, Portugal.* (Sponsor: Bo Fernhall, FACSM)

(No relevant relationships reported)

Low intensity blood flow restricted exercise (LIBFRE) elicits acute changes in torque output and muscle activation. The magnitude of these changes affect the chronic adaptions to this type of training. Despite its widespread use by men and women, it is not known whether the acute impact of LIBFRE follows a sexually dimorphic pattern. This is important because, when compared to men, women have muscle fibers of smaller diameter, higher density of type I muscle fibers, higher muscle capillarization and heightened muscle perfusion. All these factors likely influence blood flow, as well as acute muscle fatigue, during LIBFRE. **PURPOSE**: To explore whether muscle fatigue post-acute LIBFRE and high intensity resistance (HI) training follows a sexually dimorphic pattern. **METHODS** 62 healthy young persons (31 men: 21.7 ± 2.3; 31 women: 22.0 ± 2.0 yrs) were included in this study. One-repetition maximum (1RM) was determined in each participant before training. Participants completed 4 sets of unilateral biceps curl with (30+15+15+15 reps) and without BFR (10+10+10+10 reps). HI was performed at 75% 1RM and LIBFR at 20% 1RM with BFR (60% of arterial occlusion pressure). Maximum voluntary contraction (MVC) was measured at pre- and post-training time points. Muscle fatigue was quantified as the percent difference between pre- and post- training MVC. **RESULTS**: Both HI and LIBFR training protocols induced significant muscle fatigue in men and women from pre- to post-training (p<0.05). HI was more fatiguing than LIBFRE in both sexes (HI: ~ 35% vs. LIBFRE: ~ 25%, p<0.05). These results were sustained even after controlling

for the differences in volume load between protocols. As importantly, the magnitude of torque decrement was similar between men and women after HI and LIBFR training (p>0.05). **CONCLUSIONS:** Performing upper-limb LIBFRE, using a multiple-set training protocol, is less fatiguing than HI resistance exercise in both men and women. Additionally, this effect is independent of differences in volume load between exercise protocols. Torque decrements in response to LIBFR and HI do not follow a sexually dimorphic pattern, providing evidence that there is no need to establish different guidelines for men and women when prescribing upper-limb LIBFR exercise. Postactivation Potentiation during Blood Flow Restricted Complex Training
Christopher J. Cleary, Dylan A. DiScenza, Summer B. Cook, FACSM. *University of New Hampshire, Durham, NH.* (Sponsor: Summer B. Cook, FACSM)
(No relevant relationships reported)

Complex training incorporates a high-load (HL) resistance exercise, such as the back-squat, with a biomechanically similar plyometric exercise, like a vertical jump (VJ), to elicit postactivation potentiation (PAP). This often results in an enhanced rate of muscular force development in the form of a higher VJ. Low-load blood flow restricted (BFR) resistance exercise is an alternate modality to HL resistance exercise, but its use during complex training has never been evaluated. **PURPOSE**: To compare how HL and BFR complex training impacts PAP measured through VJ height and electromyography (EMG). **METHODS:** Twelve healthy males that had been resistance training at least 3 times per week for the past 2 years (mean $\pm$ SD; age: 20.4 $\pm$ 0.9 years, body mass: 83.6 $\pm$ 6.7 kg, stature: 1.81 $\pm$ 0.5 m, back-squat 1-RM: 147.9 $\pm$ 25.2 kg) completed two randomized exercise sessions separated by ~1-week. Prior to each session, the VJ was performed, then either the HL (2 sets of 5 repetitions at 85% 1-RM) or BFR (2 sets of 30 at 30% 1-RM with BFR) complex training sessions, with a VJ 4-minutes after each set were performed. EMG data of the left vastus lateralis and hamstrings were collected, quantified to root-mean square values, and expressed as a percentage of the 1-RM squat. PAP percent was defined as the post-squat VJ height divided by the pre-squat VJ height and multiplied by 100. Data were analyzed using a within-subjects repeated-measures ANOVA between the two conditions and sets. Post-hoc tests in the form of t-tests were conducted if data reached significance. **RESULTS:** Neither condition induced PAP (PAP percent > 100%), but the HL condition was greater than the BFR condition (96.1 $\pm$ 4.8% to 90.8 $\pm$ 8.5%, p = 0.034). EMG activation was greater during the HL condition in the vastus lateralis (HL: 104.6 $\pm$ 27.7% to BFR: 79.6 $\pm$ 33.4%, p = 0.002) and the hamstrings (HL: 112.3 $\pm$ 59.6% to BFR: 51.9 $\pm$ 30.2%, p = 0.001). **CONCLUSION:** Despite EMG amplitude being greatest for the HL condition, PAP did not occur. Similarly, BFR complex training also did not produce PAP. Fatigue and unsatisfactory rest periods should be investigated in future protocols. Supported by: 2017 Summer Undergraduate Research Fellowship Grant from the University of New Hampshire.

Muscular Responses To Very Low Load Resistance Exercise With Blood Flow restriction In The Upper Body
Samuel L. Buckner, Matthew B. Jessee, Scott J. Dankel, J Grant Mouser, Kevin T. Mattocks, Zachary W. Bell, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*
(No relevant relationships reported)

Low load exercise performed to failure appears to elicit a similar skeletal muscle response to that of high load exercise. There may be a point where a load becomes too low to elicit an anabolic response. In situations where the load becomes too low, blood flow restriction (BFR) might augment the response. **PURPOSE**: Examine the acute skeletal muscle response to high load exercise and low load exercise with and without BFR. **METHODS**: 20 participants completed four conditions in the upper body (one condition per arm) over 2 visits. Conditions consisted of elbow flexion exercise to failure using a traditional high load [70% 1RM, (HL)], low load [15% 1RM, (LL)], low load with moderate BFR [15% 1RM + 40%BFR (BFR40)], or low load with greater BFR [15% 1RM + 80%BFR (BFR80)]. Torque and muscle thickness were measured prior to, immediately post, and 15 min post exercise. Muscle electromyography (EMG) amplitude was measured throughout. Repeated measure ANOVA was used to determine differences. Results are displayed as mean (SD). **RESULTS**: There was an interaction (p < 0.001) for changes in muscle thickness. Immediately post-exercise all low load conditions demonstrated greater swelling compared to the HL condition [Pre to Post Change: LL= 0.56cm (0.22), BFR40 = 0.53cm (0.19), BFR80= 0.55cm (0.20), HL = 0.28cm (0.13)]. Muscle thickness remained elevated above baseline 15 min post exercise in all conditions, but was maintained to a greater extent in the low load conditions relative to HL exercise [Pre to 15 min post difference: LL= 0.46cm (0.16), BFR40 = 0.39cm (0.13), BFR80= 0.44cm

---

(0.19), HL = 0.21cm (0.12)]. There was an interaction for acute changes in torque (p $\leq$ 0.001). The LL, BFR40 and BFR80 conditions decreased 20 Nm (11), 24 Nm (11), 26 Nm (13) respectively, and to a greater extent compared to the HL condition [15 Nm (9)]. Torque remained depressed at 15 min post. In the last three repetitions, there was a main effect of time (p < 0.001). EMG amplitude was higher during set 2 [70 (23) %MVC] compared to set 1 [65 (22) %MVC], set 3 [62 (20) %MVC] and set 4 [64 (21) %MVC]. **CONCLUSIONS:** Very low load exercise (with or without BFR) appears to result in greater acute muscle swelling, greater muscular fatigue and similar EMG amplitude compared to HL exercise. Further study is needed to determine if these acute changes would manifest muscular adaptations.

Sex Differences In The Estimation Of Blood Flow Restriction Before Exercise
Goncalo V. Mendonca, Afonso Borges, Carolina Teodósio, Pedro Matos, Pedro Mil-Homens, Pedro Pezarat Correia. *Faculdade de Motricidade Humana, Lisboa, Portugal.* (Sponsor: Bo Fernhall, FACSM)
(No relevant relationships reported)

Arterial occlusion pressure (AOP) is typically used to normalize blood flow restriction (BFR) during low intensity blood flow restricted exercise. AOP varies as a function of individual factors such as limb circumference and systolic blood pressure (BP). Despite strong evidence for sexual dimorphism in muscle blood flow, sex-related differences in AOP estimation have not been previously explored. **PURPOSE:** To determine whether the relationship of upper-limb AOP with arm circumference and systolic BP differs between men and women. **METHODS:** 62 healthy young persons (31 men: 21.7 $\pm$ 2.3; 31 women: 22.0 $\pm$ 2.0 yrs) were included in this study. Arm circumference, resting BP and AOP were taken during a single testing session. Resting BP and AOP were measured twice (post-5 and 30 min of seared rest) to examine their stability over time. Multiple linear regression analysis was used to determine whether the relationship of AOP with arm circumference and resting BP differed between sexes. Prediction accuracy was assessed with the mean absolute percent error and Bland-Altman plots. **RESULTS**: Men had higher systolic BP and larger arm circumference than women (p<0.05). Nevertheless, AOP was similar between sexes (men: 138.5 $\pm$ 11.8; women: 136.4 $\pm$ 11.3 mmHg). Arm circumference, systolic BP and sex were all significant predictors of AOP (p<0.05), explaining 42% of its variance. For women, the prediction equation was: AOP = 35.278 + (1.711 x arm circumference) + (0.47 x systolic BP). For men, the prediction equation was: AOP = 35.278 + (1.711 x arm circumference) + (0.47 x systolic BP) - 5.704. The absolute percent error was similar in both sexes (men: - 0.55 $\pm$ 7.12; women: - 0.39 $\pm$ 6.31%, p>0.05). Bland-Altman plots showed that the mean difference between actual and estimated AOP was nearly zero in both groups (men: -0.14; women: -0.01 mmHg), with no systematic over or under-estimation. **CONCLUSIONS**: Arm circumference, systolic BP as well as sex are all significant predictors of upper-limb AOP. Their measurement allows the indirect estimation of BFR pressure within the context of exercise training. Supported by the Portuguese Science Foundation PTDC/DTP-DES/5714/2014.

Blood-flow-restricted Training Augments Improvements In Muscle K$^+$ Handling, Antioxidant Capacity And Exercise Performance In Men
Danny Christiansen, Jens Bangsbo. *University of Copenhagen, Copenhagen, Denmark.*
(No relevant relationships reported)

Exercise performance is partly limited by the muscle potassium ion (K$^+$) transport capacity, which is determined by the function of the Na$^+$,K$^+$-ATPase (NKA). Studies *in vitro* suggest high levels of reactive oxygen species (ROS) compromise NKA function, and increased antioxidant content protects against NKA dysfunction. However, it remains unknown in humans if ROS affect muscle K$^+$ handling, and if this capability is related to the antioxidant capacity. Exercise with reduced muscle blood flow (blood flow restriction, BFR) promote ROS production, which is important for increases in NKA and antioxidant content. Whether BFR may augment increases in muscle K$^+$ handling and NKA content in humans are yet to be explored. **PURPOSE**: To examine if BFR can augment training-induced improvements in muscle K$^+$ handling and exercise performance, and if these changes are related to an increased antioxidant capacity in men. **METHODS**: Ten healthy men (25 $\pm$ 4 y) performed 6 weeks of interval cycling without (CON-leg) or with BFR (170 mmHg, BFR-leg). Before and after training, catheters were inserted into the fem. artery and vein in both legs, and blood flow was assessed by ultrasound Doppler, to determine thigh K$^+$ release during single-legged, knee-extensions at 25% (Ex1) and 90% W_{max} (Ex2) under intravenous infusion of placebo (saline) or N-acetylcysteine (NAC). A muscle biopsy was collected before and after Ex2 to assess catalase activity, and NKA and antioxidant content in type-I and II fibres. **RESULTS**: Performance of the CON-leg (11%) and BFR-leg (23%) increased with training (p<0.05), with a greater increase in BFR-leg (p<0.05, 12%). After training, K$^+$ release was attenuated in Ex2 in the BFR-leg (p<0.05), but

---

THURSDAY, MAY 31, 2018

not in CON-leg (p>0.05). Before training, NAC attenuated K⁺ release in Ex1 (p<0.05), but not in Ex2 (p>0.05), in both legs. After training, the effect of NAC was blunted and catalase activity increased in the BFR-leg only (p<0.05). NKA-isoform and antioxidant content are currently being analysed. **CONCLUSION**: BFR training augments improvements in muscle K⁺ handling and exercise performance in men. These effects are related to an increased muscle antioxidant capacity. In addition, ROS appear involved in the regulation of muscle K⁺ release during submaximal exercise in humans. Supported by the Danish Ministry of Culture (FPK.2015-0017)

Very Low Load resistance Exercise Is Augmented By Blood Flow Restriction In The Lower Body

Matthew B. Jessee, Samuel L. Buckner, Kevin T. Mattocks, J Grant Mouser, Scott J. Dankel, Zachary W. Bell, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

Low load exercise to failure has been shown to elicit muscle hypertrophy similar to high load exercise. However, if the load is very low [i.e. 15% of one repetition maximum (1RM)], the contraction intensity may not disrupt blood flow enough to induce failure. Although unknown, the application of blood flow restriction (BFR) during very low load exercise may be necessary in order to reach failure. **PURPOSE**: To compare the acute responses associated with a hypertrophic stimulus during lower body exercise using a traditional high load (70% 1RM), very low load (15% 1RM) with no BFR, or in combination with moderate (40% arterial occlusion pressure (AOP)) or high (80% AOP) BFR pressure; coded as 70/0, 15/0, 15/40, and 15/80 respectively. **METHODS**: 22 participants completed 4 sets of unilateral knee extensions to failure (up to 90 repetitions) with each condition. Muscle thickness (MTh) and maximal voluntary contractions (MVC) were assessed before (Pre), immediately following (Post), and 15 minutes after exercise (15-Post). Electromyography (EMG) amplitude of the rectus femoris (RF) and vastus lateralis (VL) was assessed during the last 3 repetitions of each set. Data presented as mean (SD) with p≤0.05. **RESULTS**: There was an interaction for MTh, however, follow up tests revealed no differences within time points. Overall, MTh increased from Pre to Post [0.48 (0.17) cm], decreased at 15-post [-0.11 (0.18) cm], but remained elevated over Pre [0.36 (0.07) cm]. There was an interaction for MVC and follow up tests revealed differences at Post [15/80 < 15/0, 15/40, < 70/0] and 15-Post [15/0 < 15/80, 70/0]. All conditions decreased MVC at Post [-111.1 (48) Nm] and increased from Post to 15-Post [79.2 (43.1) Nm]. There was a main effect of condition for RF EMG, with 70/0 being greater than 15/80 [83 (37) vs. 57 (27) %MVC]. For VL EMG, there was a main effect of condition [70/0 > 15/80, 15/40, 15/0] and time [set 1< 2, 3, 4]. Typically, VL EMG was greater for 70/0 [106 (70) %MVC] compared to 15/0 [73 (21)], 15/40 [72 (30)], and 15/80 [64 (21)]. **CONCLUSIONS**: BFR with a higher pressure seemed to augment the acute muscular response to very low load exercise, making it closer to the response observed during high load exercise. This suggests that a higher BFR pressure may be necessary to induce hypertrophy when resistance training with very low loads.

C-36   Free Communication/Poster - Measurement of Physical Activity and Sedentary Behavior

The National Collaborative on Childhood Obesity Research's Measures Registry and User Guides: Highlights and Reach

David R. Brown, FACSM[1], Rachel Ballard[2], Jill Reedy[2], David Berrigan[2], Amanda Samuels[3]. *[1]Centers for Disease Control and Prevention, Atlanta, GA. [2]National Institutes of Health, Bethesda, MD. [3]FHI 360, Washington, DC.*

(No relevant relationships reported)

There are many types of physical activity and food intake measures. These measures often lack validity and reliability, making it difficult to compare findings across childhood obesity research and evaluation studies.
Purpose: The National Collaborative on Childhood Obesity Research's (NCCOR) Measures Registry (nccor.org/mruserguides) promotes consistent use of high-quality, comparable measures and methods across childhood obesity studies. The Registry User Guides extend the reach and usefulness of these resources. Herein we describe the Registry and User Guides and examine their reach to nutrition, physical activity, and obesity researchers and practitioners.

Methods: A search of peer reviewed literature published 1999-2009 was conducted. Measurement experts reviewed and abstracted articles meeting inclusion criteria in four domains: physical activity, diet, physical activity environment, and food environment. The Registry was launched in 2011 and has been updated on an ongoing basis since August 2015. In 2017, subject matter experts authored four User Guides for the measurement domains. The Guides include case studies to help users' select appropriate measures. The number of web visitors to the Registry and Guides was tracked providing an indicator of reach.
Results: The Registry contains 1207 published studies of validation research using measures of physical activity (n=403), diet (n=330), physical activity environment (n=273), and food environment (n=331). Measures include GIS (n=127); 24-hour dietary recall (n=52); food frequency (n=69); electronic monitor (n=121); environmental observation (n=153); questionnaire (n=498); record or log (n=97), and other (n=207). Over 17,100 unique visitors have accessed the Registry since its launch, including visitors from 41 countries. Since their release there have been over 8000 page views of the User Guides from 3633 unique visitors.
Conclusion: The NCCOR Measures Registry and User Guides can assist researchers and practitioners conducting childhood obesity prevention research and evaluation to select high quality, comparable measures of physical activity, diet, and the environments in which these behaviors occur. Website traffic reflecting access to the materials indicates a large reach.

The Effect of Activity Courses on Student's Physical Activity In and Out of Activity Courses

Michael Kantor, Emily Novak, Jessica Albers. *Minnesota State University, Mankato, Mankato, MN.*

(No relevant relationships reported)

Recent research indicates that 51.7% of adults meet the 2008 Physical Activity (PA) Guidelines (Tainya et al, 2017). Activity courses are offered at 87% of 4-year colleges and Universities which directly facilitate some increase levels of PA during class time (Strand et al, 2010) and have been shown to increase PA outside of class (Annesi et al, 2017). The Physical Activity Vital Sign is a clinical tool designed to screen for PA in adults. **PURPOSE:** The aim was to use PAVS to analyze the relationship between PA level changes throughout the semester, PA intensities spent in class, and how many students met the 2008 PA Guidelines for Americans. **METHODS:** Subjects self-enrolled in one PA course. Each subject (n=41; 31 females, 10 males; 21.4 years ± 4.50) completed an emailed questionnaire (Qualtrics) at the beginning, middle, and end of the class term (weeks 2-3, 8, and 16), and wore an accelerometer (Actigraph wGT3X-BT accelerometers with a 15 second epoch collection rate) while in the class at the same three timepoints (Freedson 1998 counts). The Qualtrics Survey included: Demographic information (at timepoint 1 only), and PAVS Survey. **RESULTS:** The mean PAVS score was 180.1 minutes ± 146.6, 217.2 minutes ± 167.5, and 226.76 minutes ± 173.3 for each timepoint respectively. The percent of subjects who met PA recommendations increase from 41.6% to 63.4%. PAVS score was not significantly different from time point one to timepoint three $t_{(40)}$=-1.949, p=0.058, even when controlling for sex (Males: $t_{(9)}$ = -1.340, p=0.213; Females: $t_{(31)}$ = -1.594, p=0.122). For the each timepoint, PAVS scores were not significantly correlated to time spent in PA intensities during the activity class: $r_{PAVS-1-Sedentary}$=-0.28, p=0.864; $r_{PAVS-1-Light}$= 0.022, p=0.890; $r_{PAVS-1-Moderate}$=0.021, p=0.897; $r_{PAVS-1-Vigorous}$= 0.144, p=0.370, : $r_{PAVS-2-Sedentary}$=0.081, p=0.613; $r_{PAVS-2-Light}$= -0.050, p=0.757; $r_{PAVS-2-Moderate}$=-0.111, p=0.491; $r_{PAVS-2-Vigorous}$= 0.022, p=0.893, : $r_{PAVS-3-Sedentary}$=0.078, p=0.628; $r_{PAVS-3-Light}$= -0.214, p=0.179; $r_{PAVS-3-Moderate}$=-0.169, p=0.290. **CONCLUSION:** PAVS was not a significant predictor of PA intensity in college level activity course nor did it significantly change throughout the semester. However, students who met PA requirement increased from (41.6%) to (63.4%) at the end of the semester.

Comparison of Previously Used Methods for Analyzing Global Positioning System Plus Accelerometry Data from Recess

Kimberly A. Clevenger[1], Karin A. Pfeiffer, FACSM[1], Cheryl A. Howe, FACSM[2]. *[1]Michigan State University, East Lansing, MI. [2]Ohio University, Athens, OH.*

(No relevant relationships reported)

Global Positioning System (GPS) receivers plus accelerometry can identify how physical activity (PA) varies by schoolyard location, but the accuracy and comparability of existing approaches to analyzing this data are unknown. **PURPOSE**: To compare previously used methods for analyzing GPS plus accelerometry data from recess. **METHODS**: Children (N=23) wore an accelerometer and GPS on their hip for two recesses to determine location and PA intensity (counts/sec or classified by cut-points). Recesses were videotaped, and location and PA intensity were coded. Five approaches for interpreting GPS and accelerometer data were used and compared to the video: 1) graduated color *dot* map, 2) 1 m fishnet *grid*, 3) *hot spot* analysis with

Getis Ord G* statistic, 4) *zonal* approach, and 5) *interpolation* of a continuous surface of intensity over the schoolyard. For the *zonal* approach, weighted kappa compared GPS and video location second-by-second, and paired t-tests compared proportion of time in each location and intensity for GPS plus accelerometry versus video (*p*<0.05). **RESULTS**: *Hot spot* analysis revealed significant (*p*<0.01*)* clusters of high counts/sec on the field and court and near the swings, which was supported by *dot* and *grid* maps. *Interpolation* indicated a high intensity peak in the court. These patterns were supported by video observation. Weighted kappa was 0.76, and there were no differences in time spent in each zone according to GPS versus video (court: 45.2 vs. 43.7%, fixed equipment: 31.1 vs. 33.2%, field: 23.7 vs. 26.2%). Sedentary behavior was higher according to GPS versus video overall (22.1 vs. 12.1%) and for court (21.9 vs. 10.1%) and fixed equipment (19.7 vs. 7.1%). Moderate-to-vigorous PA was lower according to GPS versus video overall (43.9 vs. 62.2%) and for court (42.6 vs. 68.6%) and fixed equipment (45.2 vs. 80.6%). **CONCLUSIONS**: GPS plus accelerometry accurately classified location, and the PA patterns identified by *dot*, *grid*, and *hot spot* were similar to video. Quantification of the proportion of time in each intensity by location was not similar to video, possibly due to missing data or differences in how accelerometer and video intensity are classified. Interpolation is not an appropriate analysis for this research question and is not recommended for future use.

Implications Of Direct Observation Methods For Describing Drivers Of Children's Physical Activity

Chelsey R. Schlechter[1], Justin M. Guagliano[2], Richard R. Rosenkranz, FACSM[2], David A. Dzewaltowski[3]. *[1]Kansas State University, University of Nebraska Medical Center, Manhattan, Omaha, KS. [2]Kansas State University, Manhattan, KS. [3]University of Nebraska Medical Center, Omaha, NE.* (Sponsor: Richard R. Rosenkranz, FACSM)
(No relevant relationships reported)

Direct observation (DO) is a popular objective method to describe children's physical activity (PA) and setting context. DO is a category of methodologies that vary by the time unit of analysis (e.g., total setting time or segmented setting time) and sampling method (e.g., momentary or continuous). We propose that the DO method determines the temporal variability in data collected, and therefore defines the ecological processes that can be studied.
Purpose: To examine implications of DO methods for observing drivers of children's PA.
Methods: Research assistants (RA) video-recorded basketball practices (*n* = 24) from 12 boys' and girls' teams (2 practices/team) where children (*n* = 105, 7-12y, mean ± *SD* = 9.4 ± 1.1y) wore ActiGraph GT1M accelerometers. RAs coded each practice using two DO systems. SOFIT uses momentary time sampling and observes every 20 seconds over total practice time (TPT) to assess percentage of TPT in PA, in different contexts types (e.g., fitness, skill), and in PA within context across TPT. Our alternate method (CLOUDEE) uses continuous sampling to define continuous context time segments during practice. Metrics calculated from CLOUDEE were frequency, duration, and order of segments, and %time spent in PA within segments. Inter-rater reliability was calculated on a subset of practices (*n* = 5/system). We analyzed accelerometer data using Evenson et al. cut-points and paired the data with context time segments from CLOUDEE. **Results:** Inter-rater reliability was >85% for both systems. Most of TPT, assessed by SOFIT, was spent in skill (mean ± *SE* = 47.4 ± 0.8%). Fitness had the greatest percentage of MVPA (moderate-to-vigorous physical activity) (mean ± *SE* = 81.6 ± 3.2%) across TPT. Using CLOUDEE, we identified 256 time segments (mean/practice ± *SE* =10.7 ± 2.5) during practices. Skill segments occurred most frequently (mean/practice ± *SE* = 3.5 ± 2.3; mean length ± *SE* = 4.75 ± 3.41 minutes). Free-play segments were the most frequently occurring first segment in the practice routine (81.8%; mean length ± *SE* = 4.32 ± 2.51) and had the greatest %time spent in MVPA (mean ± *SE* = 57.7 ± 2.8%). **Conclusion:** The systems comprise distinct methods and thus examined different processes as drivers of children's PA. When using DO, researchers should ensure appropriate methods are used to examine the ecological process of interest.

Evaluation Of In-School Physical Activity During Recess, P.E., And Academically-Related Movement Activities

Robert Booker, Riley Galloway, Trisha Doering. *Missouri State University, Springfield, MO.* (Sponsor: Barbara A Bushman, FACSM)
(No relevant relationships reported)

PURPOSE: Schools provide ample opportunity to address physical inactivity patterns, which have been established as a crucial risk factor of health concerns. As evidence of associations between morbidity and progression of childhood obesity to adult obesity expand along with the inverse relationship between school year and physical activity

(PA), an urgency remains for schools to implement mandatory policies addressing the accumulated moderate-to-vigorous physical activity (MVPA) per week. The purpose of this study was to quantify in-school PA levels among elementary students during recess, P.E., and academically-related movement activities (ARMA) and determine if state-wide recommended levels of MVPA are being met.
METHODS: Third through sixth grade students (N=71) volunteered to participate in the evaluation of PA levels during recess, P.E., and ARMA during summer school. Accelerometry data was obtained to quantify the amount of PA being achieved. Data collection commenced at the beginning of and ceased at the end of each school day for five consecutive days. Accelerometers were used to provide tri-axial movement analysis according to 5-second 'epochs' to quantify levels of PA. A one-way ANOVA was employed to examine PA between grades.
RESULTS: Of the weekly recess minutes offered (332.39 ± 24.49), 31% classified as MVPA while 35.44% was completely sedentary. Combining sedentary and light accounted for 68.09% of the total time. Of the weekly P.E. minutes offered (72.75 ± 31.29), 23.83% classified as MVPA while 41.44% was completely sedentary. Combing sedentary and light accounted for 72.8% of the total time. Of the weekly ARMA minutes offered (14.93 ± 17.65), 15% classified as MVPA while 35.37% was completely sedentary. Combining sedentary and light accounted for 63.5% of the total time. Percentages significantly increased across each category after omitting 6th grade due to inflation.
CONCLUSION: Overall, students failed to achieve recommended amounts of MVPA during school hours and recommended amounts of P.E. of at least moderate intensity although there was opportunity to achieve both. This research provides insight to PA levels and potential health status of children during school hours, which confirms the need for enhanced attention to meeting state standards of school-related PA.

Accuracy of Wrist-Worn Activity Monitors during Wheelchair Use

John Smith. *Texas A&M University-San Antonio, San Antonio, TX.*
(No relevant relationships reported)

Activity monitors are used to track activity and exercise intensity in the bi-pedal population, however, there is a lack of studies examining these devices for those using manual wheelchairs. **PURPOSE**: To assess activity monitor accuracy during wheelchair use (WC). **METHODS**: Forty-four subjects (non-wheelchair users; age=26.7±4.9 yrs, ht=1683.7±10.2 cm, wt=76.75±16.7 kg) wore six commercially-available wrist activity monitors (FF, FC, & PL on the right wrist; GV, MV, & LT on the left wrist) and a heart rate (HR) monitor while walking 150m in an indoor hallway at a self-selected pace. Subjects traversed the same path in a wheelchair. Video was used to determine actual counts using a hand tally (AC). During WC, a count was recorded as the hand went forward and again as the hand recovered for each hand. Repeated measures ANOVA determined significant differences between the counts. Error was calculated as [(monitor counts-actual counts)/actual counts]*100. Alpha was set at .05 for all tests. **RESULTS**: During walking, FF, FC, PL and MV (263.7±37.3, 270.5±29.6, 228.5±49.9, & 264.6±30.3 counts, respectively) were significantly lower than AC (286.4±24.4 counts), p<.05, except for LT (267.3±41.4 counts) and GV (281.1±24.4 counts), p>.05. During WC use, FF (305.7±83.7 counts) and FC (306.6±80.8 counts) were significantly greater than AC (273.9±101.3 counts), p<.05. PL (279.2±92.7 counts) was not significantly different than AC. Similarly, MV (248.1±63.8 counts) and LT (344.6±128.2 counts) were significantly different than AC (297.1±98.1 counts), p<.05, whereas GV (299.0±116.8 counts) was not significantly different than AC. During walking, PL had greatest error (20.8±15.3%), followed by FF (7.8±11.3%), MV (7.4±8.2%), LT (6.8±13.5%), FC (5.9±7.4%), and GV (2.3±4.1%). Error was high in all conditions during WC use, with LT exhibiting the greatest error (29.6±21.0%), followed by FC (23.5±20.3%), FF (21.9±20.1%), GV (18.9±21.75%), MV (18.5±14.3%), and PL (16.2±12.8%). **CONCLUSION**: Although substantial error is still evident, PL seems to be the most accurate for wheelchair use among the devices assessed. Manufacturers should consider developing an activity monitor specifically for wheelchair users.

Assessment of Physical Activity & Sedentary Behavior in Individuals with Chronic Low Back Pain

Jeni E. Lansing, Maria Perez, Kathryn J. Southard, Laura D. Ellingson. *Iowa State University, Ames, IA.*
(No relevant relationships reported)

Low back pain affects >80% of adults in their lifetime, with 4-14% experiencing chronic low back pain (CLBP). Exercise training can reduce pain in CLBP patients, but activity patterns in this population have yet to be well-described, with existing data coming solely from self-report measures. **PURPOSE:** Our aim was to describe physical activity (PA) and sedentary (SED) behaviors and compare patterns assessed using objective vs. self-report measures in individuals with CLBP. **METHODS:**

Measures of PA and SED were obtained from ActiGraph and activPAL accelerometers and the International Physical Activity Questionnaire (IPAQ) in individuals with CLBP (N=57; 52% female; 43±10 years old). Accelerometer data were processed using the Sojourns Including Posture (SIP) method and the IPAQ was scored to calculate time spent in moderate and vigorous PA (MVPA) and SED. Minutes of MVPA and SED from each method were analyzed descriptively (means (SD)) and compared using correlation coefficients and Bland-Altman Plots. **RESULTS:** Objective data demonstrated that few (12.3%) participants met recommended levels of PA. Contrasting this, self-report data showed that 81.7% were active enough to meet guidelines. Average minutes of MVPA per week in bouts of 10+ minutes measured objectively and subjectively were 57.1 (59) and 430.1 (330) minutes, respectively. Objective and subjective measure of MVPA were weakly correlated (r=0.25), and the Bland-Altman plot demonstrated wide limits of agreement (311.3 and -1097) and a systematic bias for over-reporting PA. For SED, mean minutes per day measured objectively and subjectively were 530.3 (85.7) and 458.3 (138.8), respectively. Measures were also weakly correlated (r=0.13). The Bland-Altman plot had wide limits of agreement (373.2 and -229.3) and demonstrated a systematic bias for under-reporting SED. **CONCLUSION:** Objective data demonstrate that patients with CLBP are inactive and highly sedentary. Their tendency to under-report SED and over-report MVPA indicates they may lack awareness regarding their actual levels of these behaviors. The identified disconnect between perceived and actual PA and SED behavior in the CLBP population suggests that addressing these misconceptions may be critical for the success of future interventions aiming to alter movement patterns to reduce pain.

Development of Step Count Cut-Points for School Day Sedentary Behavior

Timothy A. Brusseau, Ryan D. Burns. *University of Utah, Salt Lake City, UT.*

(No relevant relationships reported)

PURPOSE: No study has established step count cut-points for varying minutes of accelerometer-assessed sedentary behavior accrued during the school day in children. The purpose of this study was to establish step count cut-points for discriminating children meeting sedentary behavior ranging from 3-hours to 6-hours per 7-hour school day.
METHODS: Participants were a convenience sample of 2,119 children (mean age = 8.5 (1.9) years) recruited from 5 schools from the Mountain West region of the U.S. Step counts and time in sedentary were assessed using ActiGraph wGT3X-BT triaxial accelerometers that were worn during the entirety of a 7-hour school day for one school week. Average censored step counts and minutes in sedentary behavior were calculated across 3 to 5 days. Receiver operating characteristic (ROC) curves were employed to derive step counts discriminating children that met 3-hours (180 minutes) to 6-hours (360-minutes) of sedentary time ($\leq$ 100 accelerometer counts per minute) per school day via calculation of the maximum Youden's J statistic. The sedentary count cut-points were derived from Evenson et al. (2008) using 15-second epochs (25 counts per 15-seconds). However, within the ActiLife software, sedentary cut-points were multiplied by four to align with 60-second epochs.
RESULTS: Area-under-the-curve (AUC) scores ranged from AUC = 0.92 (95% C.I.: 0.90-0.93; $p < 0.001$) for meeting at least 3-hours per school day of sedentary to AUC = 0.78 (95% C.I.: 0.75-0.81, $p < 0.001$) for meeting at least 6-hours of school day sedentary. Approximately 4,090 steps best-discriminated children meeting 3-hours of school day sedentary (Sensitivity = 87.4%, Specificity = 78.3%, Accuracy = 85.5%) and approximately 2,465 steps best discriminated children meeting 6-hours of school day
sedentary (Sensitivity = 60.9%, Specificity = 75.9%, Accuracy = 74.1%).
CONCLUSION: Step counts can discriminate with reasonable accuracy children that meet at least 6-hours of school day sedentary and with good accuracy children that meet 3-hours of school day sedentary.

Comparing Two Generations of ActiGraph Accelerometers: Coronary Artery Risk Development in Young Adults (CARDIA)

Kara M. Whitaker[1], Kelley Pettee Gabriel, FACSM[2], David R. Jacobs, Jr.[3], Stephen Sidney[4], Barbara Sternfeld, FACSM[4]. *[1]University of Iowa, Iowa City, IA. [2]University of Texas Health Science Center at Houston, Austin, TX. [3]University of Minnesota, Minneapolis, MN. [4]Kaiser Permanente, Oakland, CA.* (Sponsor: Kelley Gabriel, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the comparability of the ActiGraph 7164 uniaxial accelerometer and the ActiGraph wGT3X-BT triaxial accelerometer (low frequency extension) in wear time, count based estimates (vertical axis), and average time/day in physical activity of different intensities. **METHODS:** Data are from 87 CARDIA

---

participants, aged 48-60 years, who simultaneously wore the 7164 and wGT3X-BT accelerometers at the waist in 2015-16, with wear time $\geq$4 or 7 days, $\geq$10 hr/day. Freedson adult cut points (ct/min) were used to define sedentary (<100), light (100-1951), moderate (1952-5724), and vigorous activity ($\geq$5725). Paired difference tests were used to compare mean or median values between the two accelerometers. Agreement was evaluated using intraclass correlation coefficients and Bland-Altman plots. A calibration formula applied to the wGT3X-BT values was obtained by linear regression. **RESULTS:** Minute by minute within-person correlations of ct/min/day averaged r=0.74, despite the $\geq$10 year age of the 7164 devices. Total recorded wear time min/day was nearly identical between the 7164 and wGT3X-BT (881.5 ± 70.9 vs. 880.3 ± 78.1, p=0.72). Linear regression of the wGT3X-BT on the 7164 ct/min/day passed very close to the origin; therefore, the slope of the 7164 ct/min/day (1.088) was the calibration proportionality. After calibrating the wGT3X-BT values (dividing by 1.088), no differences were observed between the 7164 and wGT3X-BT in total accelerometer ct/day (310,184 ± 129,189 vs. 307,085 ± 135,362, p=0.48), average ct/min/day (349.5 ± 139.5 vs. 346.5 ± 147.2, p = 0.54), sedentary (513.2 ± 93.6 vs. 509.6 ± 98.6, p=0.23), light (335.3 ± 81.5 vs. 338.7 ± 81.1, p=0.22), or moderate min/day (31.0 ± 21.9 vs. 30.3 ± 23.4, p=0.31). A significant difference was observed for vigorous min/day in the total sample (0.2 ± 1.0 vs. 0.0 ± 0.3, p<0.01), and also among those with >0 vigorous min/day (N=28, 2.8 ± 4.5 vs. 1.3 ± 2.9, p=0.01). Intraclass correlation coefficients showed excellent agreement for all measures (ICC range = 0.97-0.99). Bland-Altman plots demonstrated acceptable levels of agreement. **CONCLUSIONS:** After applying a calibration formula, the 7164 and wGT3X-BT are comparable for total wear time, count based estimates, and average min/day in sedentary, light, and moderate activity, but not for vigorous activity.

Statistical Assessment of Yoga Posture Acquisition using a 3D Room Sensor

Paula R. Pullen[1], Hannah Crumley[1], Samuel M. Fouche[1], Molly Martin[1], Ryan Martucci[1], William Seffens[2]. *[1]University of North GA, Oakwood, GA. [2]Seftec, Inc., Atlanta, GA.* (Sponsor: Walter R Thompson, FACSM)

(No relevant relationships reported)

Many innovative information technology applications use gestures as input. We are exploring gesture analysis for incorporation into exergames for personalized medical interventions using yoga as therapy (YT). **PURPOSE:** A data-driven machine learning solution for gesture detection was used to classify captured yoga poses with high accuracy. The research goal is to test whether a machine learning algorithm in a basic computer video exergame can assess yoga skill acquisition in targeted select populations as a means to promote healthy physical activity. **METHODS:** Convenience sample of 20 adult students, male and female of any race/ethnicity, were briefly instructed and shown poses to perform, while recorded by the Kinect attached to a PC. Three yoga sessions (pre-test, mid-way and a post-test) were captured during the regularly scheduled yoga class which met twice weekly for 75 minutes, over a 10-week period. **RESULTS:** We recorded 6 yoga instructors while performing a series of yoga postures, and recorded clips were tagged or labelled in all of the frames in the recordings that defined a yoga gesture by consensus of two yoga instructors. Default settings produced solutions with high True Positives (99.5%) and low False Positives (0.03%) for most yoga postures sampled. Depth stream and skeleton coordinates for the 20 participants were acquired and analyzed against the previous trained solution. Analysis of summary statistics was done for five yoga poses comparing initial, mid-session, and final session captures. Sensitivity showed consistent trends for Mountain, Forward Bend, and Upward Salute. For Mountain, Sensitivity went from 0.78 to 0.87, while the expert test clip scored 0.94. Informedness also showed similar consistent trends for those poses. Based on these results the higher sensitivity score predicts greater training and closer the postures were to the "gold standard". **CONCLUSIONS:** Gesture analysis for yoga alignment training may be a useful tool for the development of home and clinical yoga therapy for hard to reach populations. The experimental exergame developed here provides a tool that scores the performance of yoga postures and provides improvement metrics. Our plans are to target special aging populations with YT, and study the potential effects of body mass and age on posture alignment and limb stretch.

Muscular Strength Attenuates Adverse Effects Of Overweight On Cardiometabolic Risk Factors But Not In Its Counterparts With Higher Fat Among Collegiate Students

Robinson Ramírez-Vélez[1], Jorge E. Correa-Bautista[1], Antonio García-Hermoso[2], Alejandra Tordecilla-Sanders[1], Daniel H. Prieto-Benavides[1], Carolina Sandoval-Cuellar[3], Katherine González-Ruíz[4], Elisa Andrea Cobo-Mejía[3], Rocío del Pilar Castellanos-Vega[3]. *[1]Universidad del Rosario, Bogotá D.C, Colombia. [2]Universidad de Santiago de Chile, USACH, Bogotá D.C, Colombia. [3]Universidad de Boyacá, Tunjá, Colombia. [4]Universidad Manuela Beltrán, Bogotá D.C, Colombia.*
(No relevant relationships reported)

PURPOSE: The aims of the study were to: 1) analyze differences in composite metabolic syndrome score (MetScore) and fatness across body mass index (BMI) categories in college students; and 2) to determine whether fit individuals have significantly lower MetScore, fewer individual metabolic syndrome components, and less fatness than unfit individuals in each BMI category. **METHODS**: A total of 1,795 college students (61.4% female, mean age = 20.7 ± 2.9 years old), ranging between the ages of 18 and 30 years participated in the study. Muscular strength was estimated using a hand-held dynamometer and used to classify adults as fit or unfit. A MetScore was computed as a sum of the typified Z-scores per age and gender from the following components: waist circumference, triglycerides, high-density lipoprotein cholesterol, glucose, and systolic and diastolic blood pressure. **RESULTS**: MetScore, percentage of body fat, and visceral adiposity increased linearly across the BMI categories among college students (all $p<0.001$). Individuals who were overweight and fit had lower MetScore (-0.6 SD; P =0.02), body fat percentage (-2.6%; P <0.001) and visceral adiposity (-0.2; P =0.01) than unfit peers. Moderately fit, obese individuals had significantly lower visceral fat levels than unfit, obese peers (-3.0; P =0.03). **CONCLUSIONS**: These results suggest that adequate muscular strength may help to attenuate cardiometabolic risk that is associated with being overweight and obese, and that weight loss could be recommended to all individuals with obesity, including those who are currently defined as fit.

Accelerometer Positioning Issues and Implications for Contemporary Analysis Methods

Kristen M. Metcalf, Jacob E. Simmering, Steven M. Levy, Kathleen F. Janz, FACSM. *The University of Iowa, Iowa City, IA.*
(No relevant relationships reported)

PURPOSE: While accelerometry is widely used to objectively measure physical activity (PA), methods are not standardized. The aim of this work was to understand how accelerometry output (vector magnitude, VM) differs between accelerometers worn on the non-dominant wrist (NDW), dominant wrist (DW), and hip, and if their relationships differ by activity type and intensity.
METHODS: Forty participants (16.8 - 64.2 yr) completed sedentary and PAs in a laboratory while wearing accelerometers on the NDW, DW, and hip. 1-s VM values were compared across locations by activity type and intensity. Oxygen consumption was measured with a portable VO$_2$ analyzer.
RESULTS: The figure shows mean VM for all activities, by increasing intensity. When grouped by intensity, the DW and hip had significantly different VM for light (LPA), moderate (MPA), and vigorous (VPA) PA. The NDW and hip had significantly different VM for LPA and VPA. The DW and NDW had significantly different VM for LPA and MPA.
CONCLUSION: The differing trajectories, and the differential relationships between VM from the NDW, DW, and hip indicate that accelerometer output differ based on activity type and intensity. This non-systematic error prevents scaling or comparing data collected at different wear locations, including the NDW and DW. Additionally, accelerometer data were processed using the accelerometer software. MVPA estimates from the NDW, DW, and hip differed by an average of 13.8 mins (range: 0 - 36), for the 3 hours analyzed. This indicates that substantial error is possible, and analysis methods are not interchangeable across locations. Site-specific analysis methods are needed for accurate, comparable estimates of PA.

Mean Vector Magnitude by Wear Location

Evaluation Of Physical Activity And Sedentary Time In Women Of Varying BMI Using Accelerometers And IPAQ

Samantha Banister, Elizabeth James, Adam Sparks, Travis Gladney, Edna Hamilton, Sankela Dowdell, Kate Early, Clayton Nicks, Brian Tyo. *Columbus State University, Columbus, GA.*
(No relevant relationships reported)

Purpose: To evaluate measures of physical activity in women among varying body mass index (BMI) categories using accelerometers worn on the wrist and thigh. In addition, to determine if measures of sedentary time among women are similar among BMI categories using the International Physical Activity Questionnaire (IPAQ) and an accelerometer worn on the thigh. **Methods**: Thirty five women (24.0 ± 0.7 y) participated in this study. There were 13 normal weight (18.5-24.9 kg m^{-2}), 10 overweight (25.0-29.9 kg m^{-2}), and 12 obese ($\geq$30.0 kg m^{-2}) participants that wore the ActivPal (AP) on the thigh and Actigraph GT3x-BT (AG) on the wrist twenty four hours per day for seven consecutive days. After seven days participants completed the IPAQ. **Results**: The AG recorded significantly more steps per day than the AP within each BMI category ($p<0.01$). There were no differences among BMI categories for physical activity or sedentary time using objective measures ($p>0.05$). There was an insignificant trend for IPAQ Met minutes to increase with higher BMI categories. Sedentary time was similar among BMI categories using IPAQ ($p>0.05$). **Conclusion**: Steps per day may vary depending on the location of the accelerometer which may limit comparisons to other reported findings. Obese groups may tend to report more physical activity when using questionnaires. However, physical activity recorded using objective monitors may tend to find smaller differences among BMI categories. BMI category does not appear to impact measures of sedentary time by objective monitor (AP) or questionnaire (IPAQ).

Comparing Hip and Wrist Accelerometer Estimates of Moderate-Vigorous Physical Activity Across Activity Domains

Mami M. Takeda, Julian Martinez, Sarah K. Keadle. *California Polytechnic State University- San Luis Obispo, San Luis Obispo, CA.* (Sponsor: Todd Alan Hagobian, FACSM)
(No relevant relationships reported)

PURPOSE: Both hip/thigh and wrist-worn accelerometers are used to estimate moderate-vigorous intensity physical activity (MVPA). Few studies have directly compared these MVPA estimates in free-living environments across distinct activity domains. The purpose of this study was to compare AG wrist estimates of MVPA to AG-hip and the thigh-worn AP in five activity domains.
METHODS: Fifteen adults (10F and 5M; age 18-36y) participated in two, 2-hr sessions that were categorized by activity domains; household (H, N=5), active leisure (AL, N=8), sedentary leisure (SL, N=6), work (W, N=7), and transportation/errands (TE, N=4). Participants were given general instructions (e.g., at least 45 min spent on household-related behaviors), but sessions took place in the participants' natural environment. During the sessions, participants wore AG (non-dominant wrist, right hip) and AP on the right thigh. MVPA was estimated for AG-hip using machine learning (S3x), Freedson (F), Crouter (C2), and Sasaki (VM) methods. The AG-wrist data was processed using a random forest (RF). Pearson correlations and paired t-tests were used to compare MVPA estimates across methods. Linear mixed effects models were used to test if there was a significant difference in MVPA estimates between wrist and hip methods across activity domains. P-values <0.05 were considered statistically significant.

RESULTS: Correlation between wrist RF and the hip methods ranged from R=0.63-0.66, while hip/thigh methods were all highly correlated (R=0.94-0.99). The AL domain had the highest time spent in MVPA (between method range: 50.7-60.6 min), while SL (range: 1.3-15.8 min), and W (range: 2.0-23.5 min) were the lowest. Wrist estimates of MVPA were significantly higher than the S3x (+10.8 min), F (+15.3 min), AP (+12.7 min), and VM (+12.1 min), all p<0.01. The estimates of MVPA from the RF were not significantly different than C2, p=0.11. Agreement between methods did not differ by activity domain (p>0.05).
CONCLUSIONS: The wrist RF method was moderately correlated with hip/thigh measures and consistently produced higher estimates of MVPA compared to hip/thigh algorithms, across all activity types. Future research using direct observation as a criterion measures is needed. Supported by Bill and Linda Frost Fund.

Impact Of Placement Of Wrist-worn Activity Monitors During The Lab And Free-living Settings

Minsoo Kang, FACSM[1], Nan Hee Lee[2], Hyun Chul Jung[3], Soeun Jeon[4], Sukho Lee[4]. *[1]The University of Mississippi, University, MS. [2]Georgia Institute of Technology, Atlanta, GA. [3]University of Louisiana at Monroe, Monroe, LA. [4]Texas A&M University-San Antonio, San Antonio, TX.*
(No relevant relationships reported)

Wrist-worn activity monitors have been widely used to measure heart rates, step counts, and/or calories. While the versatility of altering the wearing locations (i.e., left vs. right; distal vs. proximal) may prove appealing, the influence of monitor placement on the outcome measurements needs to be examined. **PURPOSE:** This study was to examine the difference in measurements of heart rates, step counts, and calories estimated from the Fitbit monitors worn at different locations. **METHODS:** Thirty-two healthy male and female, aged 26.03 ± 6.59 years, participated in this study. Participants wore Fitbit monitors at four different locations [Right Proximal (RP), Right Distal (RD), Left Proximal (LP), Left Distal (LD)]. Lab testing consisted of four 5-min phases: slow and brisk walking and jogging at 53.6, 107.3, 160.9 m/min on a treadmill and a recovery. Free living activities involved ten 5-min activities with different intensity levels (e.g., stretching, climbing stairs, jogging). Heart rates, step counts, and calories were recorded during various activities. Repeated measures ANOVAs were performed with a monitor placement as a within-subjects factor on 14 lab and free-living activities for each outcome measurement. Bonferroni technique was used to adjust the alpha level of .004 (.05/14). The Greenhouse-Geisser (G-G) adjusted *F* and degrees of freedom were reported. **RESULTS:** Overall, there were no significant differences in measurements of heart rates, step counts, and calories estimated from the four Fitbit monitors during the lab activities. In free-living activities, step counts were significantly different during climbing stairs, $F(2.86, 88.76) = 5.16$, G-G p = .003 and sports, $F(1.24, 38.40) = 27.93$, G-G p < .001. Step counts estimated from LD (446 ± 49) were significantly higher than Fitbit monitors worn at RP (413 ± 61) and RD (417 ± 49) when climbing stairs. Fitbit monitors worn at LP (649 ± 64) and LD (642 ± 70) estimated significantly higher step counts than Fitbit monitors worn at RP (587 ± 75) and RD (565 ± 73) as participated in sports. **CONCLUSION:** This study revealed that monitor placement does not make a significant influence on the measurements of heart rates and calories during the lab and free-living settings. Further studies on the impact of monitor placement against criterion measures are warranted.

1259   Board #67   May 31 9:00 AM - 10:30 AM

Pregnancy Walking Cadence Does Not Vary By Trimester

Mallory R. Marshall[1], Alexander H.K. Montoye[2], Ashley J. George[1]. *[1]Samford University, Birmingham, AL. [2]Alma College, Alma, MI.*
(No relevant relationships reported)

PURPOSE: Walking is the most commonly reported mode of physical activity among the general population and also among pregnant women. Pregnancy-related changes in walking speed, gait dynamics, and total physical activity have been reported in past research, but free-living step cadences and their rates of change across pregnancy have not been studied. The purpose of this study was to describe free-living stepping cadence in pregnant women and examine differences between second and third trimester women. **METHODS**: Fifty pregnant women were recruited for this study and n=45 was the analytic sample size; 46.7% were in their second trimester (13-25 weeks) while 53.3% were third trimester (≥26 weeks). Participants completed a survey of demographic characteristics and wore an accelerometer on their non-dominant wrist for 7-8 days; they were instructed to wear the device as much as possible during waking hours. These accelerometer data were downloaded in 60-sec epochs, allowing for determination of min-by-min walking cadence, defined as steps/min. Mean steps/day, mean cadence, median cadence, maximum cadence, peak cadence (average cadence over the 30 minutes of highest cadence in each day), mean time spent in moderate- to vigorous-intensity physical activity (MVPA, time spent with cadence ≥100 steps/min), and mean daily time spent in several cadence

ranges (0-9, 10-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70-79, 80-89, 90-99, 100-109. 110-119, 120-129, 130-139, 140-149, 150-159, 160-169, <50, <100, ≥100, and ≥130 steps/min) were calculated for each participant. Between-trimester differences were determined using independent-samples t-tests. **RESULTS**: Average daily steps were 11,060.1±2,955.3; 66.7% of second trimester and 54.2% of third trimester women met daily step recommendations of 10,000 steps/day, but 0.0% of the sample accumulated the recommended 150 min/wk of MVPA. There were no differences by trimester for cadence at any step rate. **CONCLUSIONS**: Overall, pregnant women accumulated high numbers of steps per day but at low cadences; neither daily steps nor cadence varied from second to third trimester. These data suggest that steps and MVPA recommendations are not equivalent and therefore should not be used interchangeably, especially during pregnancy.

Application of Geographic Information Systems (GIS) Methods in Walkability Assessment

Hai Yan, Weimo Zhu, FACSM. *University of Illinois at Urbana Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
(No relevant relationships reported)

PURPOSE: Walkability is a measure of how friendly an area is to walking. Emerging evidence has shown that neighborhood walkability has the potential to increase physical activity and reduce the risk of chronic diseases. Increasing the amount of walking is a prevalent topic for many urban planners and policymakers. A geographic information system (GIS) is a system designed to capture, store, manipulate, analyze, and present spatial or geographic data and it offers good promise for walkability assessment. The purpose of this study was to provide a systematic overview of the applications of GIS in the measurement of walkability. **METHODS**: Keyword and reference searches were conducted in PubMed and Web of Science, and the inclusion criteria included: (1) study design: cohort studies, pre-post studies, or cross-sectional studies; (2) research topic: walkability assessment through geographic information systems (GIS) methods; (3) language: articles written in English; and (4) article type: peer-reviewed articles or theses. A total of 397 articles were identified in the search, among which 328 were excluded in the title and abstract screening and 15 were excluded after full-text review. The remaining articles (n = 54) were carefully evaluated and results were summarized. **RESULTS**: The primary applications of GIS data/methods in the walkability-related research included (1) visualization of the spatial distribution of roads, walking trails, and basic environmental features; (2) construction of advanced walkability environmental indicators; and (3) assessment and comparison of the walkability of the built environment. Study design and features, including population density, street pattern, land-use mix, access to recreational facilities, varied considerably across studies, and this is probably because of lack of established guidelines and protocols in this field. Meanwhile, unique features of GIS methods such as relating information from different sources and capability of collaborating with pedometer data had a very promising future in measuring walkability. **CONCLUSIONS**: The GIS-based approach has great potential to supplement walkability assessment. However, there is still little evidence supporting the efficacy of GIS, and more studies investigating this promising area of research are called for.

1261   Board #69   May 31 9:00 AM - 10:30 AM

Moderate And Vigorous Intensity Walking Cadence (Steps/min) Thresholds In 41-60 Year Old Adults

Catrine Tudor-Locke, FACSM[1], Elroy J. Aguiar[1], Scott W. Ducharme[1], Christopher C. Moore[1], John M. Schuna, Jr.[2], Tiago V. Barreira[3], Stuart R. Chipkin[1], John Staudenmayer[1]. *[1]University of Massachusetts Amherst, Amherst, MA. [2]Oregon State University, Corvalis, OR. [3]Syracuse University, Syracuse, MA.*
(No relevant relationships reported)

Research establishing a strong relationship between cadence (steps/min) and intensity has primarily been conducted with young adult samples. **PURPOSE:** To identify reasonable heuristic (evidence-based, rounded, practical) cadence thresholds associated with absolutely-defined moderate (3 metabolic equivalents; METs) and vigorous (6 METs) intensity ambulation in middle-aged adults. **METHODS:** Ten men and 10 women from each 5-year age group between 41-60 years of age performed a series of 5-min treadmill bouts separated by 2-min rest. Bouts began at 0.5 mph and increased in 0.5 mph increments until participants: 1) chose to run, 2) achieved 75% of their predicted maximum heart rate, or 3) reported a rating of perceived exertion (RPE) > 13. Cadence was determined via direct observation. Oxygen consumption (VO_2) was measured using an indirect calorimeter. METs were calculated from the final two minutes of each stage by dividing VO_2 in mL/kg/min by 3.5. Receiver Operator Characteristic (ROC) models were used to predict moderate and vigorous intensity from cadence. Optimal cadence thresholds were identified using Youden's index. The cadence-intensity relationship was also quantified using a segmented regression model with random coefficients. Optimal positive predictive values of candidate thresholds were assessed to determine final heuristic values. **RESULTS:** Data were complete for

all 80 participants (40 men, 40 women; age=50.2±5.9 years; BMI=26.0±4.0 kg/m²; height=171.0±9.2 cm). ROC cadence thresholds for moderate and vigorous intensity were 98.5 and 117.3 steps/min, respectively. All sensitivity values were over 90% and all specificity values were over 80%. The relationship between cadence and METs was explained by two distinct linear regression trends displaying a breakpoint at 97.6 steps/min. Cadence explained 78% of the overall variance in intensity. Cadence thresholds (95% Prediction Intervals) for 3 METs and 6 METs were 101.7 (54.9 - 111.8) and 132.1 (122.0 - 142.2) steps/min, respectively. Heuristic values for moderate and vigorous intensity were 100 and 130 steps/min, respectively. **CONCLUSIONS:** Cadences of 100 and 130 steps/min are reasonable heuristic values respectively identifying moderate and vigorous intensity walking in middle-aged adults.

1262   Board #70   May 31 9:00 AM - 10:30 AM

Comparison of Physical Activity Guideline Compliance Estimates Among Active Youth Using Different Step-Based Definitions

John M. Schuna, Jr., Yu Meng, Melinda M. Manore, FACSM, Siew Sun Wong. *Oregon State University, Corvallis, OR.*

(No relevant relationships reported)

Among youth, several investigations have quantified steps/day thresholds corresponding to compliance with current physical activity guidelines (≥ 60 min/day of moderate-to-vigorous physical activity [MVPA]) while other reports have identified cadence (steps/min) cut-points consistent with MVPA. However, empirical applications of these two methods for use in estimating compliance to current physical activity guidelines are scant within the literature. **PURPOSE:** To compare physical activity guideline compliance estimates using steps/day thresholds and step-defined MVPA methods among a sample of active adolescents. **METHODS:** Step-based physical activity was assessed minute-by-minute using the waist-worn Fitbit Zip™ over a 7-day period among 291 adolescent soccer players (64.9% female, age: 15.2 ± 1.2 yrs, BMI: 22.1 ± 3.4 kg/m²) providing ≥ 4 days of valid data (≥ 10 hr/day of wear time). Compliance to current physical activity guidelines was quantified as: 1) mean steps/day ≥ 10,500 for boys or ≥ 9,500 for girls, and 2) mean step-defined MVPA (time spent at 100+ steps/min) ≥ 60 min/day. Compliance estimates were compared between methods using McNemar's test. **RESULTS:** Participants accumulated 11,100 ± 3,217 steps/day (boys: 12,201 ± 3,543 steps/day; girls: 10,506 ± 2,865 steps/day) and 36.9 ± 16.8 min/day of step-defined MVPA (boys: 42.9 ± 18.7 min/day; girls: 33.7 ± 14.8 min/day). Compliance to current physical activity guidelines among the overall sample significantly varied between the steps/day thresholds and step-defined MVPA methods (63.2% and 9.6%, respectively; χ^2 = 154.0, p < 0.001). Within sex compliance estimates also varied for the steps/day thresholds and step-defined MVPA methods among boys (65.7% and 15.7%, respectively; χ^2 = 49.0, p < 0.001) and girls (61.9% and 6.3%, respectively; χ^2 = 103.0, p < 0.001). **CONCLUSION:** Significant heterogeneity in physical activity guideline compliance estimates was observed between the steps/day thresholds and step-defined MVPA methods. It is possible that the sporadic nature of physical activity observed among youth is being obscured by the 1-min measurement epoch used herein, thereby lowering expected values of daily step-defined MVPA and associated physical activity guideline compliance estimates. Support: USDA-AFRI 2013-67001-20418

Physical Activity Category Classification Using The Actigraph Gt9x In Youth

Samuel R. LaMunion, Paul R. Hibbing, Andrew S. Kaplan, Scott E. Crouter, FACSM. *University of Tennessee, Knoxville, TN.*

(No relevant relationships reported)

The ActiGraph GT9X includes an inertial measurement unit (IMU) equipped with a triaxial gyroscope which has been shown to be a perfect classifier of sedentary behavior (SB) in adults. To date, there has been no research to explore the application of the gyroscope in youth. **PURPOSE:** The purpose of this study was to compare the use of the accelerometer and gyroscope for classifying SB and continuous walking and running (CWR) in youth. **METHODS:** Participants (N=52, mean±SD; age, 13.3±3.1 years; BMI, 20.5±5.0 kg/m²) completed sixteen activities ranging from SB to vigorous intensity. Activities were grouped as SB (lying, computer gaming, internet, reclining, and book reading), CWR (fast over-ground walking, slow over-ground walking, and over-ground running), and intermittent activities (e.g. stair walking, sweeping, stationary cycling, basketball). A GT9X was worn on the right hip, both wrists, and both ankles. Primary accelerometer data were sampled at 90 Hz and converted to the Euclidean norm minus one (ENMO) in milli-G's per second. Gyroscope data were sampled at 100 Hz and converted to vector magnitude (GVM) and reported in mean degrees per second. ENMO and GVM were assessed for classifying the following: 1). SB from all other activities and 2). SB first, then CWR from the remaining 11 activities using the mean coefficient of variation (CV) per 10-s. Thresholds were developed using receiver operating characteristics (ROC) Performance was assessed using area under the curve (AUC), sensitivity, and specificity. Performance **RESULTS**: ENMO and GVM classify SB well across all attachment sites (AUC ≥ 95.7%).

When classifying CWR after removing SB, ENMO CV had AUC between 85.0%-87.9%, while GVM was lower and more variable with AUC between 53.3%-74.7%. **CONCLUSION**: Overall, ENMO and GVM are excellent classifiers of SB in youth across all attachment sites. GVM is less effective than ENMO for classifying CWR, but has potential for future use and should continue to be explored.

	Site	Threshold ENMO	Threshold GVM	Sensitivity ENMO	Sensitivity GVM	Specificity ENMO	Specificity GVM	AUC ENMO	AUC GVM
SB	Hip	36.46	8.25	0.90	0.92	0.91	0.92	95.70	96.90
SB	Left Wrist	24.09	13.87	0.92	0.90	0.94	0.92	97.50	96.00
SB	Right Wrist	26.02	18.46	0.90	0.87	0.95	0.93	96.50	95.60
SB	Left Ankle	50.21	10.21	0.96	0.95	0.93	0.93	97.70	98.00
SB	Right Ankle	62.20	11.48	0.93	0.93	0.94	0.94	97.90	98.00
CWR	Hip	17.65	57.21	0.81	0.55	0.91	0.56	85.00	53.30
CWR	Left Wrist	27.35	49.31	0.82	0.51	0.87	0.67	86.30	59.10

Validation of Automatic Activity Detection on Wearable Activity Trackers

Diana Dorn, Ronald Gangnon, Jessica Gorzelitz, David Bell, Kelli Koltyn, FACSM, Lisa Cadmus-Bertram. *University of Wisconsin Madison, Madison, WI.* (Sponsor: Dane Cook, FACSM)

(No relevant relationships reported)

Purpose: If sufficiently valid, wearable activity trackers are promising tools for health-related research. Recent models claim to identify the type of activity being performed, but no studies have reported the validity of these features. The purpose of this study was to determine the accuracy of automatic activity detection on 4 wrist-worn, physical activity trackers; specifically, the correct type, duration, and start time of select activities.
Methods: 69 healthy adults were recruited via flyer, email, or word of mouth to complete at least one of four activity modules, comprised of activities automatically detectable by the trackers. Module A, completed on a treadmill, consisted of 3 activities separated by a 10-min rest (15-min walk, 15-min run, and 25-minute continuous series of 5-min walk, 15-min run, 5-min walk). Module B, consisted of 3 activities separated by a 10-min rest (15-min outdoor walk, 15-min outdoor run, and 15-min bout on an elliptical trainer). Module C consisted of 15 min of outdoor cycling and Module D consisted of 15 min of freestyle swimming (only one tracker was used in Module D as others are not waterproof). The actual activity type, duration, and start/stop times were recorded, then compared to device data (recognized activity type, duration, and start times).
Results: Participants (N=69) were 26.3 ± 8.7 years old, had a BMI of 23.8 ± 4.0 kg/m², and were 60.9% female. Participants reported an average rating of perceived exertion of 11.9 (6 - 19). The percentage of correctly identified activities by the four trackers was 94.7% (93.5 - 97.1) for treadmill walking, 97.7% (93.8 - 100.0) for treadmill running, 45% (35.3 - 59.4) for running in the treadmill series, 97.8% (97 - 100) for outdoor walking, 100% for outdoor running, 70.4% (3.1 - 93.9) for the elliptical, 83.1% (44.1 - 97.1) for outdoor cycling, and 87.5% for swimming. Lower accuracy for the elliptical was driven down by a low accuracy of 3.1% for one tracker.
Conclusion: The four wearable activity trackers were best at detecting outdoor running and worst at detecting running in the 25-minute treadmill series. Overall, the trackers were better at detecting ambulatory activities, apart from running in the treadmill series, than detecting swimming, cycling, or using an elliptical. This research was funded through startup funds through UW - Madison.

Dominant Vs Non-dominant Wrist: A Comparison Of Steps Per Day

Susan Park. *University of Tennessee, Knoxville, TN.* (Sponsor: David R Bassett Jr. PhD, FACSM)

(No relevant relationships reported)

With the increased popularity of activity monitors over the past decade, step counting has become a prevalent method of assessing physical activity. Although most manufacturers suggest to wear monitors on the non-dominant (ND) wrist, some consumer-grade devices can be initialized to be worn on the dominant (D) wrist. Only one study has compared the step count accuracy of devices worn on the D and ND wrists across various treadmill speeds and it found no significant differences between the D and ND wrist step counts. However, the effect of D vs ND wear on step count may be different under free-living conditions. **PURPOSE:** To compare

step counts between D and ND wrist-worn devices and hand-counted steps, under free-living conditions. **METHODS:** Twelve participants (mean±SD, age 35±13 years) wore an ActiGraph GT9X and Fitbit Charge (FC) on the D and ND wrists. The FC was initialized for each participants' D or ND wrist. A GoPro was affixed to the participant's chest and pointed down at the feet to video record the steps taken during all waking hours of one day and hand-counted steps from the video served as the criterion. Raw GT9X data were processed with the ActiLife step counting algorithm, with and without low frequency extension (AGL and AG, respectively), as well as the company's Moving Average Vector Magnitude algorithm (AGM). Fitbit step counts were recorded by the participant at the beginning and end of the day and used to obtain steps/day. Repeated measured ANOVAs were used to compare estimates between devices (AGL, AG, AGM, FC) and wrists (D and ND). For each step counting method, accuracy was determined by calculating percent of hand-counted steps. **RESULTS:** There was no significant device x wrist interaction (p<0.05). Across all step counting methods, there was a significant difference in steps per day between D and ND wrist $(F(1,11)=11.81, p=0.006)$ with the D wrist recording 1,253 more steps than the ND wrist. Percent of hand-counted steps for devices worn on the D wrist were: FC: 4%, AG: 122%, AGL: 220%, AGM: 91% and for ND wrist: FC: 77%, AG: 109%, AGL: 196%, AGM: 84%. **CONCLUSION:** Users of activity monitors should be aware of the differences in steps per day when using the D and ND wrists, even for the devices that allow the user to enter the appropriate wrist location during initialization.

Revising Free Text Inputs In Physical Activity Self-report Methods: Lessons From The ACT24

Robert W. Korycinski[1], Brian Barrett[2], Kelley Pettee Gabriel, FACSM[3], Heather R. Bowles[1]. [1]National Cancer Institute, Bethesda, MD. [2]Information Management Services, Inc., Rockville, MD. [3]University of Texas Health Science Center at Houston, Austin, TX.
(No relevant relationships reported)

PURPOSE: To examine the change in total Metabolic Equivalent of Task (MET) minutes reported by the Activities Completed over Time in 24 Hours (ACT24) physical activity self-report tool for different activity types after recoding free text entries and assigning updated MET values. **METHODS**: Men and women aged 50-70 years participating in a measurement error study on diet and physical activity were administered 6 ACT24 recalls spaced evenly over 12 months. Participants that completed at least 1 recall (n=1,023) were included in the analyses. Free text activity entries were recoded and either assigned to an existing ACT24 activity category or placed into a new activity category. Recoded free text activities, pre-defined activities, and gaps (no information recorded) were then assigned MET values from the 2011 Compendium of Physical Activities. The subsequent change in MET minutes was calculated after each of these adjustments. **RESULTS**: Participants completed 5,311 ACT24 recalls, of which 2,712 (51.1%) contained at least 1 free text entry; free text entries constituted less than 5% of all activities. Recoding free text entries increased the total reported MET minutes by 0.004% (+434.8 MET minutes), and applying the updated compendium values to all entries further increased the total by 6.3% (+743,920.9 MET minutes). Recoding free text had the largest positive effect for the "caring for or playing with others" activity category (+36.3%, or +6,455.1 MET minutes), and the largest negative effect for the "shopping, errands, and appointments" activity category (-15.4%, or -4,925.0 MET minutes). Updating MET values had the largest positive effect on "bicycle repairs" (+81.9%, or +1,226.5 MET minutes), and the largest negative effect on "covering plants" (-49.0%, or -202.0 MET minutes), although these activities were rarely reported (12 and 3 times, respectively). **CONCLUSIONS**: Recoding free text activities negligibly changes the total MET minutes reported in the ACT24, although more dramatic adjustments do occur within certain specific activity categories. Presence of free text is a data management burden that may provide little additional information, and efforts should be made for best activity classification in instrument design to eliminate the need for free text.

Diurnal Patterns of Physical Activity Illustrate Important Time-of-Day Differences Between Younger and Older Adults.

Nicolas D. Knuth[1], Jennifer A. Schrack[2], Devon A. Dobrosielski[1]. [1]Towson University, Towson, MD. [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.
(No relevant relationships reported)

Physical activity is an important risk factor for disease and functional outcomes across the age spectrum. Measurement of objective physical activity by accelerometry has become common in recent years and is often reported as total or average daily physical activity. However, accelerometry data provides the opportunity to also quantify differences in diurnal patterns of physical activity that may elucidate contributors to changes in physical activity with aging. **PURPOSE:** To evaluate differences in objectively measured PA, overall and by time of day, between younger and older

adults. **METHODS:** Physical activity (PA) was measured using wrist-worn ActiGraph accelerometers continuously over 7 days in 58 older adults (50% women, aged 72±6 yrs) and 56 younger adults (54% women, age 21±2 yrs), and body composition was measured using dual energy x-ray absorptiometry. PA data was smoothed into one-minute intervals and expressed as the vector magnitude of counts (VMC) per minute across the three axes. Diurnal patterns of activity were modeled as the average VMC over six 4-hour time bins. Subjects were categorized by age group (young or old), and the association between the mean of the VMC and age group was modeled overall and across each time bin using linear regression, adjusting for sex, fat-free mass, and fat mass. **RESULTS**: Total 24-h PA was lower in older adults compared to younger adults $(2.1 \times 10^6 \pm 0.8 \times 10^6$ vs. $2.8 \times 10^6 \pm 0.9 \times 10^6$ VMC, p < 0.0001). However, when examining diurnal patterns, early morning (4:00am-8:00am) and morning (8:00am-noon) PA was higher in older adults compared to younger adults (p<0.001 for each period) in fully adjusted models. In the remaining time bins, younger adults had higher PA than older adults (p<0.01 for each period). **CONCLUSION:** Consistent with previous studies, total daily PA was lower in older adults compared to younger adults. Importantly, examining PA across the day highlighted significant differences in activity volumes between younger and older adults that provide evidence to inform future interventions to improve PA profiles in both younger and older individuals.

Organized Physical Activity Participation From Pre-puberty To Adulthood: A Longitudinal Study In U.S. Females

Jodi N. Dowthwaite[1], Stephanie A. Kliethermes[2], Jill A. Kanaley, FACSM[3], Tamara A. Scerpella[2]. [1]SUNY Upstate Medical University; Binghamton University, Syracuse, NY. [2]University of Wisconsin, Madison, Madison, WI. [3]University of Missouri-Columbia, Columbia, MO. (Sponsor: Jill Kanaley, FACSM)
(No relevant relationships reported)

PURPOSE: Physical activity yields health benefits across the lifespan. Longitudinal data are needed to evaluate translation of childhood activity patterns to adult activity habits. We hypothesized that activity patterns would differ in gymnasts (GYM) vs. non-gymnasts (NON), and childhood activity would correlate with young adult levels. **METHODS**: Female GYM and NON were recruited in 3 cohorts: 1997/8, 2003/4, 2008-12. Organized physical activity participation (OPA h/wk) was recorded to yield annual means, excluding physical education. Pediatric OPA was recorded quarterly (1997-1999) and semi-annually (1999-2017), with parental assistance as needed. After age 18 yrs, OPA was recorded annually. GYM were defined by training ≥6 h/wk for ≥1 yr. Separate GYM and NON OPA curves were generated using cubic smoothing spline mixed effect models with 95% confidence intervals (Fig 1a, chronological age: CA; Fig 1b, gynecological age: GA, centered at menarche= time 0). Intra-individual (intraclass) correlation coefficients were evaluated (ICC). **RESULTS**: Data are included for 211 girls. GYM OPA is highest circum-menarche, peaking before high school (GA -2 to +1 yrs; CA 10-15 yrs). NON OPA is highest post-menarche, during high school (GA 0 to +5 yrs; CA 14-17 yrs). GYM OPA is significantly higher than NON throughout school and peak lean mass accrual, but curves converge at GA +3 yrs or CA 18 yrs. Inter- and intra-subject variability was higher in GYM (10.4; 22.7) than NON (4.7; 8.6), with similar, medium effects for ICC (GYM= 0.32, NON= 0.35), suggesting activity level tracking across growth. **CONCLUSIONS**: GYM are active early and maintain high activity throughout growth, while NON increase OPA parallel with middle & high school sport programs. OPA dropped in both groups after high school. These data suggest that girls who start life active maintain high activity. Our data likely represent "health-conscious" individuals; future research is needed in more generalizable cohorts.

Predicting Resistance Training Exercise Repetitions Using A Wrist-worn Activity Monitor

Scott A. Conger[1], Jun Guo[1], Kenzie Mercier[1], Cameron D. Needham[1], Clare Zamzow[1], Christopher Mecham[1], Hao Chen[1], David R. Bassett, Jr., FACSM[2]. [1]Boise State University, Boise, ID. [2]University of Tennessee, Knoxville, TN.
(No relevant relationships reported)

While wrist-worn physical activity monitors have been used to quantify exercise volume for aerobic activities, limited research has utilized activity monitors to quantify resistance training exercises. **PURPOSE**: The purpose of this study was to develop an improved method for predicting repetitions during resistance training exercises. The validity of this method was tested during an unstructured training session. **METHODS**: While wearing a wrist-worn, accelerometer-based activity monitor, 144 participants (73 M, 71 F) completed 12 different upper- and lower-body dumbbell resistance training exercises. Each participant completed one set of 12 repetitions using a lightweight (<7 kg) set of dumbbells. This data was used to develop a repetition counting algorithm by comparing minimum and maximum values for the largest X, Y, or Z plane acceleration peak/valley during each exercise. Participants were then asked to complete an unstructured, free-living resistance training exercise session. Within the training session, they were asked to complete at least one set of at least five reps of the original 12 dumbbell resistance training exercises used in the algorithm development phase of the study. A research assistant observed the training session and recorded details about the exercises, resistance, and repetitions for each exercise. A mixed-model RM ANOVA was utilized to compare the predicted repetitions to the observed repetitions for the 12 exercises. Pairwise comparisons with Bonferroni adjustment were utilized to identify the location of differences. **RESULTS**: During the free-living training sessions, a total of 2293 sets of the 12 dumbbell exercises were completed by the study participants. Mixed-model RM ANOVA indicated a significant main effect ($p<0.05$). Post-hoc analysis indicated significant differences between the predicted and observed repetitions for five of the 12 exercises. However, the differences for all exercises were within 1.2 repetitions of the actual repetitions. Across all exercises, the predicted algorithm was within 0.3 repetitions of the actual repetitions (range: 0.0 to 1.2 reps). **CONCLUSION**: While some significant differences occurred for five of the 12 exercises, the repetition prediction model was a valid method for predicting repetitions for the selected dumbbell exercises.

Modifying Accelerometer Cut-points Affects Criterion Validity in Free-living Youth and Adults

Paul R. Hibbing, David R. Bassett, FACSM, Scott E. Crouter, FACSM. University of Tennessee, Knoxville, TN.
(No relevant relationships reported)

In accelerometer-based physical activity (PA) measurements, it is common to scale a cut-point so it can be applied to data with a shorter epoch length. For example, 2020 counts per min (60-s epochs) could be divided by 4, giving 505 counts per 15 sec (15-s epochs). Researchers assume that scaling to a shorter epoch results in more moderate-to-vigorous PA (MVPA), compared to long epochs. However, no studies have compared modified estimates to a criterion measure (CM) of indirect calorimetry. **PURPOSE:** To assess the criterion validity of accelerometer estimates when using cut-points as intended (i.e. the epoch length for which they were originally developed, usually 60-s), versus modifying them for use with a different epoch length. **METHODS:** Free-living data were collected in 53 youth (2 hr each) and 29 adults (6 hr each) wearing a hip-worn accelerometer and a portable indirect calorimeter. Measured oxygen consumption (VO_2, $mL \cdot kg^{-1} \cdot min^{-1}$) was converted to metabolic equivalents (METs), by dividing by measured resting VO_2 (youth) or $3.5 mL \cdot kg^{-1} \cdot min^{-1}$ (adults). METs were then coded as sedentary behavior (SB, METs ≤ 1.5), light PA (LPA, 1.6-2.9 METs), and MVPA (METs ≥ 3.0). Accelerometer data were processed using 3 youth and 3 adult cut-points as intended, plus 5 other epoch lengths, totaling 6 estimates (1, 5, 10, 15, 30, and 60-s epochs). Mean SB, LPA, and MVPA times were compared to the CM using one-way repeated measures ANOVAs and Bonferroni-adjusted post-hoc tests. **RESULTS:** For youth, mean MVPA time in shorter epochs was further from the CM than when using the cut-points as intended, and 1- and 5-second epochs differed significantly from the CM by 23.7%-62.7% for all cut-points ($p \leq 0.04$). In contrast, for adults, mean MVPA time using shorter epochs was closer to the CM than when using cut-points as intended, although all estimates differed non-significantly by 6.6%-50.9% ($p = 0.10$-0.99). For both groups, mean SB and LPA time when using cut-points as intended differed non-significantly from the CM by 7.3%-41.0% ($p > 0.05$), while using shorter epochs led to significant differences in some cases. **CONCLUSION:** Modifying cut-points led to variable error for different intensities in youth and adults. Therefore, it is most appropriate to use accelerometer cut-points as intended, which also ensures comparability between studies.

1271   Board #79   May 31 9:00 AM - 10:30 AM

Harmonizing Physical Activity Data across Cohorts in the Lifetime Risk Pooling Project

Amanda E. Paluch[1], John T. Wilkins[1], Kelley Pettee Gabriel, FACSM[2], Victor W. Zhong[1], Donald M. Lloyd-Jones[1], Mercedes R. Carnethon[1]. [1]Northwestern University, Chicago, IL. [2]University of Texas Health Science Center, Houston, TX.
(No relevant relationships reported)

PURPOSE: The Cardiovascular Lifetime Risk Pooling Project (LRPP) is an individual-level pooled data set from 20 U.S. cohort studies. LRPP is used to describe the development of cardiovascular disease (CVD) risk across decades of follow-up and different race and sex groups. Many of the cohorts have participant-reported physical activity (PA); however, before PA data can be used in pooled cohort analyses we must harmonize the original units (i.e. convert to a common scale and distribution). **METHODS**: We tested the feasibility for harmonization of moderate-vigorous intensity PA (MVPA) using 8 of 20 the cohorts (ARIC, Atherosclerosis Risk in Communities; CARDIA, Coronary Artery Risk Development in Young Adults; CHS, Cardiovascular Health Study; FHS, Framingham Heart Study; FOS, Framingham Offspring Study; JHS, Jackson Heart Study; MESA, Multi-Ethnic Study of Atherosclerosis; and WHI, Women's Health Initiative). We recomputed MVPA variables with varying degrees of granularity ranging from MET-min/week, cohort specific z-scores, and a dichotomous variable of active (meeting 2008 PA Guidelines) vs. insufficiently active (not meeting guidelines). To examine concurrent validity, we examined unadjusted cross-sectional associations of MVPA (at first visit with PA data) with BMI separately in all 8 cohorts and then pooled. **RESULTS**: When evaluating the concurrent validity of MVPA variables with BMI, 7 of the 8 cohorts demonstrated similar inverse associations with BMI (CHS, MESA, CARDIA, FOS, FHS, JHS, ARIC; pooled z-score: n=46865, β= -0.53, CI -0.58 - -0.47, p<.0001). Harmonization of MET-min/week was possible for 2 cohorts (CHS, MESA; n=11965, median=846.3, q1=241.9, q3=2004.6); and dichotomous variable for 3 cohorts (CHS, MESA, CARDIA, n=17106, 62% meeting 2008 PAGs). **CONCLUSIONS**:A cohort specific z-score allows for inclusion of a reliable measure of MVPA to be pooled from most cohorts. Detailed PA research on specific patterns and doses is possible within the subset of cohorts with more granular measures available. We plan to harmonize additional cohorts and develop and test the validity of other variables for use in the LRPP. This harmonization provides a valuable dataset to explore longitudinal patterns in PA and their associations with the development of CVD across the life course in a large, diverse cohort.

Automated Detection of Wheelchair Propulsion Using a Single Wrist Accelerometer

Matthew N. Ahmadi[1], Kati Karinharju[2], Sjaan Gomersall[2], Kelly Clancy[3], Sean Tweedy[2], Stewart G. Trost, FACSM[1]. [1]*Queensland University of Technology, Brisbane, Australia.* [2]*University of Queensland, Brisbane, Australia.* [3]*Griffith University, Gold Coast, Australia.* (Sponsor: Stewart G. Trost, FACSM)

(No relevant relationships reported)

Purpose: Physical activity (PA) provides important health benefits such as improved cardio-metabolic health, mental health, and cognitive functioning. However, the majority of this evidence is based on research conducted in ambulatory populations. Research informing the relationship between PA and health among manual wheelchair users (MWU's) is limited. One of the barriers is the lack of valid and reliable PA measures for the population. In the current study, machine learning (ML) techniques were used to develop activity recognition models to automatically identify episodes of active self-propulsion in manual MWU's wearing a single wrist-mounted accelerometer.
Methods: 11 adult MWU's (males= 8; 7 paraplegic; 4 tetraplegic) completed a series of activity trials while wearing an ActiGraph GT9X accelerometer on the non-dominant wrist. Activities included: sitting quietly, being pushed, self-propulsion, and completing manual tasks such as drinking water, working on an iPad, and folding laundry. Trials were categorised into 3 classes: sedentary (SED), manual tasks (MT), and self-propulsion (SP). 15 time-domain features from the X, Y, and Z axis were extracted from 1 s windows with 50% overlap and inputted into 3 supervised learning algorithms Decision Tree (DT), Random Forest (RF), and Support Vector Machine (SVM). Performance was evaluated using leave-one-subject-out (LOSO) cross validation. To determine if the resultant models generalized to new data, performance was also evaluated in an independent sample of MWU's (n = 14).
Results: Cross-validation F1-scores for the DT, RF, and SVM classifiers were 0.83, 0.84 and 0.85, respectively. Classification accuracy was consistently good to excellent for SED (86.0% - 92.7%), MT (76.0% - 82.4%), and SP (76.0% - 76.8%). In the independent sample, F1-scores for the DT, RF, and SVM classifiers were, 0.80, 0.81, and 0.82, respectively. Classification accuracy remained good to excellent for SED (83.9% - 92.0%), MT (70.5% - 79.3%), and SP (74.2% - 77.6%)
Conclusion: ML models trained on simple time-domain features from a single wrist-worn accelerometer can be used to differentiate active self-propulsion from other activities in MWU's. The models generalized well to new data and could help researchers evaluate the effectiveness of interventions to promote PA in MWU's.

Validity And Reliability Of The Past Questionnaire Among Women

Brian Tyo, Kate Early, Clayton Nicks, Travis Gladney, Edna Hamilton, Elizabeth James, Adam Sparks. *Columbus State University, Columbus, GA.*

(No relevant relationships reported)

Purpose: To determine the validity and reliability of the Past-day Adults' Sedentary Time (PAST) questionnaire using the activPAL (AP) as the criterion measure.
Methods: Thirty four women (23.7 ± 4.6 y; 25.4 ± 6.2 kg m⁻²) wore the AP on the thigh and Actigraph GT3x-BT (AG) on the wrist for twenty four hours. The PAST was administered the day after the assessment day (T1) and within twenty four hours of T1 (T2). The AG was used to determine sleep time for the day assessed, which was then subtracted from the total sit/lie time recorded by the AP (sit/lie time-sleep time) to determine total sedentary time. Spearman correlation coefficients and Bland-Altman plots were calculated to determine validity and reliability of the PAST using AP. **Results:** The correlation between T1 and T2 for all PAST questions demonstrated good positive correlations ($p< 0.001$) including total sedentary time except for the last question on "sitting/lying for other purposes" which was fair ($r= 0.431$, $p=0.011$). The Bland-Altman plot revealed a mean difference of 33.7 minutes of T2 and T1 of the PAST with no significant bias ($p> 0.05$). However, using the AP as the criterion the mean difference for T1 (T1-AP) was 167.0 mins while the mean difference for T2 (T2-AP) was 200.7 mins with both demonstrating significant positive bias ($p≤0.001$).
Conclusion: The PAST is a reliable instrument when re-administered within twenty four hours. However, participants tend to over-report their sedentary time especially once reported sedentary time is >600 minutes per day. Therefore, researchers should be cautious when using the PAST in populations that report a high amount of sedentary time (e.g., >600 minutes).

1274 Board #82 May 31 9:00 AM - 10:30 AM

Comparing Accelerometry Methods in an Older Adult Physical Activity Intervention and Associations with Health Outcomes

Katie Thralls[1], Suneeta Godbole[2], Todd Manini, FACSM[3], Eileen Johnson[4], Jacqueline Kerr[2]. [1]*San Diego State University/ Univeristy California San Diego, San Diego, CA.* [2]*Univeristy California San Diego, San Diego, CA.* [3]*Univeristy of Florida, Gainesville, FL.* [4]*Univeristy California Berkeley, Berkeley, CA.*

(No relevant relationships reported)

BACKGROUND: Advancements in accelerometry have led to different methods to process the data for physical activity (PA) in older adults.
PURPOSE: The purpose of this study was to: 1.) Compare five different methods for analyzing PA in older women; 2.) Assess the relationship between changes in PA and changes in physical function and depressive symptoms over six months for each analysis method.
METHODS: Older adult females (N=144, M_{age} = 83.3 ± 6.4yrs) wore a hip accelerometer for 6 days and completed measures of physical function and depressive symptoms at baseline and 6 months. Accelerometry data were processed by 5 different methods to estimate PA: a 1041 vertical axis cut point, a 15-sec vector magnitude (VM) cut point (Evenson), a 1-sec VM algorithm (Activity Index) , a machine learned (ML) algorithm from 39 features, and an individualized cut point derived from the median counts of rapid 400-meter walk. Generalized estimating equations and a confusion matrix were used to compare and contrast PA minutes/day. Linear mixed models for each processing method tested the associations between changes in PA and changes in physical function and depressive symptoms.
RESULTS: Baseline comparisons between methods for minutes/day of PA and for each minute of PA are in Table 1. There were significant differences between some methods but not others, and methods estimated 6-month change in PA from 4 minutes to over 20 minutes. All methods, except the individualized cut point had a significant positive relationship between change in PA and improved physical functioning. There was also a significant relationship between changes in PA and decreased depressive symptoms for all methods except the individualized cut point.
CONCLUSIONS:
Time spent in PA differs by the choice of data processing method. Results from individualized cut points are counter to methods that use absolute cut points. Additional research is needed to understand these discrepancies.

Table 1.					
Confusion Matrix for each method with percent (%) overlap between methods for each minute of PA and differences (*) between methods for total minutes/day at baseline					
Method	Individual 400MW	Evenson	Activity Index	1041cpm	ML
Individual 400MW		31%*	25%*	42%*	17%*
Evenson			61%	69%*	42%*
Activity Index				63%	60%
1041cpm					43%
ML					

Note. * indicate significant differences based on total minutes/day ($p<.05$); cpm: counts per minute; ML: Machine Learned; MW: meter-walk

Accuracy And Reliability Of A Consumer-grade Activity Tracker Among Older People: A Pilot Study

Catherine Patrick, Michael A. Smith, Antonio Harris, Melissa Powers. *University of Central Oklahoma, Edmond, OK.*

(No relevant relationships reported)

Activity trackers are popular devices used to track and encourage physical activity; although the accuracy of activity trackers among older people is unknown.
PURPOSE: The purpose of this pilot study was to evaluate the accuracy and reliability of step counts from a consumer-grade activity tracker by comparing step counts to a research-grade accelerometer and video recording. **METHODS:** Ten volunteers (mean age = 71.20±6.00 years) agreed to participate. Two participants did not complete the second round of testing. Researchers collected height, weight, and age. The activity tracker and accelerometer were set-up using manufacturer's procedures. Participants wore the activity tracker and accelerometer as they walked 96 meters around an indoor gym floor at their normal walking pace. The walk was also video recorded to determine observational step count confirmed by two researchers. The same procedures were repeated on a second, non-consecutive day. Data collected from the activity tracker were compared to the accelerometer and observed step count. In addition, step counts from the first walk were compared to step counts from the second walk. **RESULTS:** At

the first walk, the activity tracker was found to significantly underestimate step counts by 16.00 steps when compared to the observed step count, $t(7) = -2.69$, $p = .031$. The activity tracker step count was not different than the accelerometer step count. At the second walk, no differences in step counts were observed between the activity tracker and the accelerometer or the observed step count ($p > .05$). In addition, no differences in step counts were observed between walk 1 and walk 2 using the activity tracker, accelerometer, and observed step count. **CONCLUSION:** Although preliminary, these data indicate fair accuracy and good reliability of a consumer-grade activity tracker when compared to the research-grade accelerometer and observed step count. We suggest this pilot study be extended to include additional participants and comparisons of other activity trackers. Activity trackers are widely used to measures physical activity, but their accuracy and reliability remains questionable especially among older people. Additionally, products and upgrades are made available so quickly that research on the accuracy and reliability of these devices is difficult to obtain.

Accuracy of Fitbit Surge and Smartphone Apps at Measuring Cycling Distance and Speed

Jose L. Gamez, Ivan A. Figueroa, Merrill D. Funk. *University of Texas Rio Grande Valley, Brownsville, TX.*
(No relevant relationships reported)

Purpose
To determine the accuracy of Fitbit Surge and two smartphone applications at measuring distance and speed while cycling outside.
Methods
Thirteen college-aged students (Mean±SD; BMI: 25.2±3.0kg/m²; 10 males, 3 females) consented to participate in one measurement session. A 0.75 mile trail along a sidewalk around the university campus was used for 3 separate trials using a mountain bike, Android smartphone running Google-Fit (G-Fit) and S-Health (SH), and Fitbit (FB) provided to each participant. A researcher rode along with each participant the entire study using a cycle computer as the standard for speed and distance. The first lap consisted of walking 0.25 miles, cycling 0.15 miles at a slow speed, cycling 0.20 miles at a fast speed, and cycling 0.15 miles at a moderate speed. The second lap consisted of 1 lap at a moderate speed. The third lap consisted in 1 lap at a slow speed. After every lap a researcher recorded the data from the phone and the Fitbit. Mean bias and mean absolute percent error (MAPE) were calculated to describe speeds and distances recorded on each device compared to the cycle computer.
Results
Thirteen participants completed all 3 trials though 2 were excluded due to a malfunction with the smartphone apps causing partial data to be collected, leaving 11 included in this analysis. Results are as follows:

Trial 1	FB Mean Bias±SD	FB MAPE	G-Fit Mean Bias±SD	G-Fit MAPE	SH Mean Bias±SD	SH MAPE
Distance (miles)	0.02±0.01	2.5	0.03±0.06	7.7	0.02±0.01	2.75
Average Speed (mph)	0.41±0.27	6.1	0.93±0.6	13.2	0.63±0.4	0.1
Max Speed (mph)	0.83±0.53	6.5	4.17±0.6	33.0	1.65±1.36	14.1
Trial 2						
Distance (miles)	0.02±0.02	4.9	0.02±0.06	7.0	0.02±0.02	3.5
Average Speed (mph)	0.45±0.2	4.8	1.31±0.82	13.6	0.53±1.36	14.1
Max Speed (mph)	5.98±1.19	41.5	4.43±1.0	29.2	0.44±2.03	11.5
Trial 3						
Distance (miles)	0.02±0.01	3.1	0.02±0.04	5.4	0.04±0.04	5.3
Average Speed (mph)	0.29±0.26	5.0	0.43±0.32	7.4	-1.37±2.07	23.7
Max Speed (mph)	1.51±0.57	9.2	6.59±2.14	37.4	1.44±0.59	8.6

Conclusion
The Fitbit Surge was most accurate at measuring speed and distance for cycling followed by the S-Health app and lastly the Google-Fit app.

1277   **Board #85**   May 31 9:00 AM - 10:30 AM
Smartphone Carrying Location and Accuracy of Popular Pedometer Smartphone Apps While Jogging

Merrill D. Funk, Murat Karabulut. *University of Texas Rio Grande Valley, Brownsville, TX.*
(No relevant relationships reported)

Common pedometer smartphone apps suggest multiple acceptable sites where the phone may be carried to obtain accurate measurements, however, the phone location may have a significant effect on outcomes reported by the app. **PURPOSE:** To determine if smartphone location has a significant effect on the accuracy of popular smartphone pedometer applications at measuring steps while jogging on a treadmill. **METHODS:** Fifty-two participants (Mean±SD; 22.9±4.2yrs; BMI: 24.8±4.1kg/m²; 22 Male, 30 Female) consented to jog on a treadmill at 5 mph for 500 steps, while using a pedometer and 4 smartphones placed in commonly used locations (pocket, armband, waistband, hand). All smartphones were simultaneously running 5 applications throughout the trial: Moves, Google-Fit (G-Fit), Runtastic, Accupedo, and S-Health. Steps were verified using a hand tally counter. Zero, negative, and significant outlier values were replaced with the mean value for that app. A separate one-way repeated measures ANOVA was used for each app with the pedometer and tally counter. Significance was set at p<0.05. Pairwise comparisons with Bonferroni corrections were used for post-hoc analysis. Mean bias scores were calculated between the step count for each app and the tally counter. **RESULTS:** Repeated Measures ANOVA detected significant differences between phone locations and the step counter for only G-Fit (p=0.029) and Runtastic (p<0.01), while other apps were not different by location (p>0.05 for all). Using pairwise comparisons, G-Fit did not show significant differences with the tally counter for any of the phone locations (p>0.05) while pairwise comparisons for Runtastic indicated differences between the arm and hand locations compared to the tally counter (p=0.039, p=0.007, respectively). Lowest mean bias values for each app were as follows: Moves, arm (mean bias ± SD; 5.8 steps ± 103.3 steps); G-Fit, hand (13.7 ± 135.4); Runtastic, waist (8.6 ± 37.1); Accupedo, pocket (17.5 ± 46.9); S-Health, arm (-1.6 ± 26.9). **CONCLUSION:** The pocket, arm, waist, and hand all appear to produce relatively accurate step counts for pedometer smartphone apps while jogging on a treadmill. Although the phone location and app did not result in significant changes in step count, some locations and apps were better at providing more consistent and accurate results.

Predictors of Central Blood Pressure in Older Adults

Emma Albin, Nathan Meier, Duck-chul Lee, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Duck-chul Lee, FACSM)
(No relevant relationships reported)

Purpose: To investigate the predictors of central blood pressure (BP) in older adults, which is suggested as an emerging marker of future cardiovascular diseases, independent of peripheral BP.
Methods: This cross-sectional study included 304 older adults aged ≥65 years (mean age 72). Central and peripheral BP were measured using Uscom BP+ while seated. Demographic (age, sex), lifestyle (smoking, alcohol intake), body composition by DXA (body weight and fatness), cardiometabolic (peripheral BP, resting heart rate [RHR], blood glucose and lipids), and physical activity (PA) (sitting time, daily steps) and fitness variables (cardiorespiratory fitness [CRF], handgrip strength) were identified as potentially predictive of central BP and included in the prediction model.
Results: Univariate regression revealed that age (p<0.001), body weight (p=0.041), percent body fat (%BF) (p=0.049), total cholesterol (TC) (p=0.042), fasting glucose (p=0.032), CRF (p=0.001) and peripheral systolic BP (PSBP) (p<0.001) were significant for central systolic BP (CSBP). Body weight (p<0.001), %BF (p<0.001), TC (p=0.005), RHR (p=0.002) and peripheral diastolic BP (PDBP) (p<0.001) were significant for central diastolic BP (CDBP). Stepwise multivariate linear regressions with p<0.2 for entry and p<0.05 for staying in the model were used to identify significant predictors of central BP. In the multivariate regression, PSBP (β=0.89, p <0.001) and male sex (β=-1.94, p<0.001) were identified as significant predictors for CSBP, and PDBP (β=0.99, p<0.001) and TC (β=0.01, p <0.011) for CDBP that accounted for 91.6% and 93.5% of the total variance in CSBP and CDBP, respectively. When stratified for BP medication, PSBP and PDBP remained significant in participants both with (33%) and without (67%) BP medication, but sex and TC remained significant only in participants without BP medication, suggesting a possible effect modification by BP medication. When stratified by PA and CRF (400m walk

test), the CSBP model was stronger for the active group (≥5,000 steps/day; R^2=0.97) than the inactive (R^2=0.89) and stronger for the high (upper third; R^2=0.95) CRF than moderate (middle third; R^2=0.91) or low (lower third; R^2=0.90) CRF groups.
Conclusion: The results suggest that peripheral BP is the strongest predictor of CBP for older adults.

Physical Activity Patterns Among Older Central Pennsylvania Cancer Survivors: A Comparison With BRFSS National Data

Wayne Foo, Kathryn Schmitz, FACSM. *Penn State Cancer Institute, Hershey, PA.* (Sponsor: Kathryn Schmitz, FACSM)
(No relevant relationships reported)

Adults can participate in a variety of physical activities to meet current federal physical activity guidelines. The differences between activity patterns of cancer survivors and the general population are not well understood. This knowledge may be useful in modifying physical activity promotion guidelines specific to cancer survivors.
PURPOSE: To compare physical activity patterns of older cancer survivors living in Central Pennsylvania (CPA) to that of a national sample of Americans using the Behavioral Risk Factor Surveillance System (BRFSS) data (≥50 years old).
METHODS: We mailed BRFSS-based questionnaires to cancer survivors living in CPA, identified using the Pennsylvania Cancer Registry. Using this data (N=541) and the 2015 BRFSS national data (N=441,456), we categorized specific types of physical activity (PA) into ten major activity types using classifications from the Compendium of Physical Activities. We fit multivariate logistic regression models to estimate the prevalence odds ratios of activity participation for each activity type. Bonferroni method was used to control for inflated error due to multiple testing (p<0.005). Effect modification by sex was analyzed for activity types that were significant in the model.
RESULTS: Walking was the most common activity in both cohorts (CPA: 58%; BRFSS: 49%), followed by garden/lawn activities (CPA: 19%; BRFSS: 14%), and then conditioning activities (CPA: 9%; BRFSS: 11%). A higher proportion of CPA cancer survivors reported at least one activity (87%) compared to the national sample of Americans (66%). Compared to the national sample, CPA cancer survivors were 1.5 times more likely to report walking (OR=1.51; 99.5% CI: 1.16-1.97), 1.4 times more likely to report garden/lawn activities (OR=1.43; 99.5% CI:1.03-1.97), 1.7 times more likely to report household activities (OR=1.67; 99.5% CI:1.06-2.61), and 3.8 times more likely to report fishing/hunting (OR=3.79; 99.5% CI: 1.38-10.46). No significant effect modification by sex was found.
CONCLUSIONS: In general, CPA cancer survivors were more likely to report participating in at least one PA. Programs aimed to increase PA among CPA cancer survivors may want to focus on walking, domestic activities such as household and garden/lawn activities, as well as outdoor activities such as fishing and hunting.

1280　　Board #88　　　　　May 31 9:00 AM - 10:30 AM

Associations of Body Fatness and Cardiorespiratory Fitness on Central Blood Pressure in Older Adults

Markus H. Flynn, Nathan F. Meier, Duck-chul Lee, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Duck-Chul Lee, FACSM)
(No relevant relationships reported)

Purpose: To investigate the associations of percent body fat (PBF) and cardiorespiratory fitness (CRF) on central blood pressure (BP), which is suggested as a greater predictor of cardiovascular disease (CVD) than peripheral BP and more closely related to CVD risk factors.
Methods: This cross-sectional study included 302 older adults aged ≥65 years (mean age 72) from the Physical Activity and Aging Study (PAAS). PBF was assessed via a DXA scan and divided into sex-specific quartiles. CRF was evaluated by a 400-meter walk test and divided into sex-specific quartiles based on completion time in minutes. Central BP was analyzed using an Uscom BP+ (Uscom Ltd., Australia). Elevated central BP was defined as sex-specific, central systolic or diastolic BP above the 75th percentile in this sample. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (95% CIs) of having an elevated central BP across PBF and CRF.
Results: In this study, 106 older adults (34.9%) had elevated central BP. Compared to the lowest PBF quartile 1 (lowest 25%), ORs (95% CIs) of having an elevated central BP in the next quartiles 2, 3, and 4 were 1.79 (0.81-3.94), 2.86 (1.31-6.23) and 4.23 (1.85-9.70), respectively, after adjusting for age, sex, blood pressure medication usage, current smoking status, and CRF. However, CRF was not significantly associated with an elevated central BP after adjusting for the previously listed confounders and PBF (trend P=0.21). In the stratified analyses by CRF, we found that higher PBF was associated with increased prevalence of elevated central BP in both lower CRF (lower 50%) (trend P<0.01) and higher CRF (upper 50%) halves (trend P=0.02).
Conclusion: These results suggest that higher PBF, independent of CRF, is associated with an increased prevalence of elevated central BP in older adults. However, further prospective studies are warranted.

Predictors of Diagnostic Variables of Sarcopenia in Older Adults

Nathan Meier, Duck-chul Lee, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Duck-chul Lee, FACSM)
(No relevant relationships reported)

Purpose: To investigate potential predictors of diagnostic variables of sarcopenia in older adults including demographic factors (e.g., age and sex), aerobic and resistance physical activity (PA), cardiorespiratory fitness (CRF), and body composition.
Methods: This cross-sectional study included 304 older adults ≥65 years (mean age 73, range 65-95). PA and sedentary variables were assessed using a self-report survey and daily steps using an accelerometer based pedometer (Omron HJ-321). CRF was the time to complete a 400m walk in minutes, thus higher number in minutes indicates a slower walking, which is a lower level of CRF. Body composition was percentage body fat (%BF) measured by DXA and body mass index (BMI). Diagnostic variables of sarcopenia include appendicular lean mass (ALM) (kg/height in meter^2) measured by DXA, handgrip strength (kg), and gait speed (m/s) from 4 meter walk test. **Results:** Univariate regression revealed significant relationships between ALM and CRF (p=0.012), light intensity (1.5-3.0 METs) aerobic PA (p<0.001), vigorous intensity (≥6.0 METs) aerobic PA (p=0.008), age (p<0.001), male sex (p<0.001), and %BF (p<0.001). Handgrip strength was related to CRF (p<0.0001), light intensity aerobic PA (p=0.002), vigorous intensity aerobic PA (p=0.002), resistance PA (p=0.031), age (p<0.001), male sex (p<0.001), and %BF (p<0.001). Gait speed was related to CRF (p<0.0001), daily steps (p=0.003), age (p<0.0001), and %BF (p=0.018). Stepwise variable selection (p<0.2 to enter the model, p<0.05 to remain in the model) was used to find significant predictors of diagnostic variables of sarcopenia. ALM was predicted by CRF (β=-0.15, p<0.001), %BF (β=-0.12, p<0.001), BMI (β=0.25, p<0.001), and male sex (β=0.29, p<0.001) (model R^2=0.93); grip strength was predicted by CRF (β=-2.50, p<0.001), age (β=-0.26, p<0.001), and male sex (β=14.6, p<0.001) (model R^2=0.63); and gait speed was predicted by CRF (β=-0.11, p<0.001) (model R^2=0.24).
Conclusion: Cardiorespiratory fitness, measured by a simple 400m walk test, was identified as a significant predictor of all three diagnostic variables of sarcopenia in older adults.

1282　　Board #90　　　　　May 31 9:00 AM - 10:30 AM

The Difference of Body Composition According to Smart Phone Proficiency in Korean Elderly

Joon-Sik Kim[1], Jung-Woon Kim[1], Sowon Hahn[2], Yeon-Soo Kim[1]. [1]*Health and Exercise Science Laboratory, Institute of Sports Science, Seoul National University, Seoul, Korea, Republic of.* [2]*Department of Psychology, Seoul National University, Seoul, Korea, Republic of.*
(No relevant relationships reported)

Purpose : Previous studies have shown associations of sedentary behavior with biomarkers of cardiometabolic risk, however the relationship between the proficiency of smart phone usage and obesity has not yet been studied. We examined the difference of body mass index (BMI) according to smart phone proficiency in the elderly.
Method : Experimental subjects included 101 elderly (50 male, 51 female) over the age of 60 who participated the local senior education program at several senior welfare service centers in Seoul, South Korea. They were divided into three groups according to proficiency of smart phone usage. Fitness characteristics related to smart phone usage were evaluated by measuring cardiorespiratory endurance, grip strength, pinch strength, eye-hand coordination and body composition. Also, smart phone proficiency was evaluated by a self-reported questionnaire and a smart phone usability task that composed of two categories: usage of the smartphone device itself and usage of phone applications. The differences in BMI of the subjects was analyzed by ANCOVA adjusting for independent variables including age, grip and pinch strength, eye-hand coordination, education and incomes. **Results** : There was a significant difference in BMI among the three groups after adjustment of age, grip and pinch strength, eye-hand coordination, education and incomes. The self-reported questionnaire showed a significant difference in BMI between high proficiency and low proficiency groups (high 25.07±2.51, low 23.52±2.19; p=.015). Smart phone usability task results also showed a significant difference in BMI among the three groups (high 25±2.64, low 23.08±2.59; p=.002 and high 25±2.64, middle 23.7±1.61; p=.011). **Conclusions** : These results suggest that high smart phone proficiency shows increased BMI in the elderly. This study suggests that people over 60 who have high smartphone proficiency should be cautious of an increased BMI score.

1283   Board #91   May 31 9:00 AM - 10:30 AM
Associations of Cardiorespiratory Fitness and Percent Body Fat with Health-Related Quality of Life in Elderly
Heather Danzer, Nathan Meier, Duck-chul Lee, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Duck-chul Lee, FACSM)
(No relevant relationships reported)

Purpose: To investigate the cross-sectional associations of cardiorespiratory fitness (CRF) and percent body fat (PBF) with Health-Related Quality of Life (HRQoL) in older adults.
Methods: Participants comprised 282 older adults aged ≥65 years (mean age 74) from the Physical Activity and Aging Study (PAAS). CRF was assessed by time in minutes to complete a 400-meter walk, and PBF was assessed by Dual-energy X-ray absorptiometry (DXA) and categorized into sex-specific quartiles for each CRF and PBF. HRQoL was assessed by the 36-Items Short Form Health Survey (SF-36) and categorized based on physical component scores (PCS) including physical health, physical role, bodily pain, and general health dimensions and mental component scores (MCS) including vitality, social functioning, emotional role, and emotional health dimensions. Average score below 50 (range 0-100) was used to define both low PCS and low MCS, indicating lower HRQoL, based on the population mean score of 50. However, due to having limited cases (n=20) for both low MCS and low PCS groups were combined into one overall HRQoL for analysis. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (95% CIs) of having a low overall HRQoL across CRF and PBF quartiles.
Results: Compared to the lowest CRF quartile 1 (lowest 25%), ORs (95% CIs) of having a low overall HRQoL in the next higher CRF quartiles 2, 3, and 4 were 0.29 (0.08, 1.01), 0.16 (0.03, 0.85), and 0.14 (0.02, 0.85), respectively, after adjusting for age, sex, smoking, alcohol intake, physical activity, and PBF (trend p=0.01). This result indicates that the two higher CRF levels (quartiles 3 & 4) are significantly associated with lower odds of having a low level of HRQoL, suggesting better overall HRQoL. However, PBF was not significantly associated with overall HRQoL after adjusting for the confounding including CRF in this study population (trend P=0.24). In the stratified analysis by PBF, although not significant due to further reduced number of cases, similar trends were observed for both low (lower 50%, lean) and high (upper 50%, fat) PBF groups.
Conclusion: This study suggests that higher CRF, independent of PBF, is associated with better HRQoL in older adults. However further exploration from prospective studies are needed.

C-38   Free Communication/Poster - Nutrition Status and Assessment

Preschool Breakfast Menus That Meet Dietary Guidelines: Comparing What Is Served And Consumed By Children
Stacie M. Kirk, Erik P. Kirk, FACSM. *Southern Illinois University Edwardsville, Edwardsville, IL.*
(No relevant relationships reported)

Preschool menus must meet the Dietary Guidelines for Americans. However, what is actually served and consumed by children is not restricted, potentially affecting consumption of a balanced diet. **PURPOSE:** Compare preschool breakfast menus meeting dietary guidelines to what is actually served and consumed by children. **METHODS:** Fifty-two preschool children (mean±SD, age 3y and 10m ± 8m) from a university early childhood center participated in the 10-week study. Each day, 15 children were randomly selected for nutritional analysis of their breakfast. Prior to and immediately after consumption, a picture of the child's tray was taken using digital photography. If a child had additional servings, additional pictures were taken. Analysis of energy and nutrient content for menus, food served, and food consumed was completed using Food Processor Nutrition Analysis by ESHA. Food color (white, brown, orange, yellow, red, green, other) was determined by observation during analysis. A food preference survey was administered verbally to children immediately after each meal. **RESULTS:** There was a significant (p<0.05) difference for total kilocalories (kcals) between menu (356 ± 117), served (330 ± 157) and consumed (184 ± 136). There was a significant (p<0.05) difference for grams of carbohydrate between menu (59.0 ± 17.6g) and served (54.2± 29.5g) compared to what was consumed (29.0 ± 19.6g). There was a significant (p<0.05) difference for grams of fat between menu (9.3 ± 6.8g), served (8.6 ± 8.1 g) and consumed (5.1 ± 7.2g). There was a significant (p<0.05) difference for protein between menu (11.7 ± 3.3g), served (11.2 ± 6.6g) and consumed (6.7 ± 6.6g). The majority of food served was white (47.7%), brown (18.7%), or orange (14.8%) with minimal yellow (8.8%), red (7.0%) or green (0.0%)

foods. Children described food as yummy (77.0%), okay (9.4%), and yucky (13.6%). Consumption of vegetables (0.0%) was significantly (p<0.05) lower than dairy (79.9%), fruits (66.1%), grains (70.8%), and meats (70.4%). Children consumed a high percentage (50.0%) of fats/sweets. **CONCLUSION:** The amount of food consumed at breakfast was significantly less than was indicated on the menu and amounts served, indicating that children were not meeting the dietary recommendations as intended, potentially contributing to long-term health consequences.

Risk Behaviors, Energy Balance and Physical Activity of University Students of a Nutrition School
Eduardo Gómez-Infante[1], Oswaldo Ceballos-Gurrola[2], María Cristina Enriquez-Reyna[2]. *[1]Universidad Estatal de Sonora, Hermosillo, Mexico. [2]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Mexico.*
(No relevant relationships reported)

The development of chronic noncommunicable diseases during youth could affect the performance and professional achievements of university students. Differences in consumption of alcohol or tobacco, energy balance and physical activity levels may have an influencing effect in the levels of obesity that affect Mexico. **PURPOSE**: To analyze the differences regarding the consumption of alcohol or tobacco in the relationship between energy balance and the physical activity level among students of a Nutrition School.
METHODS: In this study, we engaged a group of 380 university students from a Nutrition School (292 female). Habitual behaviors including consumption of alcohol and/or tabacco, 24-hour reminder, energy balance (caloric-nutritional consumption between energy expenditure) and physical activity level (International Physical Activity Questionnaire) were measured.
RESULTS: No differences were found between the energy balance and the physical activity level in men. In the whole sample alcohol consumption ($OR = 1.215$, IC $95\% = .721 - 2.045$) was associated with increased risk of low physical activity level (<600 METs). In participants who consumed alcohol a negative association was found between energy balance and the physical activity level ($r = -.132$, $p < .05$), with greater values for women ($r = -.184$, $p <. 05$). Women who consumed tobacco showed a tendency to decrease their level of physical activity ($r = -195$, $p < .05$).
CONCLUSIONS: Alcohol and tobacco consumption affected the energy balance and the physical activity level of university students of a Nutrition School. Especially in women, these habits should be modified to prevent the development of diet-dependent diseases.

Nutritional Status of Rock Climbers
Emily E. Neufeld, Michael C. Meyers, FACSM. *Idaho State University, Pocatello, ID.*
(No relevant relationships reported)

The physically intense nature of rock climbing requires that athletes maintain optimal nutrition to meet physical demands and minimize predisposition to injury. Although the sport of rock climbing has grown, limited research has been conducted on nutritional intake of these non-traditional athletes. **PURPOSE:** To quantify nutritional intake of rock climbers. **METHODS:** Following written informed consent, 3-day food recalls were obtained from 25 female and 15 male rock climbers [mean ± SD; age = 22.4 ± 3.2 yr; ht = 170.5 ± 10.4 cm; wt = 64.9 ± 8.9 kg; basal metabolic rate (BMR) = 2687.6 ± 354.6 kcals] to ascertain energy, macronutrient, and micronutrient intake. **RESULTS:** MANOVAs indicated a significant main effect between DRIs and rock climber nutrient intake by macronutrients ($F_{30,197} = 12.243$; $P < .0001$), vitamins ($F_{30,197} = 12.091$; $P < .0001$), and minerals ($F_{18,201} = 20.475$; $P < .0001$). Post hoc analyses indicated that female climbers were significantly lower in energy intake (1878.1 ± 542.9 vs. 2400.0 kcals; $P < .0001$), protein (77.1 ± 24.0 vs. 135.0 g; $P < .0001$), carbohydrates (240.8 ± 79.6 vs. 330.0 g; $P < .0001$), vitamin D (3.8 ± 5.0 vs. 15.0 μg; $P < .0001$), vitamin E (5.7 ± 4.0 vs. 15.0 mg; $P < .0001$), magnesium (219.7 ± 116.4 vs. 310.0 mg; $P = .002$), and potassium (1992.2 ± 803.1 vs. 4700.0 mg; $P < .0001$), but higher in sodium intake (2689.1 ± 933.9 vs. 1500.0 mg; $P < .0001$) than DRIs, respectively. Male climbers were significantly lower in energy intake (2124.8 ± 472.3 vs. 3000.0 kcals; $P < .0001$), protein (91.5 ± 23.0 vs. 169.0 g; $P < .0001$), carbohydrates (270.0 ± 76.5 vs. 413.0 g; $P < .0001$), fiber (27.6 ± 12.3 vs. 38.0 g; $P = .002$), unsaturated fat (55.0 ± 20.6 vs. 69.0 g; $P = .034$), saturated fat (22.4 ± 9.3 vs. 33.0 g; $P < .0001$), vitamin D (3.5 ± 3.8 vs. 15.0 μg; $P < .0001$), vitamin E (8.2 ± 64.0 vs. 15.0 mg; $P < .0001$), and potassium (2467.3 ± 910.7 vs. 4700.0 mg; $P < .0001$), but higher in vitamin C (139.2 ± 80.3 vs. 90.0 mg; $P = .021$), riboflavin (1.8 ± 0.9 vs. 1.3 mg; $P = .011$), niacin (20.9 ± 11.6 vs. 16.0 mg; $P = .021$), iron (16.2 ± 9.1 vs. 8.0 mg; $P = .009$), and sodium (2658.5 ± 684.0 vs. 1500.0 mg; $P < .0001$) than DRIs, respectively. **CONCLUSION:** Both gender differed significantly from nutritional recommendations. Given that energy and macronutrient intake are closely related to athletic performance, ensuring that optimal nutrition is achieved must be a priority.

1287   Board #95   May 31 8:00 AM - 9:30 AM

Nutrition and Energy Expenditure of Retired Professional Contact Sport Athletes and Non Contact Sport Controls

Katherine T. O'Donnell, Mohammad N. Haider, Itai Bezherano, Andrea L. Hinds, Peter J. Horvath, John J. Leddy, Barry S. Willer. *University at Buffalo, Buffalo, NY.*
(No relevant relationships reported)

Background: Chronic traumatic encephalopathy (CTE) is a neurodegenerative disorder suspected to be caused by repetitive mild traumatic brain injuries from playing contact sports. Other possible etiologies linked to brain health, nutrition, and general lifestyle have received far less attention. **Purpose:** To compare physical health, diet, and Exercise Energy Expenditure (EEE) of retired professional contact sport athletes and healthy non contact athlete controls. **Methods:** Participants completed an extensive battery of cognitive tests, were assessed on advanced imaging, and were evaluated for psychological and physical health. Participants completed the Yale Physical Activity Survey to determine EEE/physical activity and the Food Frequency Questionnaire to obtain a yearlong diet recall using Nutritionist Pro software. **Results:** Contact Athletes (n=21, 56 ± 11 yrs, 29.7 ± 3.6 kg/m^2) were significantly more overweight (n=21, 57 ± 9 yrs, 24.5 ± 2.6 kg/m^2, $p < 0.001$). Calculated kilocalorie intake was not significantly different, however, the total hours spent doing common types of physical activities was significantly lower in Contact Athletes (22.5 ± 18.7 hrs/wk vs 51.1 ± 15.0 hrs/wk, $p < 0.001$). No significant differences were seen in intake of macronutrients, but intake of many brain healthy micronutrients, including copper ($p = 0.019$), selenium ($p = 0.037$), folate ($p = 0.02$), manganese ($p = 0.002$), and riboflavin ($p = 0.047$) was significantly lower in Contact Athletes. **Conclusion:** Although retired professional contact sport athletes have similar energy intake as controls, they spend less time doing physical activities per week and consume a diet deficient in some brain healthy nutrients. This may relate to the greater degree of being overweight in the former Contact Athletes. Nutritional and cardiovascular factors should be considered in the evaluation of cognitive disorders in former contact sport athletes.

1288   Board #96   May 31 8:00 AM - 9:30 AM

Nutritional Habits And Body Composition Assessment In International Soccer Referees

Cristian Petri[1], Elena Ermini[1], Gabriele Mascherini[1], Angelo Pizzi[2], Carlo Castagna[2], Pierluigi Collina[3], Giorgio Galanti[1]. *[1]University of Florence, Florence, Italy. [2]Associazione Italiana Arbitri, Florence, Italy. [3]UEFA, Nyo, Swaziland.*
(No relevant relationships reported)

PURPOSE: Soccer referee has responsibility to verify and enforce the rules of the game and control players' behavior during matches. In order to be able to directing a football game, to have a good decision-making ability and to be close to the action the referee must be in optimal physical condition. Physical demands and nutrition are highly interrelated: the study of body composition is a method for assessing the balance between these two aspects closely related to sport performance. The aim of the present study was to evaluate nutritional habits and resulting body composition in international soccer referees called for the FIFA World Cup 2018. **METHODS:** 60 soccer referees (SR) (39.2 ± 4.2 years) were enroll in this study. The variables of body mass, height, skinfold thicknesses, body circumferences (waist, hip and biceps) were collected with the purpose of estimating Sum of 7 skinfold thicknesses ($\sum$7sk), Fat Mass (FM %), Fat Mass, Fat Mass index (FMI kg/m^2). The skinfold thickness are been evaluated with International Society for the Advancement of Kinanthropometry methodology. For the evaluation of nutritional habits (NH), athletes answered a 24 h food recall. The variables of carbohydrates (CHO), protein (PRO) and fat (FAT) are expressed in % and g/kg. Micronutrients in terms of vitamins and minerals are been collected. The data are been compared with the international guidelines. **RESULTS:** The data collected regarding the body composition describe a normal weight population (BMI = 23.3 ± 1.5 kg/m^2), but with a FM% of 11.4 ± 2.5 and a FMI of 4.9 ± 1.3 kg/m^2 above the normal range. The $\sum$7sk was 63.7 ± 17.3 mm. About NH we observed: -CHO 44.6 %, 3.1 g/kg; -PRO 16.5 %, 1.1 g/kg; -FAT 41.4 %, 1.3 g/kg; The minerals below the normal range was Calcium (661.8 ± 187.3 mg/die), Zinc (10.3 ± 2.5 mg/die), Magnesium (295.6 ± 81.8 mg/die) Iodine (21.2 ± 9.3 µg/die). The vitamins below the normal range was Folic Acid (381.0 ± 118.4 µg/die) and Vitamin A (1282.4 ± 484.1 UI/die). **CONCLUSIONS:** NH are inadequate for this category, CHO and PRO are below and the FAT above the international guidelines. These data suggested that nutritional intervention would be appropriate. Therefore, the nutritional habits must be adapted to their daily physical activities, during match refereeing, to obtain better performance.

1289   Board #97   May 31 8:00 AM - 9:30 AM

Examination of Female Athlete Triad Components in a College Dance Company

Elena Burrus[1], Toni M. Torres-McGehee, 29063[1], Kelly Pritchett[2], Kenya Moore[1], Erin M. Moore[1], Susan Anderson[1]. *[1]University of South Carolina, Columbia, SC. [2]Central Washington University, Ellensburg, WA.*
(No relevant relationships reported)

Dancers are at an increased risk for the female athlete triad (Triad) due to the discipline required in dance training and the importance placed on aesthetic appearance. Subjective judging and body size expectations may promote restrictive eating behaviors, which can lead to menstrual disturbances and poor bone mineral density (BMD). **PURPOSE:** To examine the prevalence of: (1) Triad components in collegiate, female dancers, and (2) low energy availability (LEA) in collegiate, female dancers with or without disordered eating. **METHODS:** A cross-sectional cohort study examined dancers (n=26) in a collegiate dance company (height: 165 ± 6.9 cm; weight: 56.41 ± 7.0 kg). Dependent variables for this study included Triad risk (e.g. LEA with or without eating disorder (ED), menstrual dysfunction, and low BMD). Participants completed a demographic survey, menstrual cycle questionnaire, Eating Disorder Inventory-3, ED symptoms checklist, a 7 day online dietary and exercise log, and were measured for height, weight, DXA scan (BMD), and resting metabolic rate (RMR) through indirect calorimetry (MedGem). Exercise energy expenditure (EEE) was calculated using Ainsworth equation and energy availability (EA) was calculated by EA= ((EI-EEE)/fat free mass). **RESULTS:** Overall, 73.0% of dancers were at risk for the Triad [1 component (69.2%); 2 components (3.8%)]. Most dancers were at risk for LEA (69.2%), with 61.5% of dancers with LEA and ED risk combined. Menstrual dysfunction lasting greater than 6 months was present in 7.7% of the dancers, and no low BMD was present in any participants. Overall, 88.5% of dancers displayed ED Risks (risk by EDI-3 and/or EDI SC). Energy assessment included: RMR = 1155.8 ± 206.5 kcal/day; energy intake (EI) = 1473.9 ± 321.5 kcal/day; EEE = 884.7 ± 324.9 kcal/day, and EA = 22.3 ± 19.4 kcals/kg^{-1}FFM/day. Average bone mineral density Z-score was $1.15 \pm .76$. **CONCLUSIONS:** Almost 75% of the dancers were at risk for 1 component of the Triad. Specifically, LEA with ED risk was the most common Triad component displayed in this collegiate dance population. Overall, collegiate dancers are a high-risk population not only for the Triad, but also for ED risk. Early recognition is key and qualified healthcare professionals should be accessible for these populations to integrate prevention and intervention strategies.

1290   Board #98   May 31 8:00 AM - 9:30 AM

Examination of Female Athlete Triad Components in College Softball Athletes

Brittany T. Williams[1], Zach Richards[1], Erin M. Moore[1], Ton M. Torres-McGehee[1], Clemens Drenowatz[2], Justin M. Goins[1]. *[1]University of South Carolina, Columbia, SC. [2]Pädagogische Hochschule Oberösterreich, Linz, Austria.*
(No relevant relationships reported)

Softball athletes are commonly overlooked when examining the Female Athlete Triad (Triad - low energy availability [LEA], menstrual cycle dysfunction [MCD], and low bone mineral density [BMD]) and eating disorder risk (ED). However, they engage in lengthy practices/games and anecdotally have poor eating habits and weight management issues which in turn may put them at risk. **PURPOSE:** Estimate the prevalence of Triad components in collegiate softball athletes. A secondary purpose is to examine LEA with or without ED. **METHODS:** Female NCAA Division I Softball athletes (n = 17; age 19.6 ± 1.1; height 168.6 ± 5.2 cm; weight 72.5 ± 11.23 kg) participated in this cross-sectional study. Participants completed demographic survey (age, academic status, etc.), Eating Disorder Inventory-3 (EDI-3), EDI-3 symptom checklist and menstrual cycle questionnaire. Each participant completed a DXA scan to examine BMD and completed a 7-day online dietary and exercise log. Ainsworth equation calculated exercise energy expenditure (EEE), and energy availability (EA) was calculated by EA= ((EI-EEE)/FFM). **RESULTS:** All collegiate softball athletes (n=17) were at a high risk for LEA with EA below 30 kcal/kg FFM/day for 6 of 7 days and 70.6% having LEA for 7 of 7 days of the study. Additionally, 82.3% (n = 14) were at risk for LEA with ED behaviors. None of the participants were at risk for low BMD (3.28 ± 0.9); however 29.4% (n = 5) of the participants were at risk for amenorrhea and LEA. Energy needs revealed: RMR 1874 ± 276.9 kcal, EI was 1338 ± 313.5 kcals and EEE 811 ± 130.5 kcals, and EA 7.8 ± 6.4 kcals^{-1}kg^{-1}FFM. Eating Disorder behaviors consisted of 47.1% dieting, 17.6% binge eating, 5.9% purging, 11.8% diet pills, and 47.1% used exercise to control weight 25-50% of the time. Additionally, 82.3% were at risk for EDs. **CONCLUSIONS:** Overall softball athletes are indeed at risk for at least 1-2 Triad components, more specifically LEA with ED risk behaviors and LEA with menstrual dysfunction. Education on energy needs specific for their sport demands may be beneficial for long term health and overall performance. Additional prevention and intervention strategies to decrease the risk for EDs is warranted in collegiate softball athletes.:

Pre-competition Weight Loss Strategies To Achieve The Desired Category Weight In Combat Sports Collegiate Athletes

Andrea Patricia Rohan-Lopez, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Edtna Elvira Jauregui-Ulloa, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To describe the proportion of college combat athletes that follow some dietary and non-dietary strategies to loss body weight before a competition.
METHODS: We evaluated 80 college athletes (21.1 ±2.7 y; 51 males, 29 females) from different combat sports (wrestling 23, boxing 7, judo 21, karate 14, and taekwondo 15; 77.5% of the sample had competitions at national level and 21.3% at international level). We applied a questionnaire to account for some of the followed dietary and non-dietary strategies to achieve the desired competition weight three months before a state tournament. The questionnaire consisted of 35 items. The questions asked the subject if he/she usually perform that strategy for pre-competition weight loss. Also, the questionnaire asked the subjects about if they showed some of the most common side effects of weight loss. The results were reported as frequencies and proportions.
RESULTS: The most common dietary strategies for pre-competition weight loss were to reduce or avoid the consumption of fats and flours and sugars (Table 1). On the other hand, the most common non-dietary strategies to pre-competition weight loss were increasing physical activity and using sauna (Table 1). The most common side effect related to pre-competition weight loss was overall fatigue (39, 48.8%), followed by low performance in trainings (30, 37.5%), susceptibility to diseases (29, 36.3%) and irritability or aggressiveness (27, 33.8%).
CONCLUSIONS: The reduction of fat consumption and the increase of physical activity were the most common strategies for pre-competition weight loss. Some extreme strategies were also reported but not as common. Some of the mechanisms of these strategies may be related to the side effects of weight loss and not just for the weight loss itself. A comparison by sex and by type of sports deserves further analysis.

Table 1. Proportion of dietary and non-dietary strategies for pre-competition weight loss		
Dietary strategies	(n=80)	(%)
Reduce the amount of food consumed	41	51.3
Reduce water and beverages consumption	30	37.5
Increase physical activity and reduce consumption of food and beverages	38	47.5
Reduce or avoid fat consumption	69	86.3
Reduce or avoid flours and sugars consumption	63	78.8
Reduce or avoid animal source foods consumption	13	16.3
Reduce or avoid dairy consumption	39	48.8
Non-dietary strategies		
Use of sauna	24	30
Use of laxatives	8	10
Use of diuretics	7	8.8
Induce vomiting	1	1.3
Increase physical activity	69	86.3

Fulfillment Of The Daily Protein Intake Recommendations In College Athletes Compared By Sex

Ana Gabriela Gutierrez-Muñiz, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Sergio Alejandro Copado-Aguila, Marisol Villegas-Balcazar, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To compare by sex the proportion of college athletes that consume protein below, inside and above the recommended amount.
METHODS: We evaluated 341 athletes (192 males and 149 females) from different sports. Food intake was evaluated through a 24-hour reminder for a habitual training day. Afterwards, daily protein intake was estimated and then calculated for g/kg body weight. Afterwards, subjects were categorized into one of three categories according to their daily protein intake: below (<1.4 g/kg/day); inside (1.4 to 2.0 g/kg/day), and above (>2.0 g/kg/day) the recommended amount (as suggested by the International Society of Sports Nutrition). The results were counted and expressed as percentage of subjects at each category. The 95% confidence interval (CI) was calculated for each percentage. This analysis was performed in both male and female athletes and compared by sex
RESULTS: The general characteristics of the evaluated subjects for age, weight, height and BMI were 21.2 ± 2.1 y, 74.7 ± 14.1 kg, 176.2 ± 6.9 cm, 24.0 ± 3.8 kg/m^2 for males, and 20.6 ± 1.9 y, 61.5 ±11.2 kg, 163.4 ± 6.6 cm, 23.0 ± 3.7 kg/m^2 for females, respectively. We observed that the number of male athletes that consumed protein below and inside the recommended amount was the same (61 subjects each; 31.8%, CI 25.2 - 38.5), and the remaining 70 subjects (36.4%, CI 29.5 - 42.3) consumed above the recommended amount of protein. Similarly, the majority of the female athletes consumed above the recommended protein amount (55 subjects; 36.9%, CI 29.1 - 44.7), followed for those who ingested below (53 subjects; 35.6%, CI 27.8 - 43.4) and inside (41 subjects; 27.5%, CI 20.2 - 34.8) the recommended amount. There were no significant differences by sex (p >0.05).
CONCLUSIONS: The proportion of athletes consuming protein below, inside and above the recommended amount were similar regardless of sex. Most of the male and female athletes consumed more than 2.0 g/kg/day.

Adequacy Of The Nutritional Intake In Volleyball Male College Athletes After Receiving Nutritional Counseling

Sayra Nataly Muñoz-Rodriguez, Alejandro Gaytan-Gonzalez, Sergio Alejandro Copado-Aguila, Roberto Gabriel Gonzalez-Mendoza, Clara Yunnuen Rodriguez-Ramirez, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To compare the adequacy of nutritional intake in male volleyball athletes after receiving nutritional counseling for two different training sessions.
METHODS: 13 volleyball male college athletes were enrolled. The athletes carried out a training plan which was based on training volleyball only (VO) 4 days/week and volleyball plus resistance training (VR) 2 days/week for 12 weeks. Athletes received nutritional plans according to the nutritional requirements for both VO and VR. We evaluated their food intake with a 24-h dietary recall. This evaluation was performed three times for each training day. The days evaluated were randomly selected during the study. The mean intake for each training type was calculated and compared with the indicated nutritional plan to calculate the % of adequacy. Data were reported as median, minimum - maximum, and compared between training types.
RESULTS: Only 7 athletes completed the study. It was observed that the athletes were closer to 100% of the total energy (ENG) requirement on VO (112.6%, 88.9-140.4) compared to VR (130.4%, 108.4-157.3), although there wasn't a significant difference (p = 0.10). For carbohydrates (CHO), the days of VO were closer to 100% (99.5%, 76.1-123.9) while in VR they were above (110.9%, 85.3-185.3), but not significanlyt different (p = 0.29). Otherwise, the protein intake (PRO) was adequate on VR (103.4%, 63.2-133.8) compared to VO (81.1%, 58.4-108.7) which were below the indicated and different compared with VR (p = 0.01). Fat intake were well above the indicated amount for both training types, nonetheless there was a significant difference (p = 0.01) between the days of VO (200.9%, 132-293.3), which were closer to the indicated plan than the VR days (280.2%, 176-354.7) (Figure 1).
CONCLUSIONS: In this study, subjects showed better adequacy to the indicated plan for protein intake on VR days, the opposite was true for fat intake. Similar adequacy was observed for carbohydrate and energy regardless of the day.

Comparison Of Blood Markers In College Athletes With Different Protein Intake

Brenda Guadalupe Sanchez-Conchas, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Sergio Alejandro Copado-Aguila, Marisol Villegas-Balcazar, Francisco Torres-Naranjo, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To compare the concentration of several blood markers between different absolute and relative protein intake groups by sex in college athletes.
METHODS: We evaluated 248 athletes (138 men [21 ± 3 y, 74 ± 14 kg, 176 ± 7 cm], 110 women [21 ± 2 y, 62 ± 12 kg, 164 ± 7 cm]) that competed at national level. We estimated the protein intake by a 24-hour reminder of a habitual training day. Subsequently the ingestion of absolute (g/day) and relative (g/kg/day) protein of each athlete was estimated. Then, the sample was divided by sex and by quartiles (Q) of protein intake (absolute and relative). In addition, blood chemistry was performed to evaluate uric acid, urea, creatinine, cholesterol, and triacylglycerides, which were compared between protein Q. We only analyzed the data of subjects who had the 24-hour reminder and their blood chemistry within a period of no more than 30 days difference.
RESULTS: The concentrations in creatinine, urea, uric acid and cholesterol in males showed no significant differences between absolute protein intake Q. However, there was a trend (p = 0.10) for differences on triacylglycerides concentration between Q2 and Q4 of absolute protein intake. No blood marker showed significant differences between Q of relative protein intake. In the case of females, no blood marker had a significant difference between Q of absolute protein intake. Similarly, there were no significant differences in the concentration of creatinine, uric acid, triacylglycerides and cholesterol among Q of relative protein intake. However, there was a significant difference (p=0.04) in urea concentrations between Q2 and Q4 of relative protein intake. All the mean concentrations fell within the normal ranges.
CONCLUSIONS: In this study, no significant differences were found in blood markers among both male and femlae college athletes who consumed more protein than those consuming less. However urea may differ with different protein intake amounts in female athletes.

Table 1. Blood markers according to different protein intake levels by sex								
	Q1		Q2		Q3		Q4

Blood Markers In College Athletes According To Their Vegetable/Animal Protein Intake Rate

Alejandra Karey Corona-Martinez, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Sergio Alejandro Copado-Aguila, Marisol Villegas-Balcazar, Francisco Torres-Naranjo, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To compare the blood markers of a group of college athletes with low vegetable/animal protein intake rate against a group of college athletes with high vegetable/animal protein intake rate.
METHODS: We included 141 college athletes (83 males; 58 females). We evaluated their total protein intake (vegetable and animal protein) with a 24-h dietary recall.

Their vegetable/animal protein intake rate was calculated and the sample was divided in tertiles adjusted by sex. We also evaluated cholesterol, triacylglycerides, glucose, uric acid, urea, and creatinine levels by blood samples. The blood markers were compared between the first (low vegetable/animal protein intake ratio, T1) and the third (high vegetable/animal protein intake ratio, T3) tertiles.
RESULTS: The absolute (151±82 g vs 106±4 g; p=0.03) and relative (2.1±1.0 g/kg vs 1.4±0.6 g/kg; p=0.02) protein intake was higher in males in the T1 than T3. The animal protein intake was higher in T1 than T3 (126±76 g vs 60±28 g; p=0.001), and vegetable protein intake was higher in T3 than T1 (24±14 g vs 48±17 g; p=0.001). There were no significant differences in the blood markers between males in T1 vs T3. In females, the absolute (140±51 g vs 63±2 g; p=0.001) and relative (2.2±1.0 g/kg vs 1.1±0.6 g/kg; p=0.001) protein intake was higher in T1 than T3. Similarly, the animal protein intake was higher in T1 than T3 (118±46 g vs 34±15 g; p=0.001), however, the vegetable protein intake was similar for both tertiles (T1 23±10 g vs T3 29±16 g; p=0.19). The creatinine blood concentration was significantly higher in T1 compared with T3, and there was a trend for difference in urea blood concentrations (table 1). All other blood markers did not show significant differences; and all markers were within normal values.
CONCLUSIONS: A low vegetable/animal protein intake rate may not affect the blood markers in male athletes. However, in female athletes it may be related with higher creatinine blood levels.

Table 1. Blood markers according to the vegetable/animal protein intake rate by sex.				
Sex	Blood marker	T1	T3	p
Males (n 28 per tertile)	Urea	29 ±4	28 ±3	0.35
	Uric acid	4.6 ±0.9	4.4 ±1.1	0.36
	Creatinine	1.01 ±0.21	0.97 ±0.16	0.42
	Triacylglycerides	94 ±44	81 ±34	0.30
	Cholesterol	159 ±33	167 ±31	0.36
	Glucose	73 ±10	72 ±9	0.79
Females (n 19 per tertile)	Urea	29 ±3	27 ±3	0.09
	Uric acid	4.5 ±1.4	3.8 ±1.2	0.12
	Creatinine	0.95 ±0.16	0.85 ±0.15	0.04
	Triacylglycerides	75 ±29	83 ±36	0.45
	Cholesterol	162 ±29	167 ±19	0.59
	Glucose	75 ±10	75 ±9	0.92

Carbohydrate Intake in Mexican Soccer Players in Different Training Sessions

Samuel A. García Castrejón, María de Lourdes Mayol Soto, Martha Smith Pedraza, Adriana De la Parra-Solomon, Arturo Becerra Gamboa. *Gatorade Sports Science Institute México, México City, Mexico.*

Reported Relationships: S.A. García Castrejón: *Contracted Research - Including Principle Investigator; This study was funded by the Gatorade Sports Science Institute. The views expressed in this abstract are those of the authors and do not necessarily reflect the position or policy of PepsiCo, Inc..*

PURPOSE: To investigate if carbohydrate intake in professional soccer players is the same during moderate and high intensity training and whether intake is within the recommended range established by the American College of Sports Medicine (ACSM) (30-60 g/h).
METHODS: A cross-sectional study was conducted in professional soccer players (17-37 years old) of four Mexican First Division teams (N=123) in which carbohydrate (CHO) intake in grams per hour was determined by drinking ad libitum a sports beverage with 6% of CHO or water, or any other source of CHO (gels, fruit) preferred by the player during moderate training intensity (CHI n=24, Wet Bulb Globe Temperature (WBGT) 23 ºC, humidity 51%, duration 100 min; RAYm n=25, WBGT 34ºC, humidity 42%, duration 80 min) and high intensity (SAN n=22, WBGT 32 ºC, humidity 41%, duration 125 min; XOL n= 25, WBGT 25ºC, humidity 13 %, duration 90 min; and RAYh n=27, WBGT 17ºC, humidity 69%, duration 80 min), determined by their coach. Moderate intensity versus high intensity CHO intake comparisons were analysed by Student's T test for independent samples.
RESULTS: CHO intake of soccer players in moderate intensity training was (mean ± SD) 17 ± 14 g/h and in high intensity was 14 ± 13 g/h. For moderate intensity training sessions, only 14% of the players met the CHO intake recommendations and for high intensity training sessions only 12% of the players met the recommendations When comparing moderate intensity versus high intensity between RAYm versus Rayh there was not significant difference in the ingestion of CHO (p>0.05).
CONCLUSIONS: Soccer is a high intensity intermittent sport that requires a large supply of energy from the glycolytic pathway; thus, CHO intake is important to have a constant fuel supply during training sessions with moderate to high intensity beyond 60 minutes and games. We observed that Mexican professional soccer players do not consume the minimum recommended CHO intake for moderate-high intensity

training exercise (30-60 g/h) as recommended by ACSM for exercise lasting 1-2 hours. Therefore, it is important to educate soccer players about the importance of consuming the recommended amount of CHO during training sessions and games.

Omega-3 Index in Division I Collegiate American Football Athletes

Andrew T. Askow[1], Anthony J. Anzalone[1], Jason D. Stone[1], Will Jennings[1], Aaron Carbuhn[2], Ryan Pinson[3], Amy Bragg[4], K. Michelle Kirk[1], David A. Gable[1], Stephen F. Crouse, FACSM[5], William S. Harris[6], Jonathan M. Oliver[1]. *¹Texas Christian University, Fort Worth, TX. ²University of Kansas, Lawrence, KS. ³University of Wyoming, Laramie, WY. ⁴University of Alabama, Tuscaloosa, AL. ⁵Texas A&M University, College Station, TX. ⁶OmegaQuant, LLC, Sioux Falls, SD.* (Sponsor: Stephen F. Crouse, FACSM)
(No relevant relationships reported)

American football athletes are exposed to repetitive head impacts (RHI) that, even in the absence of a clinically discernible head injury, result in quantifiable neurological damage. Pre-clinical studies utilizing rodent models indicate that traumatic brain injuries (TBI) can cause a reduction in neuronal omega-3 fatty acids (n-3FAs), specifically docosahexaenoic acid (DHA). Pre-injury administration of n-3FAs, however, has shown to effectively allay the pathological response to TBI. Furthermore, one study has demonstrated the potential neuroprotective effect of DHA supplementation in American football athletes evidenced by a marked reduction in blood biomarkers of axonal injury. Given that the American diet is scarce in the n-3FAs DHA and eicosapentaenoic acid (EPA), the potential neuroprotective effect of n-3FA supplementation may uniquely benefit American football athletes. **PURPOSE:** This descriptive study sought to examine the omega-3 index, an indicator of n-3FA status, in American collegiate football athletes not supplementing with n-3FAs. **METHODS:** One hundred twelve (n = 112) athletes participated in this study. Blood was obtained via finger stick and collected on blood spot cards pre-treated with an antioxidant cocktail. The dried blood samples were analyzed by gas chromatography for fatty acid (FA) levels (expressed as a % of total blood FAs). A regression formula (r = 0.98) was used to estimate the percentage of DHA and EPA in red blood cell phospholipids (omega-3 index). **RESULTS:** Levels of DHA, EPA, and alpha-linolenic acid (ALA) were (mean ± SD) 2.27% ± 0.01% (range = 1.1% - 5.2%), 0.39% ± 0.00% (range = 0.2% - 1.2%) and 0.39% ± 0.00% (range = 0.1% - 1.0%), respectively. Mean omega-6 levels were 9.55 ± 1.72 (range = 4.5 - 13.9) times higher than n-3FAs levels. The mean omega-3 index was 4.35% ± 0.01% (range = 2.8% - 8.0%). Sub-optimal n-3FA levels (i.e., an index < 8.0%) were observed in 99.12% of participants. **CONCLUSION:** These data suggest that dietary intake of the n-3FAs DHA and EPA may not be adequate in American collegiate football athletes. Though the current evidence relates n-3FA deficiency to an increased risk for cardiovascular risk, American football athletes may derive neuroprotective benefit from n-3FA supplementation with little to no risk.

Association between Leptin and Measures of Bone Density and Lean Mass in Long Distance Runners

Alexis Ortiz, FACSM, Dina Acosta, Jenna McManus, Dai Cheng, Rita Dellostrito, Anita Oliver, Mindy Patterson. *Texas Woman's University, Houston, TX.*
(No relevant relationships reported)

Leptin levels have been associated with greater bone mineral content (BMC) and lean mass (LM) in women. **PURPOSE**: To explore the association of fasting leptin levels and BMC and LM in female collegiate long-distance runners.
METHODS: BMC (g) and LM (g) was determined via dual-energy X-ray absorptiometry in 10 female collegiate long-distance runners (age: 22.2 ± 3.3 years; weight: 53.2 ± 6.0 kg; height: 163.6 ± 8.4 cm) with a mean BMI of 19.8 ± 1.4 kg/m² within the same running team. Fasting leptin (ng/mL) was measured via enzyme-linked immunosorbent assay. Regression analyses with leptin and fat mass (g) as predictors and BMC and LM as outcomes were used to explore the association between leptin and BMC and LM.
RESULTS: Fasting leptin (3.39 ± 1.45 ng/mL) showed a statistically significant positive association with BMC (2079.57 ± 195.30g; r=0.89, p = 0.001) explaining 75% of the variance. Adding fat mass (10333.48 ± 1903.25 g) into the model increased the variance by 22%. The association between leptin and LM (39620.11 ± 5361.65 g) was also positive (r=0.87, p = 0.001) with LM explaining 77% of the variance. Adding fat mass as predictor did not change the model.
CONCLUSIONS: Leptin is directly associated with bone health and muscle mass showing the importance of leptin towards homeostasis of these two body tissues.

Effects Of 6-week Resistance-type Exercise Training On Serum 25-hydroxyvitamin D Concentrations In Young Men

Zhen-Bo Cao[1], Xiaokai Ma[1], Lin Zhang[1], Xiaomin Sun[2], Zheng Zhu[1]. *¹Shanghai University of Sport, Shanghai, China. ²Xi'an Jiaotong University, Xi'an, China.*
(No relevant relationships reported)

Previous studies suggest that higher levels of physical activity is positively related to serum 25-hydroxyvitamin D [25(OH)D] concentrations, regardless of the sun exposure duration. However, the response of 25(OH)D concentrations to resistance-type exercise training is unclear.
PURPOSE: To clarify whether there is a direct effect of a 6-week resistance-type exercise training on serum 25(OH)D concentrations in young men.
METHODS: Eighteen young men were randomized into a no-exercise control group (n=9; 26.7 ±2.1 years; body mass index (BMI) =22.4 ±0.7 kg/m²) and a resistance-type exercise training group (supervised resistance-type exercise training was performed 3 times/wk for a 6-wk period from March to April; n=9; 24.4 ±1.1 years; BMI =22.9 ±1.0 kg/m²). Serum 25(OH)D concentrations and iPTH were assessed using commercial ELISA kits. Lean body mass and percent body fat were determined by dual energy X-ray absorptiometry (DXA). Muscle strength was assessed regularly by 1-repetition maximum strength testing. Physical activity (PA) was assessed using an ActiGraph GT3X triaxial accelerometer and quantified as time spent in moderate- and vigorous physical activity (MVPA). Two-way repeated measures ANOVA was used to detect time, group, or time x group interaction effects.
RESULTS: Serum 25(OH)D concentrations were unchanged after 6-week resistance-type exercise training (Pre: 27.8±2.0 nmol/L, Post:31.0±2.2 nmol/L, P=0.65). But a significant increase was found in the no-exercise control group (Pre: 26.2±1.4 nmol/L, Post: 34.3±2.9 nmol/L, P < 0.05). After 6-week resistance-type exercise training, lean body mass and muscle strength was significantly increased (P<0.05), while percent body fat was not changed (P=0.06).
CONCLUSION: The present study indicates that 6-week resistance-type exercise training could inhibit the seasonal increase in serum 25(OH)D concentrations. Further research is needed to determine the underlying mechanisms explaining the negative effects of resistance-type exercise training on 25(OH)D concentration.

Limited Knowledge about the Potential Chronic Effects of Excessive Iron Intake among College Distance Runners

Sarah C. Bent, Anna E. Greer, Beau K. Greer. *Sacred Heart University, Fairfield, CT.* (Sponsor: Peter Ronai, FACSM)
(No relevant relationships reported)

While distance runners' knowledge related to iron deficiency has been previously examined, knowledge of the potentially negative chronic effects of high iron intake has never been assessed. **PURPOSE**: To investigate college distance runners' knowledge concerning issues related to basic iron-related nutrition and chronically high iron intakes, as well as influences on the choice to supplement with iron. **METHODS**: Ninety-eight college distance runners (54 F; 44 M) were recruited from three Division I programs in the northeastern U.S. to participate in a 22-question, pen-and-paper questionnaire. The questionnaire examined respondents': 1) prior diagnosis of iron deficiency (yes/no); 2) knowledge of foods containing iron (100 points possible); 3) confidence in their ability to identify iron-rich foods (5-point Likert scale from no confidence to high confidence); 4) status for currently taking a multivitamin containing iron or standalone iron supplement (yes/no and mg consumed/day); 5) knowledge index of the positive and negative health and performance effects of iron (score range 0-24); and 6) whether or not a coach has ever recommended they take an iron supplement (yes/no). Descriptive statistics were used to describe the data. **RESULTS**: Only 29.6% of respondents reported an iron deficiency diagnosis at some point in life; however, 46.3% were taking either a standalone iron supplement or a multivitamin that contains iron. Of those supplementing with iron, 88.9% reported taking more than 45 mg/day, the tolerable upper limit. Approximately three-fourths (73.6%) of respondents reported moderate or high confidence in their ability to identify iron-rich foods; however, respondents' mean score on the iron knowledge index was 43/100 points. Respondents' mean score on the knowledge index of positive and negative health and performance effects of iron was only 7.5 out of 24 possible points. Finally, 52% of respondents reported that a coach has suggested iron supplementation at some point in their running career. **CONCLUSION**: College distance runners demonstrated limited knowledge about iron-rich foods as well as the potential negative chronic effects of high iron intake. Coaches may often be operating outside of their scope of practice by directly recommending iron supplementation to runners.

Macronutrient And Supplementation Distribution Evaluation From Athletes Training For The Ironman Triathlon.

Maria Cecilia L. de Carvalho[1], Caroline A. Yoshioka[2], Renata F. Viebig[1], Erico C. Caperuto[2]. [1]Mackenzie Presbiterian University, São Paulo, Brazil. [2]São Judas Tadeu University, São Paulo, Brazil.

(No relevant relationships reported)

PURPOSE: We aimed to evaluate the macronutrient and supplementation distribution of athletes training to an Ironman triathlon. **METHODS**: 13 athletes of both genders were training to the 2017 Florianópolis Ironman and were selected to be part of the study. We registered the complete food and supplements amount ingested during one day of long training (>5h). All records were calculated for calories and divided in 3 periods, before, during and after the training session (and the rest of the day). We calculated total caloric ingestion and the macronutrient distribution was relativized to each athlete body weight. **RESULTS**: Before: All athletes had most of the calories from carbohydrates, and in 77% of the athletes, protein ingestion was less than 15% of the ingested amount for this period. During: 92% of the reports showed that carbohydrate was more than 70% of the ingested calories to this period. 85% of the athletes ingested up to 10% of protein and 61% up to 10% of lipids, and 23% of the athletes ingested 0 calories from lipids during the training session. After: Protein was heavily ingested after the training session when compared to the other periods, however the most prevailing nutrient of the period was still the carbohydrates. Total consumption: all athletes consumed more than 50kcal/kg of body weight, with most of the calories coming from carbs. Regarding the supplements, more than half of the evaluated group consumed palatinose before and/or during the training. Beta alanine, glutamine and BCAA were also reported by most of the group. **CONCLUSIONS**: Our study reassures carbohydrates as the most used energy source to endurance activities and puts in evidence the importance of nutritional advising in this kind of activity, since most of the athletes have had problems with feeding during the competitions, fact that reinforces the importance of training the intestine to tolerate a larger amount of carbohydrate during exercise.

Comparison Of Dietary Habits Between Volunteer Firefighters And Non-firefighters

Deborah L. Feairheller[1], Alexandra Puryear[1], Lauren N. Chavis[2], Kelly C. McLaughlin[1], Emily Reeve[1], Meaghan E. Corbin[1], Stephanie Donahue[1], Christian K. Roberts, FACSM[3], Pamela Chlad[4]. [1]Ursinus College, HEART Laboratory, Collegeville, PA. [2]National Institute of Health, Clinical Research Associate, Bethesda, MD. [3]Geriatrics Research Education & Clinical Center, VA Greater Los Angeles Healthcare System, Los Angeles, CA. [4]Ursinus College, Sports Medicine Clinic, Collegeville, PA. (Sponsor: Christian K Roberts, FACSM)

(No relevant relationships reported)

As the global burden of cardiovascular disease (CVD) rises, public health-related interventions aimed at prevention have gained increased attention. Physicians and public health officials may be unaware that CVD or cardiac events are related to more than half of the line-of-duty deaths in firefighters (FF). Diet is one of the main modifiable CVD risk factors, yet poor diet and the risk factors it contributes to, including obesity, continue to be an issue as the prevalence of obesity is high in FF. Dietary patterns can also influence other risk factors like blood pressure, lipid levels, body composition and glucose metabolism. However, healthy diets are not always feasible for FF, due to the fast-paced unpredictable nature of work, and thus FF often rely on quick meals that may not be nutritiously optimal. Limited research has examined FF dietary intake and preferences. **PURPOSE:** To examine the dietary habits of local volunteer FF and compare these to adult non-FF in the area. **METHODS:** 76 adults (36 FF, 37.0 ±11 years, BMI 30.4 ±5.7 kg/m²; 40 non-FF, 30.6 ±11 years, BMI 28.3 ±5.7 kg/m²) were studied. All participants completed a 3-day dietary recall, and had height and weight measured. Three-day diet recalls were obtained from volunteer FF who attended dietary workshops in their firehouse and from non-FF adults in the area who were interested to find out their dietary habits. Data was analyzed using Diet Analysis Plus. **RESULTS:** Macronutrient composition of the diets were similar. The FF average diet was 2037.9 ±597.3 calories; including 34.8% fat, 46.0% carbohydrates, and 17.8% protein. The average diet for non-FF adults was 2185.7 ±405.9 calories; including 34.1% fat, 48.6% carbohydrates, and 17.8% protein. FF had significantly lower levels of vitamin B-6 (1.7 ±0.9 vs 2.3 ±1.2 mg), folate (498.3 ±253 vs 685.7 ±375 µg), and vitamin C (50.8 ±48.5 vs 111.9 ±87.8 mg) intake compared to non-FF, respectively, p<0.05. FF diets were lacking in several key micronutrients, including calcium (961.8 ± 410 mg), magnesium (227.1 ±138mg), potassium (2177.7 ± 1059 mg), and vitamin D (4.2 ±4.6 µg). For these, >90% of the FF diets did not meet recommended levels. **CONCLUSION:** These data suggests that volunteer FF exhibit deficiencies in several micronutrients and may benefit from diets that encourage increased consumption of fruits and vegetables.

Effects of Recovery Nutrition on Body Composition and Session RPE in Collegiate Tennis Players

Annika Vahk, Christi Brewer, Katrina Taylor. *Eastern Washington University, Cheney, WA.*

(No relevant relationships reported)

Athletes often overlook the psychological and physiological importance of recovery nutrition in athletic performance. Little research has investigated the role of recovery nutrition on perceived exertion in college athletes. **Purpose:** To examine the perceived and physiological effects of regular, whole food, recovery nutrition on session rating of perceived exertion (RPE) and body composition in collegiate athletes. **Methods:** Female tennis players (n=8, age 20.1±1.4 years; weight 66.8±6.9 kg) volunteered for the 8-week study during their competitive season. Air displacement plethysmography was used to estimate fat mass (FM) and fat-free mass (FFM) at baseline, 4-week, and end of the 8-week intervention. Seven training sessions (60 min), consisting of high intensity strength and power exercises, were performed during each 4-week phase of the study. Athletes continued their normal pattern during the first 4-weeks (T1) and were provided with standardized recovery nutrition at the conclusion of each training session for the second 4-weeks (T2). RPE on a scale of 0-10 was reported immediately after each training session. Recovery nutrition consisted of a 3" red apple, 7" banana, 1.05 oz. peanut butter spread, and an 85g bagel or 99g gluten-free bagel. Nutritional composition for a standard snack bag was 680kcal, 106g carbohydrate, 17.8g protein, 24.7g fat, while a gluten-free snack bag totaled 740kcal, 107g carbohydrate, 18.8g protein, 31.7g fat. Participants were instructed to consume all foods within an hour of the training session. Repeated measures ANOVA was used to examine changes in session RPE and body composition over time. **Results:** There was a main effect of recovery nutrition on session RPE (p<0.001) with a lower RPE reported in T2 (3.53±1.24) than T1 (4.50±1.44). FM and FFM decreased 0.05kg and 0.28kg, respectively; however, changes were not significant (p>0.05). Athletes reported an increased quality of training with recovery nutrition. **Conclusions:** Four weeks of recovery nutrition resulted in a ~10% decrease in session RPE in female tennis players. Further, athletes perceived they trained harder during the sessions with recovery nutrition. Future research would be beneficial to determine the direct effects of recovery nutrition on performance.

Does Exclusion of Trunk Region Improve Accuracy of DXA Lean Soft Tissue from Non-Fasted Assessments?

Grant M. Tinsley[1], Brett S. Nickerson[2]. [1]Texas Tech University, Lubbock, TX. [2]Texas A&M International University, Laredo, TX.

(No relevant relationships reported)

PURPOSE Although body composition assessment ideally takes place after an overnight fast, this is not always possible. When assessed by dual-energy x-ray absorptiometry (DXA), the trunk region is most affected by acute food and fluid intake. Therefore, the purpose of this analysis was to determine if DXA appendicular lean soft tissue (ALST) and ALST-derived skeletal muscle mass (SMM) are less susceptible than total lean soft tissue (LST) to error introduced by acute food and fluid intake due to the exclusion of the trunk region. **METHODS** Forty-eight adults were assessed by whole-body DXA scans after an overnight fast and again the same afternoon following the consumption of a standardized diet (51 ± 37 min after food consumption). Body regions were manually specified by a single trained operator based on the NHANES Body Composition Procedures Manual. Whole-body LST and ALST were obtained from DXA output, and ALST-derived SMM was calculated using a validated equation. ALST, SMM and LST were analyzed using ANOVA with repeated measures, and metrics of reliability were calculated (constant error [CE], total error [TE] and 95% limits of agreement [LOA]). **RESULTS** Acute food and fluid consumption artificially increased the quantity of ALST (p<0.001), SMM (p=0.003) and LST (p<0.001). The changes were smaller for ALST (CE: 196 grams; 0.9% of mean) and SMM (CE: 222 grams; 0.9% of mean) than LST (CE: 755 grams; 1.6% of mean). However, TE relative to mean values was higher for ALST (2.7%) and SMM (2.7%) than LST (2.1%). The 95% LOA were similar for ALST (±1072 g), SMM (±1212 grams) and LST (±1277 grams), but were greater for ALST (5.0%) and SMM (5.0%) than LST (2.7%) when expressed relative to the mean. **CONCLUSIONS** Use of the ALST or ALST-derived SMM minimizes the systematic error (CE) associated with acute food and fluid ingestion as compared to total LST. However, due to greater variability in individual CEs, the TE is slightly higher for ALST and SMM than LST. This is likely due to the variability introduced when designating the appendicular and truncal regions, which appears to outweigh the error removed by exclusion of the trunk region. Although elimination of the trunk region is

theoretically appealing for non-fasted DXA assessments (i.e. ALST and SMM), it is apparently inferior to utilizing whole-body LST as indicated by the higher 95% LOA and TE.

Food Intake And Fluid Balance Varies Between Individuals During A 120 Km Running Race

Floris Wardenaar[1], Daan Hoogervorst[2]. [1]*Arizona State University, Phoenix, AZ.* [2]*Cordes Fysiotherapie, Voorhout, Netherlands.*
(No relevant relationships reported)

Continuous data collection on fueling and food strategies of ultramarathoners during competition is scarce. Existing publications mostly report nutrient intake without much detail of fluid balance and foods consumed.
PURPOSE: To provide an overview of the consumption of carbohydrates and fluids, fluid balance and types of foods during a race comprising 10-14 hours of continuous exercise.
METHODS: Pre-race height, cm (Cescorf stadiometer) and pre- and post-race body weight, kg (Seca scale S760 mechanical) were measured. All food products were labeled and weighed (g) pre- and post-race (Cresta, CKS750). Continuous observation of food and beverage intake was performed as all runners were accompanied by a research team member on a bicycle using pre-defined lists and action cams (SJCAM, SJ4000) to record all items consumed. Fluid excretion collection was done using urine bags (Roadbag®). Results are expressed as mean±SD and range (min-max) or as percentage (%).
RESULTS: The average temperature was 7.0°C with a humidity of 67%. Five runners performed the 120 km run with an average duration of 12:19±1:29 hours (9:50-13:49). They reported 38±10 (25-48) food and beverage consumption events over the race which consisted of 4-7 different preferred food items per person. This resulted in an average carbohydrate intake of 44±19 g/h and fluid intake of 421±127 ml/h. Runners lost 2.5±1.6 kg (-0.2-3.8) of total weight during the race. The average urine excretion was 0.8±0.5 kg (0.3-1.4). This resulted in an estimated sweat loss of 6.6±2.3 kg (4.6-10.1) and four out of five runners reported a lower post-race body weight of 4±2% (0-6). During the first 60 km of the race the preferred foods and beverages were energy gels, water and sports drinks. After this, food preferences suggested a more mixed pattern including the use of cola, chocolate milk and fruit.
CONCLUSIONS: Runners consume, on average, fewer carbohydrates and fluids than recommended due to a high variability in intake. As urine excretion was relatively low, mostly a high sweat rate contributed to a lower post-race weight. Although non-specific sports nutrition foods and beverages were used, runners preferred the use of commercial sports nutrition products the most.

Physical Activity, Sedentary Behavior and Sleep in Adolescents - Weekday and Weekend Patterns

Agnes G. Bucko, Marsha Dowda, FACSM, Russ R. Pate, FACSM. *University of South Carolina, Columbia, SC.*
(No relevant relationships reported)

In adolescents sleep behavior differs markedly between weekdays and weekend days. The implications of this disparity for the associations among sleep, physical activity and sedentary behavior are unclear. **PURPOSE:** To determine if there are significant differences in physical activity and sedentary behavior between students who experience adequate vs. inadequate sleep, analyzing weekday and weekend data separately. **METHODS:** The School Sleep Habits Survey was used to measure total sleep time on weekends and weekdays. Sleeping ≥8 hours per night was considered adequate sleep (AS), while sleeping <8 hours was considered inadequate sleep (IS). Accelerometry was used to measure sedentary behavior (SB) and total physical activity (PA) on weekdays and weekends. SB was determined by the total minutes/day below 100 counts/minute, while PA was determined by the total minutes/day at, or above 100 counts/minute. The sample consisted of 261 9th grade adolescents. Over half were male (59%). A majority were African American (52%). Average weekday PA was compared between the AS group and the IS group using weekday sleep data. The same was done using weekday SB. Average weekend PA was compared between the AS group and the IS group using weekend sleep data. The same was done using weekend SB. T-tests were used to determine significant differences between groups. **RESULTS:** There were more students in the AS group (n = 156) than the IS group (n = 96) on weekends,

and more students in the IS group (n = 169) than the AS group (n = 92) on weekdays. There were no statistically significant differences between PA and SB levels by sleep group, on weekends and weekdays. **CONCLUSION:** Students who experienced adequate levels of sleep did not differ in their levels of PA from those who experienced inadequate sleep. This was the case on weekends and weekdays. Similarly, students who experienced adequate levels of sleep did not differ in their levels of SB from those who experienced inadequate sleep. This was also the case for weekends and weekdays.

Social Cognitive Theory Role in Physical Activity Behavior and Health-Related Quality of Life in Parkinson's

Melinda S. Hill, PhD. *The Ohio State University, Columbus, OH.*
(Sponsor: Brian C. Focht, PhD, FACSM, CSCS, FACSM)
(No relevant relationships reported)

Parkinson's disease (PD) is a chronic neurodegenerative disease of the brain, characterized by motor symptoms-tremor, rigidity, bradykinesia, slowness/smallness, and postural instability-as well as non-motor symptoms including anxiety, depression, sleep disorders, and cognitive deficits. Physical activity (PA) may slow the progression of PD and improve the health-related quality of life (HRQoL) of patients. **PURPOSE:** This observational cross-sectional study examined correlates of lifestyle behaviors and health-related quality of life by analysis of the relationships between demographic, PA, and psychosocial variables in this population of 500 idiopathic PD patients. **METHODS:** Study aims included examining: the relationship of self-efficacy (SE), outcome expectations (OE), and self-regulation (SR) with PA and HRQoL; the relationship between PA and HRQoL; determination if social cognitive theory (SCT) constructs mediate the relationship between PA and HRQoL in Parkinson's patients. Statistical analysis included: descriptive statistics on all variables; bivariate correlations to determine the significance of relationships between SCT constructs, PA, and HRQoL using Pearson's correlations for scale level data and Spearman's correlations for ordinal data. Data analysis of primary study aims was conducted using multiple linear regression analysis. The indirect effects in the mediation model were analyzed using Dr. Andrew Hayes' PROCESS. **RESULTS:** Participants self-reported a mean of slightly over 200 minutes of moderate to vigorous physical activity (MVPA) per week. SE and SR were the most significant predictors of PA (p&lt.001). SE, OE, and SR were predictive of physical HRQoL (p&lt.001). To a smaller extent, SE, OE, and SR were predictive of mental HRQoL (p&lt.001). Results further indicated that SCT correlates mediated the relationship of PA and physical HRQoL (p=.0851). **CONCLUSIONS:** These results suggest self-selected participation based on a high interest in PA. Self-reported average weekly mMVPA was much higher than expected. Future studies should attempt to validate self-reported physical activity with some type of validated exercise measurement tool. These results suggest further consideration of SCT constructs in the design of interventions targeted to Parkinson's patients.

Self-Selected Intensity of Four Different Modes of Aerobic Exercise in Sedentary Adults

Luke Haile[1], Heather J. Porter[2], Curt B. Dixon, FACSM[3]. [1]*Bloomsburg University, Bloomsburg, PA.* [2]*Penn State University, State College, PA.* [3]*Lock Haven University, Lock Haven, PA.* (Sponsor: Curt Dixon, PhD, FACSM)
(No relevant relationships reported)

The prescription of self-selected intensity (SSI) exercise has shown promise as a method to increase physical activity and cardiorespiratory fitness. SSI allows control over the exercise stimulus, promotes positive affect, and is often an intensity known to induce health-fitness benefits.
PURPOSE: To compare SSI between Treadmill, Elliptical, Upright Cycle, and Recumbent Cycle exercise in sedentary adults (<90 min of aerobic activity per week). **METHODS**: Ten subjects (8 w, 2 m; 31 ± 10 yr, VO_2max: 33 ± 9 ml·kg^{-1}·min^{-1}) completed five submaximal exercise trials on separate days. The first four, one trial per mode completed in random order, were 30-min each: 5 min warm-up, 20 min SSI, 5-min cool-down. Oxygen consumption (VO_2; ParvoMedics) and heart rate (HR; Polar) were monitored continuously. Ratings of perceived exertion (RPE; OMNI Scale) and affective responses (AR; Feeling Scale) were collected every 5 min. The fifth trial was a submaximal graded treadmill test to predict VO_2max. The mean values from the 20-min SSI were compared between modes using repeated-measures ANOVA. Pairwise comparisons were performed using Bonferroni corrections for significant ANOVAs.
RESULTS: ANOVAs were significant for VO_2 ($F_{3,27}$=8.6, p<.05), %VO_2Reserve ($F_{3,27}$=7.8, p<.05), Kcal ($F_{3,27}$=9.7, p<.05), and HR ($F_{3,27}$=4.2, p<.05). For each, Elliptical was significantly greater than Recumbent Cycle (20.4 ± 5.3 vs 15.4 ± 3.6

---

ml·kg⁻¹·min⁻¹; 58.5 ± 14 vs 41.3 ± 11 %VO₂Reserve; 218 ± 51 vs 160 ± 39 Kcal; 87.0 ± 7 vs 72.5 ± 9 %APMHR). Treadmill was also significantly greater than Recumbent Cycle for VO₂ (20.8 ± 6.4 ml·kg⁻¹·min⁻¹) and Kcal (211 ± 57 Kcal).
CONCLUSIONS: The mean SSI during all four modes of exercise is in line with the ACSM position stand for developing and maintaining cardiorespiratory fitness, which states that subjects with a mean VO₂max <40 ml·kg⁻¹·min⁻¹ can improve cardiorespiratory fitness with intensity prescriptions as low as 30% VO₂Reserve.

1309   Board #117   May 31 9:00 AM - 10:30 AM

Using Ecological Momentary Assessment to Explore Proposed Indices of Exercise Readiness and Subsequent Exercise Behavior

Kelley Strohacker, Michael O'Neil, Cary M. Springer, Lucas Sheridan. *University of Tennessee, Knoxville, TN.*
(No relevant relationships reported)

Flexible Nonlinear Periodization (FNLP) was developed to preserve training quality in athletes by matching workload demand to pre-exercise mental and physical states. The degree of "readiness to train" is purportedly determined via a six-part checklist: coach-athlete interactions, injury status, hydration, fatigue ratings, vertical jump power, and initial performances. Prior to adapting FNLP for untrained populations, it is important to examine if similar factors predict exercise behavior in a free-living context. **PURPOSE**: Use ecological momentary assessment to determine time-lagged and concurrent effects of factors suggestive of readiness on exercise behavior. **METHODS**: Participants (N=29, 24±6y, 55% female, 76% white) received text message prompts to their personal smartphones at 9:30am, 1:30pm, 5:30pm, and 9:30pm over 14 consecutive days. Each prompt contained a link to a survey (Qualtrics) that assessed perceptions of core affect, fatigue, bodily discomfort (e.g. pain, stiffness), and hydration, as well as self-efficacy to exercise in the subsequent four-hour block. Exercise type and duration were also collected in each survey and used to calculate bout volume expressed as MET-minutes. On average, participants were active, accumulating 1116±596 MET-minutes of structured exercise per week (min=150, max=2074). Lagged and concurrent prediction analyses were conducted using three-level (time of day, day of week, individual) linear mixed models in SAS. **RESULTS**: Self-efficacy was the only variable predictive of MET-minutes in a subsequent four-hour time block (t=7.18, p<0.0001, R²=0.43). Fatigue was the only variable concurrently related to self-efficacy (t=-3.38, p=0.0017, R²=0.18). Concurrent correlates of fatigue (R²=0.60) included core affect (t=-8.51, p<0.0001) and discomfort (t=8.66, p<0.0001) with a trend for perceived hydration (t=-1.72, p=0.09). **CONCLUSIONS**: These findings continue to support self-efficacy as a strong predictor of future exercise behavior. While measures of fatigue, affect, discomfort, and hydration did not directly predict exercise behavior, the observed inter-relationships provide some support for the key assumption of FNLP. Replication of these results in relevant target populations is necessary prior to implementing FNLP-based interventions.

1310   Board #118   May 31 9:00 AM - 10:30 AM

Affect, Eating Attitudes, And Exercise Dependence Of Personal Trainers With Different Years Of Experience

David A. Tobar, Brett C. Holcomb, Bonnie G. Berger. *Bowling Green State University, Bowling Green, OH.*
(No relevant relationships reported)

PURPOSE: To examine the affect, eating attitudes, and exercise dependence of personal trainers with different years of experience. **METHODS:** Data were collected from female personal trainers (*n* = 17; 36±10 yrs of age; 146±21 lbs) at health/fitness centers in the Midwest. Participants completed a demographic survey, Positive Affect and Negative Affects Scale, Eating Attitudes Test (EAT-26), and Exercise Dependence Scale-Revised (EDS-R). Pearson correlation coefficients were calculated between the personal trainer's years of experience (*M* = 6.9±1.7yrs, *Md* = 4yrs, *Range*: 25yrs) and the dependent variables of affect, eating attitudes, and exercise dependence. One-way ANOVAs also were performed with personal trainers (PT) categorized in three groups based on years of experience as a PT: Novice (NPT: *n* = 6; *M* = 1.8±0.9yrs), Intermediate (IPT: *n* = 6; *M* = 5.2±1.6yrs), and Experienced (EPT: *n* = 5; *M* = 15.2±7.4yrs). **RESULTS:** Personal trainer's years of experience was related to positive affect (*r* = .58, *p* = .01), EAT-26 Diet subscale (*r* = -.43, *p* = .08) and Total score (*r* = -.47, *p* = .05), and EDS-R subscales of Withdrawal Effects (*r* = -.44, *p* = .08), Reduction in Other Activities (*r* = -.50, *p* = .04), and Intention (*r* = -.42, *p* = .09). Compared to IPT and EPT, NPT reported less Positive Affect (*Ms* = 32.3, 39.3, 45.8, *p* = .001). On the EAT-26, IPT reported more Oral Control than EPT but not NPT (*Ms* = 1.8, 3.8, 0.60, *p* = .07). As for EDS-R, NPT reported more Withdrawal Effects than IPT but not EPT (*Ms* = 12.8, 6.7, 8.0, *p* = .04) and more Reduction in Other Activities than EPT but not IPT (*Ms* = 7.8, 5.7, 4.6, *p* = .08). **CONCLUSION:** In general, novice personal trainers reported less positive affect, more symptoms of exercise dependence, and poorer eating attitudes. If left unchecked, novice PTs may be at risk of developing clinical levels of exercise dependence and eating disorders, and these dangerous behavioral patterns may be passed along to their clients. These findings suggest that

less experienced personal trainers may benefit from strategies aimed at increasing awareness of eating disorder and exercise dependence behavior patterns. As with most new professionals, establishing a good support network is important, and connecting with more experienced personal trainers may help improve affect and more positive eating and exercise behaviors.

Explore Factors Associated with Exercise Behavior among the Older Chinese Adults in the Rural Area

Zi Yan[1], Ruoyan Lu[2], Yueping Li[2], Zhenquan Zheng[2], Alexandra Harrington[1]. [1]*Merrimack College, North Andover, MA.* [2]*Fujian Medical University, Fujian, China.*
(No relevant relationships reported)

Purpose. The purpose of the study was to explore factors that are associated with exercise behavior among the older Chinese adults in the rural area.
Method. The data of 2586 older Chinese adults (males=1320, females=1259, age M=69.65, SD=8.0) in the rural area were analyzed from the National Health Service survey in Fujian, China. The t-test and χ2-test were carried out to compare the differences between older Chinese adults living in the rural area who did not exercise and who exercised at least once a week, on age, family income, education level, whether having partner, whether having chronic disease or pain, as well as the physical function levels. All data were collected in 2013.
Results. The results showed that there were significant differences between individuals who did not exercise and who exercised at least once a week on the following variables: age (M=69.8, SD=8.1, M=68.6, SD=7.1, respectively, p<.01), family income (M=32178¥, SD=34430, M=38017¥, SD=30991, respectively, p<.05), education level (with elementary education or above, 49.5% vs. 68.3% respectively, P<.001), having a partner (72.9% vs. 80.8%, respectively, P<.05), having difficulties on movement (16.0% vs. 8.4%, respectively, P<.05), having difficulties on self-care (10.7% vs. 5.8%, respectively, P~.05), and having difficulties on daily activity (14.6% vs.7.2%, respectively, P<.01). There were no significant differences between individuals who did not exercise and who exercised at least once a week, on the following variables: having at least one chronic disease (44.7% vs. 45.3%, respectively) and suffering from pain (28.1%vs. 22.7%, respectively), both Ps>.05.
Conclusion. The older Chinese adults in the rural areas were more likely to exercise if they were younger, had higher income and education level, had a partner, and had no difficulties on physical functions.

Physical Activity Postings On Social Media: Physical Activity And Self-presentation Differences Between Sharers And Non-sharers

Katherine Balfany, Maria M. Beitzel, Kathleen S. Wilson. *California State University, Fullerton, Fullerton, CA.* (Sponsor: Daniela A. Rubin, FACSM)
(No relevant relationships reported)

Purpose: Sharing about physical activity (PA) on social media (SM) provides an opportunity for receiving social support from online social networks and may be related to PA levels (Pinkerton et al, 2017). People desire to be perceived positively by others, this is particularly true for SM users (Kaplan & Haenlein, 2010). As an individual shapes the content shared over SM networks, that individual may idealize their character rather than presenting an authentic version (Goffman, 2002). This study examined whether people who post about PA on SM differed in their PA levels and self-presentational efficacy (SPE) when compared to those who do not post. A secondary purpose was to describe the type of SM use across both sharers and non-sharers. **Methods:** A convenience sample of 113 kinesiology students (62M, 44F) completed a cross-sectional survey that included the Godin Leisure Time Exercise Questionnaire (Godin & Shepard, 1985) and the self-presentational efficacy scale (15 items; Gammage, Hall, & Ginis, 2004). This scale asked about confidence to present themselves in a positive fashion with regards to specific outcomes such as 'being in good shape' and 'looking fit and toned' in terms of SPE. Independent t-tests were conducted to compare sharers with non-sharers. **Results:** Students self-identified as sharers of PA on SM (*n*=39, 34.5%; 23M, 16F) or non-sharers (*n*=66, 58.4%; 38M, 28F). There were significantly different levels of PA, with those who posted about PA on SM reporting higher levels of activity (*M*=51.4, *SD*=22.5) than those who did not post about PA on SM (*M*=42.2, *SD*=22.3; *p*=.046). There were also significantly different levels of SPE, with those who posted about PA on SM having higher levels of SPE (*M*=75.1, *SD*=17.6) than those who did not post about PA on SM (*M*=64.5, *SD*=22.4; *p*=.014). Minutes spent on SM reported was similar between sharers (*M*=86.2min/day, *SD*=60.8) and non-sharers (*M*=104.8min/day, *SD*=84.9; *p*=.245). The most commonly used SM platforms for both sharers and non-sharers were Instagram (sharers: *n*=34, 87.2%; non-sharers: *n*=57, 86.3%) and Snapchat (sharers: *n*=33, 84.6%; non-sharers: *n*=54, 81.8%). **Conclusion:** Students who use SM to post about PA had higher levels of SPE and PA, suggesting the need for future research to explore how SM use may affect or be affected by self-presentation and PA levels.

Exploring Physical and Mental Readiness to Exercise in Inactive Men and Women: A Thematic Analysis

Paula-Marie M. Ferrara, Ethan T. Schaltegger, Rebecca A. Zakrajsek, Kelley Strohacker. *University of Tennessee, Knoxville, TN.*

(No relevant relationships reported)

Flexible Non-Linear Periodization (FNLP) was designed by Kraemer & Fleck to optimize athletic performance and prevent burnout by basing athletes' daily training regimens on their personal "readiness to train" (physical/mental states pre-exercise). FNLP-based prescriptions may be an effective approach in improving exercise behavior of inactive adults. However, it is necessary to operationally define readiness in specific populations, particularly between genders. **PURPOSE**: Identify and compare the underlying themes relating to readiness to complete low-demand (LDB) and high-demand (HDB) aerobic bouts between men and women who do not engage in regular aerobic activity. **METHODS**: Via Qualtrics, 1,059 respondents completed the online survey. After quality control, 166 respondents (49 ± 13y, 61.4% female) met the criteria of reporting <90 min/week of moderate aerobic activity (25.7 ± 26.3 min/week). Respondents described mental/physical states necessary to complete a LDB (10-min slow stroll) and a HBD (60-min jog). Data were analyzed using content and thematic analysis. **RESULTS**: To complete the LDB and HDB, themes among men and women included *body integrity* (free from pain/illness) and *positive affect*. A unique theme emerged for the LDB, in that many men and women indicated it could be completed under *normal or worse circumstances*. A primary difference between genders is, to complete the LDB, women needed to feel *rested*, which was not reported by men. While a theme relating to *motivation* emerged for both bouts, it appears motivation to complete the LDB is rooted in a need for change (change of scenery, clear head), where as motivation for the HDB related more to completing the bout itself (focused, determination, committed). For the HDB bout only, men and women indicated a need to feel *fueled* (enough food, hydrated), adequately *conditioned*, and *energized*. **CONCLUSIONS**: Little difference was noted between inactive men and women regarding indices of readiness. Three uncovered themes (body integrity, fueled, energized) parallel factors from Kramer & Fleck's proposed six-item readiness checklist: injury status, hydration level, and fatigue ratings. These factors represent the more personal, non-performance aspects of the checklist, providing initial support for adapting FNLP for inactive populations.

1314   Board #122   May 31 9:00 AM - 10:30 AM

Examination of Personality Related to Individuals' Reported Primary Mode of Exercise

Allyson G. Box[1], Yuri Feito, FACSM[2], Chris Brown[2], Steven J. Petruzzello, FACSM[1]. *[1]University of Illinois at Urbana-Champaign, Urbana, IL. [2]Kennesaw State University, Kennesaw, GA.* (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

Personality has been linked to various exercise behaviors. It is possible that personality dimensions are associated with the type of exercise one chooses to engage in. **PURPOSE**: To examine the relationship between personality dimensions, based on the Five Factor Model (FFM), and primary exercise modalities. **METHODS**: 576 adults (34.5 ± 11.4 yrs; 46.7% male), currently participating in any form of regular exercise, completed an online survey. The survey included questions related to their primary mode of exercise (PME) and items for the Big Five Inventory (BFI). The BFI assesses the FFM dimensions: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. PMEs were divided into 5 main groups: CrossFit® Training ($n=90$), Group Exercise ($n=59$), Aerobic Training ($n=116$), Resistance Training ($n=142$), and Sport ($n=142$), with two other categories concurrently assessed: High Intensity Training ($n=13$) and Other ($n=14$). **RESULTS**: Significant ($P < 0.05$) Spearman's correlations were observed between frequency of exercise and Agreeableness ($\rho = 0.160$), Conscientiousness ($\rho = 0.284$), Neuroticism ($\rho = -0.256$), and Openness ($\rho = -0.083$). A multivariate ANOVA revealed significant differences ($P<0.001$) between PME and Extraversion ($P<0.001$, $\eta^2_p = 0.062$), Agreeableness ($P<0.001$, $\eta^2_p = 0.165$), Conscientiousness ($P<0.001$, $\eta^2_p = 0.323$), Neuroticism ($P<0.001$, $\eta^2_p = 0.129$), and Openness ($P<0.001$, $\eta^2_p = 0.073$). **CONCLUSIONS**: These findings suggest that differences exist between personality dimensions and individuals' preferred exercise modality. As physical inactivity is a growing prominent public health concern, identifying an individual's personality and suggesting exercise modalities based on these differences may aid in exercise interest and adherence.

1315   Board #123   May 31 9:00 AM - 10:30 AM

The Relationship Among Resilience, Personality, Anxiety and Fitness in Recruit Firefighters

Dakota G. Morales, Allyson G. Box, Steven J. Petruzzello, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

Resilience (R), the ability to adapt to and rebound from adversity, has been linked to Post-Traumatic Stress Disorder (PTSD) susceptibility and to buffer against stressful events. Fitness has also been related to psychological health, thus it is of interest to examine whether R is related to personality and anxiety, as well as indices of fitness in firefighters (FFs), a group exposed to various stressors. **PURPOSE**: Examine R, personality, anxiety and fitness among recruit FFs. **METHODS**: Recruit FFs ($N=145$ males, 26.4 ± 4.0 yrs, BMI=27.1 ± 4.5) entering a 6-week FF training academy completed individual difference measures [e.g., Dispositional Resilience Scale (DRS-15), Trait Anxiety Inventory (TAI; 32.3 ± 8.0), International Personality Item Pool 50 (IPIP-50)]. The DRS-15 provided a Total score (49.5 ± 4.8) and subscores for Challenge (Ch: 13.9 ± 2.4), Commitment (Cm: 17.6 ± 2.1), and Control (Cl: 18.0 ± 2.0). The 5 personality dimensions of Extraversion (E: 33.9 ± 7.0), Emotional Stability (ES: 39.3 ± 6.6), Conscientiousness (C: 38.8 ± 4.7), Openness (O: 36.1 ± 5.4), and Agreeableness (A: 40.0 ± 5.2) were derived from the IPIP-50. **RESULTS**: Only C was associated with aerobic capacity ($r= 0.20$); no other fitness relationships were found. Significant ($P<0.005$) relationships were found between total R and TAI ($r= -0.57$) along with the personality dimensions of ES ($r= 0.46$), A ($r= 0.38$), O ($r= 0.35$), C ($r= 0.35$), and E ($r= 0.24$). Of the R subscales, Cm had the most consistent and strongest relationships with personality ($r_s= 0.30 - 0.57$). **CONCLUSIONS**: Findings support the relationship between R (especially sense of Commitment) and personality, but not fitness, in these FFs. Including the relationship between anxiety and personality, levels of resilience may influence susceptibility to PTSD (i.e., interpretation of stressful events), symptom severity of PTSD, and recovery from PTSD. With respect to traumatic experiences encountered during firefighting, these relationships may aid in understanding how FFs handle stress.

1316   Board #124   May 31 9:00 AM - 10:30 AM

Physical Activity Perceptions and Behavior of Pregnant Women with Past Miscarriage and Infertility Experiences

Christopher P. Connolly, Gretchen G. Stolte, Bryce W. Magee. *Washington State University, Pullman, WA.*

(No relevant relationships reported)

Perceptions that pregnant women have towards physical activity (PA) appear to affect levels of participation. Qualitative findings indicate that past adverse prenatal experiences may elevate pregnant women's PA concerns regarding the health of the baby. **PURPOSE**: We investigated whether PA outcome expectancy differed among pregnant women with past miscarriage or infertility experiences compared to pregnant women without. Additionally, we examined whether moderate-to-vigorous PA (MVPA) and PA discussion with a healthcare provider (HCP) differed between these two groups. **METHODS**: Pregnant women ($N=497$) completed an online survey and answered multiple questions about past pregnancy experiences, and current PA perceptions and behavior specific to various PA modalities. These included: walking, light and intense jogging, cycling, and swimming, prenatal yoga, aerobic dance, and resistance training exercises. PA outcome expectancy for each modality was assessed on an 11-pont Likert scale. Participation in each was defined as PA > 0 min/wk. MVPA was dichotomized as meeting the guideline (MVPA ≥150 min/wk) or not. Participants were also asked questions regarding PA discussion with a current HCP. Mann-Whitney U-tests were performed to examine outcome expectancy differences between women with past adverse prenatal experience and those without. Chi-square analyses were conducted to examine differences in meeting the MVPA guideline, HCP discussion, and PA modality participation. **RESULTS**: A total of 170 women (30.5%) reported past miscarriage or infertility experiences. PA outcome expectancy for these women did not significantly differ from women without past adverse prenatal experience for any specific modality of activity. However, women with past miscarriage or infertility were less likely to meet the current MVPA guideline [$\chi^2(1) = 4.32$, $p=.04$]. Participation in specific PA modalities was not significantly greater for women without past adverse prenatal experience, nor was the occurrence of PA discussion with a HCP. **CONCLUSIONS**: Pregnant women with past miscarriage or infertility did not perceive PA differently but did perform less MVPA than women without past adverse experiences. Longitudinal examinations of PA perception and behavior are needed among this subpopulation.

Older Adults' Narratives Of Physical Activity And Health: Intrinsic Goal Pursuits, Autonomy, And Healthy Identities

Christina Johnson, Neil Pagdin, Thomas Greene. *Cornell College, Mount Vernon, IA.*
(No relevant relationships reported)

The benefits of physical activity extend across the lifespan, but the psychological processes supporting active aging are not often addressed for older adults. This research explores older adults' narratives of health and physical activity experiences and applies a Self-Determination Theory (SDT) framework for understanding how basic needs are accommodated in physical activity contexts. **PURPOSE:** To examine the life-history narratives of older adults with regard to physical activity, sport participation, and health. **METHODS**: Narrative interviews were conducted with 51 older adults (65-95 yrs) to elicit life-history narratives regarding 1) experiences in physical activity and sport; 2) current perceptions of health, and 3) identity as a healthy or unhealthy person. The semi-structured interviews ranged from 1-3 hours and fostered in-depth accounts of individual's life histories. Interviews were transcribed verbatim and data was subjected to thematic narrative analysis. **RESULTS**: Data supported a SDT approach (Ryan & Deci, 2001; Ryan, Huta, & Deci, 2006) to understanding the connection between goal pursuits, achievement, and well-being. Contexts and activities that supported participants' perception of autonomy (e.g., "I have choices about the activities that are available"), competence (e.g., "I can successfully participate"), and sense of belonging (e.g., "The people are very supportive and I feel welcome") were related to participants' articulation of healthy activity as a first-order, intrinsic goal (e.g., "I golf because I love movement, not for any other reason"). Participants demonstrated an age-related shift in understanding physical activity and health. Older participants (88 ± 5 yrs) more often narrated physical activity as a first-order, intrinsic goal (e.g., movement for movement's sake), whereas younger participants (70 ± 5 yrs) more often narrated physical activity as a lower-order, extrinsic goal (e.g., "I am physically active because my doctor told me I needed exercise and/or I want to be healthier"). **CONCLUSIONS**: This research supports the SDT contention that intrinsic goal pursuits relate to greater well-being and highlights the importance of fostering perceptions of autonomy support, competence, and relatedness for physical activity among older adults.

Examination Of The Association Between Values And Physical Activity In A Behavioral Program

Lisa M. Wisniewski[1], Kelliann K. Davis, FACSM[2], John M. Jakicic, FACSM[3]. *[1]Saint Francis University, Loretto, PA. [2]University of Pittsburgh, PIttsburgh, PA. [3]University of Pittsburgh, Pittsburgh, PA.*
(No relevant relationships reported)

Theory-based approaches imply that values may be a construct that influences motivation and adherence to health behavior change. **PURPOSE:** This study examined the associations between individual values and change in physical activity in adults enrolled in a 6-month behavioral weight loss intervention. **METHODS:** Baseline data for 67 participants (age = 44.2 ± 9.0 years; body mass index = 32.6 ± 3.9 kg/m^2) and 58 participants at 6 months (age = 43.9 ± 9.2 years; body mass index = 32.6 ± 4.0 kg/m^2) were analyzed. The 6-month behavioral weight loss intervention included prescribed moderate-to-vigorous physical activity of 150 to 250min/wk. Only participants prescribed physical activity within the intervention were included in the statistical analysis. Assessments at baseline and 6 months included: 1) self-reported leisure-time physical activity, 2) personal values, 3) perception of engaging in physical activity would have on their values. **RESULTS:** At both baseline and 6 months, the three most frequently identified values were marriage/couples/intimate relationships (75.9%), family (60.3%), and parenting (56.9%). Spearman correlation coefficients were not statistically significant between change in leisure-time physical activity and perception of the impact engaging in a physical activity will have on their values at baseline (range of r's: -0.029 to 0.154, p's range: 0.364 to 0.927) and 6 months (range of r's: -0.018 to 0.098, p's range: 0.564 to 0.916). **DISCUSSION:** Self-reported values did not change following participation in a behavioral weight loss intervention. Perceptions of how engagement in physical activity would alter values were also not associated with change in leisure-time physical activity. These results suggest that linking physical activity to values would not impact the magnitude of improvement in leisure-time physical activity within the context of a comprehensive behavioral weight loss intervention. However, this warrants additional investigation to determine if interventions specifically linking values to physical activity would elicit similar effects.

Anthropometry, Physical Functioning, And Quality Of Life In The Exercising Diabetic Patient

Lena K. Perry[1], Cynthia Villalobos[1], J. Mark VanNess[1], Paul D. Vosti[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]St. Joseph Hospital, Stockton, CA.*
(No relevant relationships reported)

Among U.S. adults, more than 35% are obese and 9% are diagnosed with diabetes. Obesity and diabetes impair daily functioning and associate with poorer subjective quality of life (QOL). Exercise is an effective intervention for weight loss, functional improvement, and amelioration of psychological symptoms; however, the precise characteristics of prescription to optimally enhance QOL in this population are not well defined. **PURPOSE:** To evaluate QOL predictors in subjects with type 2 diabetes undergoing structured exercise. **METHODS:** 61 subjects with diabetes were randomized into one of two 10-week exercise interventions; 38 subjects completed the program. Group 1 (n=23) participated in organized interval training with professional supervision twice weekly; group 2 (n=15) performed the same supervised interval training but also performed two 60-min unaccompanied walking sessions per week. At baseline and follow-up, demographic, anthropometric, functional, and QOL data were collected. Multiple linear regression determined the effect of exercise, physical functioning, and anthropometric indices on QOL outcomes. **RESULTS:** At baseline, subjects were 67.9 ± 9.1 years of age, 42.1% male, and they had a composite QOL score of 58.9 ± 18.1. Older age and three assessments of physical functioning associated with higher baseline QOL; obesity associated with a trend for higher QOL (p=0.054). From baseline to posttest, QOL improved 17.7% (p<0.001). Group assignment was not a significant predictor of this change (p=0.998). Women improved more than men (p=0.031), and improvement in physical function associated with greater improvements in QOL. At the end of the intervention, age (p=0.022) and physical function corresponded to elevated QOL. Group assignment was not a significant predictor (β=9.3; p=0.098). At baseline (p<0.001), change scores (p=0.021), and at follow-up (p<0.001), the six-minute walk was the most pronounced variable of physical functioning to correspond to QOL. **CONCLUSION:** Exercise improved QOL for subjects with diabetes. Additional walking didn't help. Older men and especially women improved more. This may be a consequence of attention, as supervised sessions provided marked improvement. It may be important for exercise aimed at improving psychological wellbeing to include companionship.

The Role of Gratitude in Intrinsic and Extrinsic Exercise Motivation

Allison Hicks, Savannah Neace, Marci DeCaro, Paul Salmon. *University of Louisville, Louisville, KY.*
(No relevant relationships reported)

PURPOSE: To determine the role of positive psychology in the prediction of exercise motivation. Specifically, we examine the construct of gratitude in association with intrinsic and extrinsic exercise motivation. **METHODS**: One hundred predominantly female (84%) undergraduate participants (age: M=19.78, SD=2.43) responded to online survey questionnaires including demographics, subjective health, gratitude (GRAT-R) and Exercise Motivation (EMI-2). **RESULTS**: Hierarchical regressions including theoretically derived control variables (age, sex, minority status and subjective health) explored the role of gratitude in the prediction of intrinsic and extrinsic exercise motivation. Gratitude was significantly positively associated with intrinsic motivation (β=.397, p<.001), but not extrinsic motivation (β=.225 , p=.07). In analyzing gratitude subscales, Sense of Abundance was positively associated with intrinsic motivation (β=.296, p<.01), and Social Appreciation was positively associated with both intrinsic (β=.497, p<.001) and extrinsic motivation (β=.401, p<.001). In further examining subscales of the EMI-2, total gratitude scores were significantly positively correlated with Stress Management (r=.411, p<.001), Revitalization (r=.386, p<.001), Enjoyment (r=.411, p<.001), Challenge (r=.390, p<.001), Affiliation (r=.254, p<.01), Ill-Health Avoidance (r=.250, p<.05), Positive Health (r=.356, p<.001), Weight Management (r=.201, p<.05) and Strength/Endurance (r=.310, p<.01). **CONCLUSIONS**: Gratitude positively predicted exercise motivation, particularly intrinsic motivators of exercise. These findings suggest that positive psychological practices are associated with attitudes that encourage health behavior change.

Mindfulness and Intrinsic Exercise Motivation—The Mediating Role of Exercise Self-Efficacy

Savannah M. Neace, Allison Hicks, Paul Salmon, Marci DeCaro. *University of Louisville, Louisville, KY.*

(No relevant relationships reported)

TITLE: Mindfulness and Intrinsic Exercise Motivation: The Mediating Role of Exercise Self-Efficacy
AUTHORS: Savannah Neace, Allie Hicks, Marci DeCaro, Paul Salmon
University of Louisville, Louisville, KY
PURPOSE: We examined the role of mindfulness in predicting exercise motivation. Mindfulness is associated with health, but its influence on exercise motivation is largely unexamined. We tested the relationship between mindfulness and exercise motivation, using self-efficacy as a possible mediator of this relationship.
METHODS: Undergraduates (N = 100; 84% Female, 80% Caucasian) completed online questionnaires assessing demographics, Mindfulness (MAAS), exercise self-efficacy (SEE), and exercise motivation (EMI-2).
RESULTS: Hierarchical regressions controlling for age, sex, and minority status examined relationships among mindfulness, exercise self-efficacy, and exercise motivation. Mindfulness was positively associated with intrinsic (β=.210, p<.05), but not extrinsic motivation (β=.086, p<.438). Mindfulness was also positively associated with exercise self-efficacy (β=.244, p<.05. Exercise self-efficacy was positively associated with both intrinsic motivation (β=.484, p<.000) and extrinsic motivation (β=.218, p<.05). Mediation analysis revealed that exercise self-efficacy fully mediated the relationship between mindfulness and exercise motivation (β=.210, p<.05; β= .186, p<.285). Exploratory analyses examined correlations between facets of the EMI-2 and mindfulness and exercise self-efficacy. Mindfulness was significantly correlated with two intrinsic facets [Revitalization (r=.220, p<.028), Enjoyment (r=.254, p<.011)]. Exercise self-efficacy was significantly correlated with five intrinsic facets [Revitalization (r=.500, p<.000), Enjoyment (r=.499, p<.000), Challenge (r=.508, p<.000), Affiliation (r=.216, p<.05), Positive Health (r=.284, p<.01)] and one extrinsic facet [Competition (r=.344, p<.000)].
CONCLUSIONS: Mindfulness is moderately predictive of intrinsic exercise motivation, however, exercise self-efficacy largely mediates this relationship.

The Mediating Effect of Perceived Health on the Relationship Between Physical Activity and Subjective Well-being

Zhanjia Zhang[1], Bo Chen[2], Qiang Li[3], Weiyun Chen[1]. [1]*University of Michigan, Ann Arbor, MI.* [2]*Beijing University of Chemical Technology, Beijing, China.* [3]*Nanjing Sport University, Nanjing, China.*

(No relevant relationships reported)

Subjective well-being (SWB) is a critical indicator of positive youth development. Physical activity (PA) has been identified as a potential correlate of SWB. But the underlying mechanism for the association between PA and SWB has remained largely unexplored.
PURPOSE: To examine the association between the PA and SWB in college students, and to determine if the perceived health mediated the association between them.
METHODS: 1209 college students (631 male and 578 female, mean age = 19.63 years) voluntarily completed a questionnaire consisting of four parts: Subjective Happiness Scale with four 5-point Likert items assessing Happiness, Satisfaction with Life Scale with five 7-point Likert items measuring life satisfaction, two questions adapted from the National Health and Nutrition Examination Survey (NHANES) asking the time (in minutes) spent on PA per week, and one 5-point Likert item adapted from NHANES measuring the perceived health. According to a widely used procedure to test mediation, three multiple regression models were performed. First, the perceived health (mediator) was regressed on the PA (independent variable). Second, happiness and life satisfaction (dependent variables) were respectively regressed on the PA (independent variable). Finally, happiness and life satisfaction (dependent variables) were respectively regressed on both the PA (independent variable) and perceived health (mediator). Age, gender, and weight status were obtained by self-report and added to all models as covariates.
RESULTS: The first model revealed that PA was a significant predictor of perceived health (t = 5.30, p < 0.01). In the second model, PA significantly contributed to the happiness (t = 3.43, p < 0.01) and life satisfaction (t = 3.62, p < 0.01), respectively. However, after including the perceived health to the second model, the coefficient of PA was no longer significant for both happiness and life satisfaction (p's > 0.05). Our result showed that the independent variable had no effect when the mediator was controlled, suggesting a mediating effect of the perceived health on the relationship between PA and SWB.
CONCLUSIONS: The increased time spent on PA is associated with a higher level of SWB among college students. Moreover, this positive association is mediated by the individual level of perceived health.

Testing The Effects Of Message Framing On Physical Activity Motivation: Does Stage Of Change Matter?

Derek J. Hevel, Anthony J. Amorose, Kristen M. Lagally, FACSM, Anna Rinaldi-Miles, Scott Pierce. *Illinois State University, Normal, IL.*

(No relevant relationships reported)

PURPOSE: Understanding how to best "sell" physical activity (PA) is a critical goal. This study investigated the effects of message framing on motivation to participate in a PA program, and tested whether the effectiveness of messages framed to promote either affective benefits, physical health benefits, or a combination benefits varied based on one's current PA status. **METHODS**: Adult participants (*N*=188) from a Midwestern university, who were recruited via email, completed an online survey assessing demographic information and current stage of change. They then viewed one of four randomly assigned promotional flyers for a PA program offered on campus. The flyers mentioned either the: (a) affective benefits of program participation (e.g., improved mood), (b) physical health benefits (e.g., improved fitness), (c) a combination of affective and physical health benefits, or (d) a control message noting some generic aspects of the program (e.g., clean facilities). After viewing the flyer, participants responded to a series of questions about the content of the flyers (manipulation checks) and their perceived behavioral control for participating in the program, followed by their interest in the program, intention to participate, the likelihood of participating, and whether they wanted to sign-up. **RESULTS**: A series of 2 (PA status: active, non-active) x 4 (message: affective, physical health, combination, control) ANOVAs found that, after accounting for perceived control, the effectiveness of the different promotional messages on intention and likelihood of participating varied based on the respondents' PA status. The major finding was the message promoting affective benefits led to significantly greater intention and likelihood of participation than the other messages for those who were active, but the opposite occurred for non-active participants. No group or message differences were found with regard to interest in the program. Further, a chi-square analysis found no differences in participants' yes or no response to wanting to schedule a session in the program at that time. **CONCLUSIONS**: Using message framing to sell PA may help increase intention to participate. However, the type of message that effectively promotes PA appears to vary depending on the message receiver's current physical activity.

Race and Types of Motivation in Indoor Group Cycling

Alvin L. Morton, Derrick T. Yates, Miguel Aranda, Lyndsey Hornbuckle. *University of Tenessee, Knoxville, TN.*

(No relevant relationships reported)

As racial health disparities persist in the U.S. for conditions that can be mitigated by regular exercise (e.g. cardiovascular disease, type II diabetes), identifying the types of motivation that drive various racial groups to participate in exercise may be a strategy to help inform intervention efforts and reduce these health disparities. **PURPOSE:** To identify racial differences in the type of motivation (autonomous, controlled, or amotivation) that influence regular participation in indoor group cycling classes. **METHODS:** Twenty-one indoor group cyclists currently participating in classes $\geq$ 1 day/week for $\geq$ 3 consecutive months (non-Hispanic Whites (NHW) = 14, non-Hispanic Black (NHB) = 4, mixed-race = 3; age: 43.6 $\pm$ 14.5 yrs.; body mass index: 26 $\pm$ 3.8 kg/m^2) were recruited for this study. Participants completed the Treatment Self-Regulation Questionnaire (TSRQ) using a 7-point Likert scale to indicate why they continue to utilize indoor group cycling classes as an exercise modality. Average TSRQ scores of autonomous and controlled motivation, and amotivation were examined by race. One-way ANOVA was used to examine between-group differences. Significance was accepted at p < 0.05. **RESULTS:** There were no racial differences in autonomous (p = 0.44) or controlled motivation (p = 0.84) by race, but there was a significant difference in amotivation (p = 0.02). Tukey post hoc analyses showed that NHB had higher amotivation (3.5 $\pm$ 1.0) compared to NHW (2.0 $\pm$ 1.1) and mixed-race (1.3 $\pm$ 0.4) participants. **CONCLUSION**: Compared to the other race groups in this sample, NHB had higher amotivation despite continued participation in indoor group cycling. This suggests that other factors (e.g. group dynamics, environment) may be driving NHB to continue participation. Further research using racially diverse samples is needed to identify possible factors related to motivation in NHB and other race groups, as they may be valuable in the development of culturally relevant exercise programs.

Cardiorespiratory Fitness, Physical Activity, and Psychological Effects of an Acute Bout Of Cycling Exercise in People with Epilepsy

Kristen E. Johnson, Patrick J. O'Connor, FACSM. *University of Georgia, Athens, GA.* (Sponsor: Patrick O'Connor, FACSM)
(No relevant relationships reported)

PURPOSE: The primary purpose of this study was to test if an acute bout of cycling exercise in a sample of young adults with epilepsy would improve feelings of energy and enhance executive function. Secondary aims included evaluating cardiorespiratory fitness and physical activity level. **METHODS:** A within-participants crossover design was used to compare seated rest to 20 minutes of moderate-intensity cycling. Ten people diagnosed with epilepsy completed the Profile of Mood States (POMS) and the Wisconsin Card Sorting Task (WCST) before and twice after the treatments. Cardiorespiratory fitness was assessed with a standardized, graded maximal cycling exercise test. Physical activity level was assessed with a hip-worn accelerometer (ActiGraph GT3X+) and a self-reported past-year physical activity questionnaire (CARDIA Physical Activity History). **RESULTS:** Within-participants repeated measures ANCOVAs controlling for initial values and order of treatments showed a significant interaction for POMS Vigor, $F(2,32)=4.21$, $p=.024$. Immediately after exercise, vigor scores were higher than after seated rest. WCST performance was not influenced by acute exercise. Independent t-tests revealed that this sample of people with epilepsy was similarly fit and similarly active compared to reference groups of young adults without epilepsy. **CONCLUSION:** Acute cycling transiently increases feelings of energy without altering executive functioning in normally active and fit people with epilepsy.

Machines versus Free Weights: Does Exercise Mode Influence Affect and Perceived Exertion?

Daniel J. Cavarretta, Walter R. Bixby, FACSM, Eric E. Hall, FACSM. *Elon University, Elon, NC.*
(No relevant relationships reported)

Resistance exercise reduces the risk of chronic disease and promotes numerous health benefits. Due to the low rates of participation in resistance exercise, research is needed to create a more positive affective response from exercise. This has been shown to increase rates of adherence in aerobic exercise. **PURPOSE:** To compare the affective responses of performing resistance exercise on machines (MA) and free weights (FW). **METHODS:** Novice participants (4 Males: 20.8±0.5yrs; 75.2±17kg; 180±2.4cm; 14 Females: 25.7±9.8yrs; 67.9±19kg; 163±5.6cm) completed a MA workout consisting of the leg press, row, chest press, and leg curl and a FW workout consisting of a goblet squat, row, bench press, and stiff leg deadlift. Each exercise was performed at 80% 10RM for 3 sets of 9-11 repetitions with 90 secs of rest between each set. Feeling Scale (FS) and Felt Arousal Scale (FAS) were assessed before exercise, after the completion of the 7th repetition of the 2nd set of each exercise, after the 3rd set of each exercise, immediately after, 30 min after, and 60 min after. **RESULTS:** Repeated measures ANOVA from before to after exercise revealed a condition x time interaction for FS where FS in the MA condition increased immediately and 60 minutes following exercise, there was no change across time for FW, and FS for MA was significantly higher at 60 minutes following exercise than FW, $F(3, 51) = 3.26$, $p = 0.040$. For FAS before and after exercise, FAS significantly increased immediately following exercise and then decreased to below exercise levels at 30 and 60 min regardless of condition, $F(3, 51) = 11.91$, $p < 0.001$. Repeated measures ANOVA for RPE during the exercise revealed a condition x time interaction where RPE was higher in FW for all exercises except those of the chest where RPE was higher for MA, $F(7, 119) = 3.285$, $p = 0.015$. **CONCLUSION:** The more positive affective response from the MA workout immediately and 60 minutes after exercise suggests that MA exercises may be better for novice lifters when beginning a resistance training regimen.

C-40   Free Communication/Poster - Correlates and Behavioral Aspects of Physical Activity in College Students

Thursday, May 31, 2018, 7:30 AM - 12:30 PM
Room: CC-Hall B

1327   Board #135   May 31 9:00 AM - 10:30 AM

The Impact of Body Fat Percentage on Appearance and Weight Management Related Motivations to Exercise in College Age Men

Elizabeth A. Easley, Molly N. Melton, Rhiannon J. Schofield, Ashley M. Garris, Sarah H. Sellhorst, William F. Riner, FACSM. *University of South Carolina Lancaster, Lancaster, SC.*
(No relevant relationships reported)

Physical activity and exercise levels have been shown to decline throughout childhood and adolescence with a noticeable decrease occurring during the transition to college. The Exercise Motivation Inventory-2 (EMI-2) has been used to identify factors that potentially affect exercise levels in adults. There is little known research regarding the motivation to exercise in college students at a rural, commuter-based, two-year University campus. **PURPOSE:** The purpose of this study was to determine whether differences existed in enjoyment, appearance, and weight management related motivations and MVPA based on body fat percentage levels in male college students. **METHODS:** Thirty-nine, traditional-age (18-25 y), full-time (>12 credit hours) male college students were recruited for this study. The participants completed the EMI-2 instrument and then anthropometric measures (height, weight, and BF%; dual energy x-ray absorptiometry) were collected. All participants were then asked to wear an accelerometer for 7 consecutive days to measure MVPA. Participants were then divided into two groups, a healthy body fat group, (HBF; ≤ 22 BF%, n = 16) and an overfat group (OBF; > 22 BF%, n = 23). A one-way MANOVA was used to determine differences in exercise motivations and physical activity levels based on body fat percentage. **RESULTS:** A significant main effect was determined for body fat category, Wilks' lambda=.533, F(4, 34) = 7.439, p <0.001, η_p^2 = .467. Pairwise comparisons of EMI-2 scores determined that OBF men had greater motivation scores based on appearance (3.565 vs. 2.703, p = .026) and weight management (3.685 vs 1.781, p < .001) compared to their healthy-fat counterparts. There were no significant differences in enjoyment scores (3.533, OBF vs. 3.203, HBF, p = .465) or time spent in MVPA (OBF, 289 min/week vs. HBF, 371 min/week, p = .064). **CONCLUSION:** Body fat percentage can impact the motivations to exercise in college age men. OBF reported stronger motivations to exercise based on appearance or weight management compared to the HBF. Despite these stronger motivations, this did not translate into greater time spent in MVPA compared to their HBF counterparts. More research is necessary to determine motivation and barriers to exercise in this population, while considering the impact of body composition.

1328   Board #136   May 31 9:00 AM - 10:30 AM

Self-Reported Wellness Benefits of Recreational Sports Use in College Freshmen

Kerri L. Vasold[1], Samantha J. Deere[2], James M. Pivarnik, FACSM[1]. *[1]Michigan State University, East Lansing, MI. [2]Saginaw Valley State University, University Center, MI.*
(No relevant relationships reported)

Previous research has shown a positive relationship between academic success and recreational sports participation. Few studies have investigated the relationships between recreational sports participation and psychosocial/physical health indicators. **PURPOSE:** To investigate the impact of recreational sports on psychosocial and physical health indicators in college freshmen, and determine differences in impact between high and low users. **METHODS:** Participants included freshmen students who participated in an online survey and consented to recreational sports usage tracking. Usage was collected via ID card swipe each time the student utilized the University fitness centers, group fitness classes, and participated in intramural sports games. Users were categorized as high or low (median split) based on total usage during their 1st year. The survey was administered during the 2nd semester of participants' 1st year. Participants reported the impact (1=very negatively to 5=very positively) of their usage on psychosocial and physical health variables. Responses were categorized into negative/no impact (1-3) and positive impact (4,5). Frequencies were calculated for variables of interest. Logistic regression was utilized to investigate the impact of recreational sports use on psychosocial and physical health variables. **RESULTS:** The sample (N=131) was 51.1 percent male and primarily Caucasian (82.4%). On average, high users had 48.1±39.2 ID card swipes per year; low users had 6.1±3.3. Most participants reported that recreational sports participation had a positive impact on psychosocial and physical health: overall well-being (86.3%); sense of belonging (83.2%); stress management (77.9%); self-confidence (77.9%); time

---

management (68.7%); overall health (90.8%); fitness level (89.3%); weight control (64.9%); balance and coordination (74.8%); and sleep (61.8%). High users were more likely than low users to report positive impacts on overall well-being (OR: 3.2; 95%CI: 1.1-9.5), fitness level (OR: 4.4; 95%CI: 1.2-16.7), and self-confidence (OR: 3.0; 95%CI: 1.2-7.1). **CONCLUSIONS**: Recreational sports participation had a positive impact on self-reported psychosocial and physical health in college freshmen, and frequency of participation played a role in some of these relationships.

Academic and Non-Academic Stress of College Students Enrolled in Physical Activity Classes

Lauren Kizlik, Kristin Nassen, Dr. Jessica Albers. *Minnesota State University, Mankato, Mankato, MN.*

(No relevant relationships reported)

College students often see a decline in their physical activity, in pair with an increase in psychological stress. Many universities aim to increase physical activity and spark new interest by offering a wide variety of health and physical activity classes for all students.
PURPOSE: To explore demographic differences among students in the physical activity classes and to examine how stress relates to how students self-select into different types of physical activity classes.
METHODS: Potential participants were students who self-enrolled in physical activity classes at the University. Participants (n=155) completed consent forms, a demographics questionnaire, and two surveys were sent out electronically through Qualtrics during the first, ninth, and fifteenth week of the semester. The surveys assessed psychological stress, both academically related (Academic Stress Scale) and non-academically related (Perceived Stress PSS-10). Between group differences were analyzed using One-Way ANOVA's to find using SPSS.
RESULTS: Results of the One-Way ANOVA on Academic Stress showed female students (mean = 9.61) to have statistically significant higher academic stress levels compared to male students (mean = 7.82) (p < .001). While not significant, the students on the spectrum of gender identity reported higher academic stress levels than both male and female students (mean = 9.82). Females also reported higher overall (non-academic) stress (mean = 17.53) than males (mean = 15.42) (p = .030). Female students reported more academic stress (mean = 9.67) than males (mean = 7.63). Students in the College of Education reporting the highest overall stress (mean = 20.33) on the Perceived Stress Scale. Time point three will be analyzed to assess changes in stress through the semester.
CONCLUSIONS: This study explored the descriptive statistics of students self-enroll in physical activity classes and examine differences in their stress levels through the semester. The results of this study can be used to reach students who's major may not require physical activity classes. Results can also be used to try to get more students involved in physical activity classes, or which courses certain colleges should consider requiring students to take.

1330   Board #138   May 31 9:00 AM - 10:30 AM

Gender Differences In College Student Physical Activity Based On The Use Of Wearables, Apps, And Social Media

Oliver W. Wilson, Melissa Bopp, FACSM, Samantha Shields, Zack Papalia, Michele Duffey. *The Pennsylvania State University, State College, PA.* (Sponsor: Dr. Melissa Bopp, FACSM)

(No relevant relationships reported)

College students Physical Activity (PA) continues to remain low and decline, whilst the utilization and availability/accessibility of wearables, apps and social media continues to increase. Understanding the relationship between the use of such technologies and PA may provide insight valuable to college student PA promotion.
PURPOSE: To investigate gender differences in PA between users and non-users of wearables, physical activity and weightless apps, as well as those who shared their PA on social media and those who did not. **METHODS:** This cross-sectional study collected data using an online survey from a volunteer sample of students enrolled in a PA class. The survey examined a range of variables, including demographic information, self-reported PA levels and height, weight, as well as the use of wearables, PA apps, weightloss apps, and social media to share about PA. Basic descriptives were computed, and differences in technologies usage were assessed using independent sample *t*-tests **RESULTS:** The final sample included 2341 participants, 56% women; 78.7% Non-Hispanic White, with an average age of 21.1±1.5y. Among students, 85.9% met or exceeded PA recommendations, 27.1% reported using a wearable, 30.1% a PA app, and 16.7% a weightloss app, and 12.7% reported sharing their PA on social media. Wearable users reported greater MPA ($p<.001$, $\eta^2=.009$), PA app users reported greater VPA ($p=.001$, $\eta^2=.004$), and weightloss app users reported higher BMIs ($p=.001$, $\eta^2=.004$) compared to non-users of such technologies respectively. Those who shared their PA on social media reported greater MPA ($p=.033$, $\eta^2=.002$), and VPA ($p<.001$, $\eta^2=.011$). Among males, wearable users reported greater MPA ($p<.001$, $\eta^2=.015$),

whereas female users reported greater MPA ($p=.005$, $\eta^2=.006$), and VPA ($p<.001$, $\eta^2=.013$). Male PA app users had higher BMIs, ($p=.018$, $\eta^2=.006$) and reported more VPA ($p=.012$, $\eta^2=.007$), whereas female PA app users reported significantly higher MPA ($p=.050$, $\eta^2=.003$), and VPA ($p<.001$, $\eta^2=.012$). Males who shared about PA on social media reported higher MPA ($p=.004$, $\eta^2=.009$), and VPA ($p<.001$, $\eta^2=.013$), whereas females reported only higher VPA ($p<.001$, $\eta^2=.016$). **CONCLUSION**: Technologies had positive associations with PA, indicating that they have the potential to increase and/or sustain PA in certain individuals.

1331   Board #139   May 31 9:00 AM - 10:30 AM

Cellular Telephone Use Predicts the Likelihood of Being an "Active Couch Potato" in College Students

Hannah Altsman, Andrew Lepp, Jacob E. Barkley. *Kent State University, Kent, OH.* (Sponsor: Ellen Glickman, FACSM)

(No relevant relationships reported)

The term "active couch potato" was developed to describe individuals who participate in regular, planned physical activity yet are also highly sedentary. These individuals are of interest as participation in excessive amounts of sedentary behavior, even in individuals which are regularly physically active, increases the risk for cardio-metabolic disease. Our group has demonstrated that cellular telephone (cell phone) use is positively associated with sedentary behavior, but not related to physical activity. Therefore, it is possible that individuals who use their cell phone heavily may participate in large amounts of sedentary behavior while also regularly participating in physical activity. In other words, cell phone use may predict the likelihood of being an "active couch potato." **PURPOSE:** To assess the relationship between cell phone use and the likelihood of being an "active couch potato."
METHODS: A sample of 228 college students completed validated survey items to assess their daily cell phone use, physical activity, and sedentary behavior. Tertile splits were performed and participants were categorized into *low, moderate* or *high* groups for each of these three variables. Participants were then categorized as "active couch potatoes" if they were a) in the *high* physical activity group and also in a *high* or *moderate* sitting group, or b) in the *moderate* physical activity group and also in the *high* sitting group. Mann-Whitney U tests compared the number of "active couch potatoes" across the three cell phone use groups and binary logistic regression was used to test if cell phone use group predicted being an "active couch potato."
RESULTS: There were a greater ($Z \geq 1.9$, $p \leq 0.05$) number of "active couch potatoes" in the *moderate* ($n = 21$) and *high* ($n = 28$) cell phone use groups versus the *low* ($n = 11$) use group. The likelihood of being an "active couch potato" was significantly ($\chi2 = 11.0$, $p = 0.01$) associated with cell phone use. Specifically, individuals in the *moderate* and *high* cell phone use groups were 2.3 and 3.5 times more likely (Wald ≥ 3.9, $p < 0.05$), respectively, to be an active couch potato than *low* users.
CONCLUSION: Among a sample of college students, *moderate* and *high* cell phone users were significantly more likely to being categorized as "active couch potatoes" than their *low* use peers.

Motivations for Moving: An Analysis of Physical Activity in Residential College Students

Cassandra I. Eddy, Ladasia Cooke, Thomas Hart, Jennifer McDonald. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Denise Smith, FACSM)

(No relevant relationships reported)

Physical activity (PA) habits developed in college can have health effects that extend well into adulthood. **PURPOSE**: To examine the relationship between social and ecological determinants of PA in residential college students. **METHODS**: A random sample of 162 students from a liberal arts college was surveyed. A 35-question web survey was used to collect data about on-campus residence, demographics, access to walking resources pre-college, knowledge and use of the college PA resources, and PA patterns. A hot spot analysis was conducted to determine geographic patterns of PA level or use of PA resources. The Wilcoxon signed-rank test was used to compare median energy expenditure (METs) per week between demographic groups. Multiple linear regression was used to find predictors of log METs per week based on demographic groups that were found to have significantly different median METs per week; a log transformation was used to correct for a skewed distribution. Logistic regression was used to find predictors of respondents having used the cardiovascular exercise room (CR). **RESULTS**: Residence halls and apartments closest to the CR were more likely to have residents who had used the CR. Having used the CR was significantly positively related to log METs (p<.05). There was a trend for a positive relationship (p=.055) between having used the racquetball courts and log METs and a trend for a negative relationship (p=.054) for having access to walking resources before attending the college and log METs. Holding other variables constant, the odds of having used the CR were 15% higher among respondents who lived in apartments (beta=.16, odds=1.17) vs. those who lived in residence halls, 50% higher among respondents who had used the weight room (beta=.41, odds=1.50), 58% higher among only white respondents (beta=.46, odds=1.58) vs. non-white respondents, 67% higher

THURSDAY, MAY 31, 2018

among multiracial white respondents (beta=.51, odds=1.67) vs. non-white respondents, and 15% higher among respondents who had not used exercise equipment in the residence halls (=.14, odds=1.15). **CONCLUSIONS**: Colleges may be able to enhance participation in PA by providing well-distributed resources throughout campuses. Colleges should be aware that social and ecological factors may also influence PA and associated health benefits.

1333   Board #141   May 31 9:00 AM - 10:30 AM

An Examination of Obligatory Exercise, Eating Attitudes, and Perceived Body Image Among Collegiate Males and Females

Cherilyn McLester, Bethany Wheeler, Emily Bechke, Cassie Williamson, John R. McLester, FACSM. *Kennesaw State University, Kennesaw, GA.* (Sponsor: John R. McLester, FACSM)

(No relevant relationships reported)

Eating and exercise behaviors among college students remains an area of interest as habits formed during these years may affect future behavior. Additionally, individuals who engage in extreme eating and exercise behaviors may be at risk for compromised health and well-being. **PURPOSE:** To investigate the relationship between obligatory exercise, eating attitudes, and perceived body image among collegiate males and females. **METHODS:** 222 females aged 20.1 ± 1.9 yrs, and 136 males aged 20.1 ± 2.2 yrs voluntarily completed a demographic questionnaire, the Obligatory Exercise Questionnaire (OEQ), Compulsive Exercise Teat (CET), Social Physique Anxiety Scale (SPAS), and the Eating Attitudes Test (EAT). Variables were analyzed with one-way ANOVA and Pearson product coefficient correlations. **RESULTS:** Overall 15% of women and 6% of men scored higher than 20 on the EAT indicating a high level of concern about dieting, body weight or eating behaviors where counseling is recommended. One-way ANOVA revealed that men were more obligated to exercise than women (47.7 ± 8.4 vs. 44.7 ± 9.3, p = 0.004), men had lower SPAS scores compared to women (28.7 ± 10.9 vs. 36.5 ± 11.3, p < 0.001), and men had lower scores on the EAT (7.2 ± 6.3 vs. 10.5 ± 9.3, p < 0.001). Correlations by sex revealed that men had a significant correlation for OEQ and CET (r = 0.618, p < 0.001), CET and EAT (r = 0.313, p < 0.001), and SPAS and EAT (r = 0.234, p = 0.007). Women had a significant correlation for OEQ and CET (r = 0.685, p < 0.001), OEQ and EAT (r = 0.261, p < 0.001), SPAS and CET (r = 0.328, p < 0.001), SPAS and EAT (r = 0.490, p < 0.001), and CET and EAT (r = 0.446, p < 0.001). **CONCLUSION:** While it may appear that a low percentage of participants had concerning scores on the EAT, this sample indicated that approximately 1 in 10 college students may need proper counseling in this area. Although women were more likely to have higher scores on EAT and SPAS, both males and females demonstrated relationships between OEQ, CET, SPAS, and EAT. Further investigation is warranted to determine the extent of these relationships and to possibly use these data to direct health and wellness initiatives on campuses to best serve young adults.

C-41   Free Communication/Poster - Correlates and Behavioral Aspects of Physical Activity in Youth and Teens

1334   Board #142   May 31 9:00 AM - 10:30 AM

Understanding the Relation Between Physical Fitness and Executive Function among Adolescents: An Expectancy-value Approach

Xiaoxia Zhang, Joonyoung Lee, Georgina Vint, Xiangli Gu, Tao Zhang. *University of North Texas, Denton, TX.*

(No relevant relationships reported)

Research indicated that maintaining adequate physical fitness may benefit cognitive health among adolescents. It was noticed that psychosocial process may be the underlying mechanism to understand cognitive health (Lubans et al., 2016). Current literature has no sufficient evidence to conclude the responsible mechanism to cognitive health.
PURPOSE: Guided by expectancy-value theory (Eccles et al., 1983), this study was to explore how psychosocial process (i.e., expectancy-value beliefs) interact with fitness components (i.e., cardiovascular fitness, muscular fitness, flexibility, and body mass index [BMI]) to affect cognitive health (i.e., executive function) among adolescents. The direct and indirect effects of expectancy-value beliefs on executive function through fitness were tested.
METHODS: Participants were adolescents ($N = 424$; 58% female; $M_{age} = 12.7$, $SD = .93$) recruited from Southwest region of the U.S. to complete this cross-sectional study.

FITNESSGRAM® test battery was utilized to measure fitness components. Participants self-reported their expectancy-value beliefs (Xiang et al., 2003). The Behavior Rating Inventory of Executive Function–Self-Report Form (BRIEF-SR®, Guy et al., 2004) was used to assess executive function. Higher scores of BRIEF-SR® indicate lower executive function.
RESULTS: Correlation analysis demonstrated that expectancy-value beliefs were significantly related to each component of physical fitness. Cardiovascular fitness and muscular fitness were negatively associated with executive function, while BMI was positively correlated with executive function. The structural equation modelling (AMOS 22.0) supported the significant indirect effect of expectancy-value beliefs on executive function ($\beta = -.11$) through physical fitness ($\chi^2/df = 284.16/113$, p < .001; NFI = .85; IFI = .90; CFI = .90; RMSEA = .06; 90% CI [.05, .07]). The variance explained by the model was 12% for physical fitness and 9% for executive function.
CONCLUSION: The findings support the psychosocial mechanism towards adolescents' cognitive function proposed by Lubans et al.'s conceptual model (2016). School-based interventions focused on building perceived confidence and values may directly augment physical fitness and may serve to enhance executive function during adolescence.

1335   Board #143   May 31 9:00 AM - 10:30 AM

School'S Physical Environment And Children'S Physical Activity Self-efficacy

Maria E. Santiago-Rodriguez[1], Mercedes Rivera[2], Farah A. Ramirez-Marrero, FACSM[2]. *[1]University of Illinois at Chicago, Chicago, IL. [2]University of Puerto Rico, Rio Piedras, PR.*

(No relevant relationships reported)

Physical activity self-efficacy (PASE) and the school's physical environment (SPE) can influence children's moderate-to-vigorous physical activity (MVPA) participation. However, the association between PASE and the SPE has not been clearly established in this population. **PURPOSE**: To evaluate the relationship between PASE and SPE among elementary school children in Puerto Rico. **METHODS**: Sixty-eight girls and 63 boys (age= 7.8 ± 0.7 years) completed a questionnaire to assess PASE by interview. SPE was evaluated taking into consideration the physical education class, recess time, and use of facilities that promoted PA. Time in physical education and recess was provided by the school's administration. To determine the use of facilities, a score was generated based on self-reported activities and time spent in each. Children wore a GT3X+ accelerometer during 5 consecutive school days to determine MVPA and sedentary time (ST) during school time. MVPA and ST data was included if participants wore accelerometers ≥ 3 school days for ≥ 3 hr/day. Correlation analysis was conducted to test the relationship between the use of facilities and PASE. Mann-Whitney U-test was conducted to test the difference in PASE by recess time and Kruskal-Wallis test was used to evaluate difference in PASE by physical education time. Secondary correlation analyses were conducted to test the relationship between 1) PASE and MVPA (min/wk); and 2) PASE and ST (hr/wk). **RESULTS**: Participants accumulated 110.94 ± 21.81 min/wk in MVPA, and 3.48 ± 0.48 hr/wk in ST. No significant correlations were observed between: 1) use of facilities and PASE ($r_s = 0.122$, p = 0.22); 2) PASE and MVPA ($r_s = 0.010$, p = 0.91); and 3) PASE and ST ($r_s = 0.068$, p = 0.45). No significant differences were found in PASE by recess time (U = 1815.00, p = 0.86) and by physical education time (H(2) = 0.830, p = 0.66). **CONCLUSIONS**: School time allowed participants to comply with one fourth of the PA recommendation (60 min/day ≈ 420 min/wk). Lack of relationship between SPE and PASE could be explained by an overall high PA self-efficacy score, which requires further investigation. Funded by University of PR -FIPI Institutional Grant.

Childhood Experiences in Physical Education May Have Long-term Implications

Matthew A. Ladwig, Panteleimon Ekkekakis, FACSM, Spyridoula Vazou. *Iowa State University, Ames, IA.*

(No relevant relationships reported)

PURPOSE: The transition from childhood to adolescence is marked by a dramatic decrease in physical activity (PA). While many mediating factors have been suggested to explain this drop, one of the most influential may be the experiences children derive from physical education (PE). Scholars have been voicing concerns about the potential long-term implications of early PE experiences for nearly 100 years. However, there has been surprisingly little empirical investigation into this subject. Using a retrospective survey, we examined whether memories of enjoyment or non-enjoyment of PE relate to present-day attitudes and intentions for PA, and PA participation, among adults. **METHODS**: An online questionnaire was completed by 1,028 adult respondents (18-45 years), representing 47 of the 48 contiguous United States. The participants rated their retrospective enjoyment of PE and their present attitudes and intentions for PA, as well as their present PA and sedentary behavior. In addition, participants recorded their best and worst PE memories in an open-ended fashion. **RESULTS**: Retrospective enjoyment of PE as a child was significantly and positively associated with present-day attitude (r = .37) and intention (r = .23) for PA, days per

week engaging in vigorous-intensity PA ($r = .11$) and moderate-intensity PA ($r = .13$), as well as negatively associated with sedentary time both on the weekdays ($r = -.13$) and on the weekend ($r = -.14$). Of the worst memories, 34% related to embarrassment during PE, 18% to lack of enjoyment, 17% to bullying, 14% to social-physique anxiety, 16% to injury, and 2% to being punished by the PE teacher. "Worst" memories increased sharply between 6th and 10th grades. Notably, participants reported being ridiculed by teachers or peers and feeling that they lacked physical competence for the sport or fitness tests. **CONCLUSIONS**: An important relationship may exist between childhood memories of PE and present-day PA attitude and behavior as an adult. As also demonstrated in other domains of development, negative PE experiences during childhood may be influential throughout the lifetime. Intensified research efforts should be directed toward understanding the factors and processes that lead to the formation of negative memories of PE.

1337   **Board #145**   May 31 9:00 AM - 10:30 AM

Weight Dependent Disparities in Adolescent Girls: The Impact of Brief Interventions on Exercise and Healthy Eater Identity

Eydie N. Kramer, Daheia J. Barr-Anderson, FACSM. *University of Minnesota, Minneapolis, MN.*

(No relevant relationships reported)

Adolescents girls report low efficacy in healthy behavior engagement, and are disproportionately affected by obesity. Short-term interventions, such as behavior change summer camps, may positively influence psychological correlates of healthy behavior, particularly Exercise Identity (EI) and Healthy Eater Identity (HEI). However, previous studies lack family involvement, and do not take into consideration potential disparities in EI and HEI based upon weight status (healthy vs. obese). **PURPOSE:** To determine if the combination of a 1-week intervention and an 8-week family-oriented eHealth program will increase EI, HEI, and subsequent healthy behaviors in adolescent girls. Additionally, we sought to determine if EI and HEI scores differ between normal-weight and obese groups.
METHODS: Twenty-one participants (age=11.3±1.0 years, BMI=20.2±6.4 kg/m^2) were recruited from a prevention camp (no BMI inclusion criteria), and twenty participants (age=12.4±1.5 years, BMI=31.6±6.6 kg/m^2) were from a treatment camp (elevated BMI inclusion criteria). Both camps ran 1-week in duration, and had similar intervention components. Participants self-reported EI, HEI, physical activity, screen-time, and dietary behavior at baseline and post-intervention. All families were given access to an 8-week eHealth program, and measures were repeated three months following camp.
RESULTS: EI and HEI role-identities significantly differed between the prevention and treatment groups at baseline (ΔEI=4.0, p=0.007; ΔHEI=4.5, p=0.001). Positive trends in increasing EI and HEI scores were seen in both groups following the 1-week intervention; however, mean role-identity disparities remained between groups. Participation in the eHealth program was low-moderate. At follow-up, the treatment group had increased EI and HEI role-identities in such that the groups no longer significantly differed (ΔEI=3.2 p=0.161; ΔHEI=1.5, p=0.464). Minimal changes in health behaviors were experienced in each group.
CONCLUSION: Findings indicate that EI and HEI role-identities may differ in adolescent girls based upon weight status; 1-week interventions may positively influence EI and HEI, mitigating these differences. Further investigation is warranted to address eHealth compliance, and subsequent changes in health behavior.

Positive Body Image And Compliance With Physical Activity Recommendations Across Physical Activity Contexts In Adolescents

Christine Sundgot-Borgen[1], Kethe M.E Engen[1], Jan H. Rosenvinge[2], Gunn Pettersen[2], Oddgeir Friborg[2], Monica K. Torstveit[3], Elin Kolle[1], Jorunn Sundgot-Borgen, FACSM[1], Solfrid Bratland-Sanda[4]. *[1]Norwegian School of Sport Sciences, Oslo, Norway. [2]UiT -The Arctic University of Norway, Tromsø, Norway. [3]University of Agder, Kristiansand, Norway. [4]University College of Southeast Norway, Bø, Norway.* (Sponsor: Jorunn Sundgot-Borgen, FACSM)

(No relevant relationships reported)

Introduction: Being physically active is associated with a positive body image (PBI). Gyms offer a popular physical activity (PA) context for adolescents, and such contexts may motivate adolescents to meet PA recommendations. However, it has been suggested that exercising at gyms has been associated with a negative body image, i.e. unhealthy appearance and body composition focus. It is however, unknown whether gyms as opposed to a context of organized sports or a non-member context is differently associated with body image and PA recommendations for adolescents. **Purpose:** To investigate 1) the degree of PBI in different PA contexts and 2) if the criteria for PA recommendations are met in the different PA context groups. **Methods:** Baseline data was used from an ongoing RCT aiming to promote

PBI and prevent disordered eating among high-school students in Norway. Students aged 16-17 years (630 boys and 1073 girls) with BMI values within normal range completed the Experience of Embodiment Scale (EES) measuring PBI (score range 34-170). PA context (gym, organized sports, mixed and non-members) and meeting PA recommendations (PA ≥7 hours/week) or not (PA<7 hours/week) were assessed. ANOVA was used to investigate group differences in EES score.
Results:
Table 1: Mean PBI scores (SD) between PA contexts and compliance with PA recommendations.

Context	PBI (SD)	Meeting criteria	PBI (SD)	Meeting criteria
	BOYS		GIRLS	
Non-member	117.00 (18.4)*	No	112.00 (18.4)	No
Organized sport	125.00 (16.1)	Yes	117.93 (17.1)*	Yes
Gym	124.33 (16.2)	Yes	112.74 (19.2)	No
Mixed	126.04 (15.6)	Yes	112.30 (18.8)	Yes

* Differed significantly ($p < .001$) from other groups.
"Non-member" boys had a significantly lower PBI score than boys in other PA contexts. Girls in organized sports had a significantly higher PBI score than girls in other PA contexts.
Conclusion: For boys and girls, being a non-member, and for girls, being a gym member, are associated with not meeting PA recommendations. Further research is needed to validate these findings. The fact that non-members in agencies that offer organized PA display a low degree of PBI and not meeting PA recommendations is a matter of societal concern in the pursuit of promoting physical and mental health as well as PBI.

Exploring Predictors of Concussion Concerns in Youth Sport Parents

Nathan D'Amico[1], RJ Elbin[1], Philip Schatz[2], Anthony Kontos[3]. *[1]University of Arkansas, Fayetteville, AR. [2]Saint Joseph's University, Philadelphia, PA. [3]University of Pittsburgh Medical Center, Pittsburgh, PA.* (Sponsor: Dr. Matthew Ganio, FACSM)

(No relevant relationships reported)

PURPOSE: To explore predictors of parental concerns about sport-related concussion (SRC) and chronic traumatic encephalopathy (CTE). **METHODS:** A 22-item online survey was emailed to 5,366 youth sport parents, assessing parents' perceptions of the long-term effects of SRC and CTE. A series of chi-squares, odds ratios (ORs), and logistic regressions (LRs) were used to analyze the data. **RESULTS:** Total response rate was 14% (739/5,366). Parents that were ≥ 18 years, had a child aged 5-12 years, and did not have a child that currently played football were included, resulting in 434 (8%) respondents. The parents were 42 ± 4.82 years, 64% (277/432) female, and the majority did not report SRC history (83%, 358/434). Their children were 9 ± 2.13 years and the majority did not have a SRC history (78%, 335/431). Key findings include: 60% (257/431) of the respondents perceive SRC as a problem in youth sports. 39% (163/416) have attended a SRC talk, 72% (297/415) have talked with their child about SRC, 77% (320/418) are concerned that their child will get a SRC, 96% (403/418) believe there are long-term effects from SRC, 45% (186/418) claim to know about CTE, and 41% (172/418) have considered not allowing their child to play youth sports due to concerns about long-term effects of SRC or CTE. Respondents were more likely to consider not allowing their child to play youth sports if their child had a SRC history (OR=1.93, p=.005), thought SRC was a problem (OR=1.54, p=.03), and were concerned their child might have a SRC (OR=1.92, p=.008). Respondents' gender, SRC history, attendance at a concussion talk, and knowledge about CTE were not significant predictors of not allowing their child to play youth sports. Results of the LR (X^2 (3, *N*= 414) = 12.829, p<.001) for predictors of not allowing their child to play youth sports were significant, with child SRC history as the only significant predictor in the model (adjusted OR=1.72, p=.04). **CONCLUSION:** A majority of parents perceive long-term effects from SRC to be a problem and are concerned about CTE. A child's SRC history and parental concerns about SRC influence decisions to allow youth sport participation. There is a need for accurate information on the benefits/risks of youth sports, factors that influence parents' concerns about SRC and CTE, and decisions to allow their children to play youth sports.

Understanding Mothers And Daughters Physical And Emotional Health

Kellie A. Walters[1], Denise M. Anderson[2], Katherine A. Jordan[2], Christine A. Chard[3]. [1]California State University, Long Beach, Long Beach, CA. [2]Clemson University, Clemson, SC. [3]Colorado State University, Fort Collins, CO.
(No relevant relationships reported)

Compared to boys, adolescent girls have a higher prevalence of obesity, are more sedentary, and suffer more from psychosocial distress. It has been theorized that girls imitate their mothers' body image concerns and physical activity habits. **PURPOSE:** The aim of this study was to explore the relationship between adolescent girls' and mothers' perceived physical and emotional health. **METHODS:** Adolescent girls (N = 44) and their mothers (N = 19) participated in seven and four focus groups, respectively. Each focus group lasted 30-45 minutes and included an average of six and five participants for girls and mothers, respectively. Questions focused on physical activity behaviors of mothers and daughters as well as their perceptions of body image and self-esteem. The focus groups were analyzed using "Framework Analysis". Intercoder reliability was addressed through an iterative coding process (initial coding, code modification, recoding) whereby three of the authors developed and agreed upon the codes and subsequent collapsed themes. **RESULTS:** The thematic analysis resulted in four major themes and five subthemes: 1) Health related conversations are complex and result in a) daughters feeling frustrated and b) mothers feeling confused, 2) Social expectations influence body image through a) social networks and b) women's changing bodies, 3) Social comparison is common in women and girls in a) their comparison of one another which b)influences the daughter's perception of herself, and 4) Mothers' health behaviors are noticed by daughters who report very little physical activity participation with mothers. **CONCLUSION:** Results from this study highlight the type of health communication that mothers and daughters perceive as most challenging; daughters struggled with indirect conversations with their moms about health, whereas their mothers struggled with direct communication about health. Potential implications of this research include the support for targeting mothers, in addition to adolescent girls, in interventions aimed at improving mother-daughter communication as well as adolescent girls' health. Other possible implications include targeting psychosocial health (e.g., body image) and including a mothers' educational component for programs aimed at improving adolescent girls' health.

Physical Activity and Play Behaviors during Indoor and Outdoor Free Play in Toddlers

Tyler Kybartas, Jake T. Ramsey, Dawn P. Coe, FACSM. *University of Tennessee, Knoxvile, TN.*
(No relevant relationships reported)

Young children should be provided with physical activity (PA) opportunities that promote both skill and cognitive development. Unstructured free play, both indoors and outdoors, allows young children to accumulate PA while engaging in diverse types of play behaviors, which include social and cognitive components. Cognitive play behaviors focus on the purpose of the children's activity and are classified as constructive, dramatic, exploratory, functional, and game play. **PURPOSE:** To determine PA levels and cognitive play behaviors in toddlers during indoor and outdoor free play time. **METHODS:** Participants were 25 toddlers (2.9±0.6y) enrolled in a university laboratory school, who were observed for four 20-min free play segments (2 indoor and 2 outdoor). PA was assessed using the ActiGraph GT3X+ accelerometer worn on the right hip. Each free play assessment was video recorded for analysis using the Noldus Observer XT system. The Play Observation Scale was used to classify cognitive play behaviors (constructive, dramatic, exploratory, functional, and game). The percentage of time spent in each play behavior was averaged for indoor and outdoor segments. Paired samples t-tests were used to determine differences in mean vector magnitude (VM; counts/15sec) between environments (indoors and outdoors). A 2X5 repeated measures ANOVA was used to determine the main effects of environment (indoor, outdoor) and play behavior (constructive, dramatic, exploratory, functional, game) and the interaction between these variables. **RESULTS:** There were no differences in VM counts between indoors and outdoors (541±173 vs. 657±327 counts/15sec, $p>0.05$). A significant interaction ($p<0.05$) was found between the environment and play behavior. Compared to outdoors, the participants engaged in 8.5% and 8.9%, more time in constructive and dramatic play, respectively, indoors ($p<0.05$). The children engaged in 1.4% more time in exploratory play ($p<0.05$) outdoors compared to indoors. There were no differences in percent time spent in functional (6.3%) and game (2.3%) play between environments ($p>0.05$). **CONCLUSIONS:** While there were no differences in VM counts, it appears that environment has an impact on the type of play behaviors children engage in. Indoor and outdoor play opportunities may encourage a variety of play behaviors.

Activity Type, Play Context, and Group Composition during Indoor and Outdoor Free Play in Toddlers

Vincenzo G. Nocera, Tyler J. Kybartas, Jake T. Ramsey, Dawn P. Coe, FACSM. *University of Tennessee Knoxville, Knoxville, TN.*
(No relevant relationships reported)

PURPOSE: To determine the type of physical activity (PA), play context, and group composition in toddlers during indoor and outdoor free play time. **METHODS:** Twenty-five toddlers (2.9±0.6y; 12 male) were video-recorded during four 20-minute free play segments (2 indoor and 2 outdoor). Each free play assessment was coded for type of PA, play context, and group composition using the Noldus Observer XT system and the percentage of time spent in each variable was averaged for indoor and outdoor segments. The Observational System for Recording Physical Activity in Children – Preschool (OSRAC-P) was used to classify the type of PA and play context. The three most common PA types (sit/squat, stand, and walk), indoor (transition, manipulatives, and sociodramatic), and outdoor (open space, portable equipment, and fixed equipment) contexts were included in the analyses. Group composition (solitary, parallel, or group) was assessed using the Play Observation Scale. Multiple repeated measures ANOVAs with post hoc analysis (LSD) were used to determine the effects of environment (indoors vs. outdoors) and PA type, environment and context, and environment and group composition as well as any interactions among these variables. **RESULTS:** The children spent 5.6% more time walking outdoors and 15.5% more time sitting/squatting indoors ($p<0.05$). The children spent less time on fixed equipment and in sociodramatic play compared to using manipulatives/portable equipment (13.7%) and transitioning or being in an open space (9.9%; $p<0.05$). Finally, the participants engaged in 13.5% more parallel and 11.1% more group play compared to solitary play ($p<0.05$). **CONCLUSION:** The type of PA varied by environment and consisted primarily of sitting/squatting, standing, and walking. The contexts were similar despite differing environments. The children spent most of their time transitioning and in open spaces and playing with manipulatives or portable equipment and playing with or in close proximity to other children. These results provide insight into children's play and PA choices during indoor and outdoor free time.

1343   Board #151   May 31 9:00 AM - 10:30 AM

Youth Sport Coaches Perceptions and Prioritization of Sport Safety

Melissa C. Kay, Christina B. Vander Vegt, Johna K. Register-Mihalik. *University of North Carolina - Chapel Hill, Chapel Hill, NC.* (Sponsor: Kevin Guskiewicz, FACSM)
(No relevant relationships reported)

Youth sport coaches set the stage for athletes' and parents' future sport involvement, experiences, and perceptions as well as attitudes toward playing safely. If youth level coaches do not see safety as a priority, athletes and parents may not either. **PURPOSE:** To determine youth sport coaches' safety perceptions and prioritization. **METHODS:** Youth sport coaches (males: n=28; females: n=2; age=46.2±12.1yrs; yrs coached=12.1±10.6) from 10 sports completed a validated survey and participated in a qualitative focus group (FG) examining prioritization, challenges, and barriers related to implementing safety policies. Coaches reported their agreement level (1-strongly disagree to 5-strongly agree) with statements about their perceptions of sport culture, education, and preparation. Descriptive statistics described each factor's agreement. Data were analyzed separately then triangulated. **RESULTS:** 97% of youth sport coaches agreed/strongly agreed that sport safety is important (n=29, 4.3±0.5), although only 77% actually make safety a priority within their sport (n=23, 3.9±0.9). Less mean agreement existed in league mandates including: coach safety education (3.8±0.9), emergency action plans (EAP) (3.2±1.1), coaches' EAP awareness (2.7±1.0, range=1-5), concussion management policies (CMP) (3.4±1.0), coaches' CMP awareness (3.1±1.0), and being encouraged to share safety information (3.8±0.9). Challenges to implementing sport safety include: parental involvement, education, sport culture and tradition, win-at-all-costs mentality, athlete physical development, lacking medical personnel, and time. These findings are reinforced qualitatively by three main FG themes affecting youth sport safety and culture including education and athlete development, others' influence and expectations, and sport safety overall. **CONCLUSION:** These data suggest a gap among youth sport coaches who think sport safety is important at the youth level versus those who actually make it a priority. Some challenges they experience with implementation may provide future targets for sport safety initiatives at the youth level. By targeting these challenges, we can minimize the gap between importance and prioritization. Supported in part by a UNC-Chapel Hill Junior Faculty Development Award

Relationships among Weight Perception, Exercise Behaviors and Physical Fitness in Korean Elementary School Children

Woong-Hee Lee[1], Sun-Young Lim[2], Ah-Reum Jung[1], Jin-Hee Lee[2], Yoon-Hee Choi[3], Kun-Ho Yoon[3], Dae-Taek Lee[1]. [1]Kookmin University, Seoul, Korea, Republic of. [2]The Catholic University of Korea, Seoul, Korea, Republic of. [3]Seoul St. Mary's Hospital, Seoul, Korea, Republic of.
(No relevant relationships reported)

PURPOSE: This study evaluated whether young children perceive their body weight correctly, and to investigate relationships among weight perception, exercise behavior and physical fitness in elementary school children.
METHODS: We recruited 200 boys (9±1 yrs, 138±6 cm, 37±10 kg, 19±4 kg/m^2) and 197 girls (9±1 yrs, 138±6 cm, 36±9 kg, 19±3 kg/m^2). Their physical fitness such as endurance shuttle run (63±26 vs. 51±20 laps), sit-and-reach (5.8±6.5 vs. 8.8±5.6 cm), grip strength (15±3 vs. 14±3 kg), and standing long jump (137±21 vs. 123±21 cm for boys vs. girls) were measured. They responded to a questionnaire reporting weight perception, exercise participation, physical activity time, physical activity preference. Their relative weight status (BMI percentile) was categorized as; underweight (<5%, UW), normal weight (5-85%, NW), and overweight/obese (85%<, OW). Data analyses were performed using Chi-square test, Fisher's exact test, Independent t-test and One-way ANOVA.
RESULTS: More than one third (36.8%) of children misperceived their body weight compared with the actual weight. In particular, body weight misperception rate was higher in NW than UW and OW. Girls considered themselves more to be overweight while boys did more to be underweight. Physical activity time and physical activity preference were not related to weight perception. Exercise participation showed differences according to gender. Physical fitness level was related to exercise behaviors. Physical fitness was higher for children who liked to exercise or were being active than those who were not. Endurance run and standing long jump were more strongly associated with physical activity preference than physical activity time, and a dose-response relationship was observed.
CONCLUSIONS: Overall, weight perception of the children was not quite accurate when compared with their actual body weight. However, there was no difference in exercise behaviors according to weight perception. Physical fitness level was associated with exercise behaviors. Endurance run and standing long jump were more strongly associated with physical activity preference than physical activity time(NRF-2013M3C8A2A02078508).

The Effect Of Goal Structure On Vo$_2$ And Motivation In 6-10 Year Old Children During Exergame Play.

Jonathan B. Naylor, Jacob E. Barkley. *Kent State University, Kent, OH.* (Sponsor: Ellen Glickman, PhD FACSM, FACSM)
(No relevant relationships reported)

Previous research has examined contexts which may promote playing physically interactive video games (exergames) in place of traditional, sedentary video games in children. In one such study the presence of a friend did not increase children's motivation to play an exergame versus a sedentary alternative. This lack of an effect may have been due to the competitive goal structure of the exergame studied. Children may prefer a cooperative game structure when playing with a friend. **PURPOSE:** To examine physiologic response and relative reinforcing value (RRV, i.e., motivation) for playing an exergame with a friend under two different goal structures: competitive and cooperative. **METHODS:** Participants (N = 7, 7.9 ± 1.5 years old) and a same-sex friend each completed three, 10-minute conditions: supine rest, competitive, and cooperative game play. During competitive game play, participants played Nintendo Wii Tennis against their friend. During the cooperative condition, subjects and their friend played together against a computer avatar. During each 10 minute session oxygen consumption (VO$_2$ ml·kg^{-1}·min^{-1}) was recorded and children reported their liking, via visual analog scale, for that condition. After completing all three conditions, children completed an RRV computer task to assess their motivation to play the competitive versus cooperative goal structures. During the task children performed work (button presses) to gain access to competitive play, cooperative play or a combination of the two. The output maximum (O$_{max}$) or maximum amount of work (presses) for each goal structure was used as the measure of RRV.**RESULTS:** VO$_2$ was significantly ($p \leq 0.009$) greater for cooperative (8.88 ± 3.29 ml·kg^{-1}·min^{-1}) and competitive (10.24 ± 3.24 ml·kg^{-1}·min^{-1}) game play than the resting condition (5.75 ± 1.59ml·kg^{-1}·min^{-1}). Liking was also significantly ($p \leq 0.004$) greater for cooperative (8.92 ± 2.03 cm) and competitive (8.59 ± 2.39 cm) game play than rest (3.07 ± 2.59 cm). There were no differences ($p > 0.05$) between cooperative and competitive game play for: VO$_2$, liking, or O$_{max}$. **CONCLUSION:** In children, VO$_2$ and liking were both greater during exergame play versus the resting condition. However, motivation to play the competitive and cooperative game structures was not significantly different.

Using Self-determination Health Behavior Model To Examine Adolescents' Need Support, Need Satisfaction, And Health-related Outcomes

Hongying Wang[1], Xiaoxia Zhang[2], Shutang Ren[3], Xiangli Gu[2], Tao Zhang[2]. [1]Shanghai University of Sport, Shanghai, China. [2]University of North Texas, Denton, TX. [3]Putuo Education College, Shanghai, China.
(No relevant relationships reported)

Given the fact that adolescence is a critical period for establishing independent healthy lifestyle, the prevalence of physical inactivity and mental health problems should be addressed (Cai et al., 2017). Research has indicated that health-related behaviors can be promoted by satisfying individuals' basic psychological needs if we create a need-supportive social environment (Ryan & Deci, 2017). Thus, it is essential to investigate the relations among need support, need satisfaction, physical activity, and health outcomes among adolescents. **PURPOSE:** Guided by self-determination health behavior model (Ryan et al., 2008), the aim of this study was to examine the relations between perceived need support, need satisfaction, and health-related outcomes (i.e., physical activity and well-being) among middle school adolescents in China. **METHODS:** Participants were adolescents (N = 300; 50.3% female; M_{age} = 14.48) recruited from five middle schools in Shanghai, China. In this cross-sectional study, participants completed previously validated questionnaires assessing their perceived need support from PE teachers (i.e., autonomy support, competence support, and relatedness support), need satisfaction (i.e., autonomy, competence, and relatedness), physical activity, and well-being. **RESULTS:** Correlation analysis revealed significant positive associations among need support, need satisfaction, physical activity, and well-being (rs ranged from .15 to .82). The structural equation modelling (AMOS 22.0) supported the hypothesized model with a good fit to the data (χ^2/df =58.08/18, p < .001; NFI = .95; IFI = .97; CFI = .97; RMSEA = .09; 90% CI [.06, .11]). The need support had a large influence on need satisfaction (β = .80), and need satisfaction also had a significant contribution on health-related outcomes including physical activity and well-being (β = .89). **CONCLUSION:** The findings highlighted the importance of need-supportive environments, and supported the theoretical tenets of self-determination health behavior model and its generalizability among Chinese adolescents. To maintain adolescent's healthy lifestyle, school teachers and health professionals need to create a need-supportive environment to enhance adolescents' need satisfaction and health-related outcomes during adolescence.

Physical Literacy, Anxiety, And Depression In Sixth-grade Physical Education Students

Gene L. Farren[1], Paul E. Yeatts[2], Hongxin Li[3]. [1]West Texas A&M University, Canyon, TX. [2]Texas Woman's University, Denton, TX. [3]University of North Texas, Denton, TX.
(No relevant relationships reported)

In the past decade, physical literacy has been given increased research attention among educational organizations and researchers (Edwards et al., 2017). Physically literate individuals are said to have the ability, confidence, and desire to be physically active for life (SHAPE America, 2014). Though relationships among physical activity, anxiety, and depression are well-established, relationships among physical literacy, anxiety, and depression have yet been explored. **PURPOSE**: To investigate the relationships among physical literacy, anxiety, and depression in early adolescents. **METHODS**: Participants were 419 sixth-grade physical education students (58% female; M_{age} = 11.51 ± 0.5 years) from two public middle schools located in Southwestern United States. To assess physical literacy, anxiety, and depression, participants completed the PE Metrics® Overhand Throwing (SHAPE America, 2010), FITNESSGRAM® (The Cooper Institute, 2013), and Plank (NHANES, 2012) assessments, as well as three brief surveys assessing self-efficacy (Gao, Newton, & Carson, 2008), intrinsic motivation (Ryan & Connell, 1989), self-esteem (Harter, 2012), knowledge and understanding (Healthy Active Living and Obesity Research Group, 2013), and anxiety and depression (Lovibond & Lovibond, 1995). Structural Equation Modeling was used to investigate the fit of the measurement and structural models of the factors and the proposed relationships. **RESULTS**: Analyses revealed good model fit for the physical literacy, $\chi^2(167)$ = 343.38, $p < .01$, RMSEA = .05, CFI = .96, SRMR = .07, and the anxiety and depression measurement models, $\chi^2(34)$ = 73.72, $p < .01$, RMSEA = .05, CFI = .95, SRMR = .05. Physical literacy was variant between sexes; thus, boys' and girls' data were analyzed separately. Analyses indicated physical literacy was negatively related to anxiety (γ = -.41, $p < .01$) and depression (γ = -.38, $p < .01$) with female and male data (γ = -.20, $p < .01$; γ = -.22, $p < .01$, respectively). **CONCLUSION**: In both female and male six-grade physical education students, higher physical literacy related to lower levels of anxiety and depressive symptomologies. These results were consistent with previous research that suggests increasing physical literacy in children may improve psychological well-being (Olive, Telford, Telford, & Byrne, 2015).

Learning Through Play: Positive Effects Of Active Playing On Cognition In Children

Isabela A. Ramos[1], Eduardo B. Fontes[2], Raiane M dos S Pereira[3], Isabel A. David[4], Jessica Sanches[4], Stephany V. Brito[3], Rodrigo A V Browne[5], Carmen S G Campbell[3]. [1]University Catholic of Brasilia, UniProjeção, Brasília, Brazil. [2]Federal University of Rio Grande do Norte, Natal RN, Brazil. [3]University Catholic of Brasilia, Brasília, Brazil. [4]Federal Fluminense University, Rio de Janeiro, Brazil. [5]Federal University of Rio Grande do Norte, Brasília, Brazil.

(No relevant relationships reported)

The utility of physical activity, fitness to improve cognition and academic achievement is important to make pleasant learning disturbs and difficulties. **PURPOSE**: To verify the effects of three months of interdisciplinary physical education program on academic achievement and selective attention in children. **METHODS**: 60 boys and girls from 4th grade of public elementary brazilian school, underwent a Education by Movement group (EduMove) (n=39, 9.7±yr; 31.6 ± 6.2 kg; 1.4 ± 0.1 m; 17.9 ± 7.2 %body fat) with math, written and reading classes through physical education activities during a school journey (172.8±16.31bpm) (60min each class, twice a week), and a control group (Con) (n=21, 9.9±0.8yr; 30.0 ± 5.1 kg; 1.4 ± 0.1 m; 17.1 ± 8.6 %body fat) which participated at traditional classes (92.4±8.9bpm). Children performed an academic achievement standardized test (reading, writing and math), selective attention test (Stroop Go/NoGo) and anthropometric measures before and after three months. **RESULTS**: ANOVA revealed tricipital skinfold reduction for EduMove in comparison with CON at post test (11.8 ± 5.6 *vs* 12.7 ± 5.3; p=0.008), it was observed higher physical activity level for EduMovi *vs* CON (Δ 23.3 *vs* 2.9 METs; p=0.09). Children showed better results at reading capacity for EduMovi *vs* CON (65.2 ± 4.9 *vs* 64.7 ± 3.0; p=0.038). Regarding selective attention EduMovi was faster and committed less mistakes in comparison with pre test (236.1 ± 39.9 *vs* 327.9 ± 45.88 ms/%, Δ -90ms e -2% of mistakes p=0.09). **CONCLUSIONS**: A short term interdisciplinary physical education program can improve reading capacity, and selective attention in children. These results may suggest that activity breaks during a school journey could contributing to learning.

High School Adolescents' Physical Activity and Physical Fitness: A 3 × 2 Achievement Goal Approach

Liang Shen[1], JoonYoung Lee[2], Xiaoxia Zhang[2], Xiangli Gu[2], Tao Zhang[2]. [1]Shanghai University, Shanghai, China. [2]University of North Texas, Denton, TX.

(No relevant relationships reported)

Previous research has showed the majority of high school adolescents are not physically active and fit (CDC, 2010). The literature indicates that individuals' goal orientations would influence their healthy behavior (Elliot et al., 1999). The 3 × 2 Achievement Goal Model aims to understand individuals' six goal orientations (i.e., task-approach, task-avoidance, self-approach, self-avoidance, other-approach, and other-avoidance; Elliot et al., 2011). Therefore, it is important to identify high school adolescents' goal orientations toward their physical activity and fitness. **PURPOSE:** Guided by 3 × 2 achievement goal approach, this study attempted to examine the relations between six goal orientations, physical activity, and physical fitness among high school adolescents. **METHODS:** Participants were 792 adolescents (360 males, 432 females; M_{age} = 16.9) recruited from four high schools in Shanghai, China. They completed previously validated survey to measure their 3 × 2 goal orientations (Elliot et al., 2011), physical activity (Kowalski et al., 1997), and physical fitness (i.e., 50-meter run and standing long jump). **RESULTS:** Correlation analysis demonstrated that task-, self-, and other-approach goals were significantly correlated to physical activity and fitness (rs ranged from -.10 to .27). While task-, self-, and other-avoidance goals were positively related to physical activity (rs ranged from .10 to .13), they were not significantly associated with physical fitness. The results of three multiple regressions revealed that other-approach goal (β = .19), self-approach goal (β = .18), and task-avoidance goal (β = -.09) were significant predictors of physical activity (R^2 = 9.0%). Other-approach goal (β = -.19) and self-avoidance goal (β = .10) significantly contributed to 50-meter run (R^2 = 2.5%). Only self-approach goal (β = .14) significantly predicted standing long jump (R^2= 1.9%). **CONCLUSION:** The findings supported the 3 × 2 achievement goal model can be utilized to understand physical activity and fitness among high school adolescents. Specifically, creating a self- and other-approach oriented environment and designing developmentally appropriate class contents based on adolescents' level could be effective strategies to augment high school adolescents' physical activity and fitness.

Understanding High School Adolescents' Physical Activity and Depressive Symptoms from a Psychosocial Perspective

Tao Zhang[1], Xiangli Gu[1], Liang Shen[2], JoonYoung Lee[1], Xiaoxia Zhang[1]. [1]University of North Texas, Denton, TX. [2]Shanghai University, Shanghai, China.

(No relevant relationships reported)

Although regular physical activity (PA) produces significant health benefits, the majority of adolescents were physically inactive and adopting sedentary lifestyle (Zahl et al., 2017). Further, the mental health problems such as depressive symptoms were prevalent among adolescents (Schubert et al., 2017). The theory of planned behavior (TPB; Ajzen, 1991) suggests attitude, subjective norm, and perceived behavioral control can shape individuals' PA intention and PA, but there is limited empirical evidence of relationships among TPB variables, PA, and depressive symptoms among adolescents. **PURPOSE:** Guided by the TPB, this study attempted to fill the research gap and test a hypothesized model of TPB variables (i.e., attitude, subjective norm, perceived behavioral control, and intention) related to PA and depressive symptoms among high school adolescents. **METHODS:** 792 Chinese adolescents (432 females; 360 males; M_{age} = 16.9) who enrolled into four high schools in Shanghai completed previously validated questionnaires assessing their TPB variables, PA, and depressive symptoms. Correlations were used to examine the relationships among the variables, and the hypothesized model was tested using structural equation modeling (SEM; AMOS 22). **RESULTS:** Correlation analysis revealed significant positive associations among TPB variables and PA, while depression was negatively related to TPB variables and PA. The SEM analyses indicated that the hypothesized model produces a good fit to the data (χ^2/df =33.9/6, p < .01; NFI = .98; IFI = .98; CFI = .98; RMSEA = .08; 90% CI [.05, .10]). Specifically, the model accounted for 23.8% and 1.0 % of the variance in PA and depression, respectively. Path coefficients suggested that attitude (β = .33), subjective norm (β = .21), perceived behavioral control (β = .28) were positively associated with intention. Intention (β = .11) and perceived behavioral control (β = .42) significantly predicted PA. PA negatively predicted depression (β = -.09). **CONCLUSION:** The findings support the theoretical tenets of TPB and provide empirical evidence of the relationships among key TPB variables, PA, and depressive symptoms in Chinese adolescents. These findings have significant practical implications for PA intervention strategies aimed at promoting adolescents' PA and reducing depression.

Athletic Coping Skills of Female Ultrarunners

Shad K. Robinson, Ashley M. Bullers, Michael C. Meyers, FACSM. *Idaho State University, Pocatello, ID.*

(No relevant relationships reported)

A female ultrarunner's ability to cope with stressful situations during competition is crucial for optimal development. Therefore, the ability to cope under these circumstances is essential for creating a strong mental capacity that leads to competitive success. PURPOSE: To quantify the athletic coping skills of female ultra runners. METHODS: Following written informed consent, 76 female ultra runners (mean age 38.9 ± 9.4) completed the Athletic Coping Skills Inventory (ACSI; Smith et al., 1995): coping with adversity (COPE), peaking under pressure (PEAK), goal setting/mental preparation (GOAL), concentration (CONC), freedom from worry (FREE), confidence and achievement motivation (CONF), coachability (COAC), and personal coping resources (PCR). Data were grouped by distance (<50 miles, 50-99 miles, 100+ miles), experience in years (novice-3, 4-9,10+), age (20-39 years, 40+ yrs), number of ultra races completed (1-2, 3-4, 5+), ethnicity (Caucasian, other), and competitive injuries (0, 1-2, 3+). RESULTS: MANOVAs (Wilks' λ) indicated significant main coping affects by distance (F 14,134 = 1.912; P = 0.030), experience (F 14,134 = 2.123; P = 0.014), and age (F 7,68 = 2.329; P = 0.034); but not by ultra competitions completed (F 14,134 = 1.239; P = 0.255), ethnicity (F 7,68 = 1.183, P = 0.324), and number of competitive injuries (F 14,134 = .899, P = 0.562). Post hoc analyses (T scores; T = 50, SD = 10) indicated 100+ ultra milers responded significantly higher in FREE (44 vs 34 vs 41; p = 0.011) and COAC (34 vs 30 vs 30; p = 0.019) than middle and low distance class runners, respectively. Runners with 10+ years of experience responded significantly higher than less experienced (4-9 and Novice-3) in GOAL (58 vs 54 vs 51; p = 0.013), CONC (53 vs 48 vs 44; p = 0.012) and CONF (50 vs 46 vs 41; p = 0.022), respectively. Runners 40+ yrs responded higher in COPE (51 vs 47;

p= 0.025), CONC (53 vs 44; p = 0.001), and lower in FREE (37 vs 45; p = 0.013) than younger runners, respectively. **CONCLUSION:** Coping skills among this group reflected subnormal responses when compared to normative values across other athletic populations. It is recommended that ultra athletes incorporate time within their workout routines to conduct coping skills training involving sport psychologists familiar with ultra running.

Learning Effect of Anchoring Bias in Combination with Action-Perception Coupling in Novice Golf Putting

Andrew Nixon, Matthew Miltenberger, Shala Davis, FACSM, Gavin Moir. *East Stroudsburg University, East Stroudsburg, PA.*

(No relevant relationships reported)

Quality of instruction significantly influences skill acquisition and performance in sport related tasks, such as golf putting. Instruction for novice individuals should promote external focus, and constantly emphasize the relationship between motor action and task outcome. **PURPOSE:** To analyze the influence of an anchoring bias, while also examining the learning benefits of integrating action-perception external foci. **METHODS:** The putting protocol consisted of three trials: pre-test, acquisition, and post-test. Each trial was performed from a distance of eight feet on artificial turf. Subjects (6 males, 6 females) did not receive instructions or cues for any of the ten putts during the pre- or post-tests. Two counter balanced groups were made upon the completion of the pre-test. Immediately before the start of the acquisition trial subjects were provided an anchor number and asked to estimate whether their average putt would stop closer or further than the number. Group one (High) was given an anchor of 12 inches and group two (Low) was given an anchor of 3 inches. External cues were positioned in front of and behind the starting point of the ball to facilitate club and ball path for the acquisition trials. The subjects were not made aware of the cues or instructed to use them in any way. The acquisition trial contained five blocks of twenty putts with a three-minute break between each block. Twenty-four hours after the completion of the acquisition trial subjects returned to complete the post-test. Distance from the target was measured as the average sum of horizontal and vertical distance. **RESULTS:** The high anchor group responded with an average of 5.55 inches (9.3±1.96 vs 3.75±1.78, p<0.05) more than the low anchor group. This difference was found to be significant, demonstrating that anchor values may have an influence on estimation. Error was reduced in both the High (50.1±18.07 to 40.84±9.71, p<0.05) and Low (58.72± 18.59 to 35.71±7.99, p<0.05) groups from pre-test to post-test. Differences between groups were not found to be statistically significant (p = 0.262). **CONCLUSION:** Individuals used the provided anchor values to adjust their estimate of predicted performance. Significant differences in putt performance from pre to post test showed improvement in both groups. Improvement between groups were not significant.

Academic Confidence and Grit Predict Mindfulness in Collegiate Student-Athletes

Brigid M. Brennan, Caroline J. Ketcham, Kirtida Patel, Eric E. Hall, FACSM. *Elon University, Elon, NC.*

(No relevant relationships reported)

Mindfulness includes the ability to be attentive and aware of present events and experiences without making judgments based off prior beliefs. There is evidence that mindfulness is related to grit and academic performance but has not been well studied in the collegiate athletic population. **PURPOSE**: The purpose of this study was to determine if grit, academic confidence and demographic factors were predictive of mindfulness in collegiate student-athletes. **METHODS**: 349 (19.6+/-1.23yrs; 191 male, 158 female) varsity student-athletes completed the Mindfulness Attention Awareness Scale, Academic Confidence Scale, and short grit scale as part of the baseline concussion testing protocol. 177 were classified as contact and collision student-athletes (Football, Lacrosse, Soccer), 75 as contact student-athletes (Basketball, Baseball, Softball), and 96 as limited contact student-athletes (Cross-Country, Track and Field, Tennis, Golf, Volleyball). These classifications are used by the NCAA and may influence levels of mindfulness. A stepwise multiple regression was conducted to determine if gender (step 1), age (step 2), sport type (step 3), grit (step 4) and academic confidence (step 5) were predictive of mindfulness. **RESULTS**: Steps 1-3 displayed no significant change in R2(gender, age, and sport type, R2 =0.013, p>0.05) . Steps 4, grit, showed significant change in R2 (R2 change=0.159, p<0.001). In addition, step 5, academic confidence, showed a significant change in R2 (R2 change = 0.013, p<0.05). **CONCLUSION**: Demographic information including age, gender and sport classification do not significantly predict the variance of mindfulness (1.3%) but the addition of Grit and Academic Confidence accounted for 18.5% of the variance in mindfulness. This suggests that the relationship between mindfulness, grit, and academic confidence is important in collegiate student-athletes. Future research should consider how training in mindfulness impacts performance and confidence on and off the field of play.

(No relevant relationships reported)

Deception is a psychological approach to manipulate the exercise expectation (EE) before or during self-paced exercise(SIE).
PURPOSE: Verify how negative expectations would alter pacing strategy, performance and psychophysiological responses to an all-out sprint interval exercise (SIE).
METHODS: Participated of the study, eleven cyclists (34 ± 6 years old, 173 ± 4.8 cm, 73 ± 5.8 kg, 52.9±8.1 ml/kg/min, 298.4±29.9 Wpeak). After characterize the cyclists with anthropometric measurements, maximal incremental test and familiarization, two all-out SIE were performed: (1) control (CON) composed by a ten all-out sprints, with 0.1 kp.kg^{-1} body mass workload, interspersed by a 60 s of passive recovery, without manipulating the EE; (2) more demanding exercise expectation (MDEE), with the same exercise configuration as in the CON, but the cyclists were informed that the SIE have a higher demand than in CON, based on the information of they would rest for 50 s between the sprints, however they actually rested for 60 s. Performance as a peak (PPO) and mean (MPO) power output and physiological measurements (heart rate (HR), VO2 and lactate (BLC)) were recorded continuously over the SIE and psychological measurements (RPE, felling scale (FS) and felt arousal scale (FAS)) were collected during each recovery period.
RESULTS: Main effect of EE was not found on performance, however the MDEE session show a higher PPO in the last sprint (p=0.019). EE main effect was also detected for FS (p < 0.001) but not for FAS (p = 0.26) responses. Although we did not detect an effect of EE on performance between experimental sessions (CON x MDEE), affect and pacing performance (MPO) were related. These correlations seems to indicate that either valence or the arousal have better associations either for the CON (r = 0.91, P <0.001; r = - 0.90, P <0.001) than for the MDEE (r = 0.69, P = 0.026; r = - 0.79, P = 0.006), respectively. Additionally, by means of *circumplex* model, the CON affect pre-exercise and sprint 1 values, were in the calmness quadrant, contrary to what is observed is MDEE. Main effect of exercise expectation was also found in HR (p=0.002) but not for VO2 (p=0.067) and BLC (p=0.38).
CONCLUSIONS: The manipulation of pre-EE, it seems to influence psychophysiological but not physiological responses, in two all-out SIE with the same exercise configuration.

Impact Of Music On Athletes' Motivation And Flow State During Competitions

Michaela Cocca[1], Armando Cocca[1], Ney Augusto Da Silva[2], Luis Tomas Rodenas Cuenca[2]. *[1]Texas A&M University San Antonio, San Antonio, TX. [2]Autonomous University of Nuevo Leon, Monterrey, Mexico.*

(No relevant relationships reported)

Flow state (FL) and motivation (M) are among the most studied psychological conditions that may affect athletes' performance. Highly intrinsically motivated players who are fully synchronized and absorbed into their game have greater chances to perform well, to deal positively with stress and pressure associated with competitions, and to maintain a mental balance that allows them to be successful in their personal life as well. Among the strategies that athletes, or their coaches, adopt to prompt a positive mental condition before and after trainings and competition, listening to music has become a widespread trend.
PURPOSE: to determine motivational and flow profiles of athletes based on their use of music before and after trainings and competitions.
METHODS: A sample of 263 athletes participating in the 2017 University Olympics of Mexico filled a questionnaire on music habits and preferences, the Sports Motivation Scale, and the Flow State Scale. Two-step cluster analysis was performed to explore athletes' music-related profiles. RESULTS. The analysis highlighted the presence of two main groups: Music Enthusiasts (ME), athletes who listen to music often in

training and match situations, are characterized by high intrinsic (20.2), low extrinsic motivation (9.3), and null amotivation (7.5); also, they have high levels of flow state (FS > 18); and Music Hesitant (MH), athletes who listen to music seldom or never, have low intrinsic (5.1), high extrinsic motivation (20.4), as well as high amotivation (19.3); although MH's flow profile is similar as ME's in many dimensions, the formers show moderate balance between personal skills and task challenges (12.2), moderate focus on their tasks (13.1), and tend to have low self-awareness (9.9). CONCLUSIONS: Listening to music seems to trigger an optimal mental state before trainings and competitions, as well as it allows athletes to maintain a psychological balance after their performance.

Evaluating The Effectiveness Of Applying Grief-Response Models To Sport Injury In Collegiate Student-Athletes

Sydney Brown, Eric E. Hall, FACSM. *Elon University, Elon, NC.* (Sponsor: Dr. Eric Hall, FACSM)

(No relevant relationships reported)

For an athlete whose identity is contingent upon their participation in sport, an injury that forces them to cease participation can represent a significant loss. As a result, grief models are often applied to the context of sport injury. However, most models may be outdated, and little empirical research has been done to test their applicability to sport injury. **PURPOSE**: The effectiveness of grief-response models in describing emotional responses to injury was evaluated in collegiate student-athletes. Additionally, the role of social support in determining emotional response was investigated. **METHODS**: 14 collegiate student-athletes (9 female, 5 male) across five Division I sports participated in this study by completing a semi-structured interview regarding the individual's injury experience. **RESULTS**: Athletes most frequently reported feeling upset during the injury diagnosis stage. For those athletes whose injury required surgical intervention, their top reported emotional response during that time was anxiety or fear. Frustration was the most commonly expressed emotion during the rehabilitation stage. Finally, in returning to play, the top emotional response reported among participants was nervousness/anxiety. Regarding social support, participants reported one or both of their parents as their greatest source of social support, while coaches were the primary source that the student-athletes wished they had received more support. **CONCLUSION**: Preliminary findings suggest that grief models should redirect focus from shock and depression and be reworked to account for the prevalence of anxiety and frustration in multiple stages of recovery. Additionally, results identified a need for increased availability of social support resources on campus, as well as, training for coaching staff on how to better meet the expectations and needs of injured athletes.

1357   Board #165   May 31 9:00 AM - 10:30 AM

Indicators Of Burnout In College Athletes: Proportion Comparisons By Sex And Sport Type

Victor Hugo Montejo-Lambaren, Sara Ramirez-Hernandez, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To describe the proportion of burnout levels in college athletes employing a psychological instrument and compare them by sport type and sex.
METHODS: 236 college athletes from a high performance program (122 from individual sports and 124 from team sports and; 76 women and 160 men) were evaluated. Trained psychologists applied the Sport Burnout Inventory-Reviewed (IBD-R, in Spanish), conformed by 19 items that evaluate 3 Burnout dimensions in athletes: Emotional Exhaustion (EE), Depersonalization (D) and Reduced Personal Realization (RPR); finally, it brings to a Total Burnout Qualification, which let the evaluator know the burnout level in the evaluated subject. The results were classified in four categories: "Low risk" (≤50), "Moderated risk" (≥51 <60), "High risk" (≥61 <70) and "With burnout" (>70). The frequencies and proportions were counted and compared by sport type and sex.
RESULTS: Team sports showed lower proportion of "Low risk" to suffer burnout in the RPR factor than individual sports (p=0.03). As well, a trend for higher proportion of "With burnout" in EE was observed for individual than team sports (p=0.06). Conversely, a trend for higher proportion of "Moderated risk" in RPR was observed for team than individual sports (p=0.06). On the other hand, statistically significant differences were found in three factors between females and males. Males showed higher prevalence of "Low risk" in EE compared to females (p=0.006), also females presented higher proportion of "Moderated risk" to suffer burnout in the EE indicator than males (p=0.02). In the D factor, males reported a higher proportion of "High risk" to suffer burnout than females (p=0.03) (Table 1).
CONCLUSIONS: The results showed that both individual sports and female athletes presented higher proportions of risk to suffer burnout than team sports and male athletes, respectively. However, a deeper evaluation is suggested to confirm the data and make a Burnout profile in college athletes.

Table 1. Proportion of burnout indicators by sport type and sex.

By sport type

	Team sports (n 124)				Individual sports (n 112)			
	EE	D	RPR	BURN-OUT	EE	D	RPR	BURN-OUT
Low risk	53.2% (n 66)	43.6% (n 54)	54.8% (n 68)[a]	44.4% (n 55)	46.4% (n 52)	48.2% (n 54)	68.8% (n 77)[a]	47.3% (n 53)
Moderate risk	33.9% (n 42)	34.7% (n 43)	31.5% (n 39)[b]	47.6% (n 59)	34.8% (n 39)	29.5% (n 33)	20.5% (n 23)[b]	44.6% (n 50)
High risk	11.3% (n 14)	13.7% (n 17)	8.9% (n 11)	7.3% (n 9)	12.5% (n 14)	14.3% (n 16)	8.9% (n 10)	8.0% (n 9)
With burnout	1.6% (n 2)[b]	8.1% (n 10)	4.8% (n 6)	0.8% (n 1)	6.3% (n 7)[b]	8.0% (n 9)	1.8% (n 2)	0% (n 0)

By sex

	Females (n76)				Males (n 160)			
Low risk	36.8% (n 28)[c]	48.7% (n 37)	65.8% (n 50)	44.7% (n 34)	56.3% (n 90)[c]	44.4% (n 71)	59.4% (n 95)	46.3% (n 74)
Moderate risk	44.7% (n 34)[c]	32.9% (n 25)	27.6% (n 21)	47.4% (n 36)	29.4% (n 47)[c]	31.9% (n 51)	25.6% (n 41)	45.6% (n 73)
High risk	11.8% (n 9)	6.6% (n 5)[c]	5.3% (n 4)	7.9% (n 6)	11.9% (n 19)	17.5% (n 28)[c]	10.6% (n 17)	7.5% (n 12)
With burnout	6.6% (n 5)	11.8% (n 9)	1.3% (n 1)	0% (n 0)	2.5% (n 4)	6.3% (n 10)	4.4% (n 7)	0.6% (n 1)

[a] Significant differences by sport type (p<0.05).
[b] Trend for differences by sport type (p<0.1)
[c] Significant differences by sex (p<0.05).

Differences in Sport Motivation Types in NCAA Division II Athletes over Time

Mindy Hartman Mayol[1], Urska Dobersek[2], Matthew D. Beekley, FACSM[3]. *[1]University of Indianapolis, Indianapolis, IN. [2]University of Southern Indiana, Evansville, IN. [3]DePauw University, Greencastle, IN.*

(No relevant relationships reported)

Few studies have examined motivation types in collegiate athletes over time using the Self-Determination Theory (SDT) continuum. **PURPOSE:** To investigate differences in motivation types in NCAA Division II student-athletes (SAs) over three time points. **METHODS:** Overall, 530 SAs (n_{males} = 355, $n_{females}$ = 175) with an age range of 18 to 23 (M = 19.40, SD = 1.33) from 21 teams voluntarily completed a demographic questionnaire and the 18-item Sport Motivation Scale II used to measure six motivation types: intrinsic (IR), integrated (INTR), identified (IDR), introjected (INT), external (EXT), and amotivation (AMR) regulation. Six, one-way, repeated measures Analyses of Variance with Bonferroni post hoc tests were used to analyze SA motivation types over the pre-season (PS), in-season (IS), and off-season (OS). An alpha level of $p \leq .05$ was set for statistical significance. **RESULTS:** Analyses revealed statistically significant differences in IR, INTR, IDR, and AMR types over time. For IR, a difference was seen, $F(2, 710) = 3.66$, $p = .026$, between the PS and IS ($p = .028$) with lower scores in the IS (M = 16.11, SD = 4.21) versus the PS (M = 16.67, SD = 4.13). For INTR, differences were seen, $F(1.95, 691.39) = 15.75$, $p < .001$, between both the PS and IS ($p < .001$) and between the PS and OS ($p < .001$) with lower scores in the IS (M = 16.69, SD = 3.69) and OS (M = 16.53, SD = 4.05) versus in the PS (M = 17.58, SD = 3.29). For IDR, a difference was seen, $F(1.92, 680.470) = 5.89$, $p = .003$, between the PS and IS ($p = .004$) with lower scores in the IS (M = 16.43, SD = 4.09) versus in the PS (M = 17.12, SD = 3.62). For AMR, differences were seen over time, $F(1.97, 699.89) = 8.21$, $p < .001$, between both the PS and IS ($p < .001$) and between the PS and OS ($p < .001$) with higher scores in the IS (M = 7.82, SD = 4.31) and OS (M = 7.78, SD = 4.73) versus lower scores in the PS (M = 6.93, SD = 4.11). **CONCLUSIONS**: Findings demonstrated that more self-determined motivation (IR, INTR, IDR) was highest in the PS while increasing AMR scores predominated over time extending into the IS and OS. This is consistent with the athlete burnout/SDT literature where motivation extremely low in internalization (i.e., AMR) is positively associated with burnout and motivation extremely high in internalization (i.e., IR) is negatively associated with burnout (Cresswell, 2009; Cresswell & Eklund, 2005a, 2005b).

1359   Board #167   May 31 9:00 AM - 10:30 AM

Quantity Of Deliberate Play And Collegiate Sports: A Comparison Of Two Case Studies.

John Purcell[1], Kimberly Beach[1], Newsha Nikzad[2], Zacharias Papadakis[2], Andreas Stamatis[1]. *[1]SUNY Plattsburgh, Plattsburgh, NY. [2]Rice University, Houston, TX.* (Sponsor: Peter W. Grandjean, FACSM)
(No relevant relationships reported)

The National Collegiate Athletic Association has over 250,000 students competing in Division I (DI) and Division III (DIII) programs. DI colleges comprise 32% of the association while DIII accounts for 40%. Previous studies of individuals within the same collegiate level have uncovered a positive correlation between the hours of deliberate play and athletic skill level. To date, there have been no studies on comparing the two aforementioned divisions. **PURPOSE**: To investigate the quantity of deliberate play that contributes to achieving the DI and DIII statuses. **METHODS**: Using an online interview as proposed by Côté, Ericcson, and Law (2005), all student-athletes from both Rice University (DI) and State University of New York (SUNY) in Plattsburgh (DIII), were recruited via email. Sixty-three participated from DI (track and field, basketball, and football) and 90 from DIII (track and field, basketball, hockey, soccer, softball, and tennis). The response rate was 17% and 29%, respectively. Descriptive statistics and parametric tests were used in the analysis. **RESULTS**: Differences with statistical significance (p<0.05) were found in: (a) height (when younger, 100% DI to 78% DIII were average or taller than peers), (b) participation in early activities of art (17 to 37%), organized games with rules (72 to 86%), and other sport-related activities (48 to 74%), (c) parents being top athletes (24 to 48%), and (d) the current activities of sleeping (25 to 52 hours per week), socializing (9 to 21 h.), school/career (8 to 21 h.), and studying (9 to 15 h.). **CONCLUSIONS**: In both divisions, we further attest to the suggestions of Côté et al. (2003) about participation of youth in multifarious activities. Our results also align with past work from Landers et al. (2011), which has underscored the competitive advantage of athletes with longer levers than their shorter peers. The comparison of current activities indicate that a DIII school may be promoting a more wellness lifestyle (including all its dimensions, such as social, physical, occupational, and mental). Possible limitations of this study are the use of convenience and unequal samples, self-reported data, and of retrospective methods. Future research, comparing more cases of different-division schools, is recommended.

Athletic Coping Skills of Female Division I Volleyball Players

Madeline P. Casanova, Michael C. Meyers, FACSM. *Idaho State University, Pocatello, ID.*
Reported Relationships: M.P. Casanova: *Contracted Research - Including Principle Investigator; Partial support by FieldTurf USA.*

A female volleyball athlete's ability to cope within the competitive environment oftentimes determines the outcome of a match. Therefore, possessing a strong coping skill set necessary at this level of competition is essential for optimal performance potential. **PURPOSE:** To quantify the athletic coping skills of Division I female volleyball players. **METHODS:** Following written informed consent, 28 female volleyball players (mean age 19.7 ± 1.5) completed the Athletic Coping Skills Inventory (ACSI; Smith et al., 1995): coping with adversity (COPE), peaking under pressure (PEAK), goal setting/mental preparation (GOAL), concentration (CONC), freedom from worry (FREE), confidence and achievement motivation (CONF), coachability (COAC), and personal coping resources (PCR). Data were grouped by athletic rank (top, bottom), present injury status (yes, no), and by academic level (upper class, lower class). **RESULTS:** MANOVAs (Wilks' λ criterion) indicated significant main effects for athletic coping by athletic rank ($F_{13,16} = 5.046$; P = 0.002), but no significant main effects across present injury status ($F_{24,5} = 1.711$; P = 0.161) or academic level ($F_{14,15} = 0.545$; P = 0.791). Post hoc analyses (T score; T = 50, SD = 10) indicated that top-ranked athletes responded significantly higher in COPE (55 vs 42; p < 0.001), PEAK (53 vs 44; p = 0.001), GOAL (54 vs 44; p = 0.006), and CONC (53 vs 48; p = 0.025), CONF (54 vs 46; p = 0.001), COAC (52, 39; p = 0.001), and PCR (56 vs 41; p < 0.001) than bottom-ranked peers, respectively. There was also a trend for athletes experiencing trauma to respond more positively in COPE, PEAK, GOAL, CONC, FREE, CONF, and PCR than non-injured peers. Of concern, athletic coping skills among this group were below average when compared to normative values across other athletic populations. **CONCLUSION:** Although findings were influenced by limited sample size, results still support the recommendation that volleyball athletes incorporate psychological skills training into their workout routines that specifically target athletic coping skills. Further research is warranted to assess coping skills within a larger volleyball population, to assess coping skills in athletes recovering from injuries, as well as to quantify the efficacy of coping skills interventions on volleyball performance.

Effects of Mental Strength and Mindfulness Training on Exercise Performance

Timothy A. Van Haitsma[1], Stephen P. Gonzalez[2], Nicholas S. Swider[1], Amanda De Laura[1], Tyler Salinas[1], Danielle Costa[1], Sarah McGough[1]. *[1]Westmont College, Santa Barbara, CA. [2]The College at Brockport, SUNY, Brockport, NY.*
(No relevant relationships reported)

Internal self-talk has been shown to improve performance and reduce effort, but less is known about how short-term mental strength (MS) and mindfulness (MD) training affect performance and underlying physiological variables.
PURPOSE: To determine how MS (grit, resilience) or MD training affect cycling time trial to exhaustion and to determine the physiological mechanisms underlying these changes.
METHODS: 35 college-aged participants visited the lab on 4 separate days. A VO2max with ventilatory threshold (VT) was performed on day 1. The subsequent visits consisted of time trials to exhaustion (TTE) performed at 10% above VT. Between visit 3 and 4, MS (13 participants) and MD (10 participants) groups watched a video or listened to an audio recording for 15 minutes each day for one week while the control group (C) (12 participants) did no training. Heart rate (HR), rate of perceived exertion (RPE), VAS scores for pain and fatigue, and EMG were recorded during the time trials. CD-Risc, GRIT-S, and the 5-factor mindfulness surveys were also completed before study day 3 and 4. A RM-ANOVA was done to compare group and time differences.
RESULTS: TTE was significantly increased in MS ($8.6\pm13.6\%$, p<0.05) and MD ($4.3\pm5.8\%$, p<0.05) compared to C ($-4.9\pm11.6\%$). There were no changes between MS or MD and C for differences between trial 1 and trial 2 for maximum HR, average HR, maximum RPE, average RPE, or VAS scores for pain or fatigue (p>0.05). One week of MS or MD training also did not affect the GRIT-S, CD-Risc, or 5-factor mindfulness survey (p>0.05). There was a significant decrease in EMG for MS as compared to both MD (p<0.05) and C (p<0.01), but MD EMG did not change as compared to C (p>0.05).
Conclusions: One week of mental training, whether MS which included grit and resilience training or for MD, has the ability to improve TTE performance. However, current psychological surveys are not sensitive enough to detect changes in mental performance, perhaps because they are not sport/exercise specific. Further, MS may improve performance by reducing EMG input and shifting to a more external focus, allowing a decreased activation of muscle and subsequent reduced fatigue rate.

Fitness Self-perception And Lifestyle In Rugby Players In Colombia

Rosmary Martínez-Rueda[1], Adriana R. Gutíerrez-Galvis[2], Viky L. Henández Cubillos[2], Nataly Sánchez Mendoza[2], Natalia Lozada Beltrán[2]. *[1]Universidad Manuela Beltrán, Bucaramanga, Colombia. [2]Universidad Manuela Beltrán, Bogotá, Colombia.*
(No relevant relationships reported)

Background: Self-perception and Lifestyle have a significant influence on athletes´ performance. Research in Rugby had been focused mainly on the assessment of physiological and anthropometrical player´s profiles as well as injuries incidence.
Purpose: The aim of this study was to evaluate the self-perception of Fitness and Lifestyle in Rugby players in Colombia **Methods:** A cross-sectional study was conducted with Rugby players from 37 cities in Colombia aged 18 years and older, with at least one year of sport practice. Fitness self-perception was assessed with the International Fitness Scale (IFIS) and Lifestyle was evaluated with the *FANTASTIC* Questionnaire. Statistical analysis was performed with central tendency measures, standard deviation, t- student and chi-square. **Results:** 479 players were surveyed. 68% were men, 53.7% played at Backs position and 46.3% as Forwards position. The age average was 24.6 (± 4.4) years old and a practice experience of 4.2 (± 3.8) years. Most of the participants classified their Fitness and Its components: Cardiorespiratory endurance, Strength and Speed /Agility as "*Good*" (58%, 47%, 53%, 44% respectively), while Flexibility was categorized between "*Acceptable*" 36% and "*Good*" 34% mainly. Significant differences were found by position on the field (Backs and Forwards) in the Self-perception of the Strength in players (p = 0.000). Regarding to Lifestyle, evaluated with the FANTASTIC Questionnaire, the average of overall score was 75.3 (± 10.2). According to this, the majority of the players, (54.7%, n = 262), reported their lifestyle in the category "*Good*". Significant differences were also found by position on the field in the total scores (p = 0.004). It highlight the difference between Forwards and Backs in the category "*Aggressiveness*" belonging to Personality Type domain (p = 0.04). **Conclusion:** Our results are consistent with the pilot study conducted previously on the same population. The players show a good self-perception of their Fitness and its components as well as a good Lifestyle. The differences found, might be explained according to the characteristics of the player's position on the field. Furthermore studies are necessary.

Muscle Dysmorphic Disorders, Body Dissatisfaction and Eating Disorder in Male Bodybuilders

Aslı Devrim[1], Pelin Bilgic[1], Nobuko Hongu[2]. *[1]Hacettepe University, Ankara, Turkey. [2]University of Arizona, Tucson, AZ.*
(No relevant relationships reported)

Muscle dysmorphic disorders (MDD) have been described as a body image disorder, characterized by a perceived lack of muscularity, and largely affect males. **PURPOSE:** The study aimed to determine the rates and relationships among MDD, body image disturbance and eating disorders in both competitive/professional and non-competitive/recreational male bodybuilders. **METHODS:** The participants consist of 120 bodybuilders (competitive, n=62 (mean age 31.05 ± 10.60 yr) and non-competitive, n=58 (mean age 25.63 ± 6.67 yr) recruited from four bodybuilding gym centers in Ankara, Turkey. Weight, height and body fat percentage were measured with BIA (Tanita, TBF- 300). To assess symptoms of eating disorders, muscle dysmorphia, and body dissatisfaction, the participants were asked to answer four questionnaires, including Eating Attitude Test (EAT)-40, Muscle Dysmorphia Disorder Inventory (MDDI), and Bodybuilder Image Grid (BIG)-Original (BIG-O) and Scale (BIG-S), the instruments to measure the perceptual body images disturbance and perceived attractiveness. A multiple linear regression model was used to identify independent factors associating eating disorders. **RESULTS:** 81 bodybuilders (67.5%) had EAT-40 scores above its cut off point, indicating having eating disorders, and there was no significant difference between competitive and non-competitive bodybuilders (p>0.05). The average scores of BIG-O and BIG-S showed statistically significant differences (p<0.01) in current and ideal body fat and muscle mass scores, indicating the most bodybuilders desire to be leaner (less fat) and muscular than their current body sizes. According to MDDI, 70 bodybuilders (58.3%) had a risk of having MDD. Furthermore, there was a significant positive relationship between EAT-40 and MDDI total scores (r= 0.614, Φ= 0.713, p<0.001) in both competitive and non-competitive bodybuilders. A linear regression analysis predicts that the eating disorder was a relative risk factor for MDDI and muscle-related body dissatisfaction in male bodybuilders. **CONCLUSIONS:** Eating disorder psychopathology is positively related with body dissatisfaction and body dysmorphic disorders. The screening tools, EAT-40, MDDI, and BIG-O and BIG-S may provide early detections of body dissatisfaction and eating disorders in male bodybuilders.

Training Mental Toughness In Sport: A Review And Meta-analysis

Andreas Stamatis[1], Peter W. Grandjean, FACSM[2], Grant B. Morgan[2]. *[1]SUNY Plattsburgh, Plattsburgh, NY. [2]Baylor University, Waco, TX.* (Sponsor: Dr. Peter Grandjean, FACSM)
(No relevant relationships reported)

In January 2017, after a week of strenuous, military-style, and anecdotally-based workouts designed to test the level of *mental toughness* (MT), three Pac-12 football players were diagnosed with rhabdomyolysis. In sporting environments, are there any safe and effective, empirically-based MT interventions? To date, there has been no attempt to collate all available empirical evidence in regards to development of MT in Sport.
PURPOSE: To summarize evidence relating to MT training programs in developing MT levels.
METHODS: Cross-sectional designs and pre- and post-test experiments were included. No publication date restriction was imposed. Participants of any age, gender, sport, or level were included. This search was applied to Embase, Scopus, PubMed, and SPORTDiscus. Two reviewers assessed the risk of bias using: (a) for RCTs, the PED*ro* scale, (b) for before-after studies with no control group, the 'Before-After (Pre-Post) Studies With No Control Group', and (c) for single-subject research study**,** the 'Quality Indicators'. The outcomes of primary interest were the scores of MT, which were translated into standardized variables (SMD). The meta-analysis was completed using a random-effects model.
RESULTS: Nine studies were included in the systematic analysis and seven in the meta-analysis. The methodological quality of those nine studies was not high. Common areas that increased the risk of bias include: (a) RCT's: allocation was not concealed, key outcomes were self-reported, no blinding of all subjects/assessors, and no random allocation of subjects; (b) Before-After Studies With No Control Group: No enrollment of all subjects who meet the inclusion/exclusion criteria, no blinding of assessors, and no reporting of relevant information; and (c) Single-subject design: fewer than three data points per phase without justification. MT scores increased by 0.88 standard deviations (95% CI). The values contained within the confidence interval were at least medium effect sizes and the variance of this estimate was 0.23.
CONCLUSIONS: A strong positive effect was observed. Therefore, the results are promising. Nevertheless, the authors believe that conclusions cannot be drawn due to limited number of reliable results, which creates a high level of uncertainty. However, this finding itself is of value.

1365   Board #173   May 31 9:00 AM - 10:30 AM

Relationships among Perceived Recovery, Vertical Jump And Change In Repeated Sprint Performance

Justin Kraft, FACSM[1], Matt Laurent[2], Stephanie Douglas[3], Danilo Tolusso[4], Adam Fullenkamp[3], James M. Green, FACSM[5]. *[1]Missouri Western State University, St. Joseph, MO. [2]Tarleton State University, Stephenville, TX. [3]Bowling Green State University, Bowling Green, OH. [4]University of Alabama, Tuscaloosa, AL. [5]University of North Alabama, Florence, AL.*
(No relevant relationships reported)

Recovery may be determined by using a counter movement vertical jump (CMJ). While a CMJ has been shown effective to evaluate recovery, there may be more efficient, less physically taxing alternatives such as the Perceived Recovery Status (PRS) Scale. The PRS is a non-invasive, and accurate psychophysiological tool designed to measure recovery and its correlation to performance. **PURPOSE:** To determine the efficacy of CMJ and PRS as methods for monitoring recovery between repeated sprint efforts. **METHODS:** Eight college-aged individuals (age=23±0.9 years; height=1.65±0.11 meters; weight=67.1±9.3.4 kg; percent body fat=17.5±8.4%) performed repeated sprints. The protocol consisted of three sets of eight 30 meter sprints on a non-motorized treadmill with 45 seconds of rest between each sprint. The sets were separated by 5 minutes of passive rest. Mean power output (MP) was measured during each sprint. RPE (overall) was recorded immediately following each sprint. Immediately before the next set of sprints PRS was recorded and a CMJ was performed on a force plate where maximal height was recorded. **RESULTS:** A 1-way repeated measures ANOVA showed a significant main effect of sprint set on RPE (p=0.04) and PRS (p<0.01). Subsequent pairwise comparisons revealed significant differences for RPE between sprint sets 1 and 2 (p=0.05), and in PRS between sprint sets 1 and 2 (p=0.001), and sprint sets 1 and 3 (p=0.02). Correlations showed the relationship between PRS and delta MP to be moderate, and significant at (R^2=0.32) while the relationship between CMJ and MP was weak (R^2=0.04). **CONCLUSION:** Current results suggest PRS may demonstrate a stronger relationship with change in repeated sprint performance within a session than CMJ. However, neither index of recovery was robust, and may indicate that these measures may be more appropriate for use between day-to-day training sessions (as previously established) and not necessarily to gauge recovery as in the current paradigm.

1366   Board #174   May 31 9:00 AM - 10:30 AM

Cross-cultural Invariance Of The Mental Toughness Inventory Among American And Greek Athletes

Grant B. Morgan[1], Andreas Stamatis[2], Zacharias Papadakis[3], Vassilis Mougios[4], Gregory Bogdanis[5], Alexandra Spinou[6]. *[1]Baylor University, Waco, TX. [2]SUNY Plattsburgh, Plattsburgh, NY. [3]Rice University, Houston, TX. [4]Aristotelian University of Thessaloniki, Thessaloniki, Greece. [5]National and Kapodistrian University of Athens, Athens, Greece. [6]Democritus University of Thrace, Komotini, Greece.* (Sponsor: Peter Grandjean, FACSM)
(No relevant relationships reported)

The popularity of the term *mental toughness* (MT) in sporting environments, at least in the U.S., has been established. However, its worldwide cultural relevance remains to be fully uncovered. Recently, Gucciardi et al. (2016), using the Mental Toughness Index (MTI), reported intra-cultural invariance of MT in Australasia. To date, there has been no effort to uncover the extent of the universality of the term between Europe and USA via MTI.
Purpose: To examine the invariance of MT across two different cultural groups of athletes and to further validate MTI. **Method:** The MTI was completed by 99 Greek and 173 US athletes via Qualtrics. The MTI consisted of eight items with a seven-point response scale. Both samples consisted of roughly half male and half female athletes from a number of sports, including American football, basketball, baseball, softball, volleyball, golf, tennis, soccer, track and field, swimming. Judo was only reflected in Greek sample.
Invariance testing was conducted using multiple group confirmatory factor analysis with increasingly restrictive models. We first fitted a unidimensional model within each sample to ensure good model-data fit. Then we estimated configural (equal number of dimensions), metric (configural + equal loadings), and scalar invariance models (metric +equal intercepts). Scalar invariance is the minimum type of invariance to infer cross-cultural equality. To evaluate the model-data fit, we used the comparative fit index (CFI), root mean square error of approximation (RMSEA), and the differences between these indices for increasingly restrictive models.
Results: The model-data fit in both samples was very good (CFI Greek = .995, RMSEA Greek = .046; CFI US = .998, RMSEA US = .032). The scalar invariance model was selected as the best fitting (CFA scalar = .930, RMSEA scalar = .078) but with a slightly different item intercept for one item (Item 4; <.5).

Conclusion: The results of this analysis provide evidence for the partial scalar invariance of the MTI across cultural samples. This implies that the meaning of the MT construct and the levels of the underlying items are equal in both cultures. As a result, the two cultures can be directly compared on their scores in the latent variable.

Athletic Identity does not Predict Reporting Intentions in Intercollegiate Athletes

Melissa N. Anderson, Welch Suggs, Laura Bierema, L. Stephen Miller, Fred Reifsteck, Michelle L. Weber, Ron Courson, Julianne D. Schmidt. *University of Georgia, Athens, GA.*

(No relevant relationships reported)

In recent years, there has been an increased emphasis on improving athlete recognition of signs and symptoms associated with concussion. Despite these empirical advances, approximately 50% of concussions at the collegiate level are believed to go unreported. In order to understand the motivational aspect of reporting concussions, it is crucial to identify factors contributing to an athletes' intentions to report. Athletes that more strongly identify with their role in their sport may be less likely to report a concussion because they fear losing their athletic identity. **PURPOSE**: To examine the relationship between athletic identity and concussion reporting intentions in student-athletes. **METHODS**: Student-athletes from 3 universities in the state of Georgia were invited to complete a survey via Qualtrics (n=298/498 response rate = 59.7%, male=41.8%). The previously validated survey included questions to assess indirect (8 items) and direct (3 items) concussion reporting intentions and the Athletic Identity Measurement Scale which includes 10 athletic identity (AI) items. All items were answered on a seven-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree). Two separate simple linear regressions were used to determine whether AI predicted intentions (alpha=0.05). A one-way ANOVA was used to compare reporting intentions between athletes with high and low AI. **RESULTS**: Athletic identity did not significantly predict indirect (R^2=.009; $F_{(1,265)}$=0.65; p=0.12,) or direct (R^2=0.002; $F_{(1,256)}$=2.54; p=0.42) concussion reporting intentions. There were no significant differences between groups for indirect (low AI mean= 5.1, high AI mean= 5.8, $F_{(1,256)}$= 3.14, p=0.07, low AI 95% CI [5.41, 6.02], high AI 95% CI [5.12,5.51]) or direct (low AI mean=6.05, high AI mean=6.30, $F_{(1,256)}$= 1.07, p=0.30, low AI 95% CI [5.53, 7.85], high AI 95% CI [5.89, 6.21]) intention to report a concussion.**CONCLUSIONS**: Although AI does play an important role in predicting outcomes following sport-related injuries, it does not seem to significantly predict concussion reporting intentions in the current study. Results of this study suggest the importance of considering the multiple factors that may explain athletes' intentions to report concussions beyond how highly they identify themselves with their sport.

Perceived Behavioral Control is Key for Activity Tracker Usage

Mary M. Yoke, FACSM, Susan E. Middlestadt, David K. Lohrmann, Andrea K. Chomistek, Carol A. Kennedy-Armbruster, FACSM. *Indiana University, Bloomington, IN.*

(No relevant relationships reported)

Perceived Behavioral Control is Key for Activity Tracker Usage
Purpose: The Reasoned Action Approach (RAA) has not been previously used to examine activity tracker (AT) beliefs. The purpose of this study was to use the RAA to explore which global constructs (attitude toward the act (AA), perceived norm (PN), and perceived behavioral control (PBC)) would best predict trained-users' intentions to use their activity trackers for the next month. This descriptive study addresses a gap in the literature by examining the AT beliefs of 165 university faculty and staff.
Methods: A convenience sample was recruited from participants who previously took part in an on-campus physical activity program during 2014-2016. The participants were "trained-users", having been guided for 8 weeks by student coaches and provided with ATs during the program. An online survey was utilized to measure RAA constructs underlying the intention to wear, look at, and make physical activity decisions based on a wearable AT and its corresponding app's information. After data collection, four composite variables were created from 18 close-ended items. Internal consistency and regression analyses were performed for the constructs of intention, AA, PN, and PBC (a construct similar to self-efficacy).
Results: A standard regression analysis showed that 69.1% of the variance in the intention to use an AT was explained by attitude toward the act (Beta =.317), perceived norm (Beta = .153), and perceived behavioral control (Beta =.488); (R = .831, F [3, 159] = 116.37, $p < .0001$). PBC was found to be the strongest contributor towards the intention to use an AT.
Conclusion: This is the first study to examine AT usage using the RAA model. Results of this theory-based research suggest that focusing on perceived behavioral control (the perceived ease or difficulty of AT usage and a person's self-efficacy) may be the most efficacious route to helping individuals become long-term AT users.

Anxiety And Depression Indicators In College Athletes: Proportion Comparisons By Sex And Type of Sport

Sara Ramirez-Hernandez, Victor Hugo Montejo-Lambaren, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To compare by sex and by type of sport the proportion of college athletes that show the probability of Anxiety and Depression Disorders employing a screening psychological instrument
METHODS: 237 college athletes from a high performance program were evaluated. They were cataloged into two sports modalities, Individual sports (Athletics, Boxing, Fencing, Aerobic Gymnastics, Weightlifting, Wrestling, Taekwondo, Table Tennis, Archery and Triathlon) and Team sports (Basketball, Baseball, Football, Soccer, Handball, Softball, Beach Volleyball and Indoor Volleyball). The instrument used was the Goldberg Anxiety and Depression Scale (a screening test, to evaluate two subscales of Anxiety and Depression). Subsequently, subjects were categorized with "No anxiety" (score <4), "Probable anxiety" (score ≥4 <7), and "Probable severe anxiety" (score ≥7), and with "No depression" (score <2), "Probable depression" (score ≥2 <6), and "Probable severe depression" (score ≥6). Then frequencies and proportions were counted and compared by sex and by type of sport.
RESULTS: We found most of the total sample showed "Probable depression", and in the area of anxiety, most of them showed "No anxiety". Statistically significant differences were found by sex, where women showed higher proportion of "Probable severe depression" than men (p = 0.01). In the area of anxiety, men showed higher "No anxiety" prorportion than women (P = 0.003), and women showed higher proportion of "Probable anxiety" than men (P=0.03). For the comparison between type of sport, no statistically significant differences were found (Table 1).
CONCLUSIONS: The results showed that women had a higher proportion of probable anxiety and depression compared to men. The type of sport was not a significant factor for differences in the presence of anxiety and depression. However, the evaluation was done by a screening instrument, so it is advisable to carry out a thorough assessment to obtain a better diagnosis.

Table 1. Proportion of probable depression and anxiety diagnosis by sex and sport					
	Total sample	By sex		By sport	
		Females	Males	Individual	Team
Depression					
No depression	41.4% (n 98)	31.6% (n 24)	46.0% (n 74)	43.8% (n 49)	39.2% (n 49)
Probable depression	50.6% (n 120)	54.0% (n 41)	49.1% (n 79)	50.9% (n 57)	50.4% (n 63)
Probable severe depression	8.0% (n 19)	14.5% (n 11) *	5.0% (n 8) *	5.4% (n 6)	10.4% (n 13)
Total	100% (n 237)	100% (n 76)	100% (n 161)	100% (n 112)	100% (n 125)
Anxiety					
No anxiety	52.3% (n 124)	38.2% (n 29) *	59.0% (n 95) *	56.3% (n 63)	48.8% (n 61)
Probable anxiety	33.8% (n 80)	43.4% (n 33) *	29.2% (n 47) *	30.4% (n 34)	36.8% (n 46)
Probable severe anxiety	13.9% (n 33)	18.4% (n 14)	11.8% (n 19)	13.4% (n 15)	14.4% (n 18)
Total	100% (n 237)	100% (n 76)	100% (n 161)	100% (n 112)	100% (n 125)
*Significant differences by sex (p<0.05)

Effect of Watching Professional Baseball on Health Outcomes in Elderly Japanese: A Randomized Controlled Trial

Ryoko Kawakami[1], Susumu S. Sawada, FACSM[2], Tomoko Ito[1], Yuko Gando[2], Tomohiro Fukushi[3], Ryosuke Fujie[3], Satoshi Kurita[1], Koichiro Oka[1], Shizuo Sakamoto[1], Mitsuru Higuchi, FACSM[1]. [1]*Waseda University, Tokorozawa, Japan.* [2]*National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan.* [3]*Seibu Lions Company Limited, Tokorozawa, Japan.*

Reported Relationships: R. Kawakami: *Contracted Research -*

Including Principle Investigator; Seibu Lions Company Limited.

PURPOSE: To investigate the effect that watching professional baseball at a ballpark has on the elderly's health-related outcome indicators.
METHODS: Fifty-eight elderly adults aged 65-85 years were randomized into a spectator group (n = 29) and a waiting-list control group (n = 29). The intervention period was approximately 2 months. During the intervention period, 21 professional baseball games were held. The spectator group was requested to watch professional baseball games at the ballpark freely. Before and after the intervention period, executive functioning (Stroop task), cognitive function (Cognitive Assessment for Dementia, iPad version 2), health-related quality of life (Medical Outcome Study 36-Item Short-Form Health Survey), depression symptoms (Center for Epidemiological Studies Depression Scale (CES-D)), subjective happiness (Subjective Happiness Scale), and physical activity (accelerometer method) were assessed.
RESULTS: The median number of days that the spectator group watched baseball games was 6 (interquartile range (IQR): 4-10 days, range: 1-21 days). Although there were no significant differences, the reverse-Stroop interference rate showed greater improvement in the spectator group (median (IQR): 17.0% (9.2-22.8) to 13.3% (3.1-24.9)) than in the waiting-list group (19.1% (7.4-30.1) to 18.0% (9.2-33.3)) (P = 0.063). The CES-D showed significantly greater improvement in the spectator group (5 (4-12) to 3 (2-7)) than in the waiting-list group (4 (1-8) to 5 (1-8)) (P = 0.016). There were no significant differences between the two groups regarding the other health-related outcome indicators.
CONCLUSIONS: These results suggest that regularly watching professional baseball at a ballpark may positively influence elderly adults' depression symptoms.

Is Short-passing Ability Related To Anxiety And Self-confidence In Division Iii Collegiate Soccer Players?
Mohammed Bila, Angela Hillman, Alan M. Levine. *Marywood University, Scranton, PA.*
(No relevant relationships reported)

Competitive soccer players are required to perform various physiological movements including short passing under the stressful conditions of a match. Individual self-confidence and ability to perform under pressure may impact on a successful match outcome. **Purpose:** The purpose of this cross-sectional study was to examine the relationship between short-passing ability and anxiety and self-confidence among collegiate male and female soccer players. **Methods:** Participants included 17 Division III collegiate soccer players (19. ±1.1 years, 65% female, 35% male) who completed the following questionnaires on a computer to assess competitive anxiety and self-confidence: The Illinois Competitive State Anxiety Inventory-2 (CSAI-2R), Sport Competition Anxiety Test (SCAT), and Trait Sport-Confidence Inventory (TSCI). Soccer skills were then assessed indoors as measured by total time on Loughborough soccer passing test (LSPT), which consisted of 16 short passes completed as fast as possible. Data were analyzed using descriptive statistics and Spearman's *rho* correlations. **Results:** Mean short-pass total time was 55.7±12.03 seconds. We observed positive relationships between SCAT and LSPT total time (r_s =0.51, p = 0.04) and CSAI-2R and LSPT total time (r_s =0.52, p = 0.04): as anxiety increased, so did total time on the passing tests. Additionally a strong negative relationship was found between TSCI and LSPT total time (r_s =-0.68, p= 0.004): as self-confidence increased, total time on the passing test decreased. **Conclusions:** Increased anxiety and decreased confidence lead to poorer short-passing performance in collegiate soccer players. Coaches should consider interventions to decrease anxiety and improve self-confidence in preparation for soccer competition.

Effects of Mental Fatigue Induced Using the Smartphone on Physical & Technical Performance of Footballers
Gianpiero Greco, Roberto Tambolini, Pasquale Ambruosi, Francesco Fischetti. *University of Bari, Bari, Italy.*
(No relevant relationships reported)

Mobile devices (i.e., smartphones and tablets) have acquired important functions in both interpersonal and individual spheres. For this reason, they can cause a true dependence for the young people. Moreover, prolonged periods of cognitive activity induce mental fatigue, a psychobiological state which influences the performances in team sports. **PURPOSE:** The purpose of this study was to assess the effects of prolonged use of smartphones on physical and technical performance of young footballers. **METHODS:** In total, 16 young male footballers (15.0 ± 1.1 years) were randomly assigned to two studies, Study 1 (S1, n=8) or Study 2 (S2, n=8), in which the Yo-Yo Intermittent Recovery Test level 1 and the Loughborough Soccer Passing Test were performed, respectively. The soccer-specific physical and technical performance was assessed for S1 and S2. In both studies, the participants underwent to mental fatigue through the use of smartphones (Brain It On App) for 30 minutes, and to control condition (normal activities) after at least 48 hours. A crossover study design

and a paired t-test (p<0.05) were used. **RESULTS:** S1 performed shorter running distances in the state of mental fatigue than under the control condition (1610 ± 135 vs. 1780 ± 249 m, Δ -10.56%, p = 0.046). In addition, mental fatigue significantly increased the performance time in S2 compared with the control condition (51 ± 6 vs. 43 ±2.2 s, Δ +15.7%; p = 0.003). **CONCLUSION:** Our findings suggest that prolonged use of smartphones, which causes mental fatigue, can reduce the physical and technical performance of young footballers. Therefore, it is necessary to educate to the conscientious use of technology.

Effects Of Action Boundary Proximity On Perceptual-motor Judgements: Further Development Of The Pact
Caleb D. Johnson[1], Alice D. LaGoy[1], Gert-Jan Pepping[2], Shawn R. Eagle[1], Anne Beethe[1], Christopher Connaboy[1]. [1]*University of Pittsburgh, Pittsburgh, PA.* [2]*Australian Catholic University, Sydney, Australia.*
(No relevant relationships reported)

Designed as a more ecological measure of reaction times, the Perception-action Coupling Task (PACT) has shown good reliability and within-subject stability, however, a 5- to 10-minute testing period was required. Perceptual-motor judgements are known to be affected by proximity of the stimulus to the tasks action boundary. **PURPOSE:** To determine the effects of action boundary proximity on PACT performance, and whether redundant levels of stimuli, eliciting similar responses, can be eliminated to shorten the PACT while maintaining reliability, stability, and the intended behavioral responses. **METHODS:** 9 males and 7 females (Age(yrs) = 27.8 ± 3.6) completed 4 testing sessions, separated by at least 6 days. For each, participants performed 3 familiarization cycles and 6 testing cycles of the PACT. The PACT requires participants to make judgements on stimuli, in the form of whether a series of virtual balls presented on a tablet afford "posting" (can fit) through a series of virtual apertures. Eight ratios of aperture to ball size (AR) are presented, ranging from 0.2 to 1.8, with each ratio appearing 12 times per cycle. Response (time from stimulus presentation to first movement), Movement (time from first movement to initiation of ball movement), and Initiation (time from initiation to completion of ball movement) times were calculated. Accuracy was calculated as the percentage of correct judgements. All variables were averaged and plotted by AR. Based on visual inspection of plots, redundant stimuli were eliminated. ICCs (3,1) and coefficients of variation (CV) were calculated for each response variable in an iterative manner to determine the minimum number of testing cycles necessary. **RESULTS:** All variables followed an expected, quadratic trajectory, with performance the lowest near the action boundary (AR = .8 – 1.2). Ratios of .2 and 1.8 were found to elicit redundant responses to .4 and 1.6, and were eliminated. The shortened PACT showed good reliability with 1 (ICCs = .71 - .94) and 2 cycles (ICCs = .81 - .98) of testing. Further, CVs were consistent with the full PACT with 1 (CVs = .8 – 20.0 %) and 2 cycles (CVs = .6 – 14.7 %) of testing. **CONCLUSION:** The main findings support the use of the shortened PACT, limiting the testing period to 3.5 – 8.5 minutes depending on the desired level of reliability and within-subject stability.

C-43   Free Communication/Poster - **Altitude/Hypoxia**

Separate and Combined Influences of Environmental Heat and Altitude on Self-Paced Aerobic Exercise Performance
Karleigh E. Bradbury, John H. Sellers, Charles S. Fulco, Adam J. Luippold, Katherine M. Mitchell, Robert W. Kenefick, FACSM. *United States Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Nisha Charkoudian, FACSM)
(No relevant relationships reported)

Aerobic exercise performance is degraded when performed in the heat or at altitude; however, it is unknown if the combination of the two environments will lead to a greater decrement in aerobic exercise performance. **PURPOSE:** To determine the impact of the combination of heat and altitude on self-paced aerobic exercise performance. **METHODS**: In order establish a coefficient of variation (CV), 7 subjects (2F, 5M, 27 ± 5 yrs, 174 ± 11 cm, 80 ± 19 kg; SL VO$_2$peak, 42 ± 5 ml·kg^{-1}·min^{-1}) performed 3 familiarization trials consisting of 30 min of steady state (SS) cycling (50% of sea level (SL) VO$_2$peak) followed by a 15 min self-paced cycling time trial (TT) while at sea level and under thermoneutral conditions (SLTN; 250m, 20°C, 30-50% rh). Following familiarization trials, subjects completed the SS and 15 min

self-paced TT under 4 environmental conditions at random: SLTN, SL hot (SLH; 250m, 35°C, 30% rh), altitude neutral (ATN; 3,000m, 20°C, 30-50% rh) and altitude hot (AH; 3,000m, 35°C, 30% rh). Performance was assessed by the total amount of work (kilojoules, kJ) completed during each TT. Heart rate (HR) and rate of perceived exertion (RPE) were recorded during the TTs. **RESULTS**: The CV was 2.6% for familiarization trials. Differences existed in total work completed during the 15 min TT between SLTN vs ATN (167 ± 32 vs 148 ± 28 kJ, P < 0.05), SLTN vs AH (167 ± 32 kJ vs 139 ± 29 kJ, P < 0.05), and SLH vs AH (159 ± 32 kJ vs 139 ± 29 kJ, P < 0.05). No differences existed in mean HR during the TT, or in RPE at the end of exercise (P > 0.05 for both) between any of the conditions. Pacing at 3 min increments was not different between environments (P > 0.05). **CONCLUSION:** Self-paced TT performance was negatively impacted by exposure to altitude, but not heat. The combination of heat and altitude did not lead to a further decrement in exercise performance than caused by either of the two environments alone.

Multi-Environmental Exposure does not Alter Plasma Cortisol or Perceived Stress Response to Steady-State Cycle Exercise

John H. Sellers, Michelle A. King, Roy M. Salgado, Karleigh E. Bradbury, Charles S. Fulco, Robert W. Kenefick, FACSM. *USARIEM, Natick, MA.*

(No relevant relationships reported)

Objective and subjective measures of the stress response have been shown to increase in response to exercise in sea-level thermoneutral (SLTN), hot, or altitude environments. However, responses to a combination of these stressors remain unclear. **PURPOSE**: To determine if the responses of objective (serum cortisol [CORT]) and subjective (perceived strain index [PeSI]) stress indices are further increased in a combined environment of heat and altitude. **METHODS**: Six participants (1 F, 5 M) completed 30 min of steady state (SS) exercise on a cycle ergometer at 50% of SL VO_{2peak} in four separate environmental conditions: 1) SLTN (250 m, 20°C, 30-50% RH); 2) Sea-level hot (250 m, 35°C, 30% RH); 3) Altitude thermoneutral (3,000 m, 20°C, 30-50% RH); and 4) Altitude hot (3,000 m, 35°C, 30% RH) in randomized order, separated by ~1 week. Blood samples were drawn via an indwelling venous catheter: upon arrival to the laboratory (baseline, BL); 1 hr upon reaching target environmental condition but before SS (PRE); and immediately following SS exercise (POST). A seated posture was maintained for at least 20 min prior to each draw. PeSI, a product of rating of perceived exertion (RPE) and perceived thermal stress (TS), [5*(TS/16)] + [5*(RPE-6)/14], was calculated PRE and POST SS exercise. **RESULTS**: CORT (ng/ml, mean ± SD) response to SS exercise did not differ among any of the four environmental conditions at any time point (p>0.05), however, there was a main effect of time for CORT levels as shown by an increase between both BL and POST (110 ± 64 vs. 120.32 ± 72 p<0.05) and PRE and POST (113 ± 66 vs 120 ± 72, p<0.05). Similarly, no differences in PeSI (mean ± SD) were observed among any of the environmental conditions (p>0.05), yet there was a main effect of time on PeSI (p<0.05) as demonstrated by an increase from PRE (1.36 ± 0.40) to POST (4.68 ± 1.65) SS exercise. **CONCLUSION**: During SS exercise, the combination of heat and altitude resulted in similar objective and subjective stress responses compared to any singular environmental stressor, suggesting that exercise, and not environmental condition, is responsible for any observed differences.

Exhaled Nitric Oxide Levels during Acclimatization to High Altitude

Kirsten E. Coffman[1], Douglas T. Summerfield[1], Bryan J. Taylor[2], Amine N. Issa[1], Bruce D. Johnson[1]. *[1]Mayo Clinic, Rochester, MN. [2]University of Leeds, Leeds, United Kingdom.*

(No relevant relationships reported)

Introduction: During ascent to high altitude, inadequate pulmonary acclimatization may lead to high altitude pulmonary edema. One potential mechanism for acclimatization is pulmonary endothelial release of nitric oxide (NO) to reduce pulmonary pressures. **Purpose:** To characterize: 1) the change in exhaled NO concentration (eNO); and 2) the association between systolic pulmonary artery pressure (sPAP), arterial oxygen saturation (SaO_2), and eNO during acclimatization to high altitude. **Methods:** Seventeen healthy, non-smoking, adult lowlanders completed an 8- to 10-day trek to Mount Everest Base Camp (5,150m) in two groups. Group 1 arrived and stayed at base camp for ~30 days (acclimatized, 'ACC'; n=9 (7M/2F); age 38±9yr, ht 174±9cm, wt 69.7±10.1kg) prior to the arrival of group 2 (non-acclimatized, 'Non-ACC'; n=8 (8M/0F); age 36±11yr, ht 181±5cm, wt 85.9±7.8kg). Upon arrival of the Non-ACC group (*Day 1*), eNO (in triplicate via a handheld electrochemical detector), sPAP (via transthoracic echocardiography) and SaO_2 (via pulse-oximetry), were measured in each participant. In addition, eNO was measured in the Non-ACC

group after 5 and 9 days at base camp. **Results:** On Day 1, eNO was greater in the Non-ACC group vs. the ACC group (21.2 ± 8.6 vs. 9.6 ± 5.4 ppb; *P* = 0.004). In the Non-ACC group, eNO levels fell from Day 1 to Day 9 at high altitude (21.2 ± 8.6 vs. 14.5 ± 5.9 ppb; *P* = 0.032) such that eNO levels were not different compared to the ACC group by Day 9 (14.5 ± 5.9 vs. 9.6 ± 5.4 ppb; *P* = 0.095). On Day 1, lower eNO levels were associated with higher sPAP in all participants (*r* = -0.50, *P* = 0.042). There was no relationship between eNO and SaO_2. **Conclusion:** During acclimatization to high altitude, eNO levels decrease in healthy lowlanders. Moreover, there is a negative relationship between eNO and systolic pulmonary artery pressure during acclimatization to high altitude. These data suggest that eNO plays a role in pulmonary acclimatization.

The Effects of Fluid Parameters on Performance in a Simulated Altitude Environment

Jessica L. Peacock, PhD.. *Merrimack College, North Andover, MA.* (Sponsor: Vincent Paolone, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of the current research was to clarify approaches to fluid parameters which may improve exercise performance at moderate simulated altitude. The researcher aimed to determine if consuming fluid equal to fluid loss has an impact on acute performance at simulated 3048-m. **METHODS:** Nine trained male cyclists (VO_{2peak} 51.68 ± 6.66 ml^{-1}·kg^{-1}·min) performed 30 min of cycling at 75-85% of HR attained at VO_{2peak} in four different conditions: control-normoxic (CON-NORM), control-hypoxic (CON-HYP), hypoxic-hydrated (HYP-HYD), and hypoxic-ad libitum (HYP-ADLB). In all conditions, subjects consumed 250 ml of water at baseline. In the HYP-HYD session, subjects consumed 250 ml of water at baseline in addition to the fluid volume equal to 50% of the total fluid lost during the CON-HYP session. After 15 min of cycling, subjects consumed the remaining 50%. In the HYP-ADLB condition subjects were permitted to consume water ad libitum. To simulate altitude (3048 m; 10,000 ft.), an E-Cylinder hypoxic inspirate containing 14.5% O_2 and 85.5% balance N_2 was used. **RESULTS:** As expected, S_aO_2 and average workload (Watts) were significantly reduced with exposure to simulated 3048-m (p < .05). Average workload was significantly (p <.05) lower in the CON-HYP, HYP-HYP and HYP-ADLB conditions ($M_{CON-HYP}$ = 155.00 ± 24.49, $M_{HYP-HYD}$ = 162.59 ± 28.84, $M_{HYP-ADLB}$ = 156.57 ± 22.77) compared to the CON-NORM condition ($M_{CON-NORM}$ = 194.72 ± 31.50). Mean fluid intake was significantly (p<.05) higher in the HYP-HYD condition compared to the HYP-ADLB condition ($M_{HYP-HYD}$ = 668.87 ± 261.23 ml, $M_{HYP-ADLB}$ = 197.00 ± 112.74 ml). **CONCLUSION:** Inadequate fluid replacement and ad libitum fluid consumption degrade exercise performance in an additive manner with that induced by hypoxia, despite maintaining hydration prior to acute performance. Additionally, consuming 50% of fluid loss prior to and during every 15 min appears to reduce the magnitude of performance decrements during an acute bout of high intensity cycling at 3048-m. Optimizing hydration strategies for performance at altitude may always remain indefinite, however, trained athletes that ascend to altitude must be as thorough about their hydration strategies as they are about other performance factors.

Exercise At Simulated Altitude Increases Gastrointestinal Barrier Damage And Promotes Leukocyte Activation

Claire J. Lauterbach, Harrison R. Strag, Zach J. Schall, Ally M. Hamilton, Matthew R. Kuennen. *High Point University, High Point, NC.*

(No relevant relationships reported)

PURPOSE: This study tested whether altitude-associated ischemic stress damages the gastrointestinal barrier, activates leukocytes, and promotes inflammation. **METHODS**: Subjects (N = 5) completed two 60 min bouts of matched-workload treadmill exercise (65% VO_{2max}). One under control conditions (Normoxia, F_1O_2 = 20.9%) and the other at ~4000 m of simulated altitude (Hypoxia, F_1O_2 = 13.5%). Pulse oximetry was used to measure peripheral oxygen saturation (SpO_2) and near-infrared spectroscopy was used to measure absolute tissue saturation (StO_2) at 5 min intervals throughout exercise. Fatty acid-binding protein (I-FABP), markers of leukocyte activation (CD14, ICAM-1, IL-8, MCP-1, MPO), and cytokines (TNFα, IL-1β, IL-6, IL-10, IL-12) were measured in plasma samples that were collected Pre, Post, 1hr-Post, and 4hr-Post exercise. Data were analyzed with 2-Way (Condition x Time) RM ANOVAs with significance set at $p ≤ 0.05$. *Post hocs* (Newman-Keuls) were run where appropriate. **RESULTS**: Significant reductions in SpO_2 and StO_2 were shown during exercise at simulated altitude [(SpO_2: Hypoxia = 79 ± 1% *vs* Normoxia = 94 ± 0.5%, *p* = 0.03) (StO_2: Hypoxia = 61 ± 2 *vs* Normoxia = 69 ± 2, *p* < 0.01)]. A significant interaction effect was shown for I-FABP (*p* = 0.05), with *post hoc* analysis indicating I-FABP increased more from Pre to Post in Hypoxia (112%) than in Normoxia (30%). IL-8

increased more from Pre to Post (60%) and 1hr-Post (83%) in Hypoxia than in Normoxia (33% & 57%, respectively). Significant main effects were also shown for IL-6, ICAM-1, CD14, and MCP-1. All were higher in Hypoxia ($p \leq 0.05$). MPO increased at Post in Normoxia (121%, $p = 0.05$) but did not increase until 1hr-Post in Hypoxia (129%, $p = 0.02$).
CONCLUSIONS: Preliminary data suggest exercise at altitude may increase gastrointestinal barrier damage and leukocyte activation, as indicated by higher levels of I-FABP, IL-8, and MCP-1. Increased CD14 and ICAM-1 suggest TLR4-mediated inflammatory signaling may also be elevated, but the delayed increase in MPO following exercise at altitude warrants further investigation.

Cerebral Blood Flow Velocity and EEG Response during Ergometer Exercise in Normoxia and Hypoxia

Ilgyu Jeong, Heehyuk Lee, Seongdae Kim. *Hannam University, Daejeon, Korea, Republic of.*
(No relevant relationships reported)

The cerebral blood flow velocity (CBFV) response to acute hypoxia has been known to increase. But, how CBFV might respond to exercise in hypoxic condition and be associated with EEG remains unclear. PURPOSE: To evaluate the effects of exercise in hypoxic condition corresponding to the altitudes of 4000m on cerebral blood flow velocity and EEG. METHODS: In a randomized, double-blind, balanced crossover study, ten healthy volunteers (19.8±0.4yrs) were asked to perform the incremental bicycle ergometer exercise twice in hypoxic and control(sea level) condition with a week interval, respectively. Exercise intensity was set initially at 50W and increased by 25W every 2 minutes to 125W. Acute normobaric hypoxic condition was maintained for 45 minutes using low oxygen gas mixture. CBFV in middle cerebral artery (MCA) and EEG were measured at rest 5 minutes, rest 15 minutes, immediately after exercise, and 15 minutes recovery using transcranial-Doppler sonography and EEG signal was recorded from 6 scalp sites leading to analysis of alpha and beta wave relative activities. All data were analyzed using two-way ANOVA with repeated measures and Pearson's correlation. RESULTS: CBFV in MCA in hypoxic condition was significantly higher than in control condition at rest 5 minutes (83±9 vs. 69±9 cm/s, p<.01), rest 15 minutes (87±8 vs. 67±7 cm/s, p<.001), immediately after exercise (112±9 vs. 97±9 cm/s, p<.01), and 15 minutes recovery (91±11 vs. 74±7 cm/s, p<.01). However, no significant correlation was found between the changes of CBFV and EEG wave activities. CONCLUSION: These results suggest that hypoxia might amply the changes of CBFV observed during exercise. But, the changes of CBFV might have no association with the changes of EEG wave activities in hypoxia.

Effect of Hypoxia on EEG During and After Cycle Ergometer Exercise

Seongdae Kim, Heehyuk Lee, Ilgyu Jeong. *Hannam University, Daejeon, Korea, Republic of.*
(No relevant relationships reported)

How hypoxic condition influences the brain cortical activities observed by Electroencephalography (EEG) during exercise has been unknown. **PURPOSE:** To determine the effect of hypoxia on electroencephalographic activity during and after cycle ergometer exercise. **METHODS:** In a randomized, double-blind, crossover study, Eleven healthy volunteers (21.4±0.7yrs) were asked to perform the bicycle ergometer exercise twice in hypoxic condition and control(sea level) condition with a week interval, respectively. Exercise intensity was set initially at 50W and increased by 25W every 2 minutes until 125W, then maintained for 14 minutes. Acute normobaric hypoxic condition corresponding to the altitudes of 3150m was maintained using low oxygen gas mixture for the whole procedure of 60 minutes. EEG was measured prior to the onset of exercise, immediately after exercise and 20 minutes recovery. EEG signal was recorded from 6 scalp sites (frontal, temporal and occipital lobe of the international 10-20 system) leading to analysis of theta (4-7Hz), alpha (8-13Hz), beta (13-30Hz), and gamma(30-50Hz) relative activities. All data were analyzed using two-way ANOVA with repeated measures. **RESULTS:** Alpha wave activity of frontal lobe in hypoxia group was significantly lower than in control group immediately after exercise (0.24±0.13 vs. 0.41±0.15 µV, p<.05). Beta wave activity of occipital lobe in hypoxia group was significantly higher than in control group immediately after exercise (0.28±0.07 vs. 0.20±0.07 µV, p<.05). Gamma wave activity of frontal lobe in hypoxia group was significantly higher than in control group immediately after exercise (0.25±0.12 vs. 0.12±0.08 µV, p<.05). Theta wave activity of left frontal lobe in hypoxia group was significantly lower than in control group at 20 minutes recovery (0.08±0.05 vs. 0.15±0.05 µV, p<.05). **CONCLUSION:** These results suggest that acute exposure to mild hypoxic condition may amplify the change of EEG activities which has been commonly observed during exercise.

Cardiovascular Adjustments During Steady-state Cycling: Effects Of Heat And Altitude.

Robert W. Kenefick, FACSM, Karleigh E. Bradbury, John H. Sellers, Adam J. Luippold, Katherine M. Mitchell, Charles S. Fulco. *U.S. Army Ressearch Institute of Environmental Medicine, Natick, MA.*
(No relevant relationships reported)

Compared to exercise in a thermo-neutral environment or at sea level (SL), heart rate is elevated to a greater extent during exercise in the heat or at altitude, to compensate for either increased skin blood flow or decreased arterial oxygen saturation (S_aO_2).
PURPOSE: To determine the compensatory heart rate response [% Δ heart rate (HR)] to steady-state cycling during *combined* heat and altitude exposure. **METHODS**: Seven subjects (2F, 5M, age: 27 ± 5 yrs; height: 175 ± 10 cm, weight: 80 ± 19 kg, SL VO_{2peak}: 42 ± 5 ml·kg⁻¹·min⁻¹) performed 30 min of steady-state cycling at an identical power output (50% of SL VO_2peak) in 4 randomly assigned environmental conditions in a hypobaric chamber: SL thermo-neutral (SLTN; 250m, 20°C, 30-50% rh), SL hot (SLH; 250m, 35°C, 30% rh), altitude thermo-neutral (ATN; 3000m, 20°C, 30-50% rh) and altitude and hot (AH; 3000m, 35°C, 30% rh). There was a minimum of 3-5 rest days between experimental trials. HR and S_aO_2 were measured throughout exercise. %Δ HR and %Δ S_aO_2 were calculated relative to SLTN (control) at the 24th min of exercise. **RESULTS**: %S_aO_2 was reduced (P<0.05) from SLTN for ATN (-12.1 ± 3.3%) and AH (-11.3 ± 2.0%) but not for SLH (-0.7 ± 0.5%). %Δ HR was increased (P<0.05) from SLTN for SLH (10.0 ± 5.2%), ATN (10.5 ± 2.0%), and AH (16.7 ± 5.5%). The %Δ HR for AH also was greater (P<0.05) compared to either SLH or ATN. **CONCLUSION:** Exposure to either heat or altitude resulted in a ~10% Δ HR compensatory response compared to exercise at SL in a thermo-neutral environment. The combination of both environments resulted in a potentiated compensatory %Δ HR of ~17% but was less than the summation of %Δ HR for both environments. These results suggest that the combination of heat and altitude evoked other compensatory adjustments (e.g., increased stroke volume or myocardial contractility; greater splanchnic vasoconstriction, etc.) in order to meet the combined demands of increased skin blood flow for thermoregulation and O_2 delivery during 30 min of moderate intensity, steady-state exercise. Disclaimer: The opinions or assertions contained herein are the private views of the author(s) and are not to be construed as official or reflecting the views of the Army or the Department of Defense.

Between Individual Variability in Sleep and Awake Pulse Oximetry During Ascent Of Mt. Kilimanjaro

Stephen R. Muza, FACSM, Robert W. Kenefick, FACSM, Beth A. Beidleman, Charles S. Fulco, Scott W. Hamilton. *US Army Research Institute of Environmental Medicine, Natick, MA.*
(No relevant relationships reported)

Between individual variability in awake arterial pulse oximetry ($aSpO_2$) is well known and has been proposed for field assessment of altitude acclimatization. Sleep SpO_2 ($sSpO_2$) is known to be lower than $aSpO_2$ at high altitude, but the between individual variability in $sSpO_2$ is not as well known. **PURPOSE:** Compare between individual variability and relationship between $sSpO_2$ and $aSpO_2$ during a 6 day ascent of Mt. Kilimanjaro. **METHODS:** In 18 (12 men/6 women), age range 18-62 yr, low-altitude residents over 5 of 6 nights $sSpO_2$ was assessed using a finger sensor recording pulse oximeter and compared to a morning $aSpO_2$ measured for 1 minute while the subject was quietly seated. Each individual's mean SpO_2 was calculated for their sleep and awake measurements. Correlations (Pearson product-moment) between sleep and awake SpO_2 were evaluated. **RESULTS:**

	2280 m	2875 m	3200 m	3850 m	4830 m
$sSpO_2$ (mean±SD)	91 ± 2%	87 ± 3%	83 ± 4%	78 ± 5%	69 ± 4%
$sSpO_2$ (range)	88 – 95%	83 – 91%	78 - 88%	74 – 87%	57 – 76%
$sSpO_2$ (CV)	2.2	3.4	4.8	6.4	5.8
$aSpO_2$ (mean±SD)	94 ± 2%	90 ± 4%	88 ± 4%	83 ± 4%	72 ± 5%
$aSpO_2$ (range)	91 – 99%	86 – 99%	82 – 96%	76 – 91%	62 – 83%
$aSpO_2$ (CV)	2.1	4.4	4.5	4.8	9.7
$sSpO_2$ vs $aSpO_2$ (R)	0.78	0.77	0.71	0.75	0.69

As expected, both $sSpO_2$ and $aSpO_2$ decreased with increasing altitude. The Coefficient of Variation (CV), of both $sSpO_2$ and $aSpO_2$ increased with increasing altitude. Individual $sSpO_2$ and the next morning $aSpO_2$ were strongly correlated at all altitudes. **CONCLUSION:** In low altitude residents climbing to 4830 m over 6 days, sleep and awake SpO_2 have similar between subject variability (dispersion) that more than doubles with increasing altitude indicating a broadening of individual ventilation and pulmonary gas exchange responses to the hypoxic environment. Also, individual

$sSpO_2$ and $aSpO_2$ are highly correlated to each other. Funding: USAMRMC. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government.

Combined Effects of Heat and Altitude on Sweating Responses during Steady-State Cycling Exercise

Adam J. Luippold, Karleigh E. Bradbury, Katherine M. Mitchell, Beau R. Yurkevicius, John H. Sellers, Robert W. Kenefick, FACSM. *United States Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Robert W. Kenefick, FACSM)

(No relevant relationships reported)

Exposure to high altitude could increase sweating responses as a result of widening the air-to-skin water vapor pressure gradient. Previous laboratory studies have reported both lower and higher sweat losses at altitude. **PURPOSE:** To determine if exposure to altitude in a thermo-neutral environment, and exposure to altitude in the heat will alter the onset time of sweating (OTS) and sweat rate (SR) during 30 minutes of steady state (SS) exercise. **METHODS:** Seven healthy volunteers (2F, 5M, age: 27 ± 5 yrs, height: 175 ± 10 cm, weight: 79.7 ± 18.5 kg, sea level (SL) VO_{2peak}: 41.8 ± 4.6 ml·kg^{-1}·min^{-1}) completed 30 minutes of SS cycling exercise (50% SL VO_{2peak}) in four randomly assigned conditions: SL thermo-neutral (SLTN; 250m, 20°C, vapor pressure (VP): 5.3-8.8 mmhg), SL hot (SLH; 250m, 35°C, VP: 12.7 mmhg), altitude thermo-neutral (ATN; 3,000m, 20°C, VP: 5.3-8.8 mmhg), altitude hot (AH; 3,000m, 35°C, VP: 12.7 mmhg). Prior to exercise, a ventilated sweat capsule (surface area: 15.9 cm^2, air flow: 2 standard liters/min) was applied to the supinated forearm of the volunteer. Ambient temperature (°C) and relative humidity of the capsule interior were recorded throughout SS exercise. The time at which OTS occurred (minute) and SR (mg·cm^2·min^{-1}) were calculated. **RESULTS:** OTS and SR were not different (P > 0.05) between SLTN vs. ATN conditions (7.58 ± 2.90 vs. 7.43 ± 2.90 min; 0.70 ± 0.32 vs. 0.78 ± 0.33 mg·cm^2·min^{-1}, respectively). Furthermore, in the heat OTS and SR were not different (P > 0.05) between SLH vs. AH conditions (1.28 ± 1.64 vs. 0.83 ± 1.31 min; 1.55 ± 0.25 vs. 1.51 ± 0.20 mg·cm^2·min^{-1}, respectively). **CONCLUSION:** Both exposure to altitude in a thermo-neutral environment and exposure to altitude in the heat did not alter either OTS or SR. This suggests the water vapor pressure gradient at 3,000m was not great enough to have a marked effect on sweating responses. Heart Rate Variability And Body Composition As A Hypoxia Risk Factor In Military Pilots.

JUAN MIGUEL CASTRO HERRERA. *FUERZA AEREA COLOMBIANA, BOGOTA, Colombia.*

(No relevant relationships reported)

PURPOSE: To determine if heart rate variability, body composition and hypoxia exposure time could help to identify risk of hypoxia in a group of COLAF aircrew that train in hypobaric Chamber at the Aerospace Medical Center.
METHODS: Previous ethics committee approval and signing of the informed consent, 60 pilots between 20 and 40 years were selected. Body composition was obtained by impedance with a Tanita ® bascule TBA-300A (weight, height, BMI, muscle weight, fat percentage and water percentage). The volunteers attended to a hypoxia physiological training where they were exposed to profile IV-A COLAF (30 minutes denitrogenation with 100% oxygen (DNT), climb to 25,000 feet with exposure to hypoxia and descent to ground level). During this profile heart rate was monitored through the RR record with a Polar ® heart rate monitor RS800 and the minimum percentage of oxygen saturation in hypoxia exercise previous recovery was recorded. Hypoxia permanence time (TH) and power frequency response ANS Low Frequency (LF), High Frequency (HF) and LF / HF were analyzed. For LF and HF, modeling by Fast Fourier Transform (FFT) was implemented. Lilliefors test to verify normality was applied. For the relationship between variables with non-normal distribution Chi square test was applied. And for normal distribution direct correlation was applied.
RESULTS: Direct correlation (p-value <0.05) between TH (4.24 ± 1.74 min) and water percentage (44.46 ± 6.11) was observed. Additionally, a significant difference in LF / H was found among the three moments of the flight profile using the Wilcoxon test was observed in 21 pilots due to loss of signal in the other 39. While in HF there were only significant between moments: DNT - Hypoxia and Hypoxia - descent to ground level.
CONCLUSIONS: Pilots with highest percentage of water and muscular mass tolerated longer exposure to hypoxia at 25000 feet. Also, changes in oxygen partial pressure determine changes on autonomic nervous system, thus hypoxia exposure increase sympathetic modulation over parasympathetic that could be modify by body composition.

Differences of Surface Electromyography during Incremental Cycling Exercise in Hypoxia and Normoxia Using Wavelet Transform Analysis

Hayato Ohnuma[1], Ryo Yamanaka[2], Toshiyuki Ohya[3], Masahiro Hagiwara[4], Ryota Akagi[5], Yasuhiro Suzuki[1]. *[1]Japanese Institute of Sports Science, Tokyo, Japan. [2]Teikyo Heisei University, Chiba, Japan. [3]Chukyo University, Aichi, Japan. [4]Japanese Olympic Committee, Tokyo, Japan. [5]Shibaura Institute of Technology, Saitama, Japan.*

(No relevant relationships reported)

Previous studies indicated that there was a difference between hypoxia and normoxia for amplitude parameters of surface electromyography (EMG). However, there are few reports on frequency parameters of EMG because of limitations of traditional analytical methods. **PURPOSE:** The purpose of this study was to investigate the differences of surface electromyography during incremental cycling exercise in hypoxia and normoxia using wavelet transform analysis. **METHODS:** Subjects were fourteen active and healthy men. (mean±SD; age: 21.08 ± 1.50 years; height: 1.69 ± 0.06 m; weight: 60.16 ± 7.77 kg; maximal oxygen consumption: 51.11. ±9.54 ml / min / kg). The subjects performed incremental cycling exercise test to exhaustion in hypoxia (F_IO_2: 13.4%) and normoxia conditions (F_IO_2: 20.9%). EMG activities of vastus lateralis (VL), vastus medialis (VM), rectus femoris (RF) and biceps femoris (BF) were recorded during cycling exercise test at a sampling rate of 2000 Hz. Integrated electromyogram (iEMG) and mean power frequency (MPF) for each exercise intensity were calculated from the EMG data. Contentious wavelet analysis was used to calculate MPF, and mother wavelet was set at morlet wavelet. The differences between exercise intensities and F_IO_2 conditions were compared using a two-way analysis of variance. The significance level was set at $p < 0.05$. **RESULTS:** iEMG of each muscle significantly increased with increasing exercise intensities (all: p < 0.01). However, there were no significant differences between F_IO_2 conditions for each muscle (VL: p = 0.37; VM: p = 0.49; RF: p = 0.37; BF: p = 0.64). MPF of VL significantly decreased with increasing exercise intensities (p < 0.01), and MPF in hypoxia was higher than that in normoxia (p < 0.01). MPF of VM significantly decreased with increasing exercise intensities (p<0.01), but there were no significant differences between F_IO_2 conditions (p = 0.37). In addition, there were no significant differences between exercise intensities (RF: p = 0.49; BF: p = 0.57) and F_IO_2 conditions (RF: p = 0.49; BF: p = 0.19) for RF and BF. **CONCLUSION:** The current results demonstrated that the change in MPF was different for each muscle, and MPF of VL in hypoxia was only higher than that in normoxia, and suggested hypoxia exposure affects neuromuscular activity agonist muscle during exercise.

The Effect of Endurance Exercise in Hypoxia on Hepcidin Response in Athletes

Daichi Sumi, Chihiro Kojima, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.* (Sponsor: Robert R Kraemer, FACSM)

(No relevant relationships reported)

Training in hypoxia has been widely utilized to improve endurance capacity. On the other hand, the influence of the endurance training in hypoxia on hepcidin (a liver-derived, iron regulating hormone) response remains unclear. This information would be a great help for preventing iron deficiency in endurance athletes. **PURPOSE**: The purpose of the present study was to determine the influence of endurance exercise under hypoxic condition on post-exercise hepcidin levels in endurance athletes. **METHODS**: Nine trained endurance athletes (19.7 ± 0.3 years, 169.8 ± 2.2cm, 57.1 ± 1.1kg, VO_2max 62.8 ± 1.6ml · kg · min) completed two different trials on different days, consisting of exercise in under moderate hypoxic (H, FiO_2:14.5%) and normoxic (N, FiO_2:20.9%) conditions. They performed interval type of endurance exercise (10×3-min running at 95% of VO_2max with 60s of active rest at 60% of VO_2max) followed by 30-min of continuous running at 85% of VO_2max under hypoxic or normoxic conditions. Venous blood samples were collected before the exercise and during 120-min of post-exercise period. **RESULTS**: Running velocities during interval and continuous exercise were significantly lower in the H trial than in the N trial ($P < 0.0001$). Exercise-induced blood lactate elevation was significantly greater in the H trial (5.1 ± 0.5mmol/L) than the N trial (3.2 ± 0.7mmol/L, $P < 0.05$). There were significant increases in plasma interleukin-6, serum iron, and blood glucose levels after exercise, but these responses were not significantly different between the two trials. Serum hepcidin levels increased significantly at 120-min after completing exercise (H: from 10.7 ± 9.4 ng/mL to 15.8 ± 11.2 ng/mL; N: from 7.9 ± 4.7 ng/mL to 13.2 ± 7.9 ng/mL. $P < 0.05$). However, there was no significant difference between the two trials. **CONCLUSIONS**: Endurance exercise under moderate hypoxic conditions resulted in similar exercise-induced serum hepcidin response compared with equivalent exercise under normoxic condition in endurance athletes.

Blood Oxidative Stress Following Exercise Recovery in Normobaric and Hypobaric Hypoxic Environments

John C. Quindry, FACSM[1], Tiffany S. Quindry[1], Katheryn Tiemessen[1], Roksana Zak[2], Robert Shute[2], John Cuddy[1], Walter Hailes[1], Dustin Slivka, FACSM[2], Brent Ruby, FACSM[1]. [1]University of Montana, Missoula, MT. [2]University of Nebraska - Omaha, Omaha, NE.
(No relevant relationships reported)

PURPOSE: Hypobaria and hypoxia exert independent effects on exercise-induced oxidative stress in blood, while the hypobaric and hypoxic influences are not well defined. The current study was undertaken to quantify exercise-induced oxidative stress recovery during lab-simulated hypoxic and hypobaric conditions following a common bout of exercise.
METHODS: At a base elevation of 975m, physically active participants (n=16), ages 18-40, provided informed consent prior to performing 60 minutes of cycle ergometry at 70% watts max. Using a randomized counter-balanced crossover design participants recovered for 4 hours in 3 lab-simulated conditions; 1000m normobaric normoxia (NN, 675mmHg, 18.8%FiO2), 4400m normobaric hypoxia (NH, 675mmHg, 12% FiO2), or 4400m hypobaric hypoxia (HH, 440mmHg, 12% FiO2). O2 saturation was confirmed via pulse oximetry throughout the 3 exercise-recovery trials. Blood samples were collected in heparinized vacutainer tubes at time points Pre, Post, 2 Hours Post, and 4 Hours Post exercise. Blood plasma was analyzed for the quantification of oxidative stress to proteins (protein carbonyls, PC; 3-nitrotyrosines, 3NT), lipid (lipid hydroperoxides, LOOH; 8-isoprostanes, 8-ISO), and antioxidant capacity (ferric reducing ability of plasma, FRAP; trolox equivalent antioxidant capacity, TEAC).
RESULTS: Plasma TEAC, FRAP, 3NT and PC were unaltered by exercise and recovery environments (p>0.05). Exercise-induced increases in LOOH and 8-ISO were observed, although time-by-trial differences were not present.
CONCLUSIONS: These data indicate that exercise recovery in simulated conditions of NH and HH do not impact a common panel of blood oxidative stress measures.

Cardiopulmonary Responses, Brain and Muscle Oxygenation during Exercise on Hypoxia as Acclimatization to Hypoxic Training

Jin Uchimaru, Yi-Zhen Yu, Fan Chen, Hidekazu Takemura, Hirohiko Takahashi, Shozo Suzuki. Sendai University, Shibata, Japan.
(No relevant relationships reported)

It is well known that altitude/hypoxic training enhance to exercise performance. But there are individual differences in physiological responses and training effects on hypoxic training. Thus, acclimatize to altitude/hypoxic environment would be also very important factor for successful training. **PURPOSE**: Our study focuses on changes in cardiopulmonary responses, brain and muscle oxygenation on incremental exercise at hypoxia as acclimatization to short periods hypoxic training. **METHODS**: Sixteen male healthy college-age students were divided into a hypoxic training (N, n=8) or a normoxic training group (H, n=8). They completed 5 days training session. All subjects underwent the incremental maximal cycling test at hypoxia on 1st and 5th day and 40-minutes submaximal exercise under 50-70%VO2max on 2nd, 3rd and 4th day at both each environment. We measured cardiopulmonary measurements (VE, VO2, VCO2, HR and SpO2) and blood lactate concentration on incremental exercise. Near-infrared spectroscopy (NIRS) was also used to monitor concentration (μM) changes of oxy- and deoxyhemoglobin (Δ[O2Hb], Δ[HHb]) in left frontal cortex region of the forehead and ipsilateral vastus lateralis muscle. Changes in total Hb and StO2 were calculated and used as index of change in regional blood volume. Paired T-test were performed across treatments. **RESULTS**: VO2max (41.8±4.6 ml/kg/min) and exercise time (911±40 sec) on 5th day of H group were significantly improved from that of 1st day (38.7±3.7 ml/kg/min, 847±62 sec)(p<0.05). VE, VO2 and VCO2 at submaximal exercise (180W) on 5th day of H group were significantly improved from that of 1st day (p<0.05). Also, in H group, SpO2 during submaximal and maximal exercise on 5th day were significantly higher than that of 1st day (p<0.05). There was no significant difference in brain and muscle oxygenation during exercise in both group. **CONCLUSIONS**: We suggest that short period hypoxic training would be improve cardiopulmonary and oxygen-carrying capacity during exercise and exercise capacity under moderate hypoxia. Further study is needed to clarify the mechanism of physiological acclimatization to hypoxia.

Precooling With An Ice Vest: Effect On Core Temperature And Heart Rate While Swimming

Brent Alumbaugh, Shelbi Peters, Leah Hendrick, Michael Reeder. Colorado Mesa University, Grand Junction, CO.
(No relevant relationships reported)

Precooling has been shown to improve athletic performance by decreasing core body temperature prior to exercise, thus delaying the onset of core heating and decreasing heart rate at given intensities during training and competition. Previous research has studied the effect of precooling on cyclists and runners, but very little research has observed core temperature (CT) and heart rate (HR) response to precooling in collegiate female swimmers. **PURPOSE:** To observe the effect of precooling on core temperature and heart rate prior to swimming 1600 yards. **METHODS:** Eleven female collegiate swimmers participated in randomized, crossover swimming trials with and without precooling. Trials were separated by one week with each subsequent trial performed at the same time of day. Precooling trials started 45 minutes prior to non-precooling trials and subjects precooled wearing an ice vest with a wet t-shirt prior to the exercise trial. All trials had a 15 minute warm up consisting of a 400yd swim, 200yd kick, and four sets of 50yd drill, followed by a 200yd cool down. Core temperature monitoring was performed during a main set of 1600 yards, swam at 75% of fastest mile pace, broken into eight, 200yd intervals. CT, heart rate (HR), and rating of perceived exertion (RPE) were measured before and after warm-up and at 200yd intervals for the remainder of the trial. **RESULTS:** Group precooling CTs were significantly (p=.02) lower. Group precooling HRs were not significantly different (p=.20), however seven of the subjects did present significantly (p<.05) lower HRs during the precooling trial. **CONCLUSION:** Precooling, using an ice vest 45 minutes prior to exercise, was shown to significantly reduce core temperature during swimming compared to non-precooling. Individual response in HR between subjects was observed, with the majority of subjects (n=7) responding with a significant decrease in HR in the precooling condition.

Effects Of Cycling In The Cold On Neuromuscular Activation And Fatigue

Brittany N. Followay, Jeremiah A. Vaughan, Savannah R. Hall, Eliott Arroyo, Cody S. Dulaney, Joseph A. Laudato, Ellen L. Glickman, Adam R. Jajtner. Kent State University, Kent, OH.
(Sponsor: Ellen Glickman, FACSM)
(No relevant relationships reported)

PURPOSE: To examine the effects of cold exposure on neuromuscular activation and fatigue during aerobic cycling exercise. **METHODS:** Five apparently healthy males (24.8 ± 2.9 years; 183.1 ± 2.2cm; 80.5 ± 4.4kg; 11.3 ± 2.8%BF; 3.97 ± 0.34 L·min[-1]) visited the laboratory on three separate occasions. During the first visit, participants performed a VO2max test on a Velotron cycle ergometer. During the two remaining trials, participants performed two, five-second maximal isometric voluntary contractions (MVICs) of the right leg extensors prior to entering the environmental chamber. In the environmental chamber, volunteers cycled for 60 min at 60% of their VO2max in either a low- (5°C / 45%RH; LT), or moderate-temperature (22°C / 45%; MT), in counterbalanced fashion. Electromyography (EMG) of the vastus lateralis was recorded during the 60-minute exercise protocol during the first two minutes, and during the last two minutes of every 10-minute period (0-2min, 8-10min, 18-20min, 28-30min, 38-40min, 48-50min, 58-60min). Root mean square (RMS), mean power frequency (MPF) and median power frequency (MEDPF) were then normalized to the MVIC for each time point. Data were analyzed using a within subjects repeated measures ANOVA. **RESULTS:** No significant differences were observed between conditions (LT and MT) for RMS (F = 0.341; p = 0.591) MPF (F = 0.003; p = 0.959), or MEDPF (F = 1.438; p=0.297). A significant main effect of time was observed for RMS F = 8.187, p<0.001. Specifically, RMS at 8-10Min (26.369 ± 3.542%), 18-20Min (24.782 ± 3.572%), 38-40Min (25.722 ± 3.534%) and 48-50Min (26.070 ± 3.451%) were significantly lower than RMS at 58-60Min (27.091 ± 3.521%). There was also a significant effect of time for MPF (F = 3.049; p = .023), with a significantly higher MPF at 18-20min (85.694 ± 1.467%) and 38-40min (85.942 ± 1.408%) compared to 8-10min (83.165 ± 1.215%). **CONCLUSION:** The increase in RMS observed at the end of exercise suggests an increase in neural drive and motor unit activity, suggestive of an increase in motor unit recruitment and fatigue during aerobic

cycling exercise at 60% VO_2max. Furthermore, MPF significantly increased from the beginning of exercise, suggesting an increase in action potential conduction velocity. <!--EndFragment-->

Habituation to the Cold Pressor Test

Alyssa Leger, David Bellar. *University of Louisiana at Lafayette, Lafayette, LA.*

(No relevant relationships reported)

During acute cold exposure, a stress response is induced. **PURPOSE**: The purpose of this study was to see if daily, cold water exposure to the dominant hand causes habituation to the stress responses that occur due to cold exposure. **METHODS**: Fourteen seemingly healthy men (age=22 ± 2 years, height=70 ± 3cm, body fat %= 17.5 ± 12.9%) participated in the study. Subjects performed the cold pressor test (CPT) a total of 20 times for 4 weeks (5 times per week). Data was collected during the first and final day of the 20-day habituation period. Blood glucose levels were measured before and immediately after the CPT. Subjects were asked to respond to both pain and thermal sensation scale every 30 seconds during the CPT testing. **RESULTS**: A repeated measures ANOVA showed a significant main effect for time for glucose, day 1 versus the final day (F=5.16; p=.04). A paired T-test also revealed a significant difference between the changes in glucose levels (pre-CPT-post-CPT), day 1 versus the final day (mean difference=11.79; t-ratio=2.27; p=.02). The mean change pre to post CPT in glucose on day one was 12 ± 13 mmol/L, and the mean change in glucose on the final day was $.5\pm 18$ mmol/L. Repeated measures ANOVA showed a significant main effect for time for pain scale, but there was no significant main effect for time for thermal sensations (pain scale: F=27.39; p=.01) (thermal sensation: F=.68; p=.72). Pain scale responses decreased significantly while thermal sensations remained unaltered. The average pain scale response on day one was 5 ± 5, and on the final day 1 ± 1. **CONCLUSION**: This study found a significantly decreased glucose response after 20 days of cold water exposure to the hand. This demonstrates habituation to the stress response. The perception of pain decreased significantly, but not thermal discomfort. More studies are needed to further the investigation on the physiological processes that habituated due to repeated cold exposure.

Afterdrop Effect during Recovery after Aerobic Exercise in a Cold vs Moderate Temperature Environment

Jeremaih A. Vaughan, Brittany N. Followay, Savannah R. Hall, Joseph A. Laudato, Eliott Arroyo, Cody S. Dulaney, Adam R. Jajtner, Ellen L. Glickman, FACSM. *Kent State University, Kent, OH.* (Sponsor: Ellen L. Glickman, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the effect of after drop following a bout of aerobic exercise and exposure to a cold compared to moderate temperature during recovery. **METHODS**: Five active men (24.8 ± 2.9 yrs; 183.1 ± 6.2 cm; 80.8 ± 4.5 kg; 11.3 ± 2.8 %; 3.97 ± 0.34 L/min^{-1}) were counterbalanced between a cold (5°C; CLD) and moderate (22°C with 45% RH; MOD) temperature trial. Exercise trials consisted of 60min of cycling at 60% of their previously determined VO_2max, 15min of rest, and a time to exhaustion at 90% VO_2max. Rectal temperatures (Tre) were recorded at baseline (BAS), end of 60 min exercise (EX60), 15 min rest (RST), Time Trial (TT), 3 min recovery (Rec3), 10 min recovery (Rec10), 30 min recovery (Rec30), and 60 min recovery (Rec60); while oxygen consumption (VO2) was recorded at 3 min of exercise (Ex3), Ex60, TT, Rec3, 15 min recovery (Rec15), Rec30, and Rec60. The data were analyzed via a two factor within-subjects repeated measures ANOVA. **RESULTS**: A trial x time interaction was observed for VO_2 (F = 6.838, p = 0.001), which was greater in CLD at Rec30 (0.50 0.60 L·min^{-1}) and Rec60 (0.57 ± 0.10 L·min^{-1}) compared to MOD at Rec30 (0.33 ± 0.03 L/min^{-1}; p = 0.008) and Rec60 (0.37 ± 0.03 L/min^{-1}; p = 0.012). A main effect of time was observed for VO_2 (F = 282.52, p < 0.001), where Ex3 (2.06 ± 0.10 L·min^{-1}) was lower than Ex60 (2.3 ± 0.09 L·min^{-1}; p = 0.027) and TT (3.36 ± 0.18 L·min^{-1}; p = 0.001) and higher than Rec3 (0.5 ± 0.02 L·min^{-1}; p < 0.001), Rec15 (0.43 ± 0.05 L·min^{-1}; p < 0.001), Rec30 (0.42 ± 0.02 L·min^{-1}; p < 0.001) and Rec60 (0.47 ± 0.03 L·min^{-1}; p < 0.001). Ex60 was significantly lower than TT (p = 0.007) and higher than Rec3, Rec15, Rec30 and Rec60 (p < 0.05). TT was higher from Rec3, Rec15, Rec30, and Rec60 (p < 0.05). A trial x time interaction was observed for the change in Tre (F = 7.28, p < 0.001), which changed less than in the CLD at Rec3 (0.37 ± 0.58 $^\circ$C;), Rec10 (0.16 ± 0.58 $^\circ$C), Rec30 (-0.29 $\pm$ 0.67 $^\circ$C) and Rec60 (-0.69 $\pm$ 0.94 $^\circ$C) compared to MOD at Rec3 (0.94 ± 0.35 $^\circ$C; p = 0.034), Rec10 (0.85 ± 0.48 $^\circ$C; p = 0.024), Rec30 (0.44 ± 0.55 $^\circ$C; p = 0.021), and Rec60 (0.002 ± 0.59 $^\circ$C; p = 0.045), respectively. There was a main effect of trial (F = 8.078, p = 0.047), where the change in MOD (0.707 ± 0.167 $^\circ$C) was greater than the change in CLD (0.275 ± 0.259 $^\circ$C; p = 0.047). **CONCLUSION**: Not surprisingly, Tre was significantly reduced in the CLD, with a concomitant increase in VO_2 to maintain homeostasis.

Thermal Responses Associated with Prolonged Cycling in Cold Temperature Cody S. Dulaney, Adam R. Jajtner, Jeremiah A. Vaughan, Brittany N. Followay, Elliot Arroyo, Savannah R. Hall, Joseph A. Laudato, Ellen L. Glickman FASCM Exercise Physiology Department, Kent State University, Kent, OH

cody dulaney. *Kent state university, Kent, OH.* (Sponsor: Ellen G Glickman, FACSM)

(No relevant relationships reported)

PURPOSE: To assess thermal responses to exercise in cold versus moderate temperature. **METHODS:** Recreationally active men (n=5, 23.4 ± 2.2 yrs; 183.1 ± 6.1 cm; 86.9 ± 11.9 kg; 4.44 ± 0.75 L·min^{-1}) completed a cycling protocol in 5°C (LT) and 22°C (MOD). The protocol consisted of 60-min cycling at 60% VO_2max (CT_{60}), 15-min rest, and a time to exhaustion at 90% VO_2max (TTE). Mean skin (T_{sk}), and core temperature (T_{re}) were evaluated before CT_{60} (BL) and at 3, 20, 40, and 60 min. Metabolic heat production (M) was assessed at BL, 3, 15, 30, 45, and 60 min. Tissue insulation (I) was assessed at 3, 30, and 60 min T_{sk}, T_{re} and I were measured before (PRE) and after (POST) TTE. M was measured at PRE, at the mid-point (MID), and POST TTE. Changes were analyzed using within-subjects repeated measures ANOVA. **RESULTS:** An interaction was observed for T_{sk} during CT_{60} (F = 64.00 p < 0.001, η_p^2 = 0.941). T_{sk} was lower in LT versus MT ($p \leq 0.001$) at 3 min (25.5 ± 0.7°C, 30.7 ± 0.6°C, respectively), 20 min (23.0 ± 0.7°C, 30.4 ± 0.8°C, respectively), 40 min (22.4 ± 0.6°C, 30.4 ± 0.8°C, respectively) and 60 min (21.9 ± 1.0°C, 29.9 ± 1.3°C, respectively). No interaction (F = 5.97; p = 0.071; η_p^2 = 0.599) was observed for T_{re}. A time effect was observed for M during the TC_{60} (F = 25.8, p < 0.001, η_p^2 = 0.866). M increased from 3 min (348.2 $\pm$ 36.9 W·m^{-2}) at 15 min (375.8 $\pm$ 35.6 W·m^{-2}; p = 0.006), 30 min (383.6 $\pm$ 37.6 W·m^{-2}; p < 0.001), 45 min (384.6 $\pm$ 35.28 W·m^{-2}; p < 0.001) and 60 min (391.2 $\pm$ 34.0 W·m^{-2}; p = 0.004). An interaction was observed for M during TTE (F= 29.08 p < 0.001, η_p^2 = 0.879), with M lower during LT versus MT at PRE (113.9 $\pm$ 28.7 W·m^{-2}; 305.2 $\pm$ 100.7 W·m^{-2}, respectively; p = 0.016), MID (154.3 $\pm$ 54.3; 529.8 $\pm$ 65.3 W·m^{-2}, respectively; p < 0.001), and POST (176.3 $\pm$ 26.6; 577.5 $\pm$ 59.6 W·m^{-2}, respectively; p < 0.001). An interaction was observed for I during TC_{60} (F= 18.52; p = 0.001; η_p^2 = 0.822). I was greater in LT compared to MT at 3 min (0.034 $\pm$ 0.005°C·m^{-2}·W^{-1}, 0.019 $\pm$ 0.028°C·m^{-2}·W^{-1}, respectively; p = 0.001), 30 min (0.045 $\pm$ 0.006°C·m^{-2}·W^{-1}, 0.019 $\pm$ 0.017°C·m^{-2}·W^{-1}, respectively; p = 0.001), and 60 min (0.48 $\pm$ 0.008°C·m^{-2}·W^{-1}, 0.022 $\pm$ 0.001°C·m^{-2}·W^{-1}, respectively; p = 0.003). **CONCLUSION:** As expected, I increased in 5°C compared to 23°C, while M increase during submaximal exercise. However, M decreased during exhaustive exercise perhaps due to fatigue.

The Impact Of Long Duration Spaceflight On The Function Of Plasma Cells

Guillaume Spielmann[1], John Campbell[1], Brian E. Crucian[2], Mitzi S. Laughlin[3], Richard J. Simpson, FACSM[4]. *[1]Louisiana State University, Baton Rouge, LA. [2]NASA-Johnson Space Center, Houston, TX. [3]University of Houston, Houston, TX. [4]Unviersity of Arizona, Tucson, AZ.* (Sponsor: Richard J. Simpson, FACSM)

(No relevant relationships reported)

Long duration spaceflights have been associated with profound dysregulation of the immune system, which could jeopardize crew safety and mission success. Recent studies have examined the impact of long-duration spaceflight on specific markers of adaptive and innate immunity, but no study to date has characterized humoral immunity and serological markers of B-cell function. **Purpose**: The aim of this study was to characterize acute and chronic changes in polyclonal Free Light Chains (FLC) and in Immunoglobulin class switching, indicative of overall B-cell function, by retrospectively analyzing archived plasma samples collected during long-duration spaceflight studies. **Methods:** Plasma samples were collected before flight, during ("Early flight", "Mid-flight" and "Late flight"), immediately upon return and during a recovery period (R+18, R+33 and R+66) from 23 astronauts and 6 age/gender-matched healthy ground-based controls. Plasma Kappa and Lambda Free Light Chains were measured using commercially available ELISA kits (Abingdon Health, Oxford, UK), and changes in renal function were identified by calculating Cystatin C-derived estimates of Glomerular Filtration Rate (eGFR). Finally, Immunoglobulin isotype switching was assessed by measuring changes in total plasma IgA, IgG and IgM throughout the mission using ELISA kits (eBioscience, San Diego, CA, USA). Maximum likelihood linear mixed models (LMM) were used to determine main effects of time on the concentration of serum FLC, Immunoglobulins and Cystatin C. **Results:** There was no difference in serum Kappa and Lambda FLC between pre-flight samples and either in-flight or recovery samples (p>0.05). Furthermore, serum levels of IgA, IgG and IgM remained unchanged during and after spaceflight, when compared to pre-flight values (p>0.05). Finally, there was no difference in eGFR (p>0.05) between before, during and after flight, suggesting that kidney function was not affected by spaceflight. **Conclusion:** These preliminary findings indicate that free light chains

---

and whole immunoglobulin output from plasma cells are unaffected by long-duration spaceflight, indicating that plasma cell immune competency is maintained in microgravity and risk of infection does not appear to be magnified.

Power But Not Fatigue Is Influenced By Hot And Cold Immersion Prior To Vigorous Cycling

Donald L. Hoover[1], Samuel K. Knott[2], Christopher A. Bidwell[2], Carrie A. Revlett[3], Sarah E. Parks[2], Daren T. Webb[1], Lawrence W. Judge[4], Elizabeth Norris[2], Scott W. Arnett[2]. *[1]Western Michigan University, Kalamazoo, MI. [2]Western Kentucky University, Bowling Green, KY. [3]Western Kentucky University, Bowling Green, IN. [4]Ball State University, Muncie, IN.*
(No relevant relationships reported)

PURPOSE: The impact of hot and cold immersion upon vigorous physical activity is not fully understood. Increased body temperature has been linked to improved performance during vigorous activities, whereas lower body temperature has been noted as detrimental during maximal exercise. A deeper understanding of the effect of hot and cold immersion on fatigue characteristics during the Wingate Anaerobic Test (WAnT) may lead to better understanding on how to best construct training and rehabilitation programs. The purpose of this study was to explore the effects of hot and cold immersion on measures of power and fatigue while completing a maximal bout of anaerobic cycling.
METHODS: Thirty apparently healthy and physically active women (23.00 ± 2.67 yr, 165.77 ± 5.95 cm, 61.97 ± 10.56 kg) completed this study. Participants visited the laboratory on three occasions. Using a counterbalanced design, each completed the WAnT following three immersion protocols: HOT, COLD, and no immersion (CON). Each then rode an electronically-braked cycle ergometer at maximal intensity for 30 seconds. Conditions were controlled and measured by computer. Indices of peak power (PP), mean power (MP), and fatigue index (FI) were calculated using 5-second time periods. Repeated measures ANOVA were used for statistical analysis. Statistical significance was set at the $p \le .05$ level.
RESULTS: Significant differences were found between conditions for PP [$F(2,28)=3.918, p\le 0.032$] and MP [$F(2,28)=101.71, p\le 0.000$], respectively. Pairwise comparisons using the Bonferroni correction indicated that PP ($p\le 0.024$) was significantly different between HOT and COLD conditions, and MP ($p \le 0.001$) was significantly different between HOT, COLD, and CON conditions. Non-significant differences were found between the warm-up conditions for FI [$F(2,28)=.032, p\le 0.968$].
CONCLUSIONS: The measures for PP and MP were improved following heat immersion. These findings suggest heat immersion had a stimulatory effect upon performance in this study. Conversely, no differences were found between conditions regarding FI. This element suggests that the types of immersion therapy used in this study were essentially neutral in affecting staying power during maximal cycling.

Central Chemosensitivity is Augmented during Thermoneutral Head Out Water Immersion in Healthy Adults

James R. Sackett, Zachary J. Schlader, Christopher L. Chapman, Blair D. Johnson. *University at Buffalo, Buffalo, NY.* (Sponsor: Dave Hostler, FACSM)
(No relevant relationships reported)

Carbon dioxide (CO_2) retention occurs during water immersion and increases the risk of CO_2 toxicity. The central chemoreceptors primarily mediate the rise in ventilation during hypercapnia. However, it is unknown if central chemosensitivity is altered throughout two hours of head out water immersion (HOWI) in healthy adults. **Purpose:** We tested the hypothesis that central chemosensitivity is blunted throughout two hours of HOWI in healthy adults. **Methods:** We assessed central chemosensitivity in 17 subjects (age: 22 ± 1 y, BMI: 25 ± 2 kg/m^2, 7 women) during a thermoneutral ($35\pm0°C$) HOWI trial and a time-control dry trial at baseline, 10 min, 60 min, 90 min, 120 min, and post. The partial pressure of end tidal CO_2 ($PETCO_2$; capnograph) and minute ventilation (pneumotachometer) were recorded continuously. Central chemosensitivity was evaluated via a rebreathing test. Subjects rebreathed 7% CO_2 and 93% O_2 from a 10 L bag for 3.5 min. Central chemosensitivity was calculated as the slope of the linear regression line of minute ventilation vs. $PETCO_2$ every 30 s throughout the test. Data are reported as a change from baseline (mean $\pm$ SD). **Results:** $PETCO_2$ increased from baseline during HOWI at 10 min ($+1\pm2$ mmHg), 60 min ($+2\pm2$ mmHg), 90 min ($+2\pm2$ mmHg), and 120 min ($+2\pm2$ mmHg) (all p<0.01). The change in $PETCO_2$ was greater during HOWI vs. control at 10 min, 60 min, 90 min, and 120 min (all p<0.01). The change in minute ventilation did not differ over time (p=0.50) or between conditions (p=0.09). Central chemosensitivity increased from baseline during HOWI at 10 min ($+0.68\pm0.51$ L/min/mmHg), 60 min ($+0.70\pm0.69$ L/min/mmHg), 90 min ($+0.73\pm0.92$ L/min/mmHg), 120 min ($+0.85\pm1.09$ L/min/mmHg), and post ($+0.39\pm0.72$ L/min/mmHg) (all p<0.01). Central chemosensitivity also

increased from baseline during control at 120 min ($+0.36\pm0.52$ L/min/mmHg, p=0.04). The change in central chemosensitivity was greater during HOWI vs. control at 10 min, 60 min, 90 min, and 120 min (all p<0.01). **Conclusion:** These findings indicate that central chemosensitivity is augmented during two hours of thermoneutral HOWI. Thus, it is unlikely that changes in central chemosensitivity contribute to CO_2 retention during water immersion.

The Role of Diver Hydration Status on Performance Following Head Out Water Immersion

Hayden Hess[1], David R. Pendergast[1], Zachary J. Schlader[1], Lindsey N. Russo[1], Brian M. Clemency[1], Mary G. Carey[2], David Hostler, FACSM[1]. *[1]University at Buffalo, BUFFALO, NY. [2]University of Rochester, Rochester, NY.* (Sponsor: Dave Hostler, FACSM)
(No relevant relationships reported)

Water immersion results in a diuresis, which could potentially limit exercise performance after egress to land. **PURPOSE**: We examined the effect of three rehydration strategies on an endurance run to exhaustion, cardiovascular stability, and overnight recovery following a four-hour head out water immersion (HOWI) in thermoneutral water.
METHODS: Twelve male subjects (22.7 ± 1.8 y) completed a crossover design consisting of three rehydration strategies: no rehydration (NH), hourly replacement of fluid loss during immersion (RD), and replacement of fluid after the immersion period (RA). Following immersion, subjects ran to exhaustion at ~80% maximum heart rate. After completing the run, each subject submitted to a head up tilt test (HUTT). Vital signs and ECG were monitored overnight.
RESULTS: HOWI resulted in a transient diuresis in NH and RA protocols, while it was sustained throughout immersion in the RD protocol resulting in greater total urine volume (l) output (1.27 ± 0.48 (NH), 2.32 ± 0.77 (RD), and 1.18 ± 0.43 (RA); p < 0.001). Body mass change (%) from fluid loss was greater in NH than RD, but not RA (-1.58 ± 0.56 (NH), $- 0.66 \pm 0.47$ (RD), and $- 0.92 \pm 0.76$ (RA)). Run time was 17% and 13% shorter in NH than RD and RA, respectively, but were not statistically different. Time to orthostasis, heart rate, and blood pressure during the HUTT did not differ by condition. Overnight heart rate variability and mean arterial pressure were not different between rehydration strategies.
CONCLUSIONS: Loss of body water during thermoneutral HOWI was modest and rehydration strategies minimally affected aerobic performance, cardiovascular stability, and overnight recovery in young, healthy males. Rehydration during water immersion resulted in a large, sustained diuresis without improving performance or recovery after exiting the water.

Effects Of Concurrent Exercise During Simulated Microgravity On Soleus Muscle Fiber Myonuclear Content

Kaylie R.M. Zapanta[1], Joshua A. Cotter[2], Andrew J. Galpin[3], James R. Bagley[4]. *[1]University of Southern California, Los Angeles, CA. [2]California State University, Long Beach, Long Beach, CA. [3]California State University, Fullerton, Fullerton, CA. [4]San Francisco State University, San Francisco, CA.*
(No relevant relationships reported)

Introduction: Exercise countermeasures administered on the International Space Station are time-consuming and use large/expensive equipment. Aerobic exercise has shown to maintain oxidative capacity of muscle fibers, while resistance exercise preserves muscle mass in Astronauts. Recently, Cotter et al. (2015) determined that concurrent exercise (combining aerobic and resistance exercises; CE) was effective at mitigating de-conditioning during ULLS (unilateral lower limb suspension, simulated microgravity) but resulted in differences in fiber-type responses (i.e., fast-twitch *vs* slow-twitch). This current study provides additional analyses of muscle samples used in Cotter et al. (2015), investigating soleus muscle (mostly slow-twitch) myonuclei. Modulations in fiber size and myonuclear domain (MND; the area each myonuclei controls) may provide mechanisms for preventing unloading decrements. **Purpose:** Our aim was to determine 1) if simulated microgravity affects soleus muscle fiber size and MND size and 2) if CE training mitigates these changes. Sixteen subjects were separated into two groups, 10-day ULLS and 10-day ULLS + CE. **Methods:** Muscle biopsies were taken pre- and post- intervention, which were isolated into individual fibers (muscle cells), stained for myonuclei, three-dimensionally imaged, and analyzed for fiber size and MND size. 2x2 ANOVAs determined potential differences in fiber size and MND size between groups, before and after ULLS. **Results**: No significant differences in fiber size or MND size after 10 days of ULLS were observed. These findings suggest that, while 10 days of ULLS may cause a decline in muscle function (as seen in Cotter et al., 2015), it may not significantly affect soleus muscle fiber size or MND size. However, individual variability occurred, suggesting that some people may be responders (or non-responders) to ULLS and ULLS+CE. **Conclusion:**

The results of this study suggest a need for additional analyses to help develop "personalized" exercise countermeasures for those undergoing significant periods of unloading (e.g., people in bed rest or Astronauts). <!--EndFragment-->

Reliability of the Portable Metabolic Gas Analysis System used on the International Space Station

Alan D. Moore, FACSM[1], Meghan E. Downs[2], Shannon L. Jordan[1], Alan H. Feiveson[3], Jamie R. Guined[4], Stuart MC Lee[2]. [1]Lamar University, Beaumont, TX. [2]KBRwyle, Houston, TX. [3]NASA-Johnson Space Center, Houston, TX. [4]University of Houston, Houston, TX.
(No relevant relationships reported)

Metabolic gas analysis is utilized for both research and medical operations purposes on the International Space Station (ISS). Data regarding reliability of metabolic gas analysis system used on board the ISS, the Portable Pulmonary Function System (PPFS – Danish Aerospace Corporation, Odense, DK), has not been reported. **PURPOSE:** To determine the reliability and intra-subject repeatability of metabolic gas analysis data collected by the PPFS. **METHODS:** Subjects (n=8: 5M, 3F) performed 3 peak cycle tests, consisting of three 5-min stages designed to elicit 25%, 50%, and 75% peak oxygen consumption (VO_{2peak}) followed by stepwise increases of 25 W/min until reaching volitional exhaustion. Metabolic gas analysis was performed using the PPFS during these tests. Intraclass correlation coefficients (ICC), within-subject standard deviations (WS SD), and coefficients of variation (CV %) were calculated. **RESULTS**: The ICC, WS SD and CV % for peak exercise are contained in the table below. Across all exercise stages, the ICC values for oxygen consumption (VO_2), carbon dioxide production (VCO_2), and ventilation (V_E) ranged from 0.79 to 0.99; however, the ICC for respiratory exchange ratio (RER) indicated poorer agreement between trials (ICC=0.11 to 0.51). The CV values for all dependent variables ranged from 2.6% to 6.6%, which are consistent with reported values obtained using other metabolic gas analysis devices.

Variable	ICC	WS SD	CV (%)
VO_{2peak} (L/min)	0.98	0.11	3.6
VO_{2peak} (ml/kg/min)	0.92	1.91	4.6
VCO_{2peak} (L/min)	0.94	0.18	5.4
RER_{peak}	0.51	0.05	4.0
V_{Epeak} (L/min)	0.94	6.34	5.6
Peak Watts	0.96	10.32	3.7

CONCLUSIONS: The PPFS appears to yield reliable metabolic gas analysis data. Lower reliability of RER measurements are reported in the literature using other devices and is not likely a function of the PPFS. The PPFS should provide accurate and reliable data for research and monitoring of human adaptation to spaceflight.

Physiological Response in Time to Exhaustion Trial Across Varied Environmental Conditions

Savannah R. Hall, Ellen L. Glickman, FACSM, Jeremiah A. Vaughan, Brittany N. Followay, Elliott Arroyo, Cody S. Dulaney, Joseph A. Laudato, Adam R. Jajtner. *Kent State University, Kent, OH.*
(No relevant relationships reported)

Purpose: To examine different environmental conditions on the physiological response to aerobic exercise preformed to exhaustion. **Methods:** Recreationally active men (n=5, 24.2 ± 2.6yr., 183.6 ± 5.57cm, 79.95± 3.99 kg, 11.72 ± 2.48 %BF, VO_2 =3.89 ± 0.31 L·min⁻¹) completed four trials. VO₂max was tested on the first trial, and trials were counterbalanced into: 5°C (LT), 23°C (MT), 34°C (HT). Participants cycled 60 minutes at 60% of their previously determined VO₂max, prior to a time to exhaustion (TTE) trial at 90% of VO₂max. Duration, metabolic (VO_2, VCO_2, V_E, & HR), and electromyography (EMG) of the right leg (RMS, MPF, MEDPF) were collected during TTE. Metabolic and EMG variables were assessed over the initial (PRE), middle (MID) and last (POST) 30s periods. EMG data were normalized to a 2-min reference bout in a thermoneutral condition. Data were analyzed using a within subjects repeated measures ANOVA. **Results:** A condition effect (F =5.37; p=0.033; η_p^2 = 0.573) during TTE, indicated MT (326.4 ± 231.1s) was longer than HT (143.2 ± 52.6s; p=0.034), with no differences in LT(281.6± 259.5s; p >0.05). No interactions

were observed for metabolic or EMG analyses. A time effect (F=145.23, p <0.001, η_p^2 = 0.973) was observed for VO₂. VO₂ was lower (p<0.001) at PRE (1.78 ± 0.52 L·min⁻¹) than MID (2.97 ±0.48 L·min⁻¹) and POST (3.15 ± 0.53 L·min⁻¹). A time effect (F= 222.182, p<0.001, η_p^2=0.982) was observed for VCO₂. VCO₂ was lower (p<0.001) at PRE (1.40± 0.37 L·min⁻¹) than MID (2.97 ± 0.72 L·min⁻¹) and POST (3.49± 0.48 L·min⁻¹), while MID was lower than POST. A time effect on V_E (F= 87.523, p <0.001, η_p^2=0.956) indicated increases (p<0.05) from PRE (37.44±6.95 L·min⁻¹) to MID (67.70 ±21.72 L·min⁻¹) to POST (86.12 ± 18.23 L·min⁻¹). A time effect (F= 45.382, p = 0.002, η_p^2= 0.002) for HR indicated increases (p<0.05) from PRE (150.80 ± 29.0 bpm) to MID (180.3 ± 19.7 bpm) to POST (189.3 ± 15.8 bpm). A time effect (F= 4.503, p= 0.049, η_p^2=0.530) for RMS indicated decrease (p=0.043) from PRE (135.1±25.04%) to MID (124.6±28.2%). A time effect (F= 4.720, p=0.044, η_p^2=0.541) of MPF indicated no differences across time points. **Conclusions:** LT had no effects on TTE endurance. Endurance in MT may be better compared to HT, though metabolic and EMG variables are likely not responsible for this difference.

1401   Board #209   May 31 8:00 AM - 9:30 AM

Thermoregulatory Responses To Moderate-intensity And High-intensity Cycling In The Heat

Eliott Arroyo, Brittany N. Followay, Jeremiah A. Vaughan, Cody S. Dulaney, Joseph A. Laudato, Savannah R. Hall, Ellen L. Glickman, FACSM, Adam R. Jajtner. *Kent State University, Kent, OH.*
(No relevant relationships reported)

PURPOSE: To examine the thermoregulatory responses to moderate- and high-intensity cycling in the heat. **METHODS:** Recreationally active Caucasian men (n=5, 24.2 ± 2.9 yrs; 183.6 ± 6.2 cm; 83.6 ± 8.1 kg; 11.7 ± 2.8%BF; 48.9 ± 6.2 ml·kg⁻¹·min⁻¹) completed an exercise protocol under two conditions: high temperature (HT; 35ºC) and moderate temperature (MT; 22ºC). The protocol consisted of 60 minutes of cycling at 60% VO₂max (CT_{60}), a 15-minute rest period, and a time to exhaustion trial at 90% VO₂max (TTE). Mean skin temperature (T_{sk}; ºC), core temperature (T_{re}; ºC), and thermal sensation (TS) were evaluated before CT_{60} (BL) and at minutes 3, 20, 40, and 60. Metabolic heat production (M; W·m⁻²) was evaluated at BL and at minutes 3, 15, 30, 45, and 60. Tissue insulation (I; ºC·m²·W⁻¹) and physiological strain index (PSI) were evaluated at minutes 3, 30, and 60 of CT_{60}. T_{sk}, T_{re}, TS, PSI, and I were measured before (PRE_{TTE}) and after ($POST_{TTE}$) TTE. M was measured at PRE_{TTE}, during TTE (MID_{TTE}), and $POST_{TTE}$. Changes were analyzed using a two factor (time x trial) within-subjects repeated measures ANOVA. **RESULTS:** For HT, T_{sk} was lower at all timepoints relative to BL ($p's$ = 0.014–0.028). For HT, T_{sk} was higher at all timepoints relative to BL ($p's$ = 0.003–0.005). T_{sk} was significantly higher in HT compared to MT at minutes 3, 20, 40, and 60 ($p's$ = 0.001–0.033). T_{sk} decreased from PRE_{TTE}–$POST_{TTE}$ (p = 0.002) and was significantly higher during HT compared to MT (p < 0.001). T_{re} was higher at all timepoints relative to BL (p < 0.001–0.001) during CT_{60}, and was significantly higher during HT compared to MT (p = 0.003). In HT, T_{re} decreased from PRE_{TTE}–$POST_{TTE}$ (p = 0.032). T_{re} was significantly higher during HT compared to MT at PRE_{TTE} (p = 0.009) and $POST_{TTE}$ (p = 0.033). M was higher at minutes 15, 30, 45, and 60 relative to 3 min ($p's$ = 0.001–0.047) and increased at MID_{TTE} and $POST_{TTE}$ ($p's$ < 0.001) relative to PRE_{TTE}. I was significantly lower during HT compared to MT at minutes 3, 30, and 60 ($p's$ < 0.001–0.001). I was lower at $POST_{TTE}$ relative to PRE_{TTE} (p = 0.001). TS was higher during HT compared to MT at minutes 20, 40, and 60 (p < 0.001–0.009). PSI was significantly higher during HT compared to MT at PRE_{TTE} (p = 0.047). **CONCLUSION:** As expected, tissue insulation is decreased, and physiological strain index is increased during exercise in the heat.

Effects Of Wrist Cooling On Balance And Cognitive Performance In The Heat

Rachel K. Katch, Ryan Curtis, Andres Almeraya, Rebecca L. Stearns, Douglas J. Casa, FACSM. *University of Connecticut, Storrs, CT.* (Sponsor: Dr. Douglas J. Casa, FACSM)
(No relevant relationships reported)

Many cooling modalities exist in the literature claiming to improve performance in the heat; however, there's a paucity of literature regarding wrist cooling's effects on balance and cognitive performance after a bout of exercise in the heat. **PURPOSE:** To examine if wrist cooling influences balance and cognitive performance after a bout of cycling exercise in the heat. **METHODS:** Fourteen male participants (age, 22±4 years; height, 182±7 cm; body mass, 75.4±8.7 kg; body fat %, 10.7±3.4%) were analyzed. In an environmental heat chamber (39.5±0.9°C, 38.6±5.2% RH) participants underwent three randomized 135-minute cycling trials, which included: one wrist cooling device (W1), two wrist cooling devices (W2), and no wrist cooling device (W0) during exercise. Cognitive measures (Balance Error Scoring System [BESS], Letter Digit Substitution Test [LDST], Trail Making Test [TM]) were conducted immediately post-exercise, and delta scores were calculated from a baseline familiarization session. Rectal temperature (T_{REC}) was taken every 15 minutes during exercise. A group x time

repeated measures ANOVA was conducted to determine group differences, and paired samples *t*-tests were used to determine mean differences. **RESULTS:** No statistical difference between groups W1 and W2 occurred, therefore their data were pooled (W_P). No statistically significant difference was observed in T_{REC} between W0 and W_P (n=28; p=0.69). Additionally, no significant differences were observed in the LDST (n=27, p=0.21) and TM (n=26, p=0.64) delta scores between W0 and W_P. Significant differences were noted in BESS delta scores between W0 and W_P specifically for the single leg foam stance (0±2 vs. 1±2, respectively; p=0.002). **CONCLUSION:** Wrist cooling during exercise in the heat did not have an effect on T_{REC}, LDST, and TM scores; however, it did significantly improve single leg foam stance of the BESS testing post-exercise. Further research is warranted to investigate the potential link of body cooling and balance performance, as well as the effectiveness of wrist cooling on cognitive measures after exercising in the heat.

Game-to-Game Increases in Core TemperatureDuring Rugby 7's World Series Tournaments

Lee Taylor, FACSM[1], Heidi Thornton[2], Nick Lumley[3], Christopher Stevens[4]. [1]Aspetar – Orthopaedic and Sports Medicine Hospital, Doha, Qatar. [2]Newcastle Knights Rugby League Club, Newcastle, Australia. [3]Scottish Rugby Union, Edinburgh, United Kingdom. [4]Southern Cross University, Coffs Harbour, Australia.

(No relevant relationships reported)

PURPOSE: Characterize player core temperature (Tc) across two separate World Rugby 7's Series (WRSS) tournaments in temperate and warm environments. **METHODS:** Continuous Tc (ingestible e-Celsius™ capsule) was collected in seventeen separate playing members of one men's team (Singapore; n = 12, London; n = 11, with n = 6 competing in both tournaments) competing at the Singapore (warm) and London (temperate) WRSS tournaments. Symptoms of exertional heat illnesses (EHI), cooling strategy use, playing minutes and wet blub globe temperature (WBGT) were collected. Linear mixed models were used and a magnitude-based inference network was used to describe differences in delta Tc between all periods (baseline, pre-warm-up, warm-up, pre-game, game and post-game) within and between competitions. **RESULTS:** There were substantial game-to-game Tc increases relative to baseline, particularly within second and third games, on all match-days. Despite high peak Tc values (Singapore 39.9°C; London 39.6°C); (1) no signs and symptoms of EHI were reported by players; (2) voluntary post-game CWI usage was low; and (3) other pre-, during- and post-game cooling maneuverers were not implemented. Magnitude of Tc response was associated with playing minutes [excluding London Day 2 (Effect size; ES = 0.87–1.46)] and WBGT [excluding Singapore Day 1 (ES = 0.54–0.60)]. **CONCLUSION:** Tc demonstrated game-to-game increase with peak temperatures approaching thresholds associated with EHI (>40°C) and exceeding those demonstrated to decrement repeated sprint performance (>39°C), despite the short game duration. Practitioners may consider the use of acclimation/acclimatization programs (preferentially) and practice compatible cooling strategies to minimize Tc increase and maximize recovery and preparedness for games within and between match-days. Supported by Aspire Zone Foundation (AZF; Doha, Qatar) funding.

Effect of Thermal Stress on Cycling and Plasma Volume Shifts, Body Weight and Water Intake

Joseph A. Laudato, Ellen L. Glickman, FACSM, Brittany N. Followay, Jeremiah A. Vaughan, Eliott Arroyo, Cody S. Dulaney, Savannah R. Hall, Adam R. Jajtner. Kent State University, Kent, OH. (Sponsor: Ellen Glickman, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the effects of environmental stress while cycling, and its influence on hydration status. **METHODS:** Recreationally active men (n=5, 24.2 ± 2.6 years; 183.6 ± 5.6 cm; 80.0 ± 4.0 kg; 11.7 ± 2.5 %BF; 3.9 ± 0.3 L·min⁻¹) completed 4 trials, with the first consisting of a VO_2 max test, and the remaining 3 trials involving cycling at 5°C (LT), 23°C (MT), and 34°C (HT) in a counterbalanced manner. Each trial consisted of 60 min of cycling at 60% VO_2 max, 15-min rest, and a time to exhaustion (TTE) at 90% VO_2 max. Blood was drawn prior to (PRE), immediately following (60), after TTE and 1-hr post-trial (REC). An automated hematology analyzer examined whole blood, in which plasma volume shifts (PVS) were calculated using the formula established by Dill & Costill (1974). Body weight (BW) and water intake (WATER) was assessed at each time point, while urine specific gravity (USG) was assessed at PRE and REC. All data were analyzed using within-subjects repeated measures ANOVA. **RESULTS:** A trial x time interaction was observed for PVS (F= 5.71; p=0.041; η_p^2= 0.655). Post Hoc analysis indicated that at REC, PVS were greatest in LT (-14.75 ± 2.33%), compared to HT (-9.33 ± 1.77%; p=0.039), and MT (-3.5 ± 2.25%; p=0.015), while PVS at HT was significantly greater than MT (p=0.009). Furthermore, in MT, PVS were significantly greater at 60 (-18.06 ± 4.47%) and TTE (-16.34 ± 4.55%) than REC (-6.64 ± 7.29%; p=0.008, p=0.047 respectively). In HT,

---

PVS was significantly greater at 60 (-17.63 ± 2.52%) and TTE (-19.45 ± 2.58%) than REC (-9.33 ± 1.77%; p=0.024, p=0.001 respectively). No change was observed in LT (p=0.090). There was no trial x time interaction (F= 0.515; p= 0.435; η_p^2=0.203), nor a main effect of time (F=0.655; p=0.595; η_p^2=0.141), or trial (F=0.515; p=0.616; η_p^2=0.114) in BW. A main effect of trial was observed in WATER (F= 29.156; p=<0.001; η_p^2=0.879). WATER was lower in LT (399.2 ± 186.9 ml) than MT (903.9 ± 302.6 ml; p=<0.001) and HT (1386.0 ± 216.8 ml; p=0.021), and greater in HT than MT (p=0.033). There was no trial x time interaction nor main effect of time or trial in USG. **CONCLUSIONS:** Cycling resulted in a greater PVS at REC for LT, compared to HT and MT. For MT and HT, PVS were reduced at REC when compared to 60 and TTE, revealing a resolution of plasma volume post-trial. As expected, water intake increased as trial temperature increased.

World Championship Heat Stress Preparation: A Comparison Of IAAF And UCi Athletes

Julien Périard[1], David Nichols[2], Sebastien Racinais[2]. [1]University of Canberra, Canberra, Australia. [2]Aspetar Sports Medicine Hospital, Doha, Qatar. (Sponsor: David Pyne, FACSM)

(No relevant relationships reported)

PURPOSE: To compare exertional heat illness (EHI) history and preparedness to compete in the heat at the Beijing, China 2015 IAAF (athletics) and Doha, Qatar 2016 UCI (road cycling) World Championships. **METHODS:** Responses to a pre-competition questionnaire evaluating EHI history, heat countermeasure strategies and recovery approaches were compared in 307 IAAF and 69 UCI respondents (32% and 7% participation rate, respectively). The IAAF event was held in ~29°C and ~58% RH conditions, and the UCI event in ~37°C and ~25% RH. A *Chi-square* test of independence was employed to compare sports. **RESULTS:** Both the IAAF (48%) and UCI (57%) athletes had previously experienced EHI symptoms, with 9% and 17% having been diagnosed with EHI, respectively (P<0.001). Only 15% of IAAF athletes trained in the heat (5-30 days) before the championships, in contrast to 32% of the cyclists (P<0.001). Half of the IAAF athletes (52%) had a precooling strategy compared with 96% of the cyclists (P<0.001). Ice slurry ingestion was the most prevalent strategy in athletics and wearing an ice-vest during the warm-up was most common for cyclists. Almost all IAAF (96%) and all UCI athletes (100%) had a fluid consumption strategy (P<0.001), which differed based on event category (field, sprints and distance events; time trials and road race). The volume of fluids planned on being consumed also differed between event categories within each sport, although water was the fluid most commonly consumed. Most IAAF athletes (89%) planned on using at least one recovery strategy with the most frequently employed being massage, active recovery, stretching and cold-water immersion. The majority of cyclists (92%) planned on using one or more recovery strategies with massage, stretching and active recovery the most prevalent. **CONCLUSION:** Athletes competing at the 2015 IAAF and 2016 UCI World Championships reported a similar history of heat illness. Along with most athletes competing throughout the northern hemisphere summer months, 15% of IAAF athletes surveyed prepared specifically for the event by training in the heat, whereas 32% of the cyclists reported undertaking some form of heat training. Approximately half of the IAAF athletes and almost all the UCI athletes had a precooling strategy. Most athletes in each sport had a fluid consumption and recovery strategy.

Gastrointestinal Telemetric Pills Used as Rectal Probes Provide Inaccurate Measurements of Absolute Rectal Temperatures

Jonathan Gosselin[1], Jeff Béliveau[1], Mathieu Hamel[1], Douglas Casa, FACSM[2], Yuri Hosokawa[2], José A. Morais[3], Eric D.B. Goulet[1]. [1]University of Sherbrooke, Sherbrooke, QC, Canada. [2]University of Connecticut, Storrs, CT. [3]McGill University, Montreal, QC, Canada.

(No relevant relationships reported)

Continuous measurement of rectal temperature (RT) using a wired rectal probe (WRP) comes with obvious technical difficulties and practical limitations. Measurement of RT using a telemetric pill (TP) inserted as a suppository to act as a rectal probe would circumvent some of those problems. **PURPOSE:** Validate the use of a commercially available gastrointestinal TP (HQ Inc.) for the continuous measurement of RT during slow and rapid increase and decrease in core temperature induced by periods of passive cooling, passive heating, active heating and active cooling. **METHODS:** Nine (8 men, 1 woman) physically active participants (30 ± 9 yrs; 175 ± 7 cm; 75 ± 9 kg) underwent a research protocol where they completed, while wearing a WRP (YSI 401) linked to a TP: 1) a 30 min sitting period (23°C) followed by 2) a 45 min sitting period inside a head-out environmental chamber (40-42 °C); 3) a 45 min sitting period (23°C) while ingesting, over the first 30 min, 7.5 g of shaved-ice (-1°C)/kg body weight; 4) a running exercise period (38 °C, 20-30% RH) at 68% VO_{2max} until a WRP temperature of 39.5°C and; 5) a cold-water (10°C) immersion period until a WRP decrease in temperature of 1.5°C. The WRP and each TP were calibrated before experiments. A

bias ± random error contained within ± 0.35°C (daily variation in RT of ± 0.25°C + sensors measurement error of ± 0.1°C) around the zero line was deemed acceptable between sensors. **RESULTS:** The rate of change in WRP and TP temperatures during phases 1, 2, 3, 4 and 5 was respectively of -0.008 ± 0.007°C/min and -0.006 ± 0.004°C/min, 0.003 ± 0.005°C/min and 0.002 ± 0.004°C/min, -0.011 ± 0.004°C/min and -0.011 ± 0.002°C/min, 0.057 ± 0.010°C/min and 0.054 ± 0.008°C/min and -0.141 ± 0.124°C/min and -0.091 ± 0.065°C/min. Mean biases (WRP - TP) and random errors during phases 1, 2, 3, 4 and 5 were of 0.12°C/± 0.30°C, 0.15°C/± 0.22°C, 0.12°C/± 0.26°C, 0.21°C/± 0.34°C and 0.24°C/± 0.66°C, respectively **CONCLUSION:** The use of TPs (HQ Inc.) as suppositories tracked slow and rapid increases in RT and slow decreases in RT as measured by WRP, but did not detect the rapid decrease in RT. In all instances, however, the absolute difference between WRP and TP exceeded +/- 0.35°C. Therefore, we conclude that a TP inserted as a suppository to act as a rectal probe does not provide acceptable absolute measure of RT.

Gastrointestinal Heat Sink: Impact on Ingestible Telemetric Pill and Rectal Probe Temperature Measurements Following Exercise

Eric DB Goulet, Adrien De La Flore, Jonathan Gosselin. *University of Sherbrooke, Sherbrooke, QC, Canada.*
(No relevant relationships reported)

Measurement of core temperature at the gastrointestinal level with an ingestible telemetric pill (ITP) is increasingly used in research. But, unlike core temperature measured at the rectum *via* a rectal probe (RP), data contamination due to water or food ingestion remains a limitation of ITP. Rapid creation of a heat sink at the stomach and upper-intestinal level (duodenum to ileum), as can be obtained, for example, following shaved-ice ingestion, could potentially differently impact ITP and RP temperature measurements. In fact, the closer proximity of ITP to the heat sink than RP could result in a more important and faster rate of energy loss for ITP than RP. **PURPOSE:** To examine the impact of shaved-ice ingestion following exercise-induced increase in core body temperature on the degree of agreement between ITP and RP temperature measurements. **METHODS:** 8 healthy young men (33 ± 8 yrs, 75 ± 6 kg, 176 ± 5 cm) underwent a passive sitting period of 20 min at 20°C, after which they completed 2 exercise periods (cycling or running) at 75% of estimated maximal heart rate in a hot-dry environment (31.1 ± 1.1°C, 32% RH) with the goal of increasing rectal temperature by 1°C over baseline level. Following each exercise period, subjects passively seated in a 20°C ambient temperature for 45 min while ingesting, over the first 30 min, either 7.5 g of water provided at rectal temperature/kg body mass (after the first exercise) or 7.5 g of shaved-ice provided at -1°C/kg body mass (after the second exercise). Rectal (YSI 401) and gastrointestinal temperatures (HQ Inc.) were measured continuously during the experiments. ITPs were ingested 10 h prior to arrival time at the laboratory. **RESULTS:** The rate of decrease in RP and ITP temperatures during water ingestion was respectively of 0.017 ± 0.004°C/min and 0.018 ± 0.008°C/min, compared to 0.025 ± 0.006°C/min and 0.026 ± 0.006°C/min for shaved-ice ingestion. Mean biases (RP - ITP) and 95% limits of agreement during the passive sitting period, first exercise period, water ingestion period, second exercise period and shaved-ice ingestion period were respectively of 0.10°C/± 0.35°C, 0.09°C/± 0.31°C, 0.17°C/± 0.66°C, 0.12°C/± 0.38°C and 0.16°C/± 0.64°C. **CONCLUSION:** The present results indicate that the creation of a heat sink at the stomach and upper-intestinal level does not alter the degree of agreement between RP and ITP.

Evidence for Seasonal Acclimatization of Behavioral Thermoregulation in Resting Humans

Zachary J. Schlader, James R. Sackett, Christopher L. Chapman, Blair D. Johnson. *University at Buffalo, Buffalo, NY.* (Sponsor: David Hostler, FACSM)
(No relevant relationships reported)

Environmental temperatures perceived as comfortable in the summer season are often perceived as uncomfortably warm during the winter, and vice versa. During rest, behavioral thermoregulation is driven by thermal discomfort, which is largely mediated by changes in skin temperature. Thus, it is likely that seasonal acclimatization shifts the skin temperature thresholds that elicit behavioral thermoregulation. However, this is unknown.
Purpose: Test the hypothesis that skin temperatures upon the decision to behaviorally thermoregulate differ between the winter and summer.
Methods: Seven healthy adults (age: 26 ± 3 y, 2 females) wearing shorts and a t-shirt underwent a 90 min behavioral test while seated in which they passively moved between a warm (40 ± 0°C, RH: 20 ± 0%) and a cool (19 ± 1°C. RH: 37 ± 14%) room when they felt 'too warm' or 'too cool'. Testing was completed during both the summer (S; average high/low: 26 ± 4°C / 18 ± 3°C) and winter (W; 0 ± 8°C / -7 ± 5°C) months in Buffalo, NY. Weighted mean skin (6 sites) and intestinal temperatures were measured continually and are reported as a 30 s average immediately prior to moving from cool to warm (C-to-W) and warm to cool (W-to-C). Thermal sensation (7 point

scale: 1 = cold, 7 = hot) and thermal discomfort (4 point scale: 1 = comfortable, 4 = very uncomfortable) were measured at C-to-W and W-to-C. Data were averaged across behaviors for a given subject.
Results: The time prior to moving from C-to-W (S: 9.4 ± 3.4 min, W: 10.5 ± 3.9 min, P=0.46) and W-to-C (S: 15.1± 4.5 min, W: 14.1± 4.2 min, P=0.51) did not differ between seasons. Intestinal temperature at C-to-W (S: 36.8 ± 0.2°C, W: 37.1 ± 0.2°C, P<0.01) and W-to-C (S: 36.7 ± 0.2°C, W: 36.8 ± 0.3°C, P=0.05) was higher in the winter. However, mean skin temperature at C-to-W (S: 33.2 ± 0.4°C, W: 31.9 ± 0.8°C, P<0.01) and W-to-C (S: 35.9 ± 0.5°C, W: 34.4 ± 0.6°C, P<0.01) was lower in the winter. Thermal sensation at C-to-W (S: 2.5 ± 0.4, W: 2.7 ± 0.3, P=0.22) and W-to-C (S: 5.5 ± 0.6, W: 5.3 ± 0.4, P=0.49) did not differ between seasons. Thermal discomfort at C-to-W (S: 1.9 ± 0.4, W: 2.0 ± 0.1, P=0.58) and W-to-C (S: 1.9 ± 0.6, W: 2.0 ± 0.2, P=0.57) also did not differ between seasons.
Conclusion: Compared to the summer, skin temperatures upon the initiation of thermoregulatory behavior are shifted to lower temperatures in the winter.

Thermoregulation And Perception Among Lean/obese And Fit/unfit Girls Cycling In The Heat

Carolina de Ávila Rodrigues, Gabriela Tomedi Leites, Flavia Meyer. *Federal University of Rio Grande do Sul, Porto Alegre, Brazil.*
(No relevant relationships reported)

Heat stress may be an extra concern to obese and unfit adolescents while exercising. Besides the higher rate of body temperature (T_{body}) increase, it is believed that heat stress aggravates perceived exertion (RPE), irritability and thermal sensations. However, no study has compared thermoregulatory and perceptual responses of obese and unfit girls in relation to their lean and fit peers under similar heat stress and metabolic heat production.**PURPOSE:** To verify thermoregulatory and perceptual responses of obese and lean girls, either fit or unfit, exercising in the heat at a similar metabolic heat production per unit of body mass (Hp).**METHODS:** 34 pubescent (Tanner 2 to 4) girls divided in four groups participated in the study. 21 were obese (12 fit and 9 unfit; 13.2±1.4yrs, 60.8±13.7kg, 158±0.1cm, 40.5±5.8% fat (DXA), VO_{2peak} 76.0±8.1 and 56.6±5.8 ml$\cdot$kg$^{\text{-musclemass-1}}\cdot$min^{-1}), and 13 lean (5 fit and 8 unfit; 13.1±1.6yrs, 44.1±6.5kg, 156±0.1cm, 24.0±4.8% fat, VO_{2peak} 74.5±2.9 and 56.2±5.0 ml$\cdot$kg$^{\text{-musclemass-1.}}$min^{-1}). They cycled 2×25 min bouts, with a 10-min rest, at ~5.4 W$\cdot$kg^{-1} (5.2±1.2 and 5.7±1.0 W$\cdot$kg^{-1} obese and lean) in the heat (36°C and 40% RH). Rectal (T_{re}) and skin (T_{sk}) temperatures and heart rate (HR) were measured every 5 min. Additionally, RPE, irritability, thermal sensation, and thermal comfort were collected throughout the exercise. Sweat losses were replenished with spring water during rest period.
RESULTS: Initial T_{re} and HR were similar between obese and lean girls (37.5±0.3 and 37.2±0.3°C and 101±13.6 and 98.8±11.9 bpm). No difference was observed among the 4 groups (obese fit, obese unfit, lean fit and lean unfit) throughout the exercise for T_{re}: 37.6±0.2, 37.5±0.3, 37.5±0.3 and 37.4±0.3 °C; T_{sk}: 34.8±0.8 ; 35.1±1.0 ; 34.4±0.9 e 35.2±0.9°C; T_{body}: 37.0±0.2, 37.0±0.4, 36.8±0.3 and 36.9±0.3 °C; HR: 128±18; 118±12, 130±16 and 119±16 bpm. Also, no differences were observed in the perceptual responses (RPE:11±2, 12±2, 11±2 and 11±2, irritability: 3±0.5, 2±0.3, 3±0.8 and 2±0.3, thermal sensation: 7±0.4, 7±0.5, 7±0.7, 6±0.7 and thermal comfort: 3±0.4, 3±0.5, 3±0,7 and 3±0.5).**CONCLUSION**: Regardless of the adiposity or aerobic fitness level, pubescent girls had similar thermoregulatory and perceptual responses while cycling under heat stress during 50 min at a mild (~5,4 W$\cdot$kg^{-1}) intensity level.

1410   Board #218   May 31 8:00 AM - 9:30 AM

Effect Of Dehydration On Cognitive Functions: A Meta-analysis

Melinda Millard-Stafford, FACSM, Matthew T. Wittbrodt. *Georgia Institute of Technology, Atlanta, GA.*
(No relevant relationships reported)

Dehydration (DEH) is believed to impair cognitive functions but which processes (e.g., from executive control to simple reaction time) are affected and at what magnitude of body mass loss (BML) remains unclear. **PURPOSE:** To systematically review the literature and examine factors influencing the effect size (ES) of DEH on cognitive functions via meta-analysis. **METHODS**: Human studies were identified through databases (PubMed, Psych Info, Sport Discus, Scopus, ISI Web of Science, Medline, ProQuest Dissertation & Theses). Thirty-one studies were identified, providing 256 ES estimates from 388 subjects with the magnitude of DEH ranging from 1 to 6% BML. Outcome variables (accuracy, reaction time), cognitive domains, and methods to induce DEH (exercise and/or heat stress and/or fluid restriction) varied. ES were calculated using standardized mean differences and a meta-analysis completed using a random-effects model. **RESULTS**: Impairment on overall cognitive performance (all domains/outcomes) with DEH was small (ES = −0.24; 95% CI [−0.38, −0.10]) but significant (p = 0.002) and due primarily to outcomes based on accuracy (ES = −0.24; [−0.39, −0.10]) versus reaction time (ES = −0.16; [− 0.34, 0.02]), although these two ES were not different (p = 0.47). Indicators of heterogeneity (τ^2 = 0.19, I^2 = 69.9%) reflected moderate to large variation across studies. Cognitive impairment

following DEH was greater ($p = 0.02$) for executive functions (ES $= -0.38$; 95% CI: $[-0.60, -0.17]$) compared to simple/choice reaction times (ES $= -0.02$; $[-0.16, 0.11]$). Based on meta-regression, the magnitude of BML was not associated with impairment of executive functions (slope $= -0.03$, $r^2 = 0.002$, $p = 0.68$). Sub-group estimates of cognitive impairment when %BML was $\leq 2\%$ (ES $= -0.20$; $[-0.40, -0.002]$) versus $> 2\%$ (ES $= -0.30$; $[-0.50, -0.10]$) were not different ($p = 0.38$) based upon 134 and 122 outcomes, respectively. **CONCLUSIONS**: Despite variability among studies, the adverse effect of DEH on human cognition appears to be small to moderate. Tasks requiring executive functions appear more vulnerable to DEH compared to tasks utilizing lower-order cognitive domains, but lacking a dose-response relationship. A minimum threshold of DEH that impairs human cognition was also not evident.

1411   Board #219   May 31 8:00 AM - 9:30 AM

Dehydration is How You Define It: Comparison of 318 Blood and Urine Spot Checks

Tamara Hew-Butler, FACSM, Christopher Eskin, Jordan Bickham, Mario Rusnak, Melissa VanderMeulen. *Oakland University, Rochester, MI.*
(No relevant relationships reported)

Clinical medicine defines dehydration using blood markers which confirm hypertonicity (serum sodium concentration/[Na$^+$] >145mmol/L) and intracellular dehydration. Sports medicine equates dehydration with a concentrated urine as defined by any urine osmolality (UOsm) ≥ 700mOsmol/kgH$_2$O or urine specific gravity (USG) ≥ 1.020. **PURPOSE**: To compare blood versus urine indices of dehydration in a cohort of athletes undergoing routine screenings. **METHODS**: 318 collegiate athletes (193 female) provided blood and urine samples and asked to rate how thirsty they were on a 10-point visual analogue scale. Serum was analyzed for serum [Na$^+$] while urine osmolality was measured using an osmometer. USG was measured using a Chemstrip. Data were categorized into Dehydrated versus Hydrated groupings based upon the above-mentioned UOsm and USG thresholds. **RESULTS**: Athletes from seven sports teams were represented (combined: height 1.75±0.1m; weight 71.9±13.5kg; body mass index 23.2±2.5kg/m^2). Overall, female athletes had lower USG vs. male athletes (1.014±0.006 vs. 1.015±0.006; $p=0.03$). Using the UOsm ≥ 700mOsmol/kgH$_2$O threshold to define dehydration, 55% of athletes were classified as dehydrated. Using any USG ≥ 1.020 to define dehydration, 27% of these same athletes were classified as dehydrated. No athlete met the clinical definition for dehydration (hypertonicity; serum [Na$^+$] >145mmol/L). Normonatremia (serum [Na$^+$] between 135-145mmol/L) was maintained in 99.7% of athletes (mean serum [Na$^+$] 139.9±2.1; range 134-145mmol/L) despite wide variation in UOsm (mean 682.7±302; range 110-1298mOsmol/kgH$_2$O). A significant correlation was confirmed between serum [Na$^+$] versus UOsm ($r=0.18$; $p=0.001$). However, urine concentration at the extreme ranges of dehydration did not reflect clinical abnormalities in serum markers or thirst rating (mean rating 4.4±1.8; range 0-10). **CONCLUSION**: Urine concentration thresholds (commonly used by sports medicine) classified 27-55% of collegiate athletes as dehydrated, while no athlete was dehydrated according to serum [Na$^+$] measurement. Practitioners should caution against using urine indices, as isolated measurements, to diagnose or monitor dehydration because urinary output is largely a response rather than a reflection of physiologically regulated blood tonicity.

Thirst Perception and Fluid Intake are not Affected by Knowledge of Water Losses During Exercise

Catalina Capitán-Jiménez, Luis Fernando Aragón-Vargas, FACSM. *University of Costa Rica, CARTAGO, Costa Rica.*
(Sponsor: Luis Fernando Aragon-Vargas, FACSM)
(No relevant relationships reported)

Thirst perception has been studied as an indicator of acute dehydration during exercise, however, as a perception, it could be affected by the information received about water (sweat) losses. **Purpose:** To identify if thirst perception (TP) can be affected by knowledge of water losses during exercise. **Methods:** 11 males exercised intermittently in the heat on two occasions (30 min bicycle-30 min treadmill, at 70-80%HRmax), to a dehydration of 3.9±0.4% and 3.8±0.4% body mass (BM). TP and heat sensation were measured every 30 minutes during exercise. During session one (S1) they received real information about their water losses; in session two (S2), they received false information about their water losses (60% of their real losses). Information was given every 30 minutes; the order of the sessions was randomly assigned. After finishing the exercise, they ingested water *ad libitum* for 30 minutes. Urine osmolality was measured preexercise, postexercise and at the end of each trial. Data were analyzed using Student's *t* and analysis of variance, as appropriate. **Results:** Preexercise conditions were not statistically different between sessions (Table).

Variable	Real Information (S1)	False Information (S2)	t	p
Body Mass (kg)	76.7±5.2	76.8±5.2	-0.389	0.706
USG (a.u)	1.019±0.07	1.018±0.07	0.135	0.895
Uosm	699.6±256.8	673.5±255.3	0.279	0.786
Thirst perception (mm)	15.09±9.6	22±15.7	-1.38	0.199
WBGT (°C)	28.8±0.1	28.9±0.3	-0.814	0.461

Exercise time was the same (115±22.3 and 110±24.4 min, t=-1.27; $p=0.232$). Thirst perception between sessions was also similar (48.26±2.11 and 51.2±3.81, for S1 and S2, respectively; $f=0.661$; $p=0.447$). Thirst percepton changed significantly over time in both sessions ($f=44.6$; $p= 0.001$), but no interaction ($f=0.382$; $p=0.559$). Power analysis for TP was 79%. Heat sensation showed no differences between sessions (8.14±2.18 and 6.00±0.23, for S1 and S2; $f=0.982$; $p=0.360$) or over time ($f=2.88$; $p=0.140$). Uosm was not different between sessions 659.94±80.59 and 636.09±79.76, for S1 and S2; $f=0.134$; $p=0.722$). Water ingestion was the same between sessions (1220.4±248.6 mL and 1228±421.8 mL; t=-0.66, $p=0.949$). **Conclusion**: these results suggest that thirst perception is not affected by knowledge of water losses during exercise.

Fluid Intake Pattern, Dehydration, And Performance In Young Athletes During A Triathlon In Tropical Climate

Anita M. Rivera-Brown, FACSM[1], José R. Quiñones-González[1], Patricia Pagán-Lasalle[2]. [1]*University of Puerto Rico School of Medicine, San Juan, Puerto Rico.* [2]*Syracuse University, Syracuse, NY.*
(No relevant relationships reported)

Mild dehydration is associated with increased core temperature and reduced performance during endurance events in adult athletes. Little is known about hydration practices, hyperthermia, and the effects of insufficient fluid replacement on performance in young athletes during real-life competitions. **PURPOSE:** Examine voluntary fluid intake, the relation between dehydration and performance, and core temperature in adolescents during a triathlon competition in tropical climate. **METHODS:** 15 junior (14-15 yr) and 21 senior (16-18 yr) athletes competed in a triathlon (750 m swim, 18 km cycle and 4 km run) in a hot and humid environment (WBGT=27.9°C; water temp=29.0°C), in July, between 7:30 to 9:30 am. Urine specific gravity (U$_{SG}$) was measured upon waking the day of competition. Water and sports drinks were carried in bottles on the bike, and available for each athlete in a fluid station during the run. Sweat loss was calculated from change in body weight [BW] (corrected for urine output) and fluid intake. Dehydration was calculated as % change in BW. Core temperature was measured in two athletes pre-competition, and at the end of the swim, cycle, and run portions, using ingestible sensors. **RESULTS:** Mean U$_{SG}$ (1.025 ± 0.001 g/mL) indicated that athletes were not in an adequate state of hydration upon waking. Fluid intake (juniors=471.8 ± 161.4 and seniors=551.3 ± 263.2 ml) replaced 46% of the sweat loss and was higher during run (juniors=10.2 ± 3.5 and seniors=12.3 ± 8.2 ml/min) compared to cycle (juniors=6.1 ± 2.5 and seniors=8.0 ± 3.4 ml/min), $P < 0.05$. At the end of the competition, 26% of juniors and 52% of seniors had dehydrated $\geq 1.5\%$. Dehydration was associated with finishing time in senior boys ($r= -0.70$; $P= 0.01$) who also showed the highest sweat rate (1.3 ± 0.8 L/h) and faster times. Core temperature rose to 40.1°C in the girl who placed 2nd, and to 39.6°C in the boy who placed 3rd. No athletes showed symptoms of heat illness. **CONCLUSIONS:** Young athletes participating in a triathlon in tropical climate show mild to moderate levels of dehydration. Higher dehydration in senior athletes may be due to higher sweat rates and faster racing. Competition organizers should be aware that young, dehydrated athletes may become hyperthermic during triathlons in tropical climate, and should be prepared for medical interventions if needed.

Effects of Hypohydration on Markers of Catabolism in Females Following Resistance Exercise

Joshua J. Gann[1], Thomas L. Andre[2], Brooke L. Roemer[3], Darryn S. Willoughby, FACSM[3]. [1]*University of Louisiana-Monroe, Monroe, LA.* [2]*Clayton St. University, Morrow, GA.* [3]*Baylor University, Waco, TX.*
(No relevant relationships reported)

BACKGROUND: Cortisol is elevated in times of stress and works as an inhibitor of muscle protein synthesis through binding to its glucocorticoid receptor (GR). This GR is expressed throughout the body and regulates the expression of glucocorticoid responsive genes that are involved in catabolic pathways. **PURPOSE:** The purpose of this study was to determine the effects of previous night dehydration on markers of catabolism in resistance-trained females following resistance exercise. **METHODS:** Ten healthy, resistance trained females (age 22.0 ± 2.1 years; height 164.5 ± 5.0 cm; mass 61.9 ± 19.0 kg; body fat 26.7 ± 2.9%) completed two bouts of resistance exercise,

either dehydrated (~3% body weight) (DT) or heat exposed with fluid replacement (HT). Each exercise bout consisted of one rep maximum (1RM) followed by 5 sets to failure of 75% of 1RM for bench press and leg press. Muscle and blood samples were obtained prior to and 1hr following exercise. Blood samples were obtained to examine cortisol. From each muscle sample, glucocorticoid receptor-DNA (GR-DNA) binding and mRNA expression were determined. Data was analyzed with separate 2 (trial) x 2 (time) analysis of variance (ANOVA). Significant interactions were further analyzed with paired t-tests. **RESULTS:** There were no significant interactions between session and time for any markers of mRNA expression. There was no significant interaction or main effects for session and time for serum cortisol. There was a significant main effect for session for GR- DNA binding (p = .043). GR-DNA binding was significantly elevated post exercise for DT (p = .016). **CONCLUSION:** Hypohydration appears to have little effect on proteolytic gene expression even though GR-DNA binding was increased. It is possible that gene expression was suppressed due to participants being resistance-trained. Further research is needed to determine if hypohydration affects proteolytic gene expression in untrained individuals. Theoretically, if an individual were to be chronically hypohydrated, a reduction in resistance training volume and increase in GR-DNA binding could diminish the anabolic response to resistance exercise and potentially lead to muscle atrophy. This study was supported by a doctoral research grant from the National Strength and Conditioning Association.

Factors Influencing Hydration Status during a NCAA Division 1 Soccer Preseason

Yasuki Sekiguchi[1], William M. Adams[2], Ryan M. Curtis[1], Courteney L. Benjamin[1], Douglas J. Casa, FACSM[1]. [1]University of Connecticut, Storrs, CT. [2]University of North Carolina, Greensboro, NC.

(No relevant relationships reported)

PURPOSE: To investigate the role that training and environmental conditions has on fluid balance during a collegiate men's soccer preseason. **METHODS:** Twenty-eight male collegiate soccer players (mean±SE; age, 20±0y; body mass (BM), 79.9±7.6kg; height, 180.9±7.0cm; VO_{2max}, 50.8±4.4ml·kg⁻¹·min⁻¹) participated in this study, which took place during the preseason period of the 2016 NCAA soccer season. Prior to each practice and game (PRE), BM and urine sample were collected to assess hydration status and then donned a heart rate and GPS enabled chest strap to measure training volume and intensity, including session time, total distance (TD), training load score, distance·session time⁻¹, average heart rate, and average speed. Players consumed 500mL of water prior to and following each practice with ad libitum access to water during practice as team customized hydration strategy. Participants provided a post-session (POST) BM to assess percent body mass loss (%BML). Average ambient temperature (T_{AMB}) and relative humidity (RH) were collected using an online environmental-based serve. Stepwise linear regression was used to identify which hydration, training, and environmental variables were predictive of %BML. Repeated measures ANOVA was used to assess changes in PRE-BM, POST-BM, and %BML across the 17-day preseason period. Significance was set a-priori p<0.05. **RESULTS:** TD predicted %BML during preseason training sessions (r²=0.252, p<0.001). When T_{AMB} and RH were added to the model these factors significantly predicted %BML (r²=0.301, p<0.001). PRE-BM, POST-BM, %BML were significantly different over the course of the study (p<0.05). However, %BML never exceeded 2% of BM during any one session and daily variations in BM were <1% from baseline measures. **CONCLUSION:** TD, T_{AMB} and RH were able to predict %BML during the preseason of a collegiate soccer season. The team customized hydration strategy utilized was successful at preventing fluid losses exceeding 2% of BM, which may adversely affect athletic performance. Future work is needed to assess 24-h fluid balance in this population to develop improved hydration strategies.

Pregame Hydration Status of Collegiate Basketball Players on Consecutive Days of Play

Daniel N. Poel, Jason C. Dorman, Elizabeth H. Kasparek, Paul A. Thompson, Thayne A. Munce, FACSM. *Sanford Health, Sioux Falls, SD.* (Sponsor: Dr. Thayne Munce, FACSM)

(No relevant relationships reported)

Collegiate basketball teams typically compete on non-consecutive days, allowing players ample time to recover from fluid loss incurred during a game and return to a euhydrated state before the next contest. However, some NCAA conferences, tournaments and invitationals require play on consecutive days, possibly leading to greater occurrences of hypohydration, which could impair performance and/or increase injury risk. **PURPOSE:** To evaluate pregame hydration status of collegiate basketball players on consecutive days of competition and determine if these measures are associated with game performance. **METHODS:** Twenty-five collegiate basketball players (14 men, 11 women) from a NCAA Division II university participated in this study. Players' urine specific gravity (USG) and body weight (BW) were assessed 1-2 hours prior to the start of 8 pairs of regular season conference games (16 games

total) played on consecutive days (Fri & Sat). Upon arrival to the locker room, each athlete was weighed on a digital scale, wearing similar clothing each time, and provided a urine sample. USG was assessed using a hand-held clinical refractometer. Box score data were used to calculate player efficiency (PE) ratings as measures of in-game statistical performance. **RESULTS:** On Sat, 61.8% of players had a BW deficit (-0.60 ± 0.42 kg) compared to Fri, with 20.2% presenting with a BW deficit ≥ 1%; however, Fri vs. Sat BW differences were not significant (P = 0.693). Overall, 25.2% of players had USG values 1.020-1.024 and 27.0% of players had USG values ≥ 1.025 before their games. Players had USG values ≥ 1.020 more often on Fri (56.2%) than Sat (48.2%), though this difference did not reach statistical significance (P = 0.834). Neither changes in BW (P = 0.659) nor USG (P = 0.854) from Fri to Sat were significantly associated with PE on Sat. **CONCLUSION:** Approximately 50% of players were mildly to severely hypohydrated before the start of each game; yet hypohydration rates were similar before games played on consecutive days. Still, the majority of players had modest BW deficits before games played on the second day, indicating insufficient rehydration from the prior game. Although collegiate basketball players were consistently hypohydrated before their games, hydration status was not associated with statistical performance in these contests.

Bilateral Differences in Muscle Activation Associated with Cycling in Varying Environmental Conditions

Adam R. Jajtner, Brittany N. Followay, Jeremiah A. Vaughan, Eliott Arroyo, Savannah R. Hall, Cody S. Dulaney, Joseph A. Laudato, Ellen L. Glickman, FACSM. *Kent State University, Kent, OH.*

(No relevant relationships reported)

PURPOSE: To examine the influence of ambient temperature on bilateral differences (DIF) in muscle activation. **METHODS**: Five recreationally active men (24.2 ± 2.9 yrs; 1.84 ± 0.06m; 80.0 ± 4.47 kg; 11.7 ± 2.8 %BF, 3.89 ± 0.34 L·min⁻¹) completed four experimental visits: a VO_2max test, and cycling in 5°C (LT), 23°C (MT) and 34°C (HT) in a counterbalanced fashion. Cycling consisted of 60 minutes at 60% of their previously determined VO_2max (TC_{60}), and a time to exhaustion trial at 90% of their VO_2max (TTE). Electromyography (EMG) was monitored on the vastus lateralis of both legs from 0-2min, 8-10min, 18-20min, 28-30min, 38-40min, 48-50min, and 58-60min during TC_{60}, as well as at the initial (PRE), middle (MID) and last (POST) 30-second periods during the TTE. Rectified EMG (RMS) and power spectra analysis (MPF and MedPF) were normalized to a standard 2-min cycling bout at 60% of VO_2max in a thermoneutral condition. DIF between legs were calculated (dominant - non-dominant), and data analyzed via a within-subjects repeated measures ANOVA. **RESULTS**: During CT_{60} a main effect of trial (F = 5.34; $p = 0.034$; $\eta_p^2 = 0.572$) was observed with differences from LT (4.29 ± 6.28%) to MT (-3.79 ± 6.98%; $p = 0.033$) and HT (-7.36 ± 10.76%; $p = 0.033$). During CT_{60}, no interaction was observed for MPF (F = 1.755; $p = 0.227$; $\eta_p^2 = 0.305$). An interaction (F = 2.883; $p = 0.033$; $\eta_p^2 = 0.419$) was observed for MedPF during CT_{60}. No differences were observed across time in LT ($p = 0.597$) or MT ($p = 0.287$), though in HT 48-50min (10.17 ± 7.79%) was different ($p < 0.05$) from 8-10min (-1.91 ± 3.77%), 18-20min (2.40 ± 4.63%), and 28-30min (4.12 ± 2.97%). Additionally, at 8-10min, HT was different from MT (10.61 ± 5.14%; $p = 0.004$). During TTE, no interactions were observed for RMS (F = 0.660; $p = 0.629$; $\eta_p^2 = 0.142$) or MPF (F = 0.840; $p = 0.520$; $\eta_p^2 = 0.174$). An interaction was observed for MedPF (F = 3.808; $p = 0.023$; $\eta_p^2 = 0.488$) during TTE. Post hoc analysis indicated that during the LT trial, DIF was different at MID (-2.63 ± 8.34%) compared to PRE (3.12 ± 8.51%; $p = 0.004$) and POST (2.54 ± 7.77%; $p = 0.004$). **CONCLUSIONS**: During prolonged exercise in cold conditions, there appears to be a greater propensity to activate muscle from the dominant limb. Similarly, as an individual fatigues in a hot condition, it appears the rate of action potential depolarization may increase more in the dominant limb.

Hydration Biomarker and Plasma Copeptin Variability in Response to Partial Rehydration After Exercise-Induced Dehydration

Colleen X. Munoz[1], Evan C. Johnson[2], Laura J. Kunces[3], Amy L. McKenzie[4], Corey Butts[5], Aaron Caldwell[5], Adam Seal[5], Brendon P. McDermott, FACSM[5], Jakob L. Vingren, FACSM[6], James Boyette[6], Colin Melford[7], Abigail Colburn[7], Skylar Wright[7], Ekow Dadzie[7], Virgilio Lopez[7], Lawrence E. Armstrong, FACSM[7], Elaine C. Lee[7]. [1]University of Hartford, West Hartford, CT. [2]University of Wyoming, Laramie, WY. [3]Arla Foods, Viby, Denmark. [4]Virta Health, San Francisco, CA. [5]University of Arkansas, Fayetteville, AR. [6]University of North Texas, Denton, TX. [7]University of Connecticut, Storrs, CT. (Sponsor: Lawrence E. Armstrong, FACSM)

(No relevant relationships reported)

Changes in plasma osmolality (P_{osm}) and arginine vasopressin (AVP)-mediated signaling regulate thirst and drinking behavior. Copeptin is a peptide derivative of the AVP preprohormone and thought to be more stable and measureable than AVP as a biomarker of the hydration process. PURPOSE: This investigation aimed to evaluate hydration biomarkers, including copeptin, responses to exercise-induced dehydration and partial rehydration. METHODS: Fifty-two registrants (mean age: 52y, range: 21-72) in a 161km cycling event under warm and humid environmental conditions (mean = 26°C, 76%RH; maximum = 30°C, 93%RH) participated. P_{osm}, urine specific gravity (U_{sg}), urine color (U_{col}), thirst, and plasma copeptin were measured at 3 time points: before (PRE) and shortly after (POST) the ride, and one hour following a 650mL water bolus at ambient temperature consumed in 6 increments within 3min (POST$_{1h}$). Subjects consumed their typical diet during, but were not permitted to eat or drink between ride completion and the 1h post period. RESULTS: Subjects lost 2.2 ± 1.1% body mass at POST, and all variables significantly increased from PRE to POST (P_{osm} = 295.8 ± 3.9 to 299.1 ± 5.6 mOsm·kg^{-1}; U_{sg} = 1.017 ± 0.005 to 1.021 ± 0.006; U_{col} = 3 ± 1 to 5 ± 2; copeptin = 7.50 ± 4.9 to 42.23 ± 35.74 pmol·L^{-1}; thirst = 3 ± 1 to 5 ± 2; all p < 0.05). At POST$_{1h}$ (body mass = -2.0 ± 1.1%) P_{osm} returned to PRE (294.4 ± 5.7 mOsm·kg^{-1}), while U_{sg} (1.021 ± 0.006), U_{col} (5 ± 2), and thirst (5 ± 2) remained elevated compared to PRE (all p < 0.05). Copeptin remained elevated at POST$_{1h}$ vs. PRE (p < 0.0001) but decreased from POST to POST$_{1h}$ (POST$_{1h}$ = 27.87 ± 28.57 pmol·L^{-1}; p < 0.0001). CONCLUSION: Well-studied hydration biomarkers and the more recent biomarker copeptin tracked exercise-induced dehydration (PRE vs. POST), but differed in response to partial rehydration with a 650mL bolus (POST$_{1h}$): copeptin tracked with partial rehydration, while P_{osm} would indicate adequate and urine markers inadequate fluid replacement occurred. Ongoing work includes analyses of the relationship between food intake during the ride and hydration biomarkers to determine factors that may contribute to change magnitude at POST and differences in biomarker responses at POST$_{1h}$. Fast Rehydration Rate Helps To Keep Positive Body Fluid Balance Longer Time: A Pilot Study

Alejandro Gaytan-Gonzalez[1], Roberto Gabriel Gonzalez-Mendoza[1], Eduardo Pinedo-Ruan[1], Sergio Alejandro Copado-Aguila[1], Jesus Eduardo Gonzalez-Rivera[2], Marisol Villegas-Balcazar[1], Juan R. Lopez-Taylor[1]. [1]Universidad de Guadalajara, Guadalajara, Mexico. [2]Universidad Autónoma de Sinaloa, Culiacán, Mexico.

(No relevant relationships reported)

PURPOSE: To compare the effects of three different post exercise rehydration rates after exercise derived dehydration on body fluid balance and subjective feelings of thirstiness and bloating.
METHODS: We evaluated five male college soccer players. They were weighted before performing a treadmill run to induce a ≈2% body weight loss by sweating. After the dehydration, subjects were rehydrated with 150% of their body weight loss with a carbohydrate electrolyte solution (5% CHO, 30 Na mEq/L). Subjects were assigned to one of three postexercise rehydration rates in a randomized, counterbalanced and crossover design. The postexercise rehydration rates consisted on drinking the whole fluid volume the first 30 minutes in 3 equal doses (H30), or the first 60 minutes in 5 equal doses (H60), or the first 120 minutes in 9 equal doses (H120) after dehydration. Subjects were weighted without clothes (after voiding their bladders and drying the skin with towels) each 30 minutes during a 240 minutes lapse. At the same time they answered a visual analogue scale to answer how thirsty and how bloated they felt at that moment. Results are presented as mean. A two-way repeated measures ANOVA was performed.
RESULTS: Positive fluid balance in H30 was significantly higher than H60 and H120 at minute 30. H30 and H60 were higher than H120 at minute 60. H60 was higher than H120 at minute 90, but H30 was not different vs H60 nor H120. H30 kept a positive

fluid balance for 2 hours, H60 for 1 hour, and H120 for 0.5 hours. Thirstiness was significantly lower in H30 than H120, but not to H60 at minute 30, no other difference was found. Bloating was significantly higher in H30 than H120, but not to H60 at minute 30, no other significant difference was found (Table 1).
CONCLUSIONS: The H30 rehydration rate was effective to keep positive fluid balance for a longer period and to rapidly achieve positive fluid balance and decrease thirstiness acutely, however bloating may be a concern employing this rehydration rate.

Error Analysis of a Commercial Water Planning Tool for Road Race Event Organizers

Kurt J. Sollanek[1], Kelly Fattman[2], Chris Troyanos[2], Samuel N. Cheuvront, FACSM[3]. [1]Sonoma State University, Rohnert Park, CA. [2]Boston Athletic Association, Boston, MA. [3]Sports Science Synergy, LLC, Franklin, MA. (Sponsor: Robert W. Kenefick, Ph.D., FACSM)

Reported Relationships: K.J. Sollanek: *Intellectual Property; Dr. Cheuvront is owner of the intellectual property and copyright related to the Road Race Water Planner app.. Ownership Interest (Stocks, Bonds); Dr. Cheuvront is owner of Sports Science Synergy, LLC and has commercial interests related to sale of RRWP on the AppStore.*

Water planning is an important logistical and risk management concern for event organizers of road races. Until now event organizers have relied upon experience to estimate water needs on race day.
PURPOSE: To compare estimated water needs using a commercial water planning tool against both 1) empirical group water losses of runners and 2) documented event water usage.
METHODS: Group sweating rates (L/h) from 14 published studies were compared to a weighted composite average using the Road Race Water Planner© app (RRWP). Estimated water (gallons) and cup (#) needs were compared to documented usage at a large marathon event. RRWP inputs were air temperature (ºC), race distance (km), numbers of runners and numbers of water stations; outputs were gallons of water, numbers of cups, and both gallons and cups per fluid station. An *a priori* constant error (y-intercept) of less than ± 0.250 L/h per runner was used as an acceptance threshold and evaluated using Deming Regression.
RESULTS: Published studies provided 14 group mean sweating rates from 321 runners for comparison to composite RRWP estimates. Air temperatures ranged from 13.4 to 28.5ºC and running distance from 11.7 to 42.2 km. Constant error was 0.203 L/h with one outlier and 0.053 L/h with outlier removed. The 2017 Boston marathon hosted 27,222 runners on a day averaging 21.5ºC. Water and cup usage was 31,740 gallons and 1,036,003 cups (51.8 cases), respectively. RRWP estimates were 33,505 gallons and 1,072,160 cups (53.6 cases), respectively. The difference in gallons expressed as liters was 0.246 L per person. For a ~4 h marathon, the difference as a rate was 0.062 L/h. The difference in cups was 1.8 cases (3.5% error).
CONCLUSIONS: The results of the RRWP analysis indicate acceptably small error, thus RRWP provides event organizers with a quantitative way to narrow the uncertainties of water planning related to changes in weather, participant numbers, and race distance.

A Comparison of Environmental Heat Stress Response in Professional and Amateur Sports Car Racing Drivers

Samuel C. Barthel, Todd M. Buckingham, David P. Ferguson. *Michigan State University, East Lansing, MI.*

(No relevant relationships reported)

It is hypothesized that heat stress in a race car can impair driving performance. Yet there is little published research on the physiological demands of driving a racing car. **PURPOSE**: The purpose of this investigation was to compare the physiological responses to racing in veteran professional drivers and amateur drivers. **METHODS**: Four male sports car drivers, two professionals (PRO) and two amateurs (AM) participated in seven nationally sanctioned sports car races in the IMSA series. Rate of perceived exertion (RPE) was collected on the Borg scale (scale of 6-20) after their driving stint. Blood lactate was measured both before and after their driving stint. Pre and post nude body weights were collected as a measure of flood loss. **RESULTS**: Over the course of the seven races, there was no significant difference in RPE between the professionals and amateurs. However, there was a significant difference in blood lactate following a driving stint (PRO 4.82mmol/dl ±0.95; AM 5.2 ±0.98 mmol·dl-1 ; P<0.05). There was also significant difference (P=0.03) in fluid loss with the PRO losing 3.05 ±.78 lbs of sweat while the AM lost 4.09 ±0.78 lbs. **CONCLUSIONS**:These findings suggest that the level of racing experience plays a critical role for a driver in the amount of work done in a race car and the associated fluid loss. These factors indicate that AM could become fatigued faster and result in a decrease in driving performance.

Effect of Fatigue and Active Hyperthermia on Proprioception

Khouloud Mtibaa[1], Nidhal Zarrouk[2], Christophe Hautier[3], Sebastien Racinais[2]. [1]*Qatar University, Doha, Qatar.* [2]*Aspetar Orthopaedic and Sports Medicine Hospital, Doha, Qatar.* [3]*University Claude Bernard Lyon 1, Villeurbanne, France.* (Sponsor: Lee Taylor, FACSM)

(No relevant relationships reported)

PURPOSE: Proprioception is of paramount importance for motor control, with any alterations likely to alter sport performance and injury risk. Passive hyperthermia impairs proprioceptive acuity, but the effect of exercise-induced fatigue and active hyperthermia remain unclear. This study sought to determine the effect of a 30-min running time-trial in temperate and hot environments on proprioception. **METHODS:** Post familiarization, 11 trained runners (maximal aerobic velocity range 18 - 21.3 km.h⁻¹) completed two 30-min running time-trials (TT) in temperate (CON, 22ºC) and hot (HOT, 39ºC) conditions on separate days in a counterbalanced manner. Proprioception was evaluated immediately pre- and post-TT by Active Movement Extent Discrimination Apparatus (AMEDA). Thermoregulatory [rectal (Tr) and skin temperature (Tsk)], physiological [heart rate (HR)] and perceptual [thermal comfort (TC)] responses were recorded. Data were compared via a two-way ANOVA for repeated measures. **RESULTS:** Tr, Tsk, HR and TC increased with exercise but reached higher values in HOT compared to CON (see Table 1, p<0.05). The average error for active movement discrimination displayed an interaction effect (p=0.029) with post-hoc analyses revealing that proprioception was impaired by running in HOT (p=0.028) but not in CON (p=0.547). **CONCLUSION:** Exercise-induced fatigue in HOT (but not CON) impaired proprioception and thus active hyperthermia may influence performance and injury risk during dynamic tasks requiring proprioceptive acuity.

Table 1. Thermoregulatory, physiological and perceptual responses				
	COOL	HOT		
	Pre	Post	Pre	Post
Rectal temperature (°C)	37.3 (±0.4)	39.3*(±0.4)	37.4 (±0.3)	39.9*(±0.3)
Skin temperature (°C)	32.2 (±1.1)	33.1*(±1.1)	34.3 (±0.5)	36.1*(±1.0)
HR (bpm)	62.0 (±9.3)	136.2*(±13.7)	64.2 (±13.1)	150.1*(±17.7)
Thermal comfort (/7)	2.6 (±0.9)	4.0*(±0.9)	3.9 (±1.2)	5.6*(±0.8)
Average error (degrees)	0.63 (±0.2)	0.60 (±0.2)	0.57 (±0.1)	0.64*(±0.2)

Whole-body Sweating Rate And Percentage Of Weight Lost By Dehydration In Two Different Volleyball Trainings

Sergio Alejandro Copado-Aguila, Sayra Nataly Muñoz-Rodriguez, Alejandro Gaytan-Gonzalez, Roberto Gabriel Gonzalez-Mendoza, Ix Chel Andalon-Gonzalez, Cesar Alonso Rodarte-Salinas, Angelica Janette Ramirez-Gonzalez, Juan R. Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To compare the whole-body sweating rate and percentage of weight lost by dehydration in two different types of indoor training in male college volleyball players. **METHODS**: 8 male college volleyball players were evaluated from February to March 2017. We calculated the whole-body sweating rate and the percentage of weight lost by dehydration in two different training session [Volleyball training (VO) and Volleyball training plus resistance training (VR)]. To evaluate the whole-body sweating rate, body and sport bottle were weighted before and after training to calculate changes in body mass and fluid intake (subjects were allowed to drink ad libitum during trainings). Subjects had to wear minimal clothing, to dry their skin with towels and to void their bladders before being weighed. Active time of each training was evaluated employing a stopwatch. Results are shown in median, minimum and maximum. **RESULTS**: The active time for VO were 117 min (72 - 135); on the other hand, for VR were 107 min (97 - 126) (p= 0.96). A higher whole-body sweating rate was found from VO (11.8 ml/min, 5.7 - 13.3) than VR (10.1 ml/min, 7.0 - 12.3) but were not significantly different (p= 0.42). Conversely, a lower percentage of weight lost by dehydration was found from VO (0.7, 0.3 - 1.4 %) than VR (0.8, 0.2 - 1.3 %), but again were not significantly different (p=0.69). **CONCLUSIONS**: In this study we found the sweating rate and body weight loss by dehydration were similar despite the training sessions were different. Maybe this happened because the active time was the same. However, it is known that intensity also plays a role in sweating rate, but it wasn't measured here, and therefore, the differences in training intensity may soft the differences in sweating rate and body weight loss despite there were the same active time.

Effects of Aerobic Cycling Exercise in the Heat on Neuromuscular Activation and Fatigue

Ellen L. Glickman, FACSM, Brittany N. Followay, Jeremiah A. Vaughan, Savannah R. Hall, Eliott Arroyo, Cody S. Dulaney, Joseph A. Laudato, Adam R. Jajtner. *Kent State University, Kent, OH.*

(No relevant relationships reported)

Purpose: To examine the effects of heat on neuromuscular activation and fatigue during aerobic cycling exercise. **Methods:** Five recreationally active men (24.8 ± 2.9 years; 183.1 ± 2.2cm; 80.5 ± 4.4kg; 11.3 ± 2.8%BF; 3.97 ± 0.34 L·min⁻¹) visited the laboratory on three separate occasions. Participants completed a VO₂max test on a Velotron cycle ergometer and underwent skinfold assessment. The remaining two visits consisted of cycling for 60 min at 60% of their previously determined VO₂max in either a high-temperature (35°C / 45%RH) (HT), or a moderate-temperature (22°C / 45%) (MT) in a counterbalanced fashion. Electromyography (EMG) of the vastus lateralis of the right leg was recorded during the 60-min exercise protocol during the first two min, and during the last two min of every 10-min period (0-2 min, 8-10 min, 18-20 min, 28-30 min, 38-40 min, 48-50 min, 58-60 min). Raw EMG recordings were normalized to maximal voluntary isometric contractions (MVICs), and analyzed for root mean square (RMS), mean power frequency (MPF) and median power frequency (MEDPF). Data were analyzed using a within-subjects repeated measures ANOVA. **Results:** No significant interaction (F = 0.519; $p = 0.788$) or main effects (Time: F = 2.069; $p = 0.095$; Condition: F = 2.742; $p = 0.173$) were observed for RMS. Additionally, no interaction was observed for MPF (F = 1.310; $p = 0.291$), however, a significant main effect of condition was observed for MPF (F = 15.325; p = 0.017), with a significantly higher MPF in HT (91.27 ± 3.03%) compared to MT ($p = 0.017$; 85.00 ± 3.07%). A significant main effect of time was also observed for MPF (F = 3.282; $p = 0.017$), with a significantly higher MPF at 58-60 min (89.30 ± 2.86%) compared to 8-10 min ($p = 0.039$; 86.34 ± 2.34%). No significant interaction was observed for MEDPF (F = 1.214; $p = 0.333$), though a significant main effect of time was observed (F = 2.841; $p = 0.031$). Pairwise comparisons indicate this difference occurred between 0-2min (82.469 ± 3.098%) and 28-30min ($p = 0.023$; 85.834 ± 2.638%). **Conclusion:** Exercise in the heat resulted in a significantly higher MPF, with an increased MPF towards the end of exercise. These data suggest that heat exposure, as well as continuous aerobic exercise, may elicit an increase in action potential conduction velocity over the vastus lateralis. <!--EndFragment-->

Predicting The Onset Of Sweat During Cycling In Simulated Environments

F. Michael Williams-Bell[1], Garrick Forman[2], Shilpa Dogra[3], Martin Agelin-Chaab[3], Michael W.R. Holmes[2]. [1]*Durham College, Oshawa, ON, Canada.* [2]*Brock University, St. Catharines, ON, Canada.* [3]*University of Ontario Institute of Technology, Oshawa, ON, Canada.*

(No relevant relationships reported)

E-bikes have become a growing alternative to traditional bikes. E-bikes are often used for transportation to and from the workplace, thus, in the initiative to promote adoption, advanced features such as appropriate assistance to eliminate the onset of sweat would be appealing to most users. **PURPOSE:** To provide a starting point for the development of a regression equation that can predict sweat onset. **METHODS:** Ten participants volunteered for this study. Participants committed to 5 experimental cycling sessions that varied by workload and climate. Participants cycled on an indoor bike trainer at 2 power outputs (25W and 75W) and 2 climatic conditions (25ºC @ 60% RH and 30ºC @ 60% RH) until sweating commenced. Physiological measures included: electromyography, heart rate, skin temperature, core temperature, galvanic skin response, and VO_2. **RESULTS:** The average subjective sweat onset time for the 75W condition was less effected by the climatic condition than the 25W condition. The subjective sweat onset times for the 75W condition was 8.53 ± 2.19 minutes and 5.83 ± 1.44 minutes for the low and high temperatures, respectively. The subjective sweat onset times for the 25W condition was 23.52 ± 7.40 minutes and 12.49 ± 7.08 minutes for the low and high temperatures, respectively. A regression equation was developed and is able to predict subjective sweat onset with 61.5% of the variance explained with two measured variables. Workload alone explained 41.5% of the variance for sweat onset determination. When the regression was designed with workload as the outcome instead of sweat onset time, subjective sweat onset time was able to predict wattage with 40.1% of the variance explained. **CONCLUSION:** For the conditions simulated in this study, external temperature had less of an influence on sweat onset times than cycling workload. Sweat onset can be predicted with 61.5% of the variance explained using only two input variables. Heart rate was a poor indicator of sweat onset and simply using power output would be a better starting point. Overall, workload proved to be the most influential variable for predicting sweat onset.

Folic Acid Improves Vascular Function, But Not Skin Blood Flow, In Heart Failure Patients

Bryce N. Balmain[1], Ollie Jay, FACSM[2], Norman R. Morris[1], Amelia J. McFarland[1], Kenji Shiino[1], Glenn M. Stewart[3], Rohan Jayasinghe[4], Jonathan Chan[4], Surendran Sabapathy[1]. [1]*Griffith University, Gold Coast, Australia.* [2]*University of Sydney, Sydney, Australia.* [3]*Mayo Clinic, Rochester, MN.* [4]*Gold Coast University Hospital, Gold Coast, Australia.*

(No relevant relationships reported)

PURPOSE: Heart failure (HF) patients' are limited in their ability to manage a thermal load during exercise secondary to impaired skin blood flow (SkBF). Folic acid has been shown to improve vascular function and accompanying changes in SkBF in healthy older individuals and in those with metabolic and cardiovascular disease. Therefore, we examined the effect of folic acid on vascular function, and SkBF responses during exercise in 10 HF patients and 10 age-matched healthy controls (CON) similar in body size during exercise at a fixed rate of metabolic heat production (Hprod) in a 30°C environment. **METHODS**: Rectal temperature (T_{rec}) and cutaneous vascular conductance (CVC) were measured during 60min of cycle ergometry before (pre) and after (post) a 6 week intervention period where participants ingested 5mg of folic acid, once daily. At these time points (pre- and post-folic acid), vascular function was assessed using flow-mediated dilation (FMD). **RESULTS**: H_{prod} was maintained at the same level for HF (pre: 332 ± 46; post: $337\pm51W$, p=0.84) and CON (pre: 323 ± 31; post: $317\pm40W$, p=0.72), and no differences were observed between groups in both exercise trials (p>0.05). T_{rec} increased to a similar extent for HF (pre: $0.76\pm0.22°C$; post: $0.70\pm0.11°C$, p=0.63) and CON (pre: 0.55 ± 0.27; post: $0.45\pm0.25°C$, p=0.84); however, the rise in T_{rec} was consistently higher in HF during both exercise trials (p<0.05). Similarly, CVC increased to a similar extent for HF (pre: 0.89 ± 0.43; post: $0.83\pm0.45au/mmHg$, p=0.80) and CON (pre: 2.01 ± 0.79; post: $2.03\pm0.72au/mmHg$, p=0.73), but the rise in CVC was consistently lower in HF during both exercise trials (p<0.05). Furthermore, folic acid improved FMD in HF (pre: 3.72 ± 1.16; post: 5.88 ± 1.29, p<0.01); however, no difference was observed in CON (pre-: 5.47 ± 1.98; post: $6.50\pm2.49\%$, p=0.20). **CONCLUSIONS**: Collectively, these findings demonstrate that folic acid supplementation does not serve to enhance SkBF responses and attenuate the rise in core temperature during exercise at a fixed H_{prod} in HF patients. However, folic acid improved vascular function to a greater extent in HF than CON.

Combined Heat Treatment and Exercise Prevents Skeletal Muscle Insulin Resistance in Wistar Rats Fed a High-Fat Diet

JIEXIU ZHAO, FEI QIN, MINXIAO XU, CHAOYI QU, YANAN DONG, ZHONGWEI WANG, ZHINING HAN. *China Institute of Sport Science, Beijing, China.* (Sponsor: Craig Crandall, FACSM)

(No relevant relationships reported)

PURPOSE: Insulin resistance (IR) is associated with many related health complications. Previous studies demonstrate that heat and exercise independently reduce IR. The purpose of this study was to test the hypothesis that combined exercise and heating is even more favorable in reducing IR.
METHODS: Male Wistar rats were randomly divided into five groups: exercise (NE; n=10), heated (HC; n=10), exercise and heated (HE; n=10), sedentary (NC; n=10), and normal diet plus sedentary (CC; n=10). All but the latter group was fed a high-fat diet (60% calories from fat) for 10 weeks while receiving heat and/or exercise exposure for latter 8 weeks. Following this regimen, protein expression from the soleus and extensor digitorum longus muscles, serum, and brown fat were analyzed using Western blotting.
RESULTS: Exercise combined with heating shifted the metabolic characteristics of rats on a high-fat diet toward that observed in the rats on a standard diet. Specifically, eight weeks of combined heat and endurance exercise increased PGC-1α, CnA, CaMKIV and p38 MAPK protein expression in the soleus (P < 0.05), insulin protein expression in the serum (P < 0.05), and UCP1 protein expression in the brown fat (P < 0.05), when compared to the high fat fed sedentary group. There were some significant differences in responses (i.e., body weight and Leptin & Adiponectin concentrations) between the combined exercise and heat group relative to the exercise alone group.
CONCLUSIONS: Exercise combined with heat exposure mitigates the development of IR, presumably from the Irisin pathway. The study provides potential non-pharmaceutical methods for therapeutic treatment of IR.
KEY WORDS: Insulin resistance (IR); Exercise; Heat; Irisin

The Effect of Mild Hypohydration on Performance and Thermoregulation in Male Cyclists: A Blinded Study

J.D. Adams[1], Dylan Scott[2], Natasha Brand[2], Hyun-Gyu Suh[2], Adam D. Seal[2], Brendon P. McDermott, FACSM[2], Matthew S. Ganio, FACSM[2], Stavros A. Kavouras, FACSM[2]. [1]*Mayo Clinic, Rochester, MN.* [2]*University of Arkansas, Fayetteville, AR.* (Sponsor: Stavros A. Kavouras, FACSM)

(No relevant relationships reported)

PURPOSE: The aim of the present study was to examine the effect of mild dehydration on thermoregulation and exercise performance with subjects blinded to their hydration status via intravenous infusion (I.V.).
METHODS: Eleven male cyclists (weight 75.8 ± 6.4 kg, VO_{2peak}: 64.9 ± 5.6 mL·kg·min⁻¹, body fat: $12.0\pm5.8\%$, $Power_{max}$: 409 ± 40 W) performed three sets of criterium-like cycling, consisting of 20 min of steady state cycling at 50% peak power output, each followed by a 5-km time-trial at 3% grade. Subjects completed the protocol, in counter-balanced fashion, on two separate occasions in dry heat (30 °C, 30% rh) either hypohydrated (HYP) or euhydrated (EUH). In both trials, subjects ingested 25 mL every 5 min during the steady-state and 25 mL every 1-km during the 5-km time-trials. In the EUH trial, sweat losses were fully replaced via intravenous infusion of isotonic saline, while in the HYP trial, a sham I.V. was instrumented.
RESULTS: Following the exercise protocol, the subjects dehydrated by $-0.1\pm0.1\%$ and $-1.8\pm0.2\%$ of their body weight for the EUH and HYP trial, respectively. During the second and third time-trials, subjects displayed faster cycling speed in the EUH trial (27.5 ± 3.0 and 27.2 ± 3.1 km·h⁻¹) compared to the HYP trial (26.2 ± 2.9 and 25.5 ± 3.3 km·h⁻¹; both $P<0.05$). Core temperature (T_{re}) was higher in the HYP trial throughout the third steady-state ($P<0.05$) and continued to be higher throughout the third 5-km time-trial ($P<0.05$). Final T_{re} of the third time-trial for HYP and EUH was 39.1 ± 0.3 vs. 38.6 ± 0.6 °C ($P<0.05$).
CONCLUSIONS: These data suggest that full fluid replacement, even in a blinded manner, provided a performance advantage of faster cycling speeds. This benefit seems to be associated with concomitant decreased thermoregulatory strain.

Thermal Behavior During Recovery From Exercise

Nicole T. Vargas[1], Christopher L. Chapman[1], James R. Sackett[1], Jabril Abdul-Rashed[1], Muhamed McBryde[1], Blair D. Johnson[1], Rob Gathercole[2], Zachary J. Schlader[1]. [1]*University at Buffalo, Buffalo, NY.* [2]*lululemon athletica inc., Vancouver, BC.* (Sponsor: Dave Hostler, PhD, FACSM)
(No relevant relationships reported)

During exercise recovery, autonomic thermoeffectors return to pre-exercise levels despite elevations in core temperature. It is unknown if thermal behavior follows a similar trajectory or compensates for elevated core temperature in lieu of autonomic thermoeffector withdrawal. **PURPOSE**: To test the hypothesis that thermal behavior during recovery remains engaged despite autonomic thermoeffector withdrawal. **METHODS**: In a $24 \pm 1°C$, $45 \pm 10\%$ RH environment, 10 subjects (6 females, 22 ± 1 y) cycled for 60 min (225 ± 46 W metabolic heat production), followed by 60 min passive recovery. Weighted mean skin (10 site) and intestinal temperatures, skin blood flow (forearm; laser Doppler), average local sweat rate (upper arm, trunk; ventilated capsule), and weighted mean skin wetness (4 site) were measured continually. Subjects controlled the temperature of their dorsal neck to their perceived thermal comfort using a custom-made fluid filled tubing device. Device temperature provided an index of thermal behavior. Mean body temperature, calculated as the unweighted average of mean skin and intestinal temperatures, provided an index of the stimulus for thermal behavior. To directly determine the effect of prior exercise, post-exercise data were analyzed the minute mean body temperature recovered to pre-exercise levels within a subject. **RESULTS**: Mean body temperature returned to pre-exercise levels 28 ± 20 min into recovery (Pre: 33.5 ± 0.2, Post: $33.5 \pm 0.2°C$, P=0.20). At this point, mean skin temperature had recovered (Pre: 29.6 ± 0.4, Post: $29.5 \pm 0.5°C$, P=0.20), yet intestinal temperature (Pre: 37.3 ± 0.2, Post: $37.5 \pm 0.3°C$, P=0.01) and skin wetness (Pre: 0.2 ± 0.1, Post: 0.3 ± 0.0 a.u., P=0.02) were elevated. Post-exercise, skin blood flow (Pre: 59 ± 78, Post: 26 ± 25 PU, P=0.10) and local sweat rate (Pre: 0.05 ± 0.25, Post: 0.13 ± 0.14 mg/cm^2·min^{-1}, P=0.09) returned to pre-exercise levels, while neck device temperature was depressed (Pre: 27.4 ± 1.1, Post: $21.6 \pm 7.4°C$, P=0.03). **CONCLUSIONS**: Mean body temperature and autonomic thermoeffectors returned to pre-exercise levels, yet thermal behavior was active during recovery. Thermal behavior may compensate for autonomic thermoeffector withdrawal in the presence of elevated intestinal temperature and mean skin wetness post-exercise.

Erk1/2 And Ccr2 Expression In Fit And Unfit Males

Anson M. Blanks, Lauren N. Pedersen, Virginia L. Mihalick, Attiya Shah, R. Lee Franco. *Virginia Commonwealth University, Richmond, VA.*
(No relevant relationships reported)

C-C chemokine receptor 2 (CCR2) is required for monocyte chemotaxis to inflamed areas. Monocytes undergo diapedesis and differentiate into inflammatory M1 or anti-inflammatory M2 macrophages. Skewing of M1/M2 balance toward M1 may lead to sustained inflammation and disease development, including cardiovascular disease (CVD). CCR2 activation increases phosphorylation of extra-cellular regulated kinase 1 and 2 (pERK) which is necessary for M2 polarization but not M1. **PURPOSE:** To evaluate the differences and time course of CCR2 and pERK in fit (FIT) and unfit (UF) males following acute exercise. **METHODS:** 5 FIT (VO2$_{peak}$ $\geq$45ml O$_2$/kg/min) and 5 UF (VO2$_{peak}$ <40ml O$_2$/kg/min) males performed 30 minutes of cycling. Intensity was adjusted to maintain an average blood lactate concentration of 8mM/L. Blood samples were taken pre-exercise, immediately (POST), 1 hour (1H), and 2 hours (2H) post. Cells were fixed and stained using antibodies against CD14, CD16, CCR2, and pERK. Monocytes were defined by CD14 and CD16 using flow cytometry. **RESULTS:** A main effect for pERK (p=0.017) suggested a difference between groups. pERK increased POST in FIT (3113 [PRE] vs. 4116 [POST], p = 0.031). CCR2 was not significantly altered within groups. However, CCR2 was significantly different between groups at POST (12316 [FIT] vs. 3253 [UNFIT], p=0.001) and CCR2 was positively correlated with pERK at POST (R=0.77, p<0.02) and at 1H (R=0.94, p<0.001) with all subjects. **CONCLUSION:** Higher pERK in FIT males may increase monocyte recruitment and differentiation to the M2 macrophage phenotype. This likely helps maintain M1/M2 macrophage balance which may decrease the incidence of CVD.

Alleles Associated with Voluntary Physical Activity are Predicted to be Older Than Anatomically Modern Humans

Ayland C. Letsinger, Alexandra R. Thompson, J Timothy Lightfoot, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: J Timothy Lightfoot, FACSM)
(No relevant relationships reported)

Voluntary physical activity (VPA) has repeatedly been shown to be partially driven by genetics. Understanding the genetic age of the specific genetic mutations associated with VPA control can help facilitate understanding of potential mechanisms underlying genetic control of physical activity level. **PURPOSE:** To determine the estimated allelic age of SNPs associated with VPA in humans. **METHODS:** All human registered SNPs (rs#) found to be associated with VPA to date were cross-referenced with the NHLBI GO ESP's Exome Variant Server to find estimated African-American (AA) and European-American (EA) allelic origin. Allelic origin predictions were published by Fu et al. (Nature, 2012) with estimates based on the Out-of-African model that characterized a bottleneck of non-African populations approximately 51 Kyrs ago and a second bottleneck for European populations 23 Kyrs ago, with accelerated population growth 5.1 Kyrs ago. The VPA-associated SNPs were located in the Fu database and the estimated age of allelic variation represented by that SNP was calculated. **RESULTS:** Only 4 of the 64 SNPs associated with various measurements of physical activity were exonnally-located missense variants. The exon-located SNPs were in the IFNAR2, PPARGC1A, PML, and APOE genes. APOE age was not estimated in the initial allelic origin predictions and thus could not be determined. For the remaining SNPs, average AA estimated allelic age was 584.7 ± 355.1 kyrs and average EA estimated allelic age was 607.6 ± 397.2 kyrs. **CONCLUSIONS:** Exon-located VPA candidate SNPs are older than the hypothesized emergence of anatomically modern humans. The predicted allelic age of these particular SNPs suggests the control of VPA in humans has been conserved throughout modern human evolution.

Aerobic Training Status and Fatty Acid-Induced hTERT mRNA Expression Following Maximal Exercise

Tiffany M. Zuniga, Aaron L. Slusher, Edmund O. Acevedo, FACSM. *Virginia Commonwealth University, Richmond, VA.*
(No relevant relationships reported)

PURPOSE: Telomeres protect the ends of cellular chromosomes from degradation. Although telomere length within immune cells shorten naturally with age, increasing risk of disease and all-cause mortality, physical activity preserves telomere length by increasing mRNA expression of the telomerase component, telomerase reverse transcriptase (hTERT). Therefore, this study examined the influence of aerobic training status on the capacity of peripheral blood mononuclear cells (PBMCs) to express hTERT mRNA following palmitate stimulation.
METHODS: PBMCs were isolated from 12 trained (T) and 11 untrained (UT) subjects pre- and post-maximal exercise, and stimulated with or without palmitate (4 hours) to examine changes in hTERT mRNA expression.
RESULTS: hTERT mRNA expression remained unaltered following palmitate stimulation in T subjects at rest and in response to maximal exercise. To the contrary, palmitate-induced hTERT mRNA expression was elevated at rest relative to unstimulated PBMCs in UT subjects and following maximal exercise was suppressed relative to unstimulated PBMCs and pre-exercise expression levels ($F_{[1, 81]} = 7.874$, $p = 0.006$). In addition, cardiorespiratory fitness (VO2$_{max}$) was negatively associated with the percent change in hTERT mRNA expression in unstimulated PBMCs (r = -0.496, $p = 0.022$) and positively associated with the percent change in hTERT mRNA expression following palmitate stimulation (r = 0.468, $p = 0.032$).
CONCLUSION: This data suggests that aerobic training may preserve the capacity of immune cells to protect against inflammatory-induced telomere shortening following acute physiological stress.

Association Between Actn3 R577x Polymorphism And Weight-lifting Performance In Japanese And Italian Atheltes.

Naoki Kikuchi[1], Myosotis Massidda[2], Tatsuru Miyamae[1], Shunsuke Suzuki[1], Akihiro Inoue[1], Naoyuki Kobatake[1], Daniele Masala[3], Carla M. Calo' CM[2], Koichi Nakazato[1]. *[1]Nippon Sport Science University, Tokyo, Japan. [2]University of Cagliari, Cagliari, Italy. [3]University of Cassino and Southern Latium, Cassino, Italy.*

(No relevant relationships reported)

α-actinin-3 (ACTN3) R577X polymorphism is associated with various aspects of muscular strength and power. **PURPOSE**: To investigate the association between ACTN3 R577X polymorphisms and athletic performance in Japanese and Italian weight-lifting athletes.
METHODS: 128 weight-lifting atheletes (n=114 Japanese; n=14 Italians) and 1323 controls (n=1227 Japanese; n=96 Italians) were included in the analysis. The data were the best crean & jerk and snatch performances obtained by athletes during official competitions. Genotyping results were analyzed using the TaqMan approach for the *ACTN3* (rs1815739) polymorphism.
RESULTS: The genotype frequencies in Japanese and Italian controls were 21%, 48%, 31% and 30%, 58%, 12% for RR, RX, and XX, respectively. There were no significant differences in the ACTN3 R577X genotype frequency distribution between athletes and controls in either Japanese and Italian cohorts. Athletes with RR genotype showed higher records of snatch and crean & jerk than athletes with XX genotype in both Japanese and Italian groups.
CONCLUSIONS: In conclusion, our data indicates an association between that *ACTN3* R577X polymorphism and weight-lifting performance, with carriers of the RR and RX genotypesthat showed higher records in crean & jerk and snatch performance than athletes with XX genotypes in both Japanese and Italian cohorts. Further studies in large cohort are required to confirm the association between genetics and weight-lifting performance

The Interplay between Genes and Psychosocial Home Environment on Leisure-time Physical Activity: a Twin Study

Sari Aaltonen[1], Jaakko Kaprio[1], Urho M. Kujala[2], Lea Pulkkinen[2], Richard J. Rose[3], Karri Silventoinen[1]. *[1]University of Helsinki, Helsinki, Finland. [2]University of Jyväskylä, Jyväskylä, Finland. [3]Indiana University, Bloomington, IN.*

(No relevant relationships reported)

PURPOSE Both genetic and environmental factors contribute to individual differences in physical activity. However, it remains uncertain whether the home environment can modify the effects of genetic factors on physical activity. We examined to what extent the psychosocial home environment in childhood and adolescence modifies the genetic influences on leisure-time physical activity in young adulthood by using Finnish twin data. **METHODS** Families with twins born between 1983 and 1987 took part in the population-based FinnTwin12 study. The psychosocial home environment was assessed by twins at ages 12, 14 and 17, as well as by their parents when the twins were age 12 using an 8-item questionnaire. At age 24, twins assessed their leisure-time physical activity based on a series of structured questions, which were used to calculate leisure-time MET hours per day. Data of 3,305 twins were analyzed using a gene-environment interaction model with OpenMx software. **RESULTS** Parental ratings of positive home atmosphere as well as the twins' ratings of both positive home atmosphere at age 14 and lower relational tensions at ages 12 and 14 predicted higher leisure-time physical activity levels in young adulthood (regression coefficients 0.33-0.64). Parental perceptions as well as the twins' perceptions of positive home atmosphere at ages 14 and 17 increased the additive genetic variation (moderation effects 0.60, 95% CI 0.26-1.05; 0.55, 95% CI 0.29-0.80 and 0.52, 95% CI 0.19-0.87, respectively). The twins' ratings of positive home atmosphere at age 12 and lower relational tensions at ages 12 and 14 increased the unique environmental variation of their subsequent physical activity (moderation effects 0.46, 95% CI 0.19-0.60; 0.48, 95% CI 0.29-0.64 and 0.85, 95% CI 0.12-0.95, respectively). **CONCLUSION** A warm and supportive psychosocial home environment in childhood and adolescence not only increases the level of leisure-time physical activity in young adulthood, but also modifies the variation of genetic and environmental influences on leisure-time physical activity. In terms of clinical implications, it would be important to find ways to help parents create a home environment that is both warm and supportive for their children because it can go a long way toward developing their offspring's interest in physical activity.

The Effect Of Exercise Mode On The Hypothalamic Expression Of Kiss-1and Gpr54 Genes Mrna In Dietinduced Obesity Rats

Yi Yan, Chunyu Liang, Rui XU. *Beijing Sport University, Beijing, China.*

(No relevant relationships reported)

Kisspeptin, a hypothalamic peptide coded by the KiSS1 gene, is a neuromodulator that controls GnRH secretion and is now recognized as a crucial regulator of the onset of puberty.**PURPOSE**: To explore the difference roles of moderate-intensity treadmill training (MIT) and high intensity interval treadmill training (HIIT) in modulating the hypothalamic expression of KiSS-1and the G-protein coupled receptor (GPR) 54 mRNA in the diet induced obesity male rats.
METHODS: After 8 weeks high fat feeding, 24 obesity 11-weeks SD rats were randomly assigned to sedentary (FS, n=8), MIT (n=8) , and HIIT (n=8) groups, 8 normal diet 11-weeks SD rats were assigned as sedentary (SS, n=8) groups. During the following 8 weeks, obesity rats were continued expose to high-fat-diet. MITgroup did the 60%-70%V(•)O$_2$max treadmill training (5 days/week, 1 hour/day). HIIT group did the HIIT training (5 days/week, 1 hour/day),which included 7 minutes warmup (70% V(•)O$_2$max), 6groups formal training(90% V(•)O$_2$max*3min+ 50% V(•)O$_2$max*3min) and 7 minutes recobery (70% V(•)O$_2$max) The V(•)O$_2$ max of exercise groups were remeasured every two weeks. The hypothalamic expression of KiSS-1 and GPR54 mRNA were tested in each group. **RESULTS**: After the first 8-weeks high fat feeding, the obesity rats were heavier than normal diet group (491.74±26.19g vs. 410.05±45.77g, p<0.01). After 8-weeks training, FS group was still heavier than SS group (681±52.56g vs. 574.27±52.43g, p<0.01), and had more hypothalamic expression of KiSS-1 mRNA(1.51±0.66 vs 0.75±0.27, p<0.05) and GPR54 mRNA (2.45±0.38 vs 0.61±0.15, p<0.01). Both MIT and HIIT groups weighted less than FS group, HIIT group had the lightest bodyweight (590.23±35.74g, 558.1±29.57g vs 681±52.56g). Compared with FS group, although both MIT and HIIT groups had lower hypothalamic expression of KiSS-1 mRNA and GPR54 mRNA, HIIT group had the lowest hypothalamic expression of KiSS-1 mRNA (0.47±0.13 vs 0.69±0.13, p<0.01) and GPR54 mRNA(0.58±0.10 vs 0.23±0.06, p<0.01).
CONCLUSIONS: Both MIT and HIIT could reduce the stimulating effect of high-fat diet induced obesity on bodywight and hypothalamic expression of KiSS-1and GPR54 mRNA, and HIIT could play a better role.

Retrocalcaneal Approach Of Ultrasound Guided Tibial Nerve Block: A Preliminary Study

Hongjae Lee. *Ilsanpaik Hosp., Inje Univ, Goyang, Korea, Republic of.*

(No relevant relationships reported)

PURPOSE: Ultrasound guided tibial nerve block has emerged as a valuable tool for various situations related to chronic heel pain. With conventional method the needle is advanced oblique angle from antero-medial side to the Achilles tendon into tarsal tunnel. However, the entire shaft of the needle is difficult to visualize. Besides, as the needle is inserted from the proximal side of posterior tibial artery, extraordinary precaution is required to avoid damage to the artery. In order to complement such shortcomings, a new tibial nerve block method was designed. The purpose of this study was to introduce, and assess the effectiveness and safety of this new approach.
METHODS: The study subjects were patients with chronic plantar heel pain. The needle was inserted from the lateral side of retrocalcaneal space, advancing medially toward tarsal tunnel space beneath the Achilles tendon. This method allowed the transducer to be nearly parallel to the needle axis, making the entire needle to be visualized. After the needle tip was positioned in the tarsal tunnel adjacent to the tibial nerve, anesthetic was injected. Revised Foot Function Index (FFI-R) was used to assess the effectiveness of the nerve block. The FFI-R questionnaire was conducted two times; before and 2 weeks after the procedure. Higher score indicated greater impairment. The safety was assessed by the presence or absence of bleeding, swelling, and inflammation after the procedure. **RESULTS**: Two patients suffering from prolonged plantar fasciitis underwent the retrocalcaneal posterior tibial nerve block. The first patient who had plantar fasciitis showed some improvement after the nerve block; FFI-R score changed from 36 to 27. The second patient who had excessively severe foot pain and activity limitation initially with FFI-R score of 55 showed dramatic improvement after the nerve block; the FFI-R score declined to 36. There were no complications such as bleeding, swelling, or inflammation in both subjects.

CONCLUSIONS: This study has introduced retrocalcaneal approach of ultrasound guided posterior tibial nerve block. It can be as effective as, and even safer than the conventional method because visualization of the entire needle is possible and the needle is advanced from the opposite direction to the posterior tibial artery.

Dynamic Quadriceps Strength are Associated with Self-Reported Disability Following ACL Reconstruction

Steven A. Garcia[1], Tyler J. Moffit[1], Mike N. Vakula[2], Skylar C. Holmes[1], Melissa M. Montgomery[1], Derek N. Pamukoff[1]. *[1]Cal State University Fullerton, Fullerton, CA. [2]Utah State, Logan, UT.* (Sponsor: Daniela A. Rubin, FACSM)
(No relevant relationships reported)

PURPOSE: Quadriceps dysfunction following ACL reconstruction contributes to the development of knee osteoarthritis. Individuals with ACLR express long-term disability that is attributed to quadriceps weakness. The purpose of this study was to (1) compare quadriceps function between individuals with and without ACLR, and (2) determine the relationship between indices of quadriceps function and self-reported disability. **METHODS**: Isometric peak torque (PT; Nm/kg) and rate of torque development (RTD; Nm/kg/s) and isokinetic (180°/sec) quadriceps PT (Nm/kg) were assessed in 46 individuals with ACLR (74% female; age=22.1±2.8 years; height=1.70±0.09m; mass=71.6±15.7kg) and 38 control participants (74% female; age=21.9±1.2 years; height=1.69±0.09m; mass=66.2±11.7kg). Self-reported disability was assessed using the International Knee Documentation Committee (IKDC) instrument. Dependent variables were compared between the involved and uninvolved limbs using paired t-tests, and involved and uninvolved limbs were compared to control limbs using independent t-tests (adjusted α=0.017). Pearson correlation was used to determine the relationship between indices of quadriceps function and IKDC (*a priori* α =0.05). **RESULTS**: Involved limbs had lower isometric PT (2.27±0.55 vs. 2.57±0.73 Nm/kg, p=0.016), RTD (11.7±5.9 vs. 15.3±6.9 Nm/kg/sec, p<0.01) and PT at 180°/s (1.72±0.48 vs. 1.91±0.47 Nm/kg, p<0.01) compared to control limbs. Uninvolved limbs had lower PT (2.29±0.53 vs. 2.57±0.73 Nm/kg, p=0.02), RTD (10.7±5.1 vs. 15.3±6.9 Nm/kg/sec, p<0.001) and PT at 180°/s (1.66±0.41 vs. 1.91±0.47 Nm/kg, p<0.01) compared to control limbs. No differences were found between involved and uninvolved limbs in PT (p=0.43), RTD (p=0.07), or PT at 180°/sec (p=0.16). Greater PT at 180°/sec (r=0.33, p=0.02), and greater RTD100 (r=0.28, p=0.03) were associated with higher IKDC score. Isometric PT was not associated with IKDC (r=0.15, p=0.31). **CONCLUSION**: Bilateral quadriceps weakness was found compared to control participants. Greater isokinetic PT and RTD were associated with higher levels of self-perceived knee joint function while maximal isometric strength was not. Assessment of maximal isometric strength following ACLR may not comprehensively evaluate quadriceps impairment after ACLR.

1438   Board #246   May 31 8:00 AM - 9:30 AM

Response Of Muscle Damage Markers After Acute Heavy Exercise In Different Ovarian Hormone Secretion

Akemi Sawai[1], Risa Mitsuhashi[1], Yuki Warashina[1], Alexander Zaboronok[2], Ryota Sone[1], Noboru Mesaki[1], Hitoshi Shiraki[1], Koichi Watanabe[1]. *[1]Tsukuba University, Tsukuba, Japan. [2]University of Tsukuba Hospital, Tsukuba, Japan.*
(No relevant relationships reported)

PURPOSE To evaluate the response of muscle damage markers to acute heavy resistance exercise in female athletes with different ovarian hormone levels.
METHODS Eleven female college athletes were enrolled. They were divided into 2 groups according to the variations in their ovarian hormone levels: the ovarian-suppression group (OVS) and the cyclic menstruation group (CYC). Measurements were taken under 2 conditions (rest and exercise) over a 3-week period. Measurements in CYC were started after the start of menstruation (week 1). The exercise involved 6 sets of 5 squats at 90% 1-RM with a 3-min rest between each set. During rest, the athletes remained quiet and sat for 30 min. Blood chemicals including serum creatine kinase (CK) and lactate dehydrogenase (LD), Profile of Mood State 2 (POMS2) TMD scores, and muscle soreness evaluated using the 100-mm Visual Analog Scale were measured before, immediately after, 30 min after, 60 min after, and 24 h after each condition.
RESULTS In CYC, week-2 estradiol (E2) levels during exercise were significantly higher than those of weeks 1 and 3 (336.7±104.6 vs 69.5±44.2 and 109.8±28.7 pg/mL). During rest, week-1 E2 levels were significantly lower than those of weeks 2 and 3 (63.2±36.9 vs 116.2±18.1 and 198.8±19.7 pg/mL). In OVS, E2 levels did not differ significantly at any point in the study (weeks 1, 2, and 3: 45±12.1, 66.2±8.8, 59.8±14.2 pg/mL during exercise and 52.2±23.2, 52.0±18.1, 43.0±20.1 pg/mL during rest). CK was significantly higher in week 2 in OVS than in CYC before both conditions (163±12.1 vs 196.1±11.0, 158.4±10.4 vs 201.3±11.4 U/L). LD and TMD scores were significantly higher in OVS than in CYC during rest and before exercise. CK in CYC increased significantly immediately after exercise when compared with its level before

exercise in week 1 (178.3±12.8 vs 218.2±39.7 U/L) and 3 (189.7±8.1 vs 207.0±7.6 U/L). CK in OVS significantly increased immediately and 30 min after exercise when compared with its level before exercise in every week (week 1: before exercise 191.1±114.0 vs immediately after 256.4±11.2 vs 30 min after 239.4±11.5; week 2: 196.3±11.0 vs 244.0±8.1 vs 239.4±13.1; week 3: 199.9±8.8 vs 240.6±5.4 vs 234.0±4.9 U/L).
CONCLUSION Ovarian suppression in athletes may lead to severer muscle damage because of lack of muscle protection by estradiol.

Within-Day Intra- And Interrater Reliability Of Ultrasonographic Measurements Of Acromion-Greater Tuberosity Distance Performed By Novice Testers

Eric Arguello. *University of North Texas Health Science Center, Fort Worth, TX.*
(No relevant relationships reported)

Introduction: The use of musculoskeletal ultrasonographic (US) measurements in Physical Therapy (PT) has recently increased and been reported to assist in the diagnosis of supraspinatus impingement syndrome (SIS). It has been proposed that the acromion-greater tuberosity distance (AGT) measurements with US may be used to determine the efficacy of PT interventions aimed at increasing AGT in patients with SIS. Limited data has been reported on the intrarater and interrater reliability of AGT measurements when performed by novice (limited US training) individuals. **Purpose:** The purpose of this study is to establish the intrarater and interrater reliability of ultrasonographic measurements of the AGT in healthy individuals when performed by novice testers. **Methods:** Participants were 7 males and 13 females (26 years; 21-38 years) with an average BMI of 24.4 (18.9-32). Two PT students took measurements with a portable ultrasound device in brightness mode (B-mode) with an 8-13 MHz linear transducer. Ultrasound images (3) were taken with participants placed in standardized position with transducer placed on lateral surface of the right shoulder aligned with long axis of humerus. AGT was measured using on-screen calipers from the inferolateral edge of the acromion to the nearest margin of the superior aspect of the greater tuberosity. Each participant was then instructed to move out of the standardized position and 3 more images were taken. A second rater repeated the process. The average of the 3 measurements were used for data analysis. Intra- and interrater reliability of measuring AGT was determined by calculating intraclass correlation coefficients (ICC$_{2,3}$) with 95% confidence intervals. **Results:** Intrarater reliability for Rater A: .872 (CI: .683-.949) with AGT distance of 2.17 cm (1.68-2.59 cm). Intrarater reliability for Rater B: .804 (CI: .503-.923) with AGT distance of 2.27 cm (1.94-2.91 cm). Interrater reliability for both raters was .741 (CI: .349-.897). **Conclusions:** This study demonstrates that intrarater and interrater measurements of AGT are very reliable in healthy individuals when performed by novice testers.

Effect Of Cryotherapy To A Muscle Versus A Joint On Functional Performance

Christine Lauber, Jennifer Dudash, Michaela Hoffman, Megan Vandergrift. *University of Indianapolis, Indianapolis, IN.* (Sponsor: Matthew Beekley, FACSM)
(No relevant relationships reported)

Cryotherapy is a common intervention used to treat acute and chronic injuries, and it can be used to facilitate rehabilitation exercises. A common practice in athletic training is allowing a patient to return to activity after the application of some type of cryotherapy. However, the effect of applying cryotherapy to a muscle or a joint on functional performance is unclear. **PURPOSE:** To investigate if cooling a muscle compared to cooling a joint affects functional performance in healthy, active individuals. **Methods:** Forty-five healthy, college student volunteers (21 males; 24 females) with ages ranging from 18 to 23 years ($M = 20.67$; $SD = 1.09$) were randomly assigned to muscle (low leg) cryotherapy, joint (ankle) cryotherapy, or control (no cryotherapy) intervention for 20 minutes. After a 10 minute warm-up, subjects performed practice trials of a shuttle run and single leg vertical jump (SLVJ). Subjects performed three trials of a shuttle run (4 – 6.1 m sprints) for time, and performed three trials of a SLVJ for height measured prior to and immediately following the intervention. A mixed model ANOVA with a Bonferroni Correction was used to determine significant interactions between intervention groups and times with an alpha level of .05 for statistical significance. **RESULTS:** For the SLVJ, there was a significant interaction between the intervention groups and time; $F(2,42)=3.349$, p=0.045; however, group differences were unable to be determined. The muscle intervention group had a significant decrease in jump height between pre- (M=12.24, SD=3.61) and post-test (M=10.89, SD=3.21); p=0.01. For the shuttle run test, there were no significant interactions between group and time; $F(2,42)=0.747$, p=0.480. The joint (pre-M=7.43, SD=0.77; post-M=7.56, SD=0.70); p=0.036, and muscle (pre-M=7.63, SD=0.71; post-M=7.79, SD=0.78); p=0.013 intervention groups had a significant increase in run times between pre- and post-test. **CONCLUSIONS:** Cryotherapy application for 20 minutes to a muscle significantly decreased SLVJ

height and increased shuttle run time, while, cryotherapy application for 20 minutes to a joint significantly increased shuttle run time pre-to post-test. If cryotherapy application is utilized prior to performance, a warm-up should be initiated to prevent a decrease in functional performance.

1441   Board #249   May 31 8:00 AM - 9:30 AM

VO$_2$max Differs Between Those with Chronic Ankle Instability and Healthy Matched Controls

Michael J. Turner, FACSM, Jimmy Joyner, Anyea King, Aregash Theodros, Tricia Hubbard-Turner, FACSM. *UNC Charlotte, Charlotte, NC.*

(No relevant relationships reported)

Previous research has reported decreased physical activity levels in those with Chronic Ankle Instability (CAI). The impact of this decrease in physical activity is known in CAI subjects. **PURPOSE**: To measure VO$_2$max in those with CAI compared to healthy matched controls. **METHODS**: Sixteen subjects participated in the study. Eight subjects with CAI were matched by age (22.4±2.8 yr and 22.3±3.0 yr, respectively), height (165.3±8.5 cm and 167.8±8.2 cm), weight (68.5±8.2 kg and 65.5±8.2 cm) and gender (five females and 3 males / group), to subjects with no history of ankle injury. All subjects reported to the Health Risk Assessment lab for one session. Subjects completed the foot and ankle disability measure (FAAM and FAAM sport) and the NASA physical activity questionnaire. After the preliminary measurements, the subjects performed a treadmill maximal exercise test. Heart rate was monitored by ECG, while oxygen consumption and carbon dioxide production were monitored using standard techniques. Every minute of the test the subjects rated their effort of exertion using the Borg RPE scale (a 6 to 20 scale). For the treadmill test we used a two-minute progressive test until volitional exertion was attained. **RESULTS**: No differences were observed between groups for age (p=0.93), height (p=0.56), and weight (p=0.48). VO$_2$max (ml/kg.min) was significantly different between Injured and Control groups (p=0.0005; 32.5±5.1 and 50.5±10.0, respectively). Time to maximal exercise test completion (p=0.26), maximal RER (p=0.57), and VEmax (p=0.44) were not different between groups. Although maximal HR (p=0.30) and peak RPE (p=0.13) were not different between groups, resting HR was observed to be different between the Injured and Control groups (p=0.0078; 75.2±11.7bpm and 58.9±7.5bpm, respectively). FAAM (p<0.0001), FAAM Sport (p<0.0001) and NASA (p<0.0001) were all observed to indicate differing activity levels between the groups. **CONCLUSIONS**: These findings suggest one's physical fitness level, as assessed by VO$_2$max, and resting HR differs in college-aged subjects with CAI, suggesting the reoccurrence of this musculoskeletal injury at a young age is serious enough to reduce physical activity levels and result in decreased fitness levels.

1442   Board #250   May 31 8:00 AM - 9:30 AM

Reliability of a Smartphone Compass App and Goniometer for Assessing Tibial Rotation Range of Motion

Justin Stanek. *Illinois State University, Normal, IL.* (Sponsor: Kristen Lagally, FACSM)

(No relevant relationships reported)

Rotational motion at the tibia is important for both knee and ankle function. Normative values for tibial rotation vary greatly and the ability to accurately assess this motion lacks reliability and clinical applicability. Increasingly, clinicians are using smartphone apps for assessing ROM. **PURPOSE**: To assess the reliability of a smartphone compass app and goniometer for measuring tibial rotation ROM. Secondarily, to compare average values for the two devices. **METHODS**: Two evaluators used a test-retest study design. Seventeen (11 male, 6 female), healthy subjects (21.0±1.3yrs, 177.2±10.8cm, 82.0±23.3kg) volunteered with a total sample of 31 qualifying limbs. Maximum internal (IR) and external rotation (ER) ROM was assessed in a seated position simultaneously using a smartphone compass app secured to the shank using an armband and with a goniometer secured to the floor. Participants sat on an adjustable stool with the limb in neutral and knee flexed to 90°. Evaluators separately recorded 3 trials of IR and ER from the goniometer and compass app. The average of 3 trials was used for analysis. Interclass correlation coefficients (ICC) were used to assess reliability. Two MANOVAs (2 devices x 2 raters x 2 times) were used to compare IR and ER ROM. **RESULTS**: ICC values from the app ranged from 0.78-0.84 and 0.78-0.88 for the goniometer. No significant differences for rater or time were found for either IR or ER. Significant differences in both IR (p=0.001) and ER (p=0.001) ROM were found between devices. Tibial IR and ER were significantly lower for the smartphone (IR=12.7±5.4°, ER=25.1±8.2°) than the goniometer (IR=39.7±8.4°, ER=43.6±7.7°). **CONCLUSIONS**: While both devices demonstrated excellent reliability, some of the differences in normative values may be attributed to the device used and/or measurement techniques. Reliability values for the smartphone app compared similarly to a previously published study using the Myrin Goniometer®, an expensive, needle-based goniometer that is no longer manufactured or sold. Assessing tibial motion using a compass app is a reliable and efficient way to assess a patient's tibial rotation,

---

although values will vary compared to traditional goniometers. Clinicians must ensure they utilize the same measurement technique and device to accurately track this motion.

Breast Injuries In Female Collegiate Athletes: Prevalence, Type, And Impact On Sport Participation

Laura J. Smith[1], Tamara Eichelberger[2], Edward J. Kane[3]. [1]*University of Michigan Flint, Flint, MI.* [2]*Azusa Pacific University, Azusa, CA.* [3]*University of St. Augustine for Health Sciences, San Marcos, CA.*

(No relevant relationships reported)

In 2015-2016, over 214,000 female athletes competed at the collegiate level in the U.S. The NCAA collects injury data; however, breast related injuries do not have a specific reporting category. The exact sequelae of breast injury is unknown; however, a relationship between breast injury and fat necrosis, which mimics breast carcinoma, is documented outside of sport participation. Breast injuries related to motor vehicle collisions, seatbelt trauma, and blunt trauma have been reported. For these reasons, it is important to investigate female breast injuries in collegiate sports. **PURPOSE:** The objectives of this study are to report the prevalence of self-reported breast injuries in female collegiate athletes, explore injury type and treatment, and investigate breast injury reporting and impact on sports participation. **METHODS:** A cross-sectional study of female collegiate athletes at four U.S. Universities participating in basketball, soccer, softball, or volleyball. The main outcome measure was a questionnaire regarding breast injuries during sport participation. **RESULTS:** Almost half of the 194 participants (47.9%) reported a breast injury during their collegiate career, less than 10% reported their injury to health personnel with 2.1% receiving treatment. Breast injuries reported by sport include softball (59.5%), basketball (48.8%), soccer (46.7%), and volleyball (34.6%). **CONCLUSION:** The long-term effects and sequelae of breast injuries reported by female collegiate athletes during sport play is unknown. Nearly 50% of participants had a breast injury during sport. Although 18.2% indicated that breast injury affected sport participation, only 9.6% of the injuries were reported to medical personnel with 2.1% receiving treatment. From a clinical perspective, this information can be used to heighten the awareness related to female breast injuries and encourage health professionals to create an environment that encourages disclosure of injures that may be perceived as personal or embarrassing to discuss.

Medical Utilisationat a Major Sporting Event- A Descriptive and Epidemiological Analysis.

Vashisht Ramlogan[1], Shammi Ramlackan[1], Alicia Ramtahal[2], Saleem Varachhia[1], Dinesha Gopee[1], Wendell Lai-Hing[2], Felix Calderon[3]. [1]*San Fernando General Hospital, San Fernando, Trinidad and Tobago.* [2]*Amateur Swimming Association of Trinidad and Tobago, Port of Spain, Trinidad and Tobago.* [3]*Central American and Caribbean Amateur Swimming Confederation, Port of Spain, Trinidad and Tobago.*

(No relevant relationships reported)

Objectives
We aimed to measure resource utilisation at the largest international aquatic sporting event in the hemisphere. We also aimed to measure epidemiological data including the type, location, sporting discipline and outcomes of medical contacts during the event.
Methods
This was a prospective observational study conducted under the auspices of the organising committee of the XXX Confederation Centroamericana y del Caribe de Natacion (CCCAN) championships held in Trinidad & Tobago. Anonymised data was collected from event medical contact records, screening and voluntarily reported contacts by team medical staff (for individuals who did not visit event medical staff). We excluded contacts by spectators. Data was collected over a 12 day competition period. Injury incidence rate (IR; number of injuries per 1000 athlete-days) and injury incidence proportion (IP; injuries per 100 athletes) were calculated.
Conclusions
There were 110 medical contacts for the event, with 80 occurring in athletes (72.7%). A significant number of non-sport related contacts was observed (60%) with a high number of complaints related to exhaustion and inadequate hydration. This was independent of country of origin. Acute gastroenteritis, ear and sinus infections were within expected frequencies. No EMS usage was necessary, and hospital transfers were for diagnostics in all cases. There were a total of 54 sport related contacts in 3956 athlete days (IR 13.65 injuries per 1000 athlete-days with an injury incidence

proportion, IP; of 6.5 per 100 athletes). Planning for aquatic events must take into consideration non-sport as well as competition related complaints. This study gives important information on medical utilisation for future event planning.

Injury Reporting in Collegiate Runners

Kristyne Wiegand, Julia Freedman Silvernail. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John Mercer, FACSM)

(No relevant relationships reported)

PURPOSE: It is well-known that runners are commonly injured, yet rates of running injuries reported in the literature vary widely, ranging from 19% to 92%. This discrepancy in reported injury rates may be due to several factors, including injury definition, the timeline used when reporting injuries, and whether the reporting method is self-report or reported by medical professionals. Therefore, the purpose of this study was to compare self-reported injury rates to medically-reported injury rates in a group of Division-I cross country runners. **METHODS**: Questionnaires regarding pain, injury, and training status were completed at the beginning and end of the 2015 and 2016 seasons. Additionally, injury reports were obtained from the team's certified athletic trainer (ATC). Data were coded as 1) self-reported only; 2) ATC-reported only; 3) self-reported and ATC-reported. Only injuries that occurred within the past year were considered in the analysis. **RESULTS**: In 2015, 12 athletes participated, with 38 reported injuries. Of those, 26 were self-reported (68.4%), 6 were ATC-reported (15.8%), and 6 were both self-reported and ATC-reported (15.8%). In 2016, 9 athletes participated, with 22 reported injuries. Of those, 13 were self-reported (59.1%), 8 were ATC-reported (36.4%), and 1 was both self-reported and ATC-reported (4.5%). Additionally, about half of the reported injuries (47% in 2015; 55% in 2016) led to missed or modified training. Of those injuries that led to missed or modified training, the majority (88% in 2015 and 91% in 2016) were self-reported only. **CONCLUSIONS**: The results indicate a marked difference in self-reported injury rates compared with medically-reported injury rates. This demonstrates that the method of reporting injuries may be a contributing factor to the wide range of reported injuries in the literature. Thus, caution should be taken when considering injury rates reported in the literature, as the method of reporting injuries may be influential.

Determining Orthopedic Knee Surgeons' Preference in using Hamstring or Patellar Tendon ACL Grafts

Scott L. Davis, Joel D. Reece. *Brigham Young University Hawaii, Laie, HI.* (Sponsor: Eli Lankford, FACSM)

(No relevant relationships reported)

The decision of which graft to choose for anterior cruciate ligament (ACL) injuries is a current a topic for debate. **PURPOSE:** To determine if athlete status or patient gender influence orthopedic surgeons' graft preference to perform ACL reconstruction (ACLR) surgery. **METHODS:** Human resource representatives of orthopedic hospitals and centers from various locations in the United States were contacted via faxes and emails to distribute access to an electronic survey. Approximately 500 orthopedic knee surgeons were invited to participate in this study through their human resource representative. A total of 31 surgeons completed the survey. Surveys were administered through Qualtircs. The survey included questions regarding preference of graft choice (i.e., Hamstring, Patellar Tendon, Other) for different demographics of patients (i.e., athlete/non-athlete, age, gender) **RESULTS:** Analysis were conducted using IBM SPSS V.23 statistical software. When combining survey responses regarding ACLR graft preference for all age groups (N=614), a one way chi-squared test determined a significant association between the type of group (i.e., Athlete (n=309) and Non-athlete (n=305)) and preference of the graft choice (Hamstring (n=408), Patellar Tendon (n=114), Other (n=92)) for orthopedic surgeons $\chi^2(2) = 261.7, p < .001$. For all age groups combined, orthopedic surgeons strongly preferred Hamstring ACLR for non-athletes (97%, Yes=297). Orthopedic preference of ACLR for athletes was similar between Patellar Tendon (37%, Yes=114) and Hamstring (36%, Yes=111). Another chi-squared analysis concluded no significant association in orthopedic surgeons' preference with type of graft choice for ACLR and patient gender $\chi^2(2) = .013, p= .993$. **CONCLUSION:** Orthopedic Surgeons appear to strongly prefer Hamstring graft ACLR for non-athletes while graft preference for athletes is similar between Patellar Tendon and Hamstring ACLR. Also, patient gender does not appear to play a role when deciding graft preference for ACLR. Future research may identify why these preferences exist between athletes and non-athletes and if surgeon demographics play a role.

Percent Body Fat Differs between those with Chronic Ankle Instability and Healthy Matched Controls

Tricia Hubbard-Turner, FACSM, Jimmy Joyner, Anyea King, Aregash Theodros, Michael Turner, FACSM. *University of North Carolina @ Charlotte, Charlotte, NC.*

(No relevant relationships reported)

Ankle sprains remain one of the most common orthopedic injuries, with a significant percentage of patients developing chronic ankle instability (CAI). The impact CAI has on overall health is unknown. **PURPOSE:** To measure body composition in those with CAI compared to healthy matched controls. **METHODS:** Sixteen subjects participated in the study. Eight subjects with CAI were matched by age (22.4±2.8 yr and 22.3±3.0 yr, respectively), height (165.3±8.5 cm and 167.8±8.2 cm), weight (68.5±8.2 kg and 65.5±8.2 cm) and gender (five females and 3 males / group), to subjects with no history of ankle injury. All subjects reported to the Health Risk Assessment lab for one session. Subjects completed the foot and ankle disability measure (FAAM and FAAM sport) and the NASA physical activity questionnaire. Body composition was measures with DEXA. Subjects laid on the DEXA table supine, arms placed down by their side and fully clothed for approximately 15 minutes while the machine conducted a whole body scan. The following measurements were obtained: lean tissue mass (muscle), total/regional body fat, and bone mineral density. Bone mineral density in the form of AP Spine (5th lumbar vertebrae) and Dual Femoral (left and right pelvic joints). **RESULTS:** No differences were observed between groups for age (p=0.93), height (p=0.56), weight (p=0.48). Percent fat was different between Injured and Control groups (p=0.016; 35.5±6.1% and 25.5±8.3%, respectively). Fat mass was significantly different (p=0.024) while lean mass was found to be similar (p=0.89) between groups. Android:Gynoid was not different (p=0.58), suggestive of no differences in regional fat deposition between groups in college-aged subjects. Total BMD was not significantly different between the Injured and Control groups (p=0.055; 1.23±0.08 and 1.32±0.10, respectively). FAAM (p<0.0001), FAAM Sport (p<0.0001) and NASA (p<0.0001) were all observed to indicate differing activity/functional levels between the groups. **CONCULSIONS:** These findings suggest CAI results in decreased physical activity levels in college-aged subjects that appears to be resulting in increased adiposity, a trend towards altered total bone mineral density, and no changes in lean body mass.

Effects of Instrument Assisted Soft Tissue Mobilization on Biceps Femoris Muscle Architecture

Will C. Hawkins[1], Ryan M. Thiele[2], John P. Vardiman[2], Philip M. Gallagher[3]. [1]*University of Southern Indiana, Evansville, IN.* [2]*Kansas State University, Manhattan, KS.* [3]*University of Kansas, Lawrence, KS.*

(No relevant relationships reported)

Instrument assisted soft tissue mobilization (IASTM) is a popular therapeutic modality that is often used to treat skeletal muscle restriction and injury. The efficacy and mechanism by which IASTM elicits a therapeutic effect is not fully understood. This study was designed to explore if any reported benefits of IASTM stem from changes in skeletal muscle architecture. **PURPOSE:** Examine the effects of IASTM on biceps femoris (BF) ultrasonography (US) baseline measurements of cross sectional area (CSA) and echo intensity (EI) as well as pennation angle (PA) at three different joint positions. Joint positions included 90°, mid- (Mid_{ROM}), and end-range of motion (ROM) (End_{ROM}). **METHODS:** Seventeen female participants (mean±SD: age=21.12±0.78 years) participated in this study. Participants were placed in a prone position for the IASTM treatment and for CSA and EI measures of the BF. Participants were also placed in a supine position, with the right hip and knee joints at 90° of flexion against a horizontal support for PA measurements. PA measurements were recorded at 90°, $Mid_{ROM,}$ and the End_{ROM} joint positions. US settings were enhanced to improve image quality, including gain (50dB), depth (8cm), and frequency (12MHz). For the IASTM protocol, the BF received 3 sets of 7 strokes in both proximal and distal directions at a treatment angle of 45°. Paired samples t-tests [Time (Pre vs Post)] were used to analyze CSA and EI US data. A two-way repeated measures ANOVA [Joint position (90° vs Mid_{ROM} vs End_{ROM}) × Time (Pre vs Post)] was used to analyze PA data. An alpha value of $P \leq 0.05$ was considered statistically significant for all comparisons. **RESULTS:** No significant difference was observed across time for CSA (p=0.220) or EI (p=0.515). Additionally, there was no significant joint position × time interaction (p=0.851) for PA. However, a significant main effect (p=0.001) for joint position was observed. Pairwise comparison revealed significant decreases in PA between 90° and Mid_{ROM} (p=0.038), 90° and End_{ROM} (p=0.001) and Mid_{ROM} and End_{ROM} (p=0.001). **CONCLUSION:** Although PA was altered with the corresponding changes in joint position, this was not a result of IASTM. These results indicate that a single bout of IASTM may not evoke architectural change in the hamstrings as measured by ultrasonography.

Analysis ofUSAWR Wheelmill VO₂ Max Testing Between Classes

Brandon Kane[1], Ellie Moore[1], Kerri Morgan[2], James Rimmer[1].
[1]*Lakeshore Foundation, Birmingham, AL. [2]Washington University, St. Louis, MO.*
(No relevant relationships reported)

PURPOSE: Little is known about how elite level training can affect the Maximum Aerobic Capacity (Max VO₂) testing for all functional classifications of national wheelchair rugby athletes. The primary purpose of this study was to review existing Max VO₂ data between Higher Classification (HC) and Lower Classification (LC) players on the USA Wheelchair Rugby Team (USAWR). **METHODS:** Data was collected during the April training camp (camp1) and August training camp (camp2) at Lakeshore Foundation during the 2017 season. All athletes followed an individualized high intensity workout plan between camp1 and camp2. Athletes (n = 12) had to perform a graded VO₂ max test on a unique Wheelmill ergometer during both camps to be included. Variables tested for significance included absolute VO₂ (aVO₂), relative VO₂ (rVO₂), Respiratory Exchange Ratio (RER), Heart Rate (HR), Ventilatory Equivalent (VE), and Rate of Perceived Exertion (RPE). International Wheelchair Rugby Federation classifications are set by functional ability starting at 0.5 and progress up in 0.5 increments to a max level of 3.5. For this study, classifications were grouped into those whose roles were primarily as a blocker (Class 0.5 – 1.5) and those whose roles were primarily ball handlers (class 2.0 – 3.5). **RESULTS:** Means for the whole team were tested for significant change between camp1 and camp2, and then between HC and LC using 2-tailed T-test (95% confidence interval). Despite whole team mean aVO₂ and mean rVO₂ was not significantly changed, whole team mean VE significantly increased from camp1 to camp2 (64.92 L/min $\pm$ 9.5601, p=0.0146), as did RER (1.0750 $\pm$ 0.0636, p=0.0387). Significant rVO₂ Max changes occurred among LC athletes (17.9300 mL/kg/min $\pm$ 1.1172, p=0.0246) and with aVO₂ Max (1.5000 L/min + 0.0990, p=0.0346), but no significant changes occurred among HC group. **CONCLUSION:** Analysis results showed significant improvements in maximum achieved VE and RER variables between camp1 and camp2 in elite wheelchair rugby athletes. When separated into LC and HC groups, only LC showed significant improvements in rVO₂ and aVO₂. This could indicate that elite USAWR training methods are more effectively improving performance in athletes with lower classifications than in their higher classification counterparts.

Predictors of Health-Related Quality of Life in Patients with Symptomatic Peripheral Arterial Disease

Polly Montgomery, Ming Wang, Cong XU, Andrew Gardner.
Pennsylvania State University, Hershey, PA.
(No relevant relationships reported)

Purpose: To identify predictors of baseline measures of health-related quality of life (HRQoL) in symptomatic patients with peripheral artery disease (PAD) from objective markers of severity of PAD, clinical and demographic characteristics, comorbid conditions, cardiovascular risk factors, objectively measured physical activity, and patient-based measures of physical function. **Methods:** HRQoL measurements of 216 symptomatic men and women with PAD were assessed with the Medical Outcomes Study Short-Form 36 survey. Patients were further characterized on demographic variables, comorbid conditions, cardiovascular risk factors, ankle/brachial index, peak walking time (PWT) during a maximal treadmill test, 6-minute walk distance (6MWD), gait speed, ambulatory activity monitored during one week, activities of daily living (ADL), mini-mental state examination questionnaire, and walking impairment questionnaire (WIQ). **Results:** For the physical function HRQoL subscale, the significant predictors included WIQ speed score (p < 0.001), a history of stumbling (p < 0.001), WIQ stair climbing score (p < 0.001), the ADL associated with bathing (p = 0.001), 6MWD (p = 0.004), and daily walking cadence (p = 0.043). For the role emotional function HRQoL subscale, the significant predictors included a history of stumbling (p < 0.001), the ADL associated with transferring from a bed to a chair (p < 0.001), and the WIQ distance score (p = 0.022). **Conclusions:** Physical and mental subscales of HRQoL in symptomatic patients with PAD are primarily predicted by patient-based physical function, rather than by more specific markers of PAD severity and comorbid conditions. The clinical significance is that interventions designed to improve HRQoL should focus on improving the quality of executing functional tasks

such as walking more steadily without stumbling, completing ADL's that are not specific to walking, such as bathing and transferring, and improving patient-based ability to walk various distances, speeds, and to climb stairs.

Impact of Cardiovascular Disease Diagnosis on All-Cause Mortality Reductions after Cardiac Rehabilitation.

Martijn Maessen[1], Thijs Eijsvogels[1], Esmée Bakker[1], Esther Meindersma[1], Niels van Gorp[2], Nicole Pijnenburg[2], Maria Hopman, FACSM[1]. [1]*Radboudumc, Nijmegen, Netherlands.* [2]*Coöperatie VGZ UA, Arnhem, Netherlands.* (Sponsor: Maria Hopman, FACSM)
(No relevant relationships reported)

Cardiac rehabilitation (CR) is known to reduce the risk for all-cause mortality. However, little is known whether the health benefits of CR differ across different types of cardiac patients.
PURPOSE. To compare the impact of CR participation on all-cause mortality between cardiac patients that were diagnosed with ST elevated MI (STEMI), non-STEMI, unstable angina pectoris (AP), stable AP, chronic heart failure (CHF), and among patients that underwent revascularisations.
METHODS. A Dutch population-based cohort study was performed using insurance claim data from 4 million individuals. Cardiac patients eligible for the study were those with STEMI (*n* 9,071), non-STEMI (*n* 11,611), unstable AP (*n* 12,182), stable AP (*n* 20,594), CHF (*n* 5824), and revascularisation (*n* 1569). Adjusted proportional hazards models (hazard ratio, HR [95%-CI]) were used to assess the efficacy of CR against all-cause mortality. All HR were adjusted for confounding factors, such as age, sex, medication use, and cardio-thoracic surgical intervention.
RESULTS. Among the 60,581 (67±12 yrs; 61.6% males) included patients, 16,598 (64±10 yrs; 71.9 %males) participated in CR. After an average follow-up time of 4 years, 533 CR participants (3.2%) and 4728 non-CR patients (10.8%) died (P<.05). CR patients had a 42% lower all-cause mortality risk compared to non-CR patients (HR$_{adjusted}$ [95%-CI]: 0.52 [0.47-0.57]). We observed similar findings for each type of diagnosis (STEMI, HR: 0.55 [0.44-0.68]; non STEMI, HR: 0.52 [0.44-0.62]; unstable AP, HR: 0.60 [0.47-0.75]; stable AP, HR: 0.63 [0.49-0.80]; CHF, HR: 0.40 [0.26-0.60]; and revascularisation, HR: 0.62 [0.41-0.94]).
CONCLUSION. Participation in cardiac rehabilitation programs lowers the risk of all-cause mortality irrespectively of the initial cardiovascular diagnosis. These findings support the need for improved referral and participation rates of cardiac patients in CR programs.

Mobile phone-based Cardiac Rehabilitation Program Improves Exercise Capacity and Clinical Outcomes in Chinese Revascularized Patients

Jing Ma[1], cheng Ge[1], yajun shi[1], yong xu[1], Chenghui Zhao[1], Chunxue Liu[1], ling Gao[1], Sidney C. Smith[2], Yundai Chen[1]. [1]*department of Cardiology, beijing, China.* [2]*heart and vascular center, Chapel Hill, NC.*
(No relevant relationships reported)

Previous studies have documented a favorable effect of cardiac rehabilitation (CR) on patients undergoing percutaneous coronary intervention (PCI). However, participation in CR is sub-optimal, especially in China. Innovative models of CR are needed to improve participation. **Purpose:** The present study assessed the effect of a mobile phone-based CR (MBCR)program on exercise capacity and clinical outcomes in patients undergoing PCI. **Methods:** Totally 212 patients following PCI referred to the CR clinic of Chinese PLA General Hospital, between Jul, 2015 and Apr, 2016, were divided into 2 groups, to participate in MBCR (n=107) or usual care program (control, n=105). Individualized exercise prescription and educational materials were sent to the participants in the MBCR group by the App named "Heartguard" regularly. Cardiopulmonary exercise testing and questionnarires were measured in 12 months. **Results:** Compared with those in the control group, participants in the MBCR group showed a greater increase in peak exercise capacity (+0.74 vs +0.08 METs,+16.4% vs +4.5%, p=0.000), VO₂ at anaerobic threshold , and dVO₂/dWR, with a greater decrease in VE/VCO₂ slope in 12 months. Range of blood pressure lowering, angina symptoms and life quality in both groups were similar, but the proportion of smoking participants in the MBCR group was lower (1.0% vs 6.3%, p=0.048). More significant lowering of low density lipoprotein, uric acid, as well as homocysteine was also showed in the MBCR group. During a median follow-up of 18 months, a lower incidence of unscheduled target vessel revascularizations , rehospitalizations , worsening angina, and combined endpoint (9/107 vs 23/105, p=0.005), was also found in the MBCR group. Multivariable Cox regression analysis of correlation showed participation in MBCR was associated with a toward decreased clinical events (HR=0.32, p=0.0064) after adjustment for many factors. Subgroup analysis demonstrated that patients with a history of smoking are more likely to benefit from the MBCR program. **Conclusions:**

The MBCR program we studied is associated with better exercise capacity, better control of risk factors, and less adverse cardiovascular events. These findings add support to the application of mobile phone-based CR programs in patients following PCI.

Relationships Between Short Physical performance Battery And Clinical and Laboratory Factors For Cardiovascular Disease Inpatients

Tomohiro Yasuda[1], Toshiaki Nakajima[2], Tatsuya Sawaguchi[2], Naohiro Nozawa[2], Tomoe Arakawa[2], Reiko Takahashi[2], Yuta Mizushima[2], Satoshi Katayanagi[2], Kazuhisa Matsumoto[2], Shigeru Toyoda[2], Teruo Inoue[2]. [1]Seirei Christopher University, Shizuoka, Japan. [2]Dokkyo Medical University Hospital, Tochigi, Japan.
(No relevant relationships reported)

A progression of muscle atrophy (secondary sarcopenia, etc.) in lower extremity function in cardiovascular disease (CVD) inpatients leads to a high need for medical and nursing care. Previous study reported that the Short Physical Performance Battery (SPPB) may be an effective assessment tool for strength and lower extremity morphological evaluation for CVD patients (mixed inpatients and outpatients). However, it is unclear the SPPB can be used to evaluate mobility capability for only CVD inpatients, although which require special attention to nutrition status and body composition. **PURPOSE**: The purpose of this study was to examine if the SPPB can validated assessment tool for strength and lower extremity morphological evaluation and the relationships between the SPPB and clinical and laboratory factors for CVD inpatients. **METHODS**: CVD male (n=318) and female (n=172) inpatients were recruited. A stepwise multiple-regression analysis was performed to predict total SPPB scores and assess variable factors (physical characteristics, functional and morphological assessments, etc.). **RESULTS**: There were significant correlations between knee extensor strength and total SPPB scores for CVD male and female inpatients (both p<0.001). There were significant correlations between mid-thigh MTH and total SPPB scores for CVD male and female inpatients (both p<0.001). To predict total SPPB scores, the predicted handgrip, Controlling Nutritional Status score, % body fat, anterior mid-thigh muscle thickness (MTH), standing height and systolic blood pressure were calculated for males and anterior mid-thigh MTH, BMI, knee extension and fat mass were calculated for females. **CONCLUSIONS**: Total SPPB scores are an effective assessment tool for the functional and morphological evaluation for CVD male and female inpatients. Notably, quadriceps femoris MTH may play an important role in high SPPB scores in CVD in patients regardless of gender.

Knowledge and Perceived Physician Encouragement Toward Exercise in Congenital Heart Disease Patients and Their Sphere

Michaela F. Martinez, Matthew J. Garver. *University of Central Missouri, Warrensburg, MO.*
(No relevant relationships reported)

Background: Congenital heart disease (CHD) affects approximately 1 in 100 babies. Patients with CHD may be dissuaded or discouraged from activities, for reasons including fear of sudden cardiac arrest. **Purpose:** The primary purpose of this study was to examine exercise-related knowledge among patients and the patient's perception of physician encouragement toward exercise. A secondary purpose was to gauge these same variables among the sphere of influence (family and friends). **Methods:** Eligibility was limited to CHD patients and their sphere. Exercise-related knowledge and disease-specific knowledge (Leuven Knowledge Questionnaire) were assessed by questionnaire. **Results:** There were 71 volunteers (age 18-66, 38.7±12.0 yrs). **Patient Focus:** Of the sample, 42 identified as CHD patients (females=36; males=6). For treatment, surgery (n=37) and medication (n=26) were common, but only 10 patients had ever been prescribed a physical intervention. Overall, 38 patients believed that regular aerobic activity would improve heart health and 35 viewed regular weight training as a means to maintain or increase muscular strength. Also, 37 patients believed that regular activity provides a great sense of accomplishment. When asked about physician influence on exercise habits, only 23 patients "agreed" they had been positively influenced, while 12 disagreed. **Sphere Focus:** Of the sample, 29 identified as sphere (female=28; male=1). All 29 believed that regular aerobic activity would improve heart health and 24 viewed regular weight training as a means to maintain or increase muscular strength. Also, 26 of the sphere believed that regular activity provides a great sense of accomplishment. When asked about physician influence on exercise habits, only 16 of the sphere "agreed" that they had been positively influenced, while 1 disagreed. **Discussion:** Certainly, cardiovascular and musculoskeletal health are necessary for all individuals. In particular, support for safe exercise is critical for CHD patients. From our findings, patients and their sphere seem to have a favorable view of exercise and physician encouragement could be improved. **Conclusions:** It would be prudent for educational efforts to become an intentional focus for physicians who are in an authoritative position in patient-care interactions.

Submaximal Oxygen Uptake Efficiency Slope as a Predictor of VO$_2$max in Men with Cardiovascular Disease

Clare M. McDermott, Ciara M. McCormack, Sarah M. Kelly, Andrew McCarren, Kieran M. Moran, Niall M. Moyna. *Dublin City University, Dublin, Ireland.*
(No relevant relationships reported)

Title: Submaximal Oxygen Uptake Efficiency Slope as a Predictor of VO$_2$max in Men with Cardiovascular Disease
Purpose: Although VO$_2$max is considered the gold standard measure of cardiorespiratory fitness, it can be difficult to attain in patients with cardiovascular disease (CVD). The submaximal oxygen uptake efficiency slope (OUES) integrates cardiovascular, musculoskeletal and respiratory function during incremental exercise into a single index and has been proposed as an alternative and effort independent measure of cardiopulmonary reserve (Baba et al., 1996). The purpose of this study was to examine the relation between VO$_2$ peak and both submaximal absolute OUES and relative OUES (OUES/kg).
Methods: A total of 42 men ((mean ± SD) age, 59.9 ± 8.7 yr; VO$_2$peak, 1.9 ± 0.5 L/min and 22.3 ± 6.1 mL/kg/min) were recruited during induction to a community based exercise referral program following completion of a phase 2 cardiac rehabilitation. Participants performed a graded exercise test on a cycle ergometer with breath-by-breath open circuit spirometry and a 12- lead ECG. Absolute OUES and OUES/kg were calculated by plotting VO$_2$ in mL/min on the x-axis, and the log transformed VE on the y-axis (VO$_2$ = a log$_{10}$ VE + b). Exercise data up to the ventilatory anaerobic threshold (VAT) was included in the analysis.
Results: The %VO$_2$ max corresponding to the VAT was 56.0 ± 10.3. Absolute OUES and OUES/kg were 2114 ± 515 and 24.5 ± 5.48, respectively. There was a significant positive correlation between VO$_2$max (L/min) and OUES (r= 0.78; p<0.001) and between VO$_2$max (mL/kg/min) and OUES/kg (r= 0.80; p<0.001).
Conclusion: Determination of VO$_2$max is not often feasible in individuals with CVD where maximal exercise testing is contraindicated or when performance may be impaired by pain, dyspnea or angina. The findings from the present study indicate that the OUES and OUES/kg are significantly related to absolute and relative VO$_2$max, respectively and may be used as a valid submaximal effort independent measure of CRF.
Baba, R. (1996). Oxygen Uptake Efficiency Slope : A New Index of Cardiorespiratory ., Functional Reserve Derived From the Relation Between Oxygen Uptake and Minute Ventilation During Incremental Exercise. *Measurement*, (6).

Unstable Surface Training Is More Effective For Improving Stability Than Walking Training In Stroke Survivors

Younsun Son[1], Eunkyung Park[2], James Johnson[3], Youngsoo Jin[4], Jaehyun Yoo[5]. [1]University of Houston, Houston, TX. [2]University of Texas Rio Grande Valley, McAllen, TX. [3]Baylor College of Medicine, Houston, TX. [4]Konkuk Medical College, Seoul, Korea, Republic of. [5]Sahmyook University, Seoul, Korea, Republic of.
(No relevant relationships reported)

BACKGROUND: Falls are of great concern in the post-stroke population. Balance and gait deficits are major risk factors but may be improved through rehabilitation. However, little research has been done comparing the efficacy of different types of rehabilitation training programs. **PURPOSE:** The purpose of this study was to determine if unstable surface training is more effective than conventional walking training for improving stability among stroke survivors. **METHODS:** Twenty male chronic stroke patients were randomly assigned into two groups, the unstable surface training group (UST; n=10, 53.9 ± 8.3 yrs) and conventional walking training group (CON; n=10, 58.3 ± 12.1 yrs). Participants trained 3 d/wk for 60 min/d for 12 weeks with BOSU half ball (UST) or treadmill (CON). Stability was evaluated using the Biodex balance system. Anterior/Posterior (Sagittal Plane), Medial/Lateral (frontal plane), and overall scores were analyses using ANCOVA. Zones and quadrants were reported with individual data. **RESULTS:** The UST group showed a significant improvement in Anterior/Posterior (1.63 ± 0.42 vs 1.15 ± 0.56, F(1, 17) = 12.62, p=.002), Medial/Lateral (1.3 ± 0.80 vs 0.64 ± 0.30, F(1, 17) = 31.38, p<.001), and overall (2.26 ± 0.81 vs 1.41 ± 0.66, F(1, 17) = 21.25, p<.001) scores whereas the CON group showed no significant improvements. **CONCLUSION:** The unstable surface training of 12-week was effective in significantly improving stability in chronic stroke survivors.

The Role of Ethnicity in Developing Cardiovascular Disease in At-Risk Populations

Nguyen D. Nguyen[1], Cynthia Villalobos[1], Natalie Figueroa[1], Tristan J. Kittinger[1], Paul D. Vosti[2], Courtney D. Jensen[1]. [1]University of the Pacific, Stockton, CA. [2]St. Joseph's Medical Center, Stockton, CA.
(No relevant relationships reported)

In the U.S., cardiovascular disease (CVD) is responsible for 1 in 4 deaths. There are known predictors (e.g., obesity, hypertension, and dyslipidemia) that increase the odds of developing CVD; however, risk is not proportionate among all ethnicities. While Hispanic Americans often display markers of elevated risk, they have longer life expectancies than their non-Hispanic counterparts. Further exploration of this phenomenon is necessary to elucidate how risk engenders disease in different ethnic groups. **PURPOSE:** To evaluate CVD risk factors and the incidence of adverse cardiovascular events among at-risk Hispanic and non-Hispanic adults. **METHODS:** We enrolled 10 Hispanic and 41 non-Hispanic men and women with Type 2 diabetes in a 10-week exercise program. Prior to initiating exercise, we documented demographic data, collected a health history, conducted 7 tests of physical functioning, and measured cardiometabolic variables, including body mass index (BMI), body fat percent (BF%), blood pressure, heart rate, and HBA1C. We repeated all assessments following the intervention. Differences between ethnic groups in baseline values and exercise responses were evaluated with independent-samples t-tests and chi-squared tests. **RESULTS:** Hispanic subjects had fewer diagnoses of hypertension (p=0.002) and no history of heart attack, compared to 25% incidence among non-Hispanics (p=0.077). Hispanic subjects were 8.1 years younger (p=0.032), 40% of them smoked (compared to 0%; p<0.001), and they had better body compositions as measured by BMI (p=0.038), BF% (p=0.021), and categorical obesity (p=0.030). Physical functioning was slightly better among Hispanic subjects as measured by the 6-minute walk (p=0.010) and functional reach (p=0.029). Participants who completed the exercise program experienced improvement in all assessments but grip strength; there were no differences in improvement between ethnic groups. **CONCLUSION:** We found Hispanic and non-Hispanic subjects similarly. Hispanic adults with diabetes had a lower incidence of heart attacks. This may be attributable to observed anthropometric differences; however, if nutritional or behavior customs confer cardio-protective effects in this population, it is important for future researchers to identify those variables.

Sex Influences Changes Over Time In Exercise Ventilatory Dynamics In Patients With Cystic Fibrosis

Matthew A. Tucker, Nichole Siegler, Jacob Looney, Paula Rodriguez-Miguelez, Kathleen T. McKie, Caralee Forseen, Reva H. Crandall, Ryan A. Harris, FACSM. Augusta University, Augusta, GA. (Sponsor: Ryan Harris, FACSM)
(No relevant relationships reported)

Exercise capacity (VO$_2$ peak), an independent predictor of mortality, declines at a substantial rate in patients with cystic fibrosis (CF). Despite a similar rate of decline in VO$_2$ peak between sexes, female patients with CF experience greater mortality compared with their male counterparts. Ventilatory dynamics (VD) during exercise provide important prognostic information in several clinical populations; however, changes over time in exercise VD in CF are not well understood. Moreover, little is known about the influence that sex may have on changes over time in exercise VD in patients with CF. **PURPOSE**: This study sought to test the hypothesis that females with CF have more pronounced decrements in VD over time compared with male patients. **METHODS**: 20 patients with CF (10 female, 10 male) were tested on two visits (V1 and V2) which were separated by a minimum of six months. On each visit, lung function (FEV$_1$, % predicted), exercise capacity (VO$_2$ peak), and VD during exercise (V$_E$/VO$_2$ max, V$_E$/VCO$_2$ max, and V$_E$/VCO$_2$ slope) were determined in all patients. Repeated-measures ANOVA were used to test the influence of sex while controlling for the time between visits and lung function as an index of disease severity. **RESULTS**: Age (15 ± 7 vs. 20 ± 11 y), FEV$_1$ (85.4 ± 16.2 vs. 96.1 ± 20.8 % predicted), VO$_2$ peak (9.4 ± 6.0 vs. 34.1 ± 6.2 ml/min/kg), and the mean time between visits (43 ± 10 vs. 35 ± 20 months) were all similar between female and male patients (all p>0.05), respectively. Significant sex by time interactions were observed such that at V2, female patients exhibited greater increases from V1 in V$_E$/VO$_2$ max (15.4 ± 2.8 vs. 4.5 ± 8.1, p=0.005), V$_E$/VCO$_2$ max (7.6 ± 3.1 vs. 2.1 ± 3.7, p=0.014), and V$_E$/VCO$_2$ slope (4.0 ± 3.4 vs. -0.2 ± 4.1, p=0.036) versus males, respectively. Changes in both VO$_2$ peak (-1.9 ± 3.8 vs. -1.9 ± 5.6 ml/min/kg, p=0.973) and FEV$_1$ (-7.8 ± 8.3 vs. -10.5 ± 9.1 % predicted, p=0.208) between visits were similar between females and males. **CONCLUSIONS**: These data suggest that females with CF have a greater decline in exercise VD over time compared with male patients, albeit similar changes in VO$_2$ peak or lung function over time. Future studies are warranted to examine the potential utility of exercise VD as a prognostic marker in CF.

Antioxidant Supplementation Improves Skeletal Muscle Metabolism During Maximal Exercise In Patients With Cystis Fibrosis

Paula Rodriguez Miguelez, Jacob Looney, Nichole Seigler, Matthew Tucker, Kathleen McKie, Caralee Forseen, Ryan Harris, FACSM. Augusta University, Augusta, GA. (Sponsor: Ryan A. Harris, FACSM)
(No relevant relationships reported)

INTRODUCTION: Patients with cystic fibrosis (CF) exhibit high levels of oxidative stress that contribute to multiple systemic dysfunctions, including exercise intolerance. Antioxidant supplementation has been shown to mitigate oxidative stress and improve exercise intolerance in other populations. Recently, our group has described that patients with CF exhibit impairments in skeletal muscle metabolism that may contribute to exercise intolerance. Whether or not antioxidants can impact muscle metabolism during exercise in patients with CF, however, has yet to be elucidated. **PURPOSE**: This study sought to test the hypothesis that 4 weeks of oral antioxidant supplementation will improve skeletal muscle metabolism during maximal exercise in patients with CF. **METHODS**: Eight patients with CF (25 ± 11 yrs.) completed an incremental exercise test on a cycle ergometer before (Pre) and after 4 weeks of oral supplementation with an antioxidant cocktail (AOC: vitamin C, vitamin E and α- lipoic). Skeletal muscle metabolism was evaluated at rest and during maximal exercise (max) through: (I) O$_2$ extraction (O$_2$Ex) calculated using a derivation of the Fick equation, (II) muscle O$_2$ utilization (HHb), using near-infrared spectroscopy and (III) exercise factor (EF), as the relative contribution of O$_2$ supply to O$_2$ consumption. **RESULTS**: A significant (p=0.039) increase in O$_2$EXmax was observed after 4 weeks of AOC when compared to baseline (Pre: 57 ± 8%, AOC: 64 ± 7%). In addition, HHbmax was significantly (p=0.046) greater (Pre: 0.97 ± 3.4 μM, AOC: 5.9 ± 2.9 μM) and EFmax was significantly (p=0.048) reduced (Pre: 7.1 ± 1.4 AU; AOC: 6.3 ± 1.3 AU) after completing the AOC treatment. No changes in resting skeletal muscle metabolism (p≥0.446) were observed following 4 weeks of supplementation. **CONCLUSIONS**:
For the first time, we have documented that four weeks of AOC supplementation improves skeletal muscle metabolism during maximal exercise in patients with CF. These findings suggest that oxidative stress may be partially involved in the reduced O$_2$ extraction and muscle O$_2$ utilization during exercise observed in patients with CF. Future studies are warranted to investigate the long term effects of antioxidants on muscle metabolism and exercise tolerance in CF. Supported in part by CFFT HARRIS14A0 (RAH).

Qigong exercise for Chronic Obstructive Pulmonary Disease Rehabilitation A Randomized Controlled Trial

Meng Ding[1], Meng Ding[1], Xiangren Yi[2], Xianhai Chen[3], Xiaosheng Dong[1], Mengyao Chao[1], Yong "Tai" Wang, FACSM[4]. [1]Shandong Normal University, Jinan, China. [2]Shandong University, Jinan, China. [3]Affiliated Hospital of Shandong University of Traditional Chinese Medicine, Jinan, China. [4]the University of Texas at Tyler, Tyler, TX. (Sponsor: Yong "Tai" Wang, FACSM)
(No relevant relationships reported)

Purpose: To compare the effects for chronic obstructive pulmonary disease (COPD) between Qigong exercise and the aerobics exercise using cycle ergometer. **Methods**: Twenty-six participants (21 males and 5 females) with COPD were recruited and randomly assigned to either the Qigong group (N=13) or the cycle ergometer group (N=13). Both interventions lasted 12 weeks and comprised of 24 supervised training sessions with 30 min for each session and twice a week. All outcome measures were recorded at baseline and at the end of the study period. The primary outcome was the endurance capacity measured by six minute walk test. The secondary outcome was the St. George's Hospital Respiratory Questionnaire (SGRQ). Paired t-tests were utilized to analyze for within-group comparisons between baseline and after three months. **Results**: The data of ten participants in each group were analyzed due to 3 participants of losing follow up in each group. The six minute walk distance (6MWD) in Qigong group was 530±75.4m at baseline, and 560.9±60.9m after intervention. The 6MWD in cycle ergometer group was 520.6±35.6 and 549.6±26.9 after intervention. The result showed that there were significant differences between before and after intervention in each group (Qigong group t= -2.520, p <0.05, cycle ergometer group t= -3.747 , p <0.05), and was no significant difference between two groups after interventions. The SGRQ score in Qigong group was 27.8±11.8 at baseline and 22.5±8.9 after intervention. The SGRQ score in cycle ergometer group was 34.4±13 at baseline and 23.4±10.4 after intervention. The cycle ergometer group has significant difference between before and after intervention in (t = 2.601, p <0.05), but no significant

difference between two groups after interventions. **Conclusions**: Both Qigong and cycle ergometer should improve the endurance capacity and quality of life of COPD patients through a 12 weeks training.

The Association of Combined Peak Oxygen Consumption and Ventilatory Efficiency with Survival in Hypertrophic Obstructive Cardiomyopathy

Jose R. Medina-Inojosa, Joshua Smith, Veronica Layrisee, Thomas P. Olson, FACSM. *Mayo Clinic Rochester, Rochester, MN.* (Sponsor: Thomas Olson PHD, FACSM)
(No relevant relationships reported)

Introduction: Hypertrophic obstructive cardiomyopathy (HOCM) patients have impaired left ventricular outflow compromising peak oxygen uptake (VO_2). HOCM patients also exhibit reduced ventilatory efficiency (i.e. greater ventilation to carbon dioxide production (V_E/VCO_2) slope). Reduced peak VO_2 and elevated V_E/VCO_2 slope have independently been associated with mortality in these patients; however, it unknown if combining these prognostic indicators will their prognostic value. **Purpose:** To determine if peak VO_2 combined with V_E/VCO_2 slope was associated with survival in HOCM patients. **Methods:** We included all consecutive patients with the diagnosis of HOCM who underwent CPET between the years 1995 to 2016. We created Cox regression models to test the association between VO_2 and V_E/VCO_2 slope with survival and the prognostic value of exercise capacity (EC) defined by the median [peak (VO_2) in mL/Kg/min] to define high and low EC. The V_E/VCO_2 slope cutpoint was defined as ≥ 34. Models were adjusted for factors known to affect both peak VO_2 and survival. **Results:** We included 926 patients (age: 53.4 ±14.1 years, 41% women) over a median follow-up of 5.1 years with 107 patient deaths. Peak VO_2 and V_E/VCO_2 slope predicted survival in HOCM patients (AUC: 0.63, p<0.001 and AUC: 0.66, p<0.001, respectively). Combining peak VO_2 and V_E/VCO_2 improved the prognostic value for survival (AUC: 0.69, p<0.001) beyond that of peak VO_2 and V_E/VCO_2 separately. HOCM patients with a low peak VO_2 and high V_E/VCO_2 slope had a greater risk of death than those with a higher VO_2 and low V_E/VCO_2 slope (HR: 5.51, 95%CI: 2.51-13.93, p<0.001). This relationship remained consistently strong after adjusting for age, sex, body mass index, New York Heart Association Functional Class, hypertension, diabetes, coronary artery disease, and smoking (adjusted HR: 3.73, 95%CI: 1.52-10.18, p=0.007). **Conclusion:** These findings demonstrate that combining peak VO_2 and ventilatory efficiency accurately predicts survival in HOCM patients even after adjustment for traditional risk factors. These results highlight the importance of CPET in HOCM patients.

Does Estimated Cardiorespiratory Fitness Accurately Predict Directly Measured Vo$_{2peak}$ In Breast Cancer Survivors?

Meghan Michalski, Catherine Capaci, Kylie Rowed, Richard Happel, Jessica Scott. *Memorial Sloan Kettering Cancer Center, New York, NY.*
(No relevant relationships reported)

The ACSM walking equation used to estimate maximal aerobic capacity (VO_{2peak}) was developed nearly 4 decades ago and based on relatively few (<100), young (19 to 26 years old) participants. The validity of estimated VO_{2peak} in clinical populations remains uncertain. **PURPOSE:** To compare estimated VO_{2peak} with actual VO_{2peak} derived from maximal treadmill testing in breast cancer survivors. **METHODS:** In the context of a randomized controlled trial, 115 survivors (mean age, 59 ± 7 yr) performed an incremental walking treadmill test to volitional fatigue with gas exchange to determine VO_{2peak}. Estimated VO_{2peak} was calculated using the ACSM walking equation and compared with actual VO_{2peak} by examining the constant error (CE) and correlation coefficient (r). . **RESULTS:** The ACSM equation significantly overestimated VO_{2peak} (CE: 6.3 ± 5.0 ml/kg/min, p<0.001; r: 0.65, p<0.001) . **CONCLUSION:** Alternative estimated VO_{2peak} models should be considered given that low VO2$_{peak}$ is associated with a higher prevalence of acute and chronic treatment-related toxicities, higher symptom burden, and increased risk of all-cause and cancer-specific mortality.

Abnormal Submaximal Cardiopulmonary Exercise Parameters Predicts Impaired Peak Exercise Performance In Sickle Cell Anemia Patients

Adam W. Powell, Tarek Alsaeid, Omar Niss, Robert J. Fleck, James Cnota, Punam Malik, Charles T. Quinn, Wayne A. Mays, Michael D. Taylor, Clifford Chin. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*
(No relevant relationships reported)

Purpose: We recently demonstrated that impaired functional capacity is associated with diastolic dysfunction in sickle cell anemia (SCA) patients. While impaired functional capacity on maximal effort testing is well described in SCA patients, less is known regarding submaximal exercise parameters. Additionally there have been no published studies investigating associations between submaximal exercise parameters and diastolic dysfunction.
Methods: A prospective longitudinal pilot study was performed in SCA patients. All patients had a resting cardiac MRI (cMRI), cardiopulmonary exercise test (CPET) with cycle ergometry using a ramp protocol and an exercise echocardiogram. Exercise data were compared to age, gender and size-matched normal controls.
Results: Compared to normal controls, the SCA group (n=19) had lower peak oxygen consumption (VO2; 1378±412 ml/min vs 2266±638.9, p<0.01), predicted peak oxygen pulse (67±15.9% vs 97±5.3%, p<0.01) and worse ventilatory efficiency (VE/VCO2 slope; 31.7±7 vs 27±4.3, p=0.03). When evaluating the submaximal exercise parameters, there was lower VO2 at the anaerobic threshold (AT; 950±311.7 vs 1497±526.8, p<0.01), oxygen uptake efficiency slope (OUES) at AT (1512±426.2 vs 2140±402.7, p<0.01) and higher VE/VCO2 slope at AT (24±6.6 vs 21±2.8, p=0.04). With the VO2 at respiratory exchange ratio 1.0, 12/19 patients were < -2 standard deviations below the mean with all 12 having a peak VO2 less than 70%. The VO2 at AT correlated with hematocrit (r=0.77, p<0.05). The OUES positively correlated with left ventricular ejection fraction (r=0.55, p=0.01) and left ventricle cardiac output by cMRI (r=0.51, p=0.02), hematocrit (r=0.52, p=0.02), and lateral E/e' (r=-0.54, p=0.01). The VO2 at respiratory exchange ratio 1.0 correlated with right ventricular (r=0.5, p=0.03) and left ventricular cardiac output by cMRI (r=0.47, p=0.04), and lateral E/e' (r=-0.51, p=0.02).
Conclusions: SCA patients have abnormal submaximal exercise measures compared to controls. The degree of submaximal abnormality correlates with the degree of diastolic dysfunction by echocardiography. These data further reinforce the scope of functional cardiovascular abnormalities in SCA.

Considering Cardiorespiratory Fitness Relative to Lean Body Mass in HIV+ compared with HIV- Hispanic Women

Farah A. Ramirez-Marrero, FACSM, Walter Frontera, FACSM, Jorge Santana-Bagur, Valerie Wojna. *University of Puerto Rico, San Juan, Puerto Rico.*
(No relevant relationships reported)

Cardiorespiratory fitness (CRF = VO_2max) is known to significantly influence the risk of morbidity and mortality from chronic diseases. Comparing CRF relative to body weight in different population groups is common. However, CRF relative to lean body mass (LBM) could be more informative due to its energy demanding characteristic; a relevant aspect in people living with debilitating chronic diseases associated with muscle wasting such as HIV infection. **PURPOSE:** To compare absolute VO_2max, and VO_2max relative to body weight and relative to LBM among community dwelling HIV+ and HIV- Hispanic women; and determine the percent VO_2max variance explained by body weight vs. LBM. **METHODS:** Measures of total mass, LBM, fat, and percent fat were conducted with DEXA scanning in a group of 32 HIV+ and 15 HIV- Hispanic women. VO_2max was measured on a cycle ergometer using increments of 25 W every 2-min until volitional fatigue. Independent t-tests were conducted to detect between group differences, and linear regressions to determine the percent variance in CRF explained by body weight and LBM. **RESULTS:** No between group differences were observed for the following variables, age (45.1±10.4 vs. 41.1±14.2 yrs), weight (73.6±15.2 vs. 72.0±12.3 kg), BMI (28.8±5.9 vs. 28.0±6.3 kg/m²), DEXA fat (41.1±7.2 vs. 43.3±4.8 %), DEXA LBM (41.6±5.7 vs. 39.6±6.7 kg), absolute VO_2max (1.40±0.34 vs. 1.53±0.34 L/min), VO_2max relative to body weight (19.3±3.6 vs. 21.4±4.2 ml·kg⁻¹·min⁻¹). However, a lower VO_2max relative to LBM was observed among HIV+ compared with HIV- women (33.4±5.3 vs. 38.6±6.3 ml·kg⁻¹·min⁻¹, P=0.006). Body weight explained 38%, and LBM explained 50% of the variance in CRF. **CONCLUSION:** These results suggest that VO_2max relative to LBM should be considered as the standard for VO_2max comparison, particularly among HIV+ women at risk of experiencing reduced muscle mass.

Impact of Primary Disease Status on Six-Minute Walking Distance.

Ulf G. Bronas, Cynthia Fritschi, Karen Vuckovic, Laurie Quinn, Eileen Collins. *University of Illinois at Chicago, Chicago, IL.*

(No relevant relationships reported)

PURPOSE: The 6-minute walk distance (6MWD) is one the most commonly used outcome assessments of physical function in exercise research. The 6MWD is predictive of health outcomes across many chronic health diseases, however, the impact of health conditions on 6MWD remains unclear; limiting its use as a clinical tool. The purpose of this study was to assess the differences in 6MWD across multiple chronic health conditions in older adults.
METHODS: We assessed the 6MWD in 337 community dwelling older adults (mean age 65 years, 225 males, 158 African American, BMI=29.4), following ATS guidelines. We separated groups by primary disease status [type 2 diabetes only (DM, n=117), moderate/severe chronic obstructive pulmonary disease (COPD, n=119), chronic kidney disease (CKD, n=40), peripheral artery disease (PAD, n=16), and moderate chronic heart failure (HF, n=45)].
RESULTS: The mean 6MWD across groups was 389 (103) meters. By disease, the mean 6MWD was 222 (78) m for HF, 364 (25) m for PAD, 425 (108) m for COPD, 458 (110) m for CKD, 477 (104) m for DM. Normative values of older adults are commonly considered to be 514 meters with the 10th percentile reported at approximately 334-361 meters. Our finding of a mean 6MWD of 389 m suggests low physical functioning status across older adults with chronic disease. Only the HF group met criteria for being in the 10th percentile although the PAD group also showed significant decline in physical function. A 6MWD of less than the 25 percentile (<470 m) is considered low functioning status. Our mean 6MWD was substantially lower than the 25th percentile in all groups except for the DM group.
CONCLUSIONS: We found that the mean 6MWD is lower in patients with HF and PAD, placing these patients at a high risk for loss of ability to conduct activities of daily living and eventually loss of independence, however all groups exhibited reduced physical function. This study highlights the importance of interpreting the 6MWD based on individual health conditions and that generalization based on 6MWD cannot be made without taking individual health conditions into account. Establishing a data register would capture data based on health conditions and enable the 6MWD to be used across disease states in a clinical setting and when prescribing exercise therapy for older adults with chronic disease.

Cardiorespiratory Fitness Is Inversely Associated With Metabolic Syndrome And Clustering Of Metabolic Risk Factors: The Ball State University Adult Physical Fitness Study

Nicole L. Koontz, Mary T. Imboden, Elizabeth P. Kelley, Matthew P. Harber, FACSM, Holmes W. Finch, Leonard A. Kaminsky, FACSM, Mitchell H. Whaley, FACSM. *Ball State University, Muncie, IN.*

(No relevant relationships reported)

The metabolic syndrome (MetSyn) is a high-risk phenotype characterized by the clustering of cardio-metabolic risk factors (RF), including obesity, elevated triglycerides, high density lipoproteins, hypertension, and impaired fasting glucose. Cardiorespiratory fitness (CRF) has been associated with metabolic RF clustering and the presence of MetSyn. Most studies assessing this relationship have estimated CRF, which is associated with estimation error up to 40%, with only few studies using directly measured CRF assessed from cardiopulmonary exercise testing (CPX). However, these studies were small in size and predominately assessed men; therefore more information from studies using CPX derived CRF in both sexes may aid in the risk assessment for MetSyn and guide clinical decisions. **Purpose:** To assess the association between directly measured CRF and MetSyn RF clustering. **Methods**: A retrospective cross-sectional analysis was performed on 3,636 self-referred men and women who completed a health assessment including a CPX between 1969-2017. Inclusion criteria consisted of being ≥ 18 years of age, attainment of a respiratory exchange ratio ≥1.0 during CPX, and complete data on MetSyn RFs. Sequential regression models were run to assess the relationship between CRF and MetSyn and a univariate analysis of variance was performed to assess differences between number of MetSyn RF present and CRF. **Results**: Individuals with MetSyn (n=953) had a mean CRF 8.8 ml/kg/min lower than those without the syndrome (n=2683). Number of RFs was inversely related to CRF; CRF was significantly lower (p<0.05) with each additional RF. There was also a negative relationship (p<0.001) between CRF quartile and the likelihood of having MetSyn. Each quartile increment was associated with a 50% relative reduction in likelihood of MetSyn (p<0.001). **Conclusion**: These findings with CPX measured CRF suggest that higher levels may confer resistance to developing metabolic RFs, which could prevent MetSyn, and ultimately decrease cardiovascular disease risk. Further, the inverse, graded relationship between CRF and

number of MetSyn RFs has public health importance, as adoption of an endurance training program may increase CRF, and therefore should be promoted as an approach to improve health and decrease MetSyn risk.

Physical Activity Patterns And Cardiorespiratory Fitness In Men With Cardiovascular Disease

Ciara M. McCormack, Clare M. McDermott, Sarah M. Kelly, Andrew McCarren, Kiernan M. Moran, Niall M. Moyna. *Dublin City University, Dublin, Ireland.*

(No relevant relationships reported)

PURPOSE: Cardiorespiratory fitness (CRF) is generally regarded as an objective and reproducible measure of recent habitual physical activity (PA). Considering that the majority of daily PA is performed at light intensity, it is likely that CRF benefits will be detected at submaximal rather than maximal exercise. The purpose of this study was to evaluate daily minutes of light (LIPA), moderate (MIPA) and vigorous (VIPA) intensity physical activity among men with cardiovascular disease (CVD), and to determine the relation between PA and submaximal (oxygen uptake efficiency slope (OUES)) and maximal (VO_2 peak) indices of CRF.
METHODS: A total 32 male participants (mean (± SD): age of 60.0 ± 8.7 yr, VO_2 peak, 2.0 ± 0.45 L/min and 23.3 ± 5.7 mL/kg/min) were recruited during an induction to a community based exercise referral program following completion of phase 2 cardiac rehabilitation. Participants underwent a graded exercise test on a cycle ergometer with breath by breath open circuit spirometry after which they wore a wrist worn accelerometer (Actigraph) for 7 d. Absolute and relative submaximal OUES were calculated by plotting VO_2 in mL/min on the x axis, and the log transformed VE on the y axis ($VO_2 = a \log_{10} VE + b$). Exercise data up to the ventilatory anaerobic threshold was included in the analysis.
RESULTS: Participants performed 589.05 ± 69.41 min of daily LIPA, 161.38 ± 66.16 min of MIPA and no daily min of VIPA. There was no significant relation between peak VO_2 and either LIPA or MIPA. There was a significant correlation between submaximal OUES (r=0.44; p<0.01) and LIPA. The relation between submaximal OUES/kg and LIPA min almost reached statistical significance (r=0.33; p<0.07). There was no significant relation between MIPA and OUES or OUES/kg.
CONCLUSIONS: Men with CVD spend the majority (78%) of their day performing LIPA. OUES, a submaximal measure of CRF was related to LIPA whereas no relation was found between VO_2 peak and LIPA.

Firefighters and Physical Function: Should There Be Annual Testing?

Hyosung Han, Alexis C. King, J. Mark VanNess, Cynthia Villalobos, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*

(No relevant relationships reported)

There are more than a million actively employed firefighters in the United States. To qualify as a firefighter, one must pass the Candidate Physical Ability Test (CPAT), a vigorous assessment of strength and endurance. Following the CPAT, there is no national or state mandate to evaluate fitness or uphold a standard of minimum physical competency. Although strength, endurance, and mobility are critical to job performance, data concerning the preservation of function throughout a firefighter's career are scarce. **PURPOSE:** To evaluate the physical functioning of firefighters.
METHODS: We enrolled 35 firefighters in California, collected demographic data, and performed a battery of tests, which included anthropometric assessments, grip strength, sit-and-reach, shoulder flexibility, vertical jump, push-ups, curl-ups, and VO_2 max. We compared mean data to normative data and used multiple linear regression to test the effect of age on physical functioning, holding potential confounders constant.
RESULTS: On average, firefighters were 33.5 ± 11.8 years of age and performed 23.9 ± 3.1 curl-ups, 32.2 ± 12.3 push-ups, had a vertical jump of 59.6 ± 10.4 cm, mean L/R grip strength of 66.0 ± 12.9 kg, sit-and-reach of 5.2 ± 9.1 cm, shoulder flexibility of 20.2 ± 6.8 cm, and VO_2 max of 40.1 ± 10.8 ml/kg/min. Compared to normative data, the mean firefighter had excellent grip strength, excellent push-ups, above average vertical jump, average shoulder flexibility, below average curl-ups, poor sit-and-reach, and poor VO_2 max; 94.1% of firefighters were classified as poor in sit-and-reach and 58.1% were classified as poor or very poor in VO_2 max. Linear regression did not find age to be a significant predictor of sit-and-reach (p=0.167) or VO_2 max (p=0.319) holding other significant predictors constant. **CONCLUSION:** In general, firefighters performed competently in assessments of strength, but poorly in flexibility and aerobic capacity. Age was not a significant predictor of performance in either assessment; the implication is that duration spent as a firefighter is not related to functional decline. There may not be a need for firefighters to complete periodic CPAT assessments, but they should be encouraged to improve capacities of endurance and flexibility.

Comparison of Six-minute Walk Test VO$_{2peak}$ Prediction Equations in Cardiac Rehabilitation Patients

Lucas K. Shrum[1], Jason D. Wagganer[1], William M. Miller[2], Majid M. Syed-Abdul[3], Dhwani S. Soni[1], Beverly J. Hoover[4], Mary McCrate[4], Beverly Kester[4], Duc T. Nguyen[4], Thomas J. Pujol, FACSM[1]. [1]*Southeast Missouri State University, Cape Girardeau, MO.* [2]*University of Mississippi, Oxford, MS.* [3]*University of Missouri-Columbia, Columbia, MO.* [4]*Saint Francis Medical Center, Cape Girardeau, MO.* (Sponsor: Thomas Joe Pujol, FACSM)
(No relevant relationships reported)

The six-minute walk test (6MWT) is a popular submaximal exercise test used in cardiac rehabilitation (CR) programs. Patients in CR characteristically have several cardiovascular risk factors present; therefore, the selection of the 6MWT over maximal treadmill testing reduces the likelihood of adverse events. Several established prediction equations exist for predicting VO$_{2peak}$ from six-minute walk speed (6MWS) and/or distance (6MWD). **PURPOSE:** To compare the predicted VO$_{2peak}$ values, calculated from 6MWS, obtained from CR patients using established equations. **METHODS:** Seventeen volunteers (age = 64 ± 16 yr) completed a pre- and post-6MWT prior to a High-intensity Interval Training (n = 6) or moderate intensity continuous exercise (n = 11) program. The Burr et al. (2011), Cahalin et al. (1996), and Ross et al. (2010) VO$_{2peak}$ prediction equations were examined for validity and reliability. A repeated measures analysis of variance (ANOVA), with subsequent paired sample t-tests, was conducted to compare differences within and between 6MWT the VO$_{2peak}$ prediction equations. A 3 x 2 mixed-design ANOVA was performed to examine the effects across VO$_{2peak}$ and time (pre- and post-). **RESULTS:** The repeated measures ANOVA revealed statistical significance within pre- [$F(2,32) = 121.40, p \leq (0.001)$] and post-program VO$_{2peak}$ values [$F(2,32) = 78.24, p \leq (0.001)$]. Sequential paired sample t-tests showed a significant difference between the three equations for both pre- and post-program VO$_{2peak}$ values (df = 16, $p \leq 0.001$). The 3 x 2 mixed-design ANOVA observed no significant differences in VO$_{2peak}$ values across the two time points. **CONCLUSION:** The three prediction equations demonstrated reliability pre- and post-programming. However, insufficient literature exists comparing the validity and reliability of VO$_{2peak}$ prediction equations. Future research should increase the sample size and consider the use of criterion measurement system (i.e., wearable metabolic system which can measure gas exchange).

Fat Mass, and Not Heart Rate Recovery is Associated With Cardiorespiratory Fitness in Young, Sedentary Adults

J. Matthew Thomas, Julie S. Pendergast, W. Scott Black, Philip A. Kern, Jody L. Clasey, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: Jody L. Clasey, FACSM)
(No relevant relationships reported)

Peak oxygen uptake resulting from maximal graded exercise testing is considered a measure of cardiorespiratory fitness. Post-exercise heart rate recovery (HRRec) measures have been used as a clinical indicator of health and mortality in older adults. However, the relationship between HRRec and cardiorespiratory fitness in young, sedentary adults has not been fully elucidated. **PURPOSE:** To examine the association between peak oxygen uptake (VO$_2$; ml·kg^{-1}·min^{-1}) and HRRec responses following a progressive maximal graded exercise test (MaxGXT; treadmill); and body composition measures in young, sedentary adults. **METHODS:** We examined peak VO$_2$ and absolute (AbsHRRec; beats·min^{-1}) and relative (RelHRRec; %) HRRec measures at 1, 3, and 5 mins post MaxGXT in 27 young (mean ± SD, age = 26.4 ± 5.7) adults (16 females). All subjects were sedentary (< 2hrs weekly structured exercise), non-smokers, free of known cardiovascular disease risk and medications. Body composition measures including fat mass (kg), fat-free mass (FFM; kg), mineral-free lean mass (MFLM; kg), and percentage body fat (%Fat; %) were determined by total body DXA scans. Pearson's correlation analysis was used to determine if significant (p < 0.05) correlations were observed between peak VO$_2$, AbsHRRec and RelHRRec, and body composition measures. **RESULTS:** No significant correlations were observed between peak VO$_2$ (36.4 ± 9.0) and AbsHRRec at 1 min (30.4 ± 7.8; r = 0.29), 3 mins (62.6 ± 8.6; r = -0.06) or 5 mins (71.1 ± 9.8; r = -0.07). Similarly, there were no significant correlations between peak VO2 and RelHRRec at 1 min (84.1 ± 4.3; r = -0.18), 3 min (67.3 ± 4.9; r = 0.20) or 5 min (62.9 ± 5.3; r = 0.21). Peak VO$_2$ was significantly correlated with %Fat (35.1 ± 9.3; r = -0.82; p<.001) and fat mass (27.8 ± 11.9; r = -0.66; p<.001), but not significantly correlated with FFM (49.7 ± 14.0; r = 0.22) or MFLM (47.0 ± 13.4; r = 0.22). **CONCLUSION:** Although heart rate recovery measures have been used as a clinical indicator of health and mortality in older adults, it may not be a valid measure of cardiorespiratory fitness in sedentary, young adults.

1471   Board #279   May 31 9:00 AM - 10:30 AM

Aerobic Exercise Capacity In Mild-to-moderate Chronic Kidney Disease Is Maintained Over A 5 Year-period

Helena Wallin[1], Anette Rickenlund[1], Maria E. Eriksson[2], Eva Jansson[1], Carin Wallquist[2], Britta Hylander Rössner[2], Stefan Jacobsson[3]. [1]*Karolinska Institutet, Huddinge, Sweden.* [2]*Karolinska Institutet, Stockholm, Sweden.* [3]*Karolinska Institutet, Danderyd, Sweden.*
(No relevant relationships reported)

PURPOSE: A reduced aerobic exercise capacity is a known feature of chronic kidney disease (CKD) and is associated with increased morbidity and mortality. Peak heart rate (peak HR) and hemoglobin level are known determinants of exercise capacity in CKD. Less is known about the change in exercise capacity over time. The purpose was to study the change in aerobic exercise capacity, peakHR and hemoglobin over a 5 year-period in mild-to moderate CKD (CKD 2-3).
METHODS: 34 patients (11 females and 23 males, 24-62 years at baseline) with CKD 2-3 and 34 age- and gender-matched healthy controls were examined at baseline and after 5 years. Peak workload, as a measure of aerobic exercise capacity, and heart rate response were measured during a maximal exercise test on a cycle ergometer. Hemoglobin was assessed in both groups and glomerular filtration rate (GFR) was measured by iohexol clearance in CKD only.
RESULTS: GFR in CKD 2-3 decreased from 60±5.2 to 47±15 mL/min/1.73 m^2 over 5 years, (p<0.001). Peak workload, peakHR and hemoglobin level were significantly reduced (p<0.05) in CKD 2-3 compared to controls at baseline and at 5 years-follow-up. The changes in these parameters over 5 years did not reach significance in either group. CKD at baseline vs 5 years-follow-up: peak workload 209±62 vs. 200±60 W; peakHR 161±22 vs. 158±21 beats per minute; hemoglobin 13.5±1.3 vs. 13.9±1.1 g/dL. Controls at baseline vs 5 years-follow-up: peak workload 247±65 vs. 244±73 W; peak HR 178±11 vs. 173±12 beats per minute; hemoglobin 14.2±1.0 vs. 14.7±1.0 g/dL. The change in peakHR was positively correlated (r=0.57, p<0.05) to the change in peak workload in CKD, but not in controls. No such correlation to the change in peak workload was found for the change in hemoglobin level or GFR.
CONCLUSION: Aerobic exercise capacity and its determinants peakHR and hemoglobin were maintained over a 5 year-period in mild-to-moderate CKD, despite a mean decline of 22 % in kidney function. Change in peak heart rate over a 5 year-period is an important determinant of the change in exercise capacity in CKD 2-3.

Bridging The Gap Between Campaigns And Programs. The Country-based Public Health Policy Issue: "Move It For Heath"

Roberto C. Burini, FACSM, Franz H. Burini. *UNESP Medical School, Botucatu, Brazil.*
(No relevant relationships reported)

Cardiovascular disease and risks factors are worldwide concerning problems leading to public health policies and strategies to avoid high costs and low outcomes to populations. Physical inactivity is a major risk factor and play an important role that should lead to global public health strategy for its cost-efficiency and cost-effectiveness. The main issues are the specific country-based public health policies, wich continuously leads to campaign to avoid sedentary behavior and physical inactivity, and not population-based exercise programs policies. **Purpose:** The purpose of our study was to share data from a community-based exercise program ("Move it") contextualized on the Brazilian public health policy (SUS) for the last 20 years. **Mehods and Results:** The program "Move it" is a multidisciplinary program that runs on primary care facilities of a inner state city of São Paulo (Botucatu), Brazil, that has been implemented 25 years ago. So far, 2% of the city population has been involved (2800 participants; 55±9 years, 74% females and 68,7% under 60 years of age), participating on protocols that runs on city's facilities (parks, public gyms and squares), involving diagnosis, fitness analysis and exercise program (80 minutes, 3 times a week). Metabolic Syndrome (ATP criteria) prevalence is 35%, with a succesfull response to the program of 20% after 10 weeks. VO$_2$ max (Balke

---

protocol) improvement is 30% and muscular strength (25%). Blood Pressure (BP) normalization occurs after 20 weeks, returning to basal levels (High BP) when detrain occurs (Hollydays). Health Eating Index (HEI) and sedentary behavior (IPAQ and Baecke questionnaires) improves after 8 weeks. Figure 1. "Move-it": Flowchart and interactions with the national public health policy (SUS): **Conclusion:** Cardiorrespiratory fitness, healthy eating index, lipid profile, insulin sensitivity and body composition were improved. Since the primary care system in Brazil is based on active search ("Estratégia Saúde da Família - agentes comunitários"), the adhesion, acceptance and effectiveness of this model should be encourage for nation wide application. Strategies leading transition from campaigns to programs should be encourage world wide.

PERCEIVED PHYSICAL LITERACY IN COLLEGE AGED STUDENTS
Victor Andrews, Kansas State University, Manhattan, Kansas
Individuals who fail to acquire adequate competencies in regards to physical activity may develop barriers that limit physical activity later in life. Physical literacy(PL) is a descriptive that is used to measure one's competence, confidence, and motivation in regards to physical activity. The goal of PL is to have all youth to be considered competent by 12 years of age in order to allow them to be physical active throughout their life-course. **PURPOSE:** To investigate the perceived physical literacy levels of college aged students. **METHODS:** The Physical Literacy Self-Assessment was distributed to college aged students to measure perceived PL through e-mail and social media. **RESULTS:** 94 college students responded (21 ± 3 years, 38 male, 56 female). SPSS vs 24 was used for frequency analysis and two independent samples t-test. Perceived PL scores were then divided into 4 graded categories: Very Low, Low, High, Very High. 49% of respondents were placed in the "Very High" category, 47% of respondents were categorized at "High", 3% of respondents were categorized as "Low", 1% of responded was categorized as "Very Low". The results indicate that there is no statistically significant difference between the PL score for male and females (t= 1.881, p= 0.63). **CONCLUSION:** The goal of PL is to have all individuals meet the criteria to be considered "Very High". Individuals graded into categories other than "Very High" are considered in need of further education and support until they are perceived to be competent in all elements of PL. PL is still a new concept within the USA. Further research is needed to better understand PL within the USA population and relationships with current physical education levels in college aged populations.

Prenatal Healthcare Provider Physical Activity And Nutrition Discussions According To BMI

Kiersten M. Mead, Samantha J. Deere, Rebecca A. Schlaff, Meghan Baruth. *Saginaw Valley State University, Saginaw, MI.*
(No relevant relationships reported)

Research suggests healthcare providers (HCP) do not regularly discuss physical activity (PA) and nutrition during patient interactions, particularly when patients are considered overweight/obese by body mass index (BMI). It is unknown if this trend extends to obstetric HCPs. **PURPOSE:** To investigate the differences in 1) patient value of prenatal HCP advice, and 2) the likelihood of prenatal HCP discussion/recommendation of PA/nutrition behaviors according to BMI. **METHODS:** Participants (n=46) included pregnant women enrolled in a PA/nutrition behavioral intervention. A survey assessed 1) demographics, 2) pre-pregnancy height and weight, 3) the degree (1=do not value to 5=highly value) participants valued their prenatal HCP's opinions, and 4) whether the patient's prenatal HCP discussed PA behaviors, recommended PA participation, or gave nutritional advice. Means(SD) and percentages were calculated. Participants were categorized into BMI categories of normal weight (<25 kg/m^2) and overweight/obese (≥25 kg/m^2). An independent samples t-test and chi-square analyses were utilized to assess differences in the value of HCP's opinions, and whether or not the patient's HCP discussed PA behaviors, recommended PA participation, or gave nutritional advice according to BMI category. **RESULTS:** Most participants were Caucasian (82%), married (70%), and college graduates (59%). Participants were 28.3(4.4) years of age, had a pre-pregnancy BMI of 28.0(9.7)kg/m^2 and valued their HCP's opinions 4.6(0.6). Most participants discussed current PA habits (61%), received a PA recommendation (57%), and received nutritional advice (59%) from their prenatal HCP. Normal (45.6%) and overweight/obese (54.4%) participants valued their HCP's advice similarly: 4.6(0.60) and 4.6(0.64), respectively (p=0.71). Although not statistically significant, more normal weight participants discussed PA and received a PA and nutrition recommendation than overweight/obese participants (p=0.10-0.50). **CONCLUSION:** Our sample highly valued prenatal HCP opinions. HCPs discussed/recommended PA/nutrition behaviors to women across BMI categories, yet many participants received no PA/nutrition advice. Future research should explore ways to consistently incorporate PA/nutrition discussions in obstetric appointments.

Physical Activity Counselling and Exercise Prescription Practices of Physiotherapists in Nova Scotia

Myles W. O'Brien[1], Chris A. Shields[2], Kristin L. Campbell[3], Bonnie Doyle[4], Sandra Crowell[4], Patrick McGrath[4], Jonathon R. Fowles[2]. [1]*Dalhousie University, Halifax, NS, Canada.* [2]*Acadia University, Wolfville, NS, Canada.* [3]*University of British Columbia, Vancouver, BC, Canada.* [4]*Nova Scotia Health Authority, Halifax, NS, Canada.*
(No relevant relationships reported)

PURPOSE: Physiotherapists (PTs) have education and scope of practice to promote the benefits of physical activity (PA) and prescribe exercise in their clinical interactions with patients. As such, they provide an avenue to increase the reach of Exercise is Medicine, to improve the PA levels of the Canadian population. However, no study has assessed Canadian physiotherapists' perceptions and practices surrounding physical activity counselling and exercise prescription (PAE). **METHODS:** PTs working in Nova Scotia (n=146) completed an online self-reflection survey regarding their current practices, confidence, barriers, and facilitators in providing PAE to their patients. **RESULTS:** Overall confidence for PAE was high (most scores >80%) except for in helping patients maintain PA (72.8±25%) and in patients following through on PAE recommendations (66.3±22.5%). PTs include PAE in 85±23% of appointments and prescribe written exercise in 80±20% of appointments, but only refer to other exercise professionals or facilities in 27±27% of appointments. The most salient barriers to providing PAE were patient's interest in PA, and patients' preference for medication management over lifestyle intervention (2.36±0.68 and 2.11±0.66 respectively, out of 4), exceeding the typically cited barrier of lack of provider time. The most helpful facilitator was PTs' perceived patients' readiness to do PAE (3.5±0.7, out of 4). PTs are most comfortable providing PAE advice to those with arthritis and musculoskeletal issues (81%) and least comfortable to those with cancer (49%), insulin requiring diabetes (33%), respiratory disease (32%) and mental health concerns (28%). **CONCLUSION:** The primary barriers for PTs in providing PAE are patient-focused and PTs may benefit from avenues that allow greater referral access to other exercise professionals and a collaborative treatment approach to help patients maintain a physically active lifestyle, especially in those with other chronic disease beyond musculo-skeletal disorders. Exercise is Medicine networks should consider greater collaborations between allied health and exercise professionals to support multi-disciplinary approaches to patient exercise management across the continuum of health care.

Participation in an Exercise Education Rotation affects Medical Students Opinions Towards a Physician's Role in Physical Activity Recommendations

Anthony A. Musto[1], Alexis Canaves[2], Michael A. Bello[2]. [1]*University of Miami, Coral Gables, FL.* [2]*University of Miami, Miami, FL.*
(No relevant relationships reported)

Physical activity is key for prevention of most chronic disease. In response, a global initiative called *Exercise is Medicine* was launched to encourage physicians to treat physical activity participation as a vital sign. However, medical students may not receive the necessary training which may inhibit the future physician's likeliness to assess or recommend physical activity participation. **Purpose**: To determine if a five day exercise education rotation affects medical student's opinion regarding a physician's role in recommending physical activity. **Methods:** Third year medical students (n=169) completed a mandatory exercise education rotation as part of general primary care clerkship. This rotation included included basic fitness assessment and consultation, one-hour observation of a clinical supervised exercise program, exercise prescription education for special populations, explanation of the *Exercise is Medicine* Initiative and mandatory attendance to five group exercise classes. All exercise activities were led by an ACSM certified exercise physiologist at a University based fitness facility. The medical students completed an 8-item Likert scale pre-post survey (1 to 4, strongly disagree, disagree, agree, strongly agree, respectively) to assess their level of agreement with statements about a physician's role in exercise prescription and personal fitness (Table 1). A paired t-test was used to compare the pre and post scores for each individual item. Significance was set at p < .05. Results: Table 1.

Item	Pre	Post	Mean Diff	p value
1. It is a physician's responsibility to discuss exercise with their patients.	3.67	3.76	.09	.059
2. Physicians are qualified to accurately prescribe exercise.	2.93	3.08	.15	.051
3. A physician's personal fitness affects the credibility of their advice.	3.28	3.30	.02	.805
4. Physicians should assess a patient's physical activity levels just like other vitals signs.	3.33	3.54	.21	.001*
5. A physician who can prescribe exercise is a better overall physician.	3.49	3.59	.10	.123
6. Exercise prescription coursework should be mandatory in medical school.	3.36	3.41	.04	.580
7. A physician should be judged based on their personal fitness.	2.36	2.58	.22	.007*
8. A physician should serve as a role model with regards to their nutrition/fitness.	3.28	3.37	.09	.201
Total Survey Score	25.66	26.57	.92	.009*

*p < .05

Conclusion: The findings demonstrate that a five-day exercise education rotation favorably impacts medical student's opinion regarding a physician's role in exercise consultation with patients. More importantly, the most significant increase in agreement was observed in the students' agreement that a physician should consider physical activity levels as a vital sign, consistent with the Exercise is Medicine initiative.

1477   Board #285   May 31 9:00 AM - 10:30 AM

Primary Care Students' Perceptions of Using Physical Activity Counseling as a Medical Intervention

Graceson C. Kerr, John E. Lowry, Samantha J. Deere. *Saginaw Valley State University, University Center, MI.*
(No relevant relationships reported)

Chronic diseases are among the most common and costly health problems in the U.S. Physical activity (PA) has been shown to be effective in treating and preventing many chronic diseases. The Exercise is Medicine initiative aims to promote PA counseling among healthcare providers. However, little is known about the education and perceptions of medical providers related to PA counseling. **PURPOSE:** To learn about the knowledge and perceptions that students in primary health care professions have related to using PA counseling. **METHODS:** Students currently enrolled in a DO or MD medical school, physician assistant, or nurse practitioner program were recruited to take an online survey. Incorporating two previously validated surveys, subjects were asked about their own PA counseling training they have received, the importance of various PA counseling tasks, and their competency to do each task. Data analyses were performed on each Likert scale question. Open ended questions were analyzed thematically. **RESULTS:** Of the participants who completed the survey (n=72), 6.8% were MD, 52.3% were DO, 21.6% were physician assistant, and 18.2% were nurse practitioner students. Primary care students rated many aspects of PA as being important (59.4-76.7% agreed/strongly agreed), but reported low confidence in their education and abilities to do them (19.7-51.3% agreed/strongly agreed). The most common barriers to PA counseling were patient motivation/compliance, lack of education, time, support system for patients, and cost/billing. The most common solutions they proposed to overcome these barriers were more education for primary care professionals, being able to refer patients to specialist, and help with psychological aspects of counseling. There was strong interest in taking an elective course, attending a CME/continuing education course, and having a certified fitness and/or nutrition professional in the office. **CONCLUSION:** There is a clear disconnect between what primary care students find important and what they feel competent to do in the field. There is a need for improving medical education related to PA counseling. There are many opportunities for PA professionals to work with primary care providers on PA counseling. Educating our healthcare professionals is essential in making them confident in PA counseling.

Resistance Exercise Does Not Improve Habitual Physical Activity Despite Pain Relief: Implications for Patient Counseling

Kevin R. Vincent, FACSM, Heather K. Vincent, FACSM. *University of Florida, Gainesville, FL.*
(No relevant relationships reported)

Osteoarthritis (OA) of the knee leads to physical disability and avoidance of activity. Resistance exercise can reduce pain and increase leg strength, but it is not yet clear how resistance exercise (RX) impacts habitual physical activity levels. **PURPOSE:** To determine whether resistance-exercise induced changes in physical function and pain relief are related to increased walking related function and habitual physical activity in older adults with knee OA. **METHODS:** Older adults (N=60; 69.0 ± 6.9 yr; 64% women) were randomized to a 4-month total body RX program or not. Knee pain was estimated using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscore. One repetition maximum of leg strength (knee extension and leg press) and walking performance measures (walking speed, walking endurance during progressive treadmill test, 6-minute walk test distance) were collected pre and post-training. Daily step count and intensity of ambulatory activity was determined by a 7-day tracking of ambulation using a StepWatch©. **RESULTS:** Knee pain severity decreased by 27% in the RX group and increased by 13% by month 4. Leg extension and leg press strength increased from 17% to 22% and decreased by 4% in the control group (p<.05). Walking speed did not differ between the two groups from pre to post-training. Walking endurance treadmill time increased from 12.5 to 13.3 min in control and from 10.1 to 11.2 min in the RX group but these changes were not different between groups. Six-minute walk distance increased by 1.0-4.2% in the RX and control groups (p=.08). Pre-training average daily step counts were 5002 ± 2125 and 3601 ± 1181 in the CON and RX groups, respectively, and decreased by 614 and 356 steps a day by month 4. **CONCLUSIONS:** Despite pain reduction and strength gains with RX, walking-related functional indices and habitual activity levels were not impacted. Patients should be counseled that RX does not replace daily physical activity, but should be added to ambulatory activity. The importance of combining ambulatory activity and strengthening exercise to maximize possible functional improvements should be discussed.

1479   Board #287   May 31 9:00 AM - 10:30 AM

"If We Knew That Exercise Could Be Our Medicine": Perceptions of Latinas in Low-Income Clinics

Andrea S. Mendoza-Vasconez[1], Aysell Medina[2], Mario Munoz[3], Britta Larsen[2], Samantha Hurst[2]. *[1]UC San Diego/San Diego State University, San Diego, CA. [2]University of California San Diego, La Jolla, CA. [3]University of Massachusetts Boston, Boston, MA.*
(No relevant relationships reported)

PURPOSE: There is scarcity of research regarding the leveraging of the healthcare setting to promote PA among Latinas specifically, though they are one of the largest and most inactive ethnic minority groups in the US. This study aimed to conduct qualitative research to understand how low-income community clinics could be capitalized on as settings for the promotion of PA among Latina women.
METHODS: In-depth individual interviews were conducted with 24 Latina patients in two low-income community clinics in San Diego, California. Data were collected in English and Spanish, transcribed, translated to English, and analyzed using structural coding procedures, under a Thematic Analysis framework. Two investigators jointly coded each interview using a codebook. Codes were then compared and grouped into themes.
RESULTS: While other themes were identified, this presentation will mainly focus on participants' perceptions regarding the role of clinics and health professionals in the promotion of PA. The majority of participants reported receiving PA advice at their doctor's office, although only some of them found this advice facilitated their participation in PA. A few participants stressed the importance of personal responsibility, rather than physicians' responsibility, for their PA. Nevertheless, most participants had expectations regarding doctors' role in the promotion of PA. Specifically, participants wanted doctors to motivate people, for example by becoming role models and by providing more specific information of places and exercises they can do.
CONCLUSIONS: The results of this qualitative study support the need to leverage the role of healthcare professionals and clinics in the promotion of PA among Latinas, as participants expressed a desire for health professionals' involvement and provided suggestions regarding how they may motivate patients to be active. Future research might benefit from including some of these suggestions for the promotion of PA among Latina women in the healthcare setting. The results of this study also highlight the importance of initiatives like ACSM's Exercise is Medicine to better equip future healthcare professionals to address the PA promotion needs and expectations of their patients.

Exercise Is Medicine On Campus 2017: Increasing Off-campus Outreach And Community Collaboration

Zack Papalia, Melissa Bopp, FACSM, Michele Duffey, Lori Gravish-Hurtack, Christopher M. Bopp, Nancy Williams, FACSM, Alexandra Telech, Britni De Castro. *Pennsylvania State University, University Park, PA.* (Sponsor: Melissa Bopp, FACSM)

(No relevant relationships reported)

PURPOSE: Exercise is Medicine on Campus (EIMOC) is an initiative promoting physical activity (PA) on college campuses. Pennsylvania State University, promoting EIMOC since 2010, has held an annual EIMOC Week since 2012. A focus of the EIMOC committee in 2017 was to expand its off-campus reach and community collaboration throughout the commonwealth of Pennsylvania and beyond. The purpose of this study is to analyze and describe the logistical challenges and lessons learned from expanding an EIMOC initiative to off-campus and out of town locations. **METHODS**: During fall 2017, EIMOC events were expanded from one, on-campus week, to a month of activities including a day of coordinated events with off-campus local businesses, travel to commonwealth campuses, and a week of collaboration with alumni-led organizations nationwide. The logistical challenges of coordinating remote events were documented and evaluated. Observational data from each event assessed popular activities and feedback from participating partners regarding the planning and execution of events was gathered. **RESULTS**: Analysis addressed three new initiatives. Partnership with local, off-campuses businesses, known as "EIM Off Campus Day," involved local fitness centers offering no-cost access to students, faculty, and staff for one day, promoted via social media and our website. Reach was assessed through social media analytics (i.e. likes, retweets), website visits and unique page views. Traveling events to commonwealth campuses occurred during "Mobile EIM Week" and were assessed based on the type of activities included, number of partners involved, and number of participants engaged, as well as feedback regarding the perceived success of each event and suggestions to improve future collaborations. Finally, a week-long initiative engaged alumni nationwide (EIM Everywhere Week) relying on email campaigns and social media to spread the word and gauge participation. **CONCLUSIONS**: The current study offered insights on the challenges and successes in leveraging an existing EIMOC program to spread the message into the community, including timing of advertising and better communication. Despite this, the new initiatives proved both popular and successful, and improving their execution will significantly benefit the future impact of EIMOC.

Preliminary Results Of An In-depth Investigation Of Exercise Is Medicine On Campus

Oliver Wilson, Nishat Bhuiyan, Melissa Bopp, FACSM, Zack Papalia. *The Pennsylvania State University, State College, PA.* (Sponsor: Dr. Melissa Bopp, FACSM)

(No relevant relationships reported)

Widespread implementation of Exercise is Medicine on Campus (EIM-OC) has potential to address college student physical inactivity, however, limited research has comprehensively assessed how EIM-OC is operationalized at campuses. **PURPOSE:** To assess EIM-OC implementation, development, and outcomes at various academic institutions. **METHODS:** A survey was developed in consultation with key EIM-OC stakeholders and administered online among EIM-OC representatives. Data collected included: institutional information; promotion, education, and healthcare system integration; partnerships; challenges; and goals. **RESULTS:** Initial responses (n=24) were received from a diverse group of academic institutions ranging in size (<10,000 to >50,000 students) and type (public, private). Campus health and recreation were considered the most important EIM-OC partners, which was attributed to these partners providing the most opportunities for and having the most interactions with students. A lack of time and wanting to focus on existing relationships were cited as reasons for not yet establishing working relationships with other partners. Multiple respondents cited lack of time, awareness, funding, and/or resources as the biggest challenges faced by their program. Bureaucracy surrounding the collaboration between university departments was also a cited as a major challenge. Implementing the physical activity vital sign emerged as a common issue, with many institutions having no protocol in place for arranging a follow-up between students and physical fitness professionals after referral acceptances (n=5), and no protocol existing for referral declinations (n=9). Despite a stated desire for greater collaboration with other universities, particularly sharing of information and ideas (n=9), most respondents (83%) had not collaborated with other programs. Social media was under-utilized, with over a third (n=9) of respondents not utilizing any social media platforms. **CONCLUSION:** EIM-OC programs at various institutions experienced similar challenges. This research will serve to inform and improve upon the implementation, development, and outcomes of EIM-OC programs and ultimately contribute to helping academic institutions increase the physical activity of students and their local communities.

Referred Students' Motivators And Barriers To Participate In An EIMOC Program

Kristen M. Lagally, FACSM, Derek Hevel, Lauren Von Schaumburg, Anna Rinaldi-Miles. *Illinois State University, Normal, IL.*

(No relevant relationships reported)

PURPOSE: The purpose of this study is to describe referred students' motives and barriers to participating in an Exercise is Medicine on Campus (EIMOC) training program at Illinois State University.
METHODS: Referrals are initiated by Student Health or Counseling Services, and referred students complete an intake session with the School of Kinesiology and Recreation's (KNR) Exercise is Medicine on Campus staff. Student Health and Student Counseling services indicated a need for physical activity (PA) programming for students with certain conditions (e.g. social anxiety, body image concerns, obesity, depression, anxiety, and eating disorders) that would benefit from increased physical activity performed in a private setting. Students are referred to the School of KNR EIMOC program, which is informed and implemented by graduate students and Exercise Science faculty with expertise in the areas of exercise physiology, biomechanics, and exercise psychology. Specific diagnoses are not currently provided by Student Health or Counseling services to EIMOC staff.
RESULTS: Since the initiation of the referral system in 2016, 40 students (Women = 30, Men = 10) have been referred to the EIMOC program - 30 from Health Services and 10 from Counseling Services. Approximately half of these were already performing some activity, but were either not meeting recommended levels of PA or needed assistance with their exercise program. At the time of submission, ten of the 40 students had completed full intake questionnaires and consent forms. Descriptive statistics were calculated on data from these ten subjects to identify reasons for pursuing participation in the EIMOC program and clients' current motivations for and barriers to PA. All subjects cited "improving energy levels" as an important motivator for PA. The top three reported barriers for PA were Lack of Willpower (M±SD = 6.1±2.9), Lack of Energy (M±SD = 4.4±2.4) and Social Influence (M±SD = 4.0±1.8). Privacy of the exercise sessions (90%), expertise of the staff (90%), and physician referral (70%) were selected as strong motivators for pursuing the EIMOC program.
CONCLUSIONS: These preliminary data suggest that students referred to Illinois State University's EIMOC program pursue it due to an interest in increasing PA levels in a private, supervised setting.

Aging, Maximal Aerobic Capacity, and Running Economy in Trained Distance Runners

Emma J. Lee, Christopher J. Lundstrom. *University of Minnesota, Minneapolis, MN.* (Sponsor: Eric M. Snyder, FACSM)

(No relevant relationships reported)

Aging, Maximal Aerobic Capacity, and Running Economy in Trained Distance Runners
Maximal aerobic capacity (VO_{2max}) tends to decline with age, even in trained long-distance runners. However, it is possible that running economy (RE), another predictor of performance, may be preserved. Furthermore, previous research has measured RE as the submaximal rate of oxygen consumption in ml O_2 *kg body mass $^{-1}$ * min $^{-1}$ (VO_2), whereas it is more valid to express RE using allometric scaling of body mass (alloVO_2) or as the energy cost of running (EC), in kcal * kg body mass $^{-1}$ * min $^{-1}$. The percent of VO_{2max} (%VO_{2max}) at which a submaximal run occurs is also related to performance. PURPOSE: To evaluate VO_{2max}, alloVO_2, EC, and %VO_{2max} in runners across a wide age range and determine whether aging is associated with these performance-related measures. METHODS: Runners aged 20-66 years completed two running tests. Study visits took place within four weeks of a goal race of 10-26.2 miles. Subjects ran for five minutes at 88% of their predicted age-based maximum heart rate, which approximates a marathon-intensity effort. Athletes then performed a VO_{2max} test. AlloVO_2 was calculated using body mass$^{0.66}$. Energy cost was determined using caloric equivalents based on mean respiratory exchange ratio, which takes substrate utilization into account. Pearson's correlations were used to determine relationships between age and running performance variables. RESULTS: Runners (n = 22, 11 females; body mass index 22.54 ± 2.9 kg * m^{-2}) had a mean VO_{2max} of 53.2 ± 10 ml O_2 * kg $^{-1}$ * min (range: 35.6-69.9). Age was not significantly correlated with VO_{2max}, alloVO_2, or %VO_{2max} (respectively: r = -0.281, p = 0.205; r =.0172, p = 0.470; r = -0.191, p = 0.42). Age was highly correlated with EC (r = 0.721, p = 0.001). CONCLUSIONS: In this population, age was not related to maximal or submaximal oxygen consumption. The strong positive relationship between age and EC suggests that substrate use during submaximal running may change with age in trained distance runners.

HoppingExercise Training Improves Postural Control in Healthy Older Adults

Toshiaki Nakatani, Kazufumi Terada, Koji Kawakami, Kazuki Kino, Mika Imai, Shota Shinomiya. *Tenri University, Tenri, Japan.*

(No relevant relationships reported)

Older adults exhibit increased postural sway motion, increasing fall risk. Exercise programs can improve postural control and reduce fall risk in older adults. **PURPOSE**: This study aimed to investigate the effects of hopping exercise training on postural control during quiet standing in healthy older adults. **METHODS**: Thirty-one community-dwelling older adults were randomly assigned to either a hopping exercise group [HEG, n = 16 (men = 3), mean age = 71.5 ± 5.3 years] or a balance exercise group [BEG, n = 15 (men = 1), mean age = 71.1 ± 4.9 years]. Both groups performed a 12-week exercise training program. HEG performed two sets of two-legged hopping at a frequency of 90 bpm until reaching a score of 15 (hard) on the Borg Rating of Perceived Exertion scale twice a week. BEG performed balance exercise on a foam stability pad or soft balance beam. At a welfare center, all subjects participated in a 60-min supervised group exercise session once every 2 weeks. Outcome measures included the center of foot pressure (CoP) sway parameters during quiet standing with eyes open (EO) and eyes closed (EC) for 30 s. **RESULTS**: Repeated measures analysis of variance showed a significant interaction effect of path length in an enveloped area with EC ($P = 0.03$) and main effects of time of path length ($P = 0.027$), enveloped area ($P = 0.029$), and sway velocity ($P = 0.031$) with EO. After the training session, HEG demonstrated a significantly increased path length in an enveloped area with EC (21.5 ± 7.9 vs. 26.3 ± 13.0 cm², $P < 0.05$) and a significantly decreased path length (45.0 ± 17.4 vs. 37.6 ± 12.5 cm, $P < 0.05$), enveloped area (2.71 ± 1.40 vs. 2.09 ± 1.25 cm², $P < 0.05$), and sway velocity (2.25 ± 0.87 vs. 1.88 ± 0.63 cm/s, $P < 0.05$) with EO. BEG demonstrated no changes in CoP sway parameters with EO or EC. **CONCLUSION**:

Twelve-week hopping exercise training can improve postural control with EO and EC in older healthy adults. Hopping exercise is a safe, practical, and effective training approach in older people. Supported by JSPS Kakenhi Grant Number 26350767.

The Effects Of Tempo-adjusted Music On Gait Speed And Functionality In Middle-aged And Older Adults

Jeffrey M. Janot, Saori Braun, Nicole Cisewski, Anna Stover, Samantha Noetzelman, Lauren Grover. *University of Wisconsin-Eau Claire, Eau Claire, WI.*

(No relevant relationships reported)

PURPOSE:Tempo-based music is capable of impacting gait patterns and functionality, however, there is little knowledge on how technological applications (apps) that match music tempo to self-selected gait speed can impact gait patterns. The purpose of this study was to determine if functionality and self-selected gait speed in community-dwelling middle aged and older adults can be improved both acutely (in one bout) and over a three-week period by utilizing an app that changes music tempo to match pace. **METHODS**: Twenty-six (14 females, 12 males) participants, aged 56-80 years old were recruited for this study. All participants were previously involved in a regular exercise program. Participants were randomly assigned to control (CTL) or training (TRN) group. The CTL group walked with the music app for one bout to measure acute effects then adhered to a 3-wk walking program (2x's/week) without music. The TRN group used the music app for the full 3-wk walking program. Main outcome measures included a 10-m walk test (10mWT), a 15-min walk test (15MWT), and the timed up-and-go test (TUG). **RESULTS**: There were significant (p < .05) improvements seen during the acute session (1.58±0.19 m/sec music app vs 1.49±0.18 m/sec no music) across all participants and improvements in TUG (CTL: 9.53±0.47 sec pre-study vs 8.83±0.52 sec post-study; TRN: 8.70±0.45 sec pre-study vs 7.92±0.50 sec post-study), regardless of group assignment. Also, there were no significant (p > .05) differences in the 10mWT (CTL: 1.48±0.09 sec pre-study vs 1.55±0.07 sec post-study; TRN: 1.66±0.09 sec pre-study vs 1.70±0.07 sec post-study) or 15MWT (CTL: 1.49±0.05 m/sec pre-study vs 1.55±0.07 m/sec post-study; TRN: 1.49±0.05 m/sec pre-study vs 1.56±0.07 m/sec post-study) tests times for both groups over the 3-wk period. **CONCLUSIONS**:These results demonstrated that a music app that matches walking tempo may be an effective means to acutely improve speed and functionality as measured by the TUG test in middle aged and older adults. Future studies should explore longer intervention programs to improve self-selected walking speeds or employ a similar program with individuals who were previously inactive.

Ipsilateral and Contralateral Rapid Torque Adaptations To Unilateral Resistance Training In Young and Older Males

Alex A. Olmos[1], Garrett M. Hester[1], Zachary K. Pope[2], Mitchel A. Magrini[2], Ryan J. Colquhoun[2], Alejandra Barrera-Curiel[2], Carlos A. Estrada[2], Jason M. DeFreitas[4]. *[1]Kennesaw State University, Kennesaw, GA. [2]Oklahoma State University, Stillwater, OK. [3]Oklahoma State Univeristy, Stillwater, OK. [4]Oklahoma State University, Stilwater, OK.*

(No relevant relationships reported)

While the efficacy of unilateral resistance training (RT) to increase strength in the untrained limb (i.e., cross-education) is well established, it is less clear if cross-transfer of rapid torque characteristics occurs, and if age affects these adaptations. **PURPOSE:** To identify the effects of short-term, unilateral RT on rapid torque characteristics in the untrained limb of young and older males. **METHODS:** Twenty-two untrained, young (age = 21.43 ± 2.29 yrs, body mass = 81.03 ± 12.71 kg) and nineteen older (age = 65.78 ± 9.83 yrs, body mass = 87.23 ± 13.34 kg) males were randomly assigned to either a training (young trained group [YTG] and old trained group [OTG]) or young and old control groups. The YTG and OTG performed 3 sessions per week of isokinetic RT for 4 weeks. RT sessions consisted of maximal concentric knee extensions at 45°·s^{-1} with an emphasis on ballistic intent for 4 sets of 10 repetitions. Maximal voluntary isometric contractions of the trained and untrained knee extensors were performed before (PRE) and after week 4 (POST) of RT on a dynamometer. Peak torque (PT) in addition to rate of torque development and impulse from contraction onset to 30 ms (RTD_{0-30} and IMP_{0-30}, respectively) and 100-200 ms ($RTD_{100-200}$ and $IMP_{100-200}$, respectively) were recorded for analysis. Three-way (age [young vs. old] × group (training vs. control) × time (PRE vs. POST) repeated measures analyses of variance were used for each dependent variable. **RESULTS:** For the untrained leg, there was no effect of training on RTD_{0-30}, IMP_{0-30}, $RTD_{100-200}$, or $IMP_{100-200}$ (p > 0.05). However, a 2-way (group × time) interaction indicated that PT increased at POST similarly between the YTG and OTG (+11%; p = 0.003) compared to the control groups. For the trained leg, a 2-way (group × time) interaction indicated that PT (+21.1%; p < 0.001) and IMP_{0-30} (+7.0%; p = 0.038) increased at POST similarly between the YTG and OTG compared to the control groups. Similarly, RTD_{0-30} demonstrated a nearly significant increase that was similar between the YTG and OTG

THURSDAY, MAY 31, 2018

(+11.2%; p = 0.051). **CONCLUSION**: Cross-education of strength was unaffected by age, however, neither young nor older males demonstrated cross-education of rapid torque characteristics. Further, while rapid torque characteristics were improved in the trained leg, age was not influential on these adaptations.

1518   Board #5   May 31 1:00 PM - 3:00 PM

Copper - Zinc Serum Traces, Lipid Profile, Geriatric Depression, and Daily Living Activities in Older Adults

Jean C. Zambrano[1], Ramón A. Marquina[2], María V. Gómez[1], Edyleiba Rojas[1], Carlos E. Rondón[1], Thairy G. Reyes-Valero[3], Rafael A. Reyes-Alvarez[2]. *[1]University of The Andes Mérida-Venezuela, Merida, Venezuela, Bolivarian Republic of. [2]University of The Andes Mérida-Venezuela, Mérida, Venezuela, Bolivarian Republic of. [3]NOVA Southeastern University, Fort Lauderdae, FL.*

(No relevant relationships reported)

This study aims to assess serum traces of copper (Cu) and zinc (Zn), lipid profiles, geriatric depression level and activities of daily living (ADL) scale index in older adults affiliated with two different programs of physical activity (PA) levels. In the first program, Exercise for Health, members perform regular PA (at least 60 minutes, 3 times per week) and the second one represents a Nursing Home (NH) without regular physical activity each week. **Methods:** Thirteen men and women in the PA group (age: 64.7±4.8 years) and 34 men and women in the NH (age: 77.9±5.3 years) with no previously documented cardiovascular disease participated in the study. Anthropometric measurements were performed and blood was drawn from left arm. Serum traces of Cu and Zn were determined by atomic absorption spectroscopy, lipid profiles by absorbance and colorimetric assays, levels of geriatric depressión with Yesavage's scale index, and activities of daily living with Katz's index of independency in ADL. **Results:** The results revealed similar serum trace of Cu (PA: 0.62±0.02; NH: 0.64±0.02 mg/L) and Zn (PA: 0.29±0.01; NH: 0.31±0.011 mg/L), and lipid profile (total cholesterol, PA: 163.92±47.24, NH: 160.06±36.16 mg/dL; HDL, PA: 38.62±9,8 mg/dl, NH: 37.79±7.53 mg/dl; LDL, PA: 102.85±33.75, NH: 109.24±29.19 mg/dl; VLDL, PA: 20.69±8.6, NH: 13.03±4.26 mg/dl; triglycerides, PA: 103.38±45.13, NH: 65.62±21.19 mg/dl) between both older adults groups. However, NH group showed higher level of geriatric depression (70.5% vs. 38.5%) and dependency when performing activities of daily living (ADL). **Conclusions:** Even though participants were involved in different levels of physical activity level, serum traces of Cu and Zn, and lipid profile were within a normal limits range, but institutionalized older adults showed higher tendency toward depression and difficulties with daily living activities.

1519   Board #6   May 31 1:00 PM - 3:00 PM

Heavier, Stronger for Better Bone Mineral Density of Middle Age and Older Adults

Xiong Qin, Weimo Zhu, FACSM. *University of Illinois at Urbana and Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)

(No relevant relationships reported)

PURPOSE: Lost of bone mineral density (BMD) could lead to a serious health consequence for middle age and older adults. It is well known that BMD declines as a person becomes aging. It is also observed that heavier individuals tended to have a better bone mineral density, which led an assumption that stronger persons should have a more dense bone. This hypothesis, however, has not been examined using the large population data. This study was to fill this gap.
METHODS: Data from the 2013-2014 National Health and Nutrition Examination Survey (NHANES) were used for the study, in which a sample of 3127 (representing a weighted national sample of 126541108 US adults), with age from 40 to 80 yr. old, were examined for their BMD, age, sex, height, weight and hand grip strength. The correlations between total femur BMD (tfBMD) and BMI (body mass index) and grip strength were examined by sex and by total.
RESULTS: Statistical findings of the study are summarized as in the table:

Correlation between total femur BMD and age, BMI and grip strength			
Correlation	Age	BMI	Grip Strength
Male	-0.171	0.434	0.285
Female	-0.449	0.496	0.414
Total	-0.291	0.411	0.475

CONCLUSIONS: As expected, age has a negative correlation with bone density and BMI and grip strength has a positive one and this is especially true for female adults and older adults. Since BMI is often associated with overweight or obesity, the best approach to improve body density is to engage in strength and conditional related exercises regularly. Future studies should focus more on dose-response issues of needed strength exercise for a better bone.

1520   Board #7   May 31 1:00 PM - 3:00 PM

Age-related Alterations In Functionality And Muscle Architecture Of The Lower Limbs In Women

Kevin C. Phillips, Byungjoo Noh, Michelle Burge, Matt Gage, Tejin Yoon. *Michigan Technological University, Houghton, MI.* (Sponsor: Sandra Hunter, FACSM)

(No relevant relationships reported)

The age-related declines in muscle mass and function are greater for women and the lower limb muscles, and these decrements accelerate during middle-age. However, it is less clear which lower limb muscles may be compromised more in middle-aged women. **PURPOSE**: To compare muscle function and architecture of the knee extensor and plantar flexor muscles in young and middle-aged women. **METHODS**: Twenty two middle-aged (years: 54 ± 6) and eight young women (years: 22 ± 2) volunteered to participate in this study. In vivo muscle architecture measurements such as muscle thickness and pennation angle of four muscles including vastus lateralis (VL), rectus femoris (RF), Gastrocnemius medialis (GM) and lateralis (GL) were measured using a B-mode real-time ultrasound scanner. Each participant performed maximal voluntary isometric contractions (MVIC) of knee extensor and plantar flexor muscles 3-4 times on the Biodex dynamometer. Interpolate twitch technique was used to assess voluntary activation (VA). Absolute and weight-normalized maximal strength and rate of torque development (RTD) were analyzed from MVIC torque data. Additionally 6 minute walk test and sit-to-stand task were performed. Age-related changes were tested using two-way ANOVA with repeated measures. **RESULTS**: Both absolute and normalized MVIC strength, RTD, and VA were similar (p > 0.05) between young and middle-aged women. There were no significant differences in muscular thickness between young and middle-aged women, however, VL thickness trended towards being larger in young women (2.31 ± 0.2 vs. 2.14 ± 0.22 cm, p = 0.067). GM pennation angle was significantly larger in young women (25.8 ± 2.5 vs. 23.6 ± 2.4 degrees, p = 0.038). Lastly, the young women performed significantly more repetitions during the sit to stand task (23.8 ± 5.7 vs. 18.3 ± 4.7, p = 0.013), whereas there were no differences in performance of the six minute walk test (p = 0.139). **CONCLUSION**: Isometric and explosive torque production was similar between young and middle-aged women. A greater decrease in GM pennation angle compared to other muscle groups suggest that the age-related alteration in muscle architecture may be more compromised for plantar flexor muscles than knee extensor muscles.

1521   Board #8   May 31 1:00 PM - 3:00 PM

Effects Of Linear Periodization Versus Concurrent Periodization Training On Adl's In An Elderly Population

Brian A. Zalma, Andrew Nl Buskard, Craig Dent, Catherine Armitage, Joseph Signorile. *University of Miami, Miami, FL.*

(No relevant relationships reported)

Aging is commonly associated with a decline in muscle size, strength and power. As a result, daily physical function also declines. Recent studies have noted that declines in muscle power are the most significant cause for decreased functional performance for older persons. No previous studies have assessed the magnitude of improvements in functional movements (activities of daily living) by implementing different methods of periodization during training. **PURPOSE:** To analyze the effects of two different periodization styles on functional strength, power, and activities of daily living (ADL) in an elderly population over a 14-week (3x weekly) training period. **METHODS:** Pretest and post-test measurements included chest and leg press 1RM and pneumatic isoinertial peak power, as well as functional performance on 5 ADL measures (gallon-jug test, 8-foot up-and-go, floor rise, 6m walk, laundry transfer, 5x repeated chair stand). After a 2-week familiarization period participants were randomly assigned to either a linear periodization group (n=16, age = 69.31 ± 4.59 y) or a concurrent periodization group (n = 14, age = 68.93 ± 6.72 y). Each protocol consisted of 12 total strength (3 x 8 reps @ 70% 1RM), power (3 x 8 @ 50% 1RM), and translational training sessions. Linear periodization consisted of 4 wk strength training, 2 wk translational training, 4 wk power training, 2 wk translational training while the concurrent periodization group completed 12 weeks of day 1: strength, day 2, power, and day 3: translational. **RESULTS:** Both groups experienced significant improvement on all strength (p<.0001), power (p<.0001), and ADL measures relative to baseline (p<.0001), with no significant between-groups differences observed on any outcome variable. **CONCLUSION:** Linear and concurrent periodization were found to be equally effective at increasing muscular strength, power, and ADL performance over the course of a 14 week training study.

Confirming Training-Related Aerobic Improvement Using Heart Rate Recovery in Older Adults with Chronic Disease

Ellie Rickman, Stacey Reading. *The University of Auckland, Auckland, New Zealand.*

(No relevant relationships reported)

PURPOSE: The efficacy of aerobic training in a rehabilitation setting is often determined by comparing changes in aerobic capacity (VO_2peak) using a cardiopulmonary maximal exercise test (CPX). In many studies, the reported pre- vs. post-training difference in VO_2peak is $\leq$ 3ml·kg^{-1}·min^{-1} and it is assumed that subjects put forth a maximal effort in both tests. A concern therefore arises that a difference in effort between tests could account for a significant portion of the reported improvement in VO_2peak; especially when those with chronic illness who are unaccustomed to maximal effort exercise are tested. In the present study we retrospectively examined data to test the hypothesis that only individuals with an improvement in VO_2peak have an improvement in steady state heart rate recovery (HRR) after completing a CPX test. METHODS: Thirty-seven chronically ill participants (57 ± 15yrs) completed a cycle CPX test to voluntary termination before and after a 12-week exercise rehabilitation program based on current guidelines for cardiac rehabilitation. VO_2peak was defined as the highest rate of O_2 uptake over 15s during the final stage of exercise. Participants were partitioned into a group of responders (RS) (n=18; VO_2peak increased > 0.2L·min^{-1}) and non-responders (NRS) (n=19; VO_2peak increased < 0.2L·min^{-1}). HRR was defined as the difference between peak HR and HR at each minute of cycling at 40% of the pre-training CPX test peak workload, which was compared between pre- and post-program tests.
RESULTS: VO_2peak significantly improved post program in RS (2.2 ± 0.6 vs. 2.6 ± 0.5 L·min^{-1}; p<.05) but not NRS (1.9 ± 0.7 vs. 1.9 ± 0.7 L·min^{-1}). The RS pre-program VO_2peak was 88% of age and gender predicted values vs. 107% in the NRS. Only RS had a greater HRR at 5 minutes (RS pre 39 ± 11 vs. post 46 ± 9bpm; p <.05 and NRS pre 37 ± 10 vs. post 39 ± 11 bpm; N.S.). Among RS, 14 of 18 improved their HRR by more than 3 bpm compared to 7 of 19 in the NRS group.
CONCLUSION: Including a fixed recovery workload following a CPX test may be useful for confirming post-program increases in VO_2peak. In the present study, participants that improved VO_2peak were more likely to have concurrent improvements in HRR after exercise-based rehabilitation.

Using the Heart Rate Index Equation to Estimate Peak METs in Physically Active Adults

Roger Sacks, Barry Franklin, FACSM, Jenna Brinks, Judy Boura, Shelby Potkin, Rima Rida, Harold Friedman, Abhay Bilolikar, Justin Trivax, Diedre Brunk. *William Beaumont Hospital, Royal Oak, MI.* (Sponsor: Dr. Barry Franklin, FACSM)

(No relevant relationships reported)

PURPOSE: Cardiorespiratory fitness (CRF) provides an independent marker for endurance performance and all-cause and cardiovascular mortality. Oxygen consumption (VO_2) during treadmill testing can be reasonably estimated from the attained speed, grade, and duration in men, women, and patients with coronary disease. Using our Cardiovascular Performance database and the Wicks equation (MSSE, 2011) to estimate maximal oxygen consumption (VO_2 max), expressed as metabolic equivalents (METs), we examined directly measured VO_2 max data on clients who self-reported performing vigorous physical activity $\geq$2 days per week to establish a prediction equation for this escalating patient cohort. **METHODS**: Our study population (n = 177) was comprised of young, middle-aged and older adults (mean ± SD age = 53.7 ± 11.0 years), including 101 men and 76 women who had completed a standard Bruce treadmill protocol to volitional fatigue. Estimated VO_2 max, expressed as maximal METs, was derived using the formula: Maximal METs = 6 (heart rate [HR] index) –5, where the HR index was calculated as the ratio between the maximal attained during cardiopulmonary exercise testing and the standing resting HR. These values were compared to the directly measured VO_2 max values using age, body mass index (BMI), and gender to further modify the Wicks equation so that it more accurately estimated CRF for this active population. **RESULTS**: For the entire study population (n = 177), mean BMI was 25.6 ± 3.8 kg/m^2. During exercise testing, resting HR increased nearly 2.4-fold (2.37 ± 0.39); directly measured VO_2 max, expressed as mean ± SD METs, was 10.2 ± 2.8. Using a linear regression model and the original Wicks prediction equation, as well as gender, age, BMI, an r-squared value of 0.62 was obtained (P-value <0.001). Two separate equations were developed using this model: Maximal METs = 20.8 + (–.08 x age) - (0.29 x BMI) + 0.24 x ([6 x heart rate index]–5) for men; and Maximal METs = 18.8 + (–0.08 x age) - (0.29 x BMI) + 0.24 x ([6 x heart rate index]–5) for women. **CONCLUSION:** These newly developed equations may help to more accurately estimate peak METs in physically active, fit men and women of varied ages. Future research with a larger patient population and additional modulators should serve to increase the coefficient of determination.

Effects of 12-weeks of Aerobic Exercise Training on Insulin Sensitivity Under Energy Balanced Conditions in Women

Christian E. Behrens, Jr. *The University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Dr. Gordon Fisher FACSM, FACSM)

(No relevant relationships reported)

Background: Exercise training is well known to improve insulin sensitivity (SI). However, the duration in which exercise –induced improvements in SI persists varies significantly between studies, ranging from 0- to 72-hrs following the last bout of exercise. One caveat that may explain the variability between studies is the magnitude of energy deficit following exercise. **Purpose:** To assess the chronic effects of 12-weeks of aerobic exercise training and the acute effects of exercise intensity for improving SI when measured under energy balanced (EB) conditions. **Methods:** Thirty three untrained premenopausal women were evaluated at baseline, after 12-weeks of training, 22 hrs after either an acute- bout of moderate-intensity continuous (MIC) aerobic exercise (50% peak VO_2) or high intensity interval (HII) exercise (84% peak VO_2). Participants stayed in a room calorimeter during and after the exercise sessions. Food intake was adjusted to obtain EB across 24-hrs. SI was measured 22hrs after all conditions using the hyperinsulinemia euglycemic clamp. Muscle biopsies were obtained in a subset of 15 participants to examine mitochondrial oxidative capacity using high resolution respirometry. **Results:** A significant increase in SI was observed only following the HII condition (P < 0.05). There were no significant improvements in SI following 12–weeks of training or the MIC session. A significant improvement in mitochondrial respiratory capacity occurred following all post-training conditions (P < 0.05). No significant differences between energy consumed and energy expended were found between all conditions. **Conclusions:** The primary finding from this study was that SI only improved following a bout of HII exercise when measured under EB, which suggests that energy deficit following exercise plays a role in exercise-induced improvements in SI. While we were unable to measure muscle glycogen, it is possible that glycogen deficit is important in determining the magnitude of these exercise-induced improvements in SI. Last, improvements in mitochondrial respiratory capacity occurred even when SI did not change, suggesting that these two responses are independent of one another.

Effect of Exercise Amount and Intensity on Change in Adipose Tissue and Skeletal Muscle Distribution

Andrea M. Brennan, Theresa E. Cowan, Paula J. Stotz, Gregory J. Clarke, Robert Ross, FACSM. *Queen's University, Kingston, ON, Canada.*

(No relevant relationships reported)

PURPOSE: Habitual exercise is associated with marked reduction in both total and abdominal adipose tissue (AT); however, the optimal dose (amount and intensity) of exercise required to elicit the greatest reduction remains unclear. The purpose of this investigation is to determine the separate effects of increasing exercise amount and intensity on AT and skeletal muscle (SM) mass in sedentary, abdominally obese adults. METHODS: Participants in this ancillary study included 105 men (40%) and women (60%) who were randomly assigned to one of four conditions for 24 weeks: control (C; n=20); low amount low intensity (LALI; 180 and 300 kcal/session for women and men, respectively, at 50% of VO_{2peak}, n=24); high amount low intensity (HALI; 360 and 600 kcal/session for women and men respectively at 50% VO_{2peak}, n=31); high amount high intensity (HAHI; 360 and 600 kcal/session for women and men, respectively, at 75% of VO_{2peak}, n=30). AT and SM mass were measured by magnetic resonance imaging at baseline and 24 weeks. RESULTS: Reductions in total AT (%; C, -0.2; LALI, -7.9; HALI, -10.8; HAHI, -11.5), abdominal subcutaneous AT (%; C, -0.3; LALI, -6.7; HALI, -10.1; HAHI, -12.9), visceral AT (%; C, -0.2; LALI, -15.5; HALI, -18.4; HAHI, -17.1), weight (%; C, -0.8; LALI, -4.7; HALI, -6.8; HAHI, -6.4) and waist circumference (%; C, -1.2; LALI, -4.5; HALI, -6.1; HAHI, -5.6) were greater in all exercise groups compared to control (p<0.0001), independent of age and sex. Reductions in total AT and abdominal subcutaneous AT were greater in HAHI compared to LALI (p=0.003). SM mass did not change at 24 weeks in any exercise

---

Abstracts were prepared by the authors and printed as submitted.

group compared to control (p>0.05). CONCLUSION: Substantial reduction in visceral AT with a preservation of SM mass is observed independent of exercise amount and intensity; however, higher intensity (HAHI) may be more effective than guideline-recommended (LALI) exercise for reducing total and subcutaneous adiposity.

Interval Training In Cardiac Rehabilitation

Rochus Pokan, FACSM[1], Stefan Heber[1], Helmuth Ocenasek[2], Serge P. von Duvillard, FACSM[3]. *[1]University of Vienna, Vienna, Austria. [2]Cardiomed Ourpatient Cardiac Rehabilitation Center, Linz, Austria. [3]University of Salzburg, 5400 Hallein/Rif, Austria.*
(No relevant relationships reported)

Rochus Pokan, FACSM[1] , Stefan Heber[1] , Helmuth Ocenasek[2], Serge P. von Duvillard, FACSM[3]
[1]University of Vienna, Vienna, Austria, [2]Cardiomed Outpatient Cardiac Rehabilitation Center Linz, Linz, Austria, [3]University of Salzburg, Salzburg, Austria.
Exercise training is a standard treatment for patients with coronary artery disease (CAD). Improvements in endurance capacity are an important aim of cardiac rehabilitation.
PURPOSE: We assessed the use of high intensity interval training (HIT) on cardiorespiratory fitness (CRF) and body mass index (BMI) compared to the isocaloric conventional endurance exercise training. **METHODS:** After initial exercise test, 50 patients were randomized into HIT and a control groups (CG). In both groups, patients exercised for 12 wks, 4 x per wk. Between inclusion and week 6, patients exercised 4 x per wk and from wk 6 to 12, patients exercised 2 x per wk, both sessions were supervised in cardiac rehabilitation center and additionally 2 x per wk on individual basis at home. Patients in CG exercised continuously only, while patients in the HIT group completed 2 interval and 2 continuous exercise training sessions per wk, in alternate sequence. After 6 wks and at the end of the training phase, exercise tests were repeated. Exercise protocol consisted of 5min of warm-up followed by 30min of continuous cycling at 60% of P_{max}. HIT exercise protocol consisted of 5min of warm-up, followed by 30min of interval training at: P_{mean}=60% P_{max}; P_{peak}=100% P_{max}; P_{rec}=20% P_{max}; t_{peak}=60s; t_{rec}=60s where P_{mean} was the mean workload during the 30min of exercise, P_{peak} was the peak workload intensity, P_{rec} was the recovery workload, t_{peak} was the peak workload duration, and t_{rec} was the recovery duration. For weeks 7-12, power output for each training session was recalculated according to P_{max} achieved in the second exercise test. **RESULTS**: The type of exercise training had a significant effect on BMI but not on absolute VO_2max. The CG reduced the BMI (-0.95) compared to the HIT group after 6 weeks, and the BMI decreased even further (-1.2) after 12 wks. **CONCLUSION:** Our results suggest that despite equal energy expenditure, HIT may be more effective in increasing muscle mass than endurance capacity.

Feasibility of Aerobic Interval Training in Non-Ambulant Persons after Stroke

Sarah R. Valkenborghs[1], Kirk I. Erickson[2], Michael Nilsson[1], Paulette van Vliet[1], Robin Callister[1]. *[1]University of Newcastle, Newcastle, Australia. [2]University of Pittsburgh, Pittsburgh, PA.*
(No relevant relationships reported)

PURPOSE: To investigate the feasibility of aerobic interval training in non-ambulant persons after stroke.
METHODS: Intervals of aerobic exercise were performed on a low entry upright (928G3, Monark) or semi-recumbent (RT2, Monark) cycle ergometer depending on individual ability and impairment. Participants were prescribed 4 × 4-minute intervals of exercise at 85%HRmax with a 3-minute active recovery at 70% HRmax between each interval per 30-minute session, 3 times per week for 10 weeks. Heart rate (T31, Polar), rating of perceived exertion (Borg 6–20), workload (W), cadence and duration of exercise achieved were recorded in the last 15 seconds of each interval. Workload was initially prescribed based on data from an incremental cycle ergometer test and, where tolerated, was progressively adjusted to maintain intensity.
RESULTS: 9 participants (aged 62±12; 5 male) unable to walk without assistance after stroke (2.9±3.9 years) were recruited. There were no adverse events and 1 drop out (due to Bronchitis). Attendance for the remaining 8 participants was 93±6%. The mean training %HRmax was 72±14% for the higher intensity interval and 57±21%HRmax for the recovery interval, with all participants bar one achieving ≥85%HRmax at least once and the mean number of times being 28±49 over the 120 intervals (30 sessions). The mean increase in training workload between weeks 1 and 10 was 11.2±11.6 W (26.9±27.7%) for the higher intensity interval and 4±7.7W (17.4±33.3%) for the recovery interval.
Mean VO2peak was 12.99±4.48mL/kg/min at baseline and 14.62±4.57 mL/kg/min after 10 weeks, showing a mean increase of 1.63±2.43 mL/kg/min (12.5±18.7%) over the 10 week intervention. The mean R-value was 1.09±0.17 at baseline and

1.19±0.19 at outcome while the mean peak HR was 79±16%HRmax at baseline and 79±15%HRmax at outcome. The mean workload was 59±23W at baseline and 78±35W at outcome, showing a mean increase of 17±23W (29±40%).
CONCLUSIONS: Aerobic interval training at a moderate-high intensity on an upright or recumbent cycle ergometer is feasible and safe for persons who are non-ambulant after stroke. It should be further researched to investigate its potential to improve cardiorespiratory fitness after stroke and risk-factors for recurrent stroke.

The Effects Of Hiit On Body Composition And Muscular Strength In Sedentary, Obese Women

Jamie DeRevere, Amy S. Clark, Annie B. De La Rosa, Todd A. Astorino. *California State University San Marcos, San Diego, CA.*
(No relevant relationships reported)

Introduction: Obesity rates are increasing, with the incidence of obese U.S. adults increasing from 30.5% in 2000 to 37.0% in 2014 (Ogden et al., 2015). Additionally, more women suffer from obesity or extreme obesity compared to men (Ogden and Carroll, 2010). A consequence of sedentary lifestyles is poor muscular strength, which is a risk factor for diabetes and cardiovascular disease (Shiroma et al., 2017), as well as all cause mortality (Rantanen et al., 2000). High intensity interval training (HIIT) is a time efficient and robust mode of exercise, which elicits similar adaptations versus moderate intensity continuous training (MICT) in obese adults (Kong et al., 2016). Previous data show that HIIT promotes weight and/or fat loss in overweight or obese populations (Gillen et al., 2013; Martins et al., 2016), yet in other studies, body composition was unchanged in response to HIIT (Nybo et al., 2010; Whyte et al., 2010; Astorino et al. 2013). A recent study (Farina et al., 2017) showed increased muscle strength in response to wk of HIIT in active men.
PURPOSE: To investigate the effects of different types of HIIT on body composition and muscular strength in sedentary, obese women.
METHODS: 17 obese sedentary women (age = 37.51±10.53 yr) participated in a six-week exercise intervention consisting of three training sessions per week. They were randomized into low volume HIIT (LO) (n=9, BMI=37.22±3.34 kg/m²) or periodized HIIT (PER) (n=8, BMI=41.00±5.33 kg/m²) which were performed on a cycle ergometer. Body composition and muscle strength were measured pre- and post-training. Fat mass and fat free mass were measured using air displacement plethysmography via a BodPod. Peak knee extension and flexion torque at 60 deg/s was assessed using an isokinetic dynamometer. Measures of dietary intake and physical activity were also obtained during the study.
RESULTS: FFM was increased in LO (52.07±5.09 kg vs. 53.93±4.69 kg) and PER (55.40±6.604 vs 56.10±6.57 kg), (p=0.03), yet there was no interaction (p=0.33). There was no significant change in body mass (p=0.075), fat mass (p=0.19), or peak extension (p=0.36) or flexion torque (p=0.75).
CONCLUSION: Regardless of protocol, HIIT elicits body composition improvements including an increase in fat free mass, but has no effect on muscular strength or body fat in sedentary, obese women.

The Effects Of A High-volume And High-intensity Resistance Training Program On Arterial Stiffness

Tim Werner[1], Thomas K. Pellinger[1], Nabil E. Boutagy[2], Demetri Rosette[1], Austin T. Ortlip[1], Morgan M. Vance[1]. *[1]Salisbury University, Salisbury, MD. [2]Yale University, New Haven, CT.*
(No relevant relationships reported)

Arterial stiffness has long been regarded as an indicator of disease and is an independent predictor of cardiovascular events. Controversies exist amongst the impact of resistance training protocols on the stiffening process in the major elastic arteries. This study was designed to address some of the controversies.
PURPOSE: To determine the vascular impact of a high-volume (HV), moderate resistance training program and a high-intensity (HI), moderate repetition training program on arterial compliance. **METHODS**: 21 otherwise healthy, male university students with limited resistance training experience (< 6 months) were randomized into one of three groups: 7 control (CO) group (22±3 yrs), 6 HI resistance exercise group (23±3 yrs), and 8 HV resistance exercise group (21±3 yrs). All were subjected to a series of tests including anthropometry, ultrasonography of the carotid artery, applanation tonometry, blood pressure acquisition, and maximal strength assessment. Subjects were instructed to maintain normal dietary patterns throughout the study period. Food consumption was monitored. All subjects in the training groups performed the same 8-10 exercises on training days. Subjects in the HV group trained at 50-70% of 1-RM with 10-15 repetitions and 2-4 sets per exercise for 3-5 days a week for 12 weeks. Subjects in the HI group trained at 70-95% of 1-RM with 3-6 repetitions and 2-3 sets per exercise for 3-5 days a week for 12 weeks. Subjects randomized to the control group were instructed to refrain from both cardiovascular and resistance exercise during the study period. Arterial stiffness comparisons

were calculated with two-way ANOVA with repeated measures. **RESULTS:** 1-RM significantly increased for squat (52% vs. 25%, p<0.05), bench press (31% vs. 27%, p<0.05) and seated rows (22% vs. 13%, p<0.05) in the HV and HI groups respectively. Carotid femoral PWV did not change in the HI (7.6±2 vs. 8.1±2 m/s, p>0.05), HV (6.3±1 vs. 6.8±2 m/s, p>0.05), and CO (6.7±1 vs. 6.7±1 m/s, p>0.05) groups. Beta stiffness index did not change in the HI (5.9±3.5 vs. 5.7±2.6 U, p>0.05), HV (6.5±1.9 vs. 6.5±2.1 U, p>0.05), and CO (7.2±4.4 vs. 6.4±3.1 m/s, p>0.05) groups. **CONCLUSION:** 12 weeks of HI and HV training does not appear to augment indices for arterial stiffness in young, adult males.

Interface Pressure Mechanics, Perceptual and Cardiovascular Responses To Different Cuffs In Blood Flow Restriction

Luke Hughes[1], Bruce M. Paton[2], Stephen Patterson[3]. *[1]St Mary's University / University College London, London, United Kingdom. [2]University College London, London, United Kingdom. [3]St Mary's University, London, United Kingdom.*

(No relevant relationships reported)

Blood flow restriction (BFR) is becoming more widely used with strength training in sports medicine and rehabilitation. It can be used passively and actively to combat muscle atrophy and strength loss observed during unloading in early post-traumatic and surgical contexts. Varied Cuff types and pressures have been used but quantification of interface pressures, safety and tolerance have not been widely investigated. **PURPOSE** : To investigate the interface pressure mechanics, perceptual and cardiovascular responses to different cuffs during acute bouts of passive blood flow restriction [BFR] and BFR exercise. **METHODS**: Eighteen participants attended three experimental sessions in a randomised, crossover, counterbalanced design. Participants underwent inflations at 40% and 80% limb occlusive pressure (LOP) at rest and completed 4 sets of unilateral leg press exercise at 30% of one repetition maximum with BFR at 80% LOP. Different cuffs were used for each session: a rapid-inflation, variable-contour and handheld cuff. Cuff-to-limb interface and Set pressure (IP, SP) were measured using a universal interface device with pressure sensors. Perceived exertion and pain were measured after each set, mean arterial pressure (MAP) was measured pre-, 1-min post- and 5-min post-exercise. **RESULTS**: IP was lower than the SP in all cuff trials at rest (p<0.05). IP was, on average, 10.24±8.01 and 47.65±35.95 mmHg higher than the SP for the rapid-inflation and handheld cuffs (p<0.01) and 2.17±6.70 mmHg lower than the SP for the variable-contour cuff (p>0.05) across all exercise sets. Pain and exertion were significantly greater in sets 3 and 4 in the rapid-inflation and handheld cuffs compared to the variable-contour cuff (p<0.05). MAP was significantly higher in the rapid-inflation and hand-held cuffs compared to the variable-contour cuff at 1-min and 5 min post-exercise (p<0.05). **CONCLUSION**: BFR cuffs that apply higher pressures than prescribed amplify CV and perceptual responses. A variable-contour cuff that regulates pressure is the most safe and effective for rehabilitative purposes in clinical populations.

Importance of Autophagy in the Recovery of Muscle Function After Injury in an Ovariectomized Model

Anna S. Nichenko, W. Michael Southern, Alexandra Flemington, Bethany L. Graulich, Jarrod A. Call. *University of Georgia, Athens, GA.*

(No relevant relationships reported)

The lack of ovarian hormones accentuates the loss of muscle contractility after muscle injury. Mitochondria are required to meet the energetic demands of muscle contractility, but whether mitochondrial function is affected by muscle injury and impacts repair is unclear in the context of ovarian hormone depletion. **PURPOSE:** To test mitochondrial dysfunction after muscle injury in the context of ovarian hormone depletion and to investigate autophagy, a cellular process for degrading damaged and dysfunctional mitochondria, as a mechanism of mitochondrial remodeling during regeneration. **METHODS:** We subjected sham surgery wildtype (WT) and ovariectomized (OVX) mice to traumatic muscle injury and assessed the recovery of in

vivo muscle strength (i.e. ankle dorsiflexion) and state 3 respiration from permeabilized muscle fibers at 7 and 14 days post-injury. To investigate autophagy, expression of autophagy-related proteins Beclin1 (Atg6) and LC3 were assessed. To determine if an interaction exists between ovarian hormones and autophagy, muscle strength and state 3 respiration were assessed 14 days post-injury following sham or OVX surgeries on Ulk1 deficient mice, a necessary protein for mitochondrial-specific autophagy, and littermate controls. **RESULTS:** OVX resulted in a 10% reduction in muscle strength (p=0.045) pre-injury compared to sham. This was exacerbated by muscle injury (14 days post-injury: OVX 25% vs. sham 35% of pre-injury, p=0.038). For state 3 respiration, there was a main effect of injury demonstrating a substantial reduction in mitochondrial function at 7 and 14 days post-injury (p<0.0001), independent of ovarian hormones. There was a large induction of autophagy as indicated by greater Beclin1 and LC3 expression at 7 and 14 days post-injury, independent of ovarian hormones (p=0.001, p=0.014 respectfully). Interestingly, OVX-Ulk1-deficient mice demonstrated less recovery of muscle strength at 14 days post-injury compared to OVX-LM (p= p=0.016). **CONCLUSIONS:** After muscle injury a robust autophagic response is required to recover muscle function in a timely manner and this occurs in the presence and absence of ovarian hormones. However, decreased strength recovery in OVX-Ulk deficient mice suggests an interaction between ovarian hormones and autophagy during muscle regeneration.

1534   Board #3   May 31 1:00 PM - 3:00 PM

Effect Of Diet And Exercise On Skeletal Muscle Morphology Following Radiation Therapy

Donna D'souza[1], Russell Emmons[2], Diego Hernández-Saavedra[2], Sophia Roubos[1], Jillian Larkin[1], Jessica Lloyd[1], Hong Chen[2], Michael De Lisio[1]. *[1]University of Ottawa, Ottawa, ON, Canada. [2]University of Illinois at Urbana-Champaign, Urbana, IL.*

(No relevant relationships reported)

With an increase in long-term cancer survival, the late effects of radiation therapy, a common treatment option, is an area of clinical concern. Furthermore, while obesity and physical activity levels are known to be associated with the risk for cancer, little is known regarding the effect of these two physiological factors on health following radiation therapy. **PURPOSE**: The purpose of the current investigation was to evaluate the influence of obesity and physical activity on skeletal muscle morphology following a sub lethal dose of radiation (IR). **METHODS**: Four-week-old male CBA mice were divided into control (CON; n=20) and high fat groups (HF; 45% fat, n=20). At 9 weeks of age mice in each group were further divided into sedentary (SED, n=10) and exercise (EX, n=10) groups. EX mice completed 4 weeks of treadmill training. At 13 weeks of age all mice were administered a therapeutic IR dose (3 Gy), and subsequently continued their previous exercise and dietary protocol for an additional 4 weeks. **RESULTS**: At 10 weeks of age HF groups had a higher percentage of body fat and higher body weight compared to controls (*p<0.05, n=9-10). At 16 weeks of age HF groups had significantly higher lean body mass and gastrocnemius/soleus complex mass compared to controls (p<0.05, n=9-10). Myofibre cross-sectional area (MCSA) analysis revealed an increase in EX groups (p<0.05, n=6-8), with a trend for an increase in HF groups (p=0.062, n=6-8). Fibre distribution analysis identified a decrease in 500-999 μm fibres (p<0.05, n=6-8), and a greater proportion of large fibres (≥2000 μm, p<0.05, n=6-8) in EX groups. Myonuclei/fibre in HF-EX was 1.3-fold higher than CON-EX and HF-SED (p<0.05, n=6-8). **CONCLUSIONS**: Diet-induced obesity resulted in an increase in body weight, adiposity, lean mass, and muscle weight. However, exercise training, but not HF, increased MCSA, and the proportion of large fibres. The increase in myonuclei content in HF-EX mice may implicate a role for muscle stem cell populations in this adaptive response. Future evaluation of distinct muscle stem cell populations and muscle morphological characteristics will be completed to further characterize the effect of diet and physical activity on skeletal muscle morphology following radiation therapy.

Plasticity Of Insulin Sensitivity And Muscle Mass In Healthy Older Adults Following Inactivity And Re-ambulation

Paul T. Reidy, Alec Mckenzie, Ziad Mahmassani, Nikol Yonemura, Vincent Morrow, Robin Marcus, Paul Hopkins, Yu K. Lin, Micah Drummond. *University of Utah, Salt Lake City, UT.*

(No relevant relationships reported)

Many older adults undergo repeated cycles of inactivity as they encounter sickness or injury. It is unknown how readily the insulin sensitivity and muscle mass of healthy older men and women are affected by modest physical inactivity (step reduction) and if these outcomes recover following a return to habitual physical activity. **PURPOSE**: To determine the changes in insulin sensitivity and leg muscle mass and function following inactivity and recovery.
METHODS: Healthy older adults (5F/7M, 70±2y, 26 kg/m² BMI, HbA1c 5.5±0.1%) were assessed before (PRE), after 2-weeks of step reduction (RA: <75% of normal

Abstracts were prepared by the authors and printed as submitted.

activity), and then following 2-weeks of baseline activity level (REC) for insulin sensitivity (euglycemic-hyperinsulinemic clamp), leg muscle mass (via DXA and pQCT) and isometric knee extension (KE) strength.
RESULTS: Participants decreased step counts during RA by ~70%. Glucose infusion rate (ml/kg FFM/min) during the clamp was 14.3±1.4 at PRE, decreased (p<0.05) to 12.5±1.7 at RA which then rebounded above PRE (p<0.05) to 16.6±1.9 at REC. This response was largely driven by the men. After removal of an outlier (+4.5% increase after RA), leg lean mass decreased after RA (p<0.05) 1.3±0.5% and then returned to PRE values at REC. Calf muscle area (pQCT) decreased (p<0.05) 2.4±0.9% from PRE to RA and then returned to PRE values at REC. KE strength decreased (p<0.05) 8.0±3.5% after RA and remained depressed 7.4±1.4% compared to PRE.
CONCLUSIONS: In healthy older men and women, insulin sensitivity as assessed via the gold standard (euglycemic hyperinsulinemic clamp) decreased (15±6%) following 2-weeks of modest physical inactivity, but unexpectedly, was able to rebound (39±8%) after re-ambulation such that it was 14±5% higher than baseline. This response may be limited to healthy older adults and therefore warrants further investigation. These older adults experienced modest muscle mass loss with step reduction that was restricted to the legs and especially the lower leg muscles. Knee extension strength was decreased after RA but did not recover following re-ambulation. Follow-up analysis may provide additional insight into the molecular mechanisms associated to the current metabolic and muscle alterations that occur with short-term physical inactivity and re-ambulation. Supported by NIH Grant R01 AG050781

Effect Of Resistance Exercise Training On Anabolic Resistance To Amino Acids In Healthy Older Adults

Tatiana Moro, Camille R. Brightwell, Rachel R. Deer, Ted G. Graber, Elfego Galvan, Christopher S. Fry, Elena Volpi, Blake B. Rasmussen. *University of Texas Medical Branch, Galveston, TX.* (Sponsor: Paddon-Jones, Douglas J, FACSM)
(No relevant relationships reported)

Aging attenuates the contraction-induced stimulation of muscle protein synthesis (MPS). This phenomenon is termed "anabolic resistance", and may contribute to the slow loss of muscle mass with advancing age (sarcopenia). Some studies also reported anabolic resistance to amino acid/protein intake with aging. However, this notion has not been firmly established. Acute bouts of exercise can improve the ability of amino acids to stimulate MPS by activating mechanistic target of rapamycin complex 1 (mTORC1) signaling and translation initiation, but it is not known whether chronic exercise training may improve muscle sensitivity to amino acid availability.
PURPOSE: The aim of this study was to determine if healthy older adults exhibit muscle anabolic resistance to essential amino acid intake (EAA), and whether resistance exercise training (RET) improves the muscle sensitivity to EAA.
METHODS: To test our hypothesis 19 healthy older adults (65-80 years old) underwent a 12-week progressive resistance exercise training program (RET). Before and after training we measured muscle mass and strength, and performed stable isotope infusion experiments with muscle biopsies to determine MPS and markers of amino acid sensing in the basal state and in response to EAA ingestion.
RESULTS: RET increased muscle strength (+15%), lean mass (+2%), and muscle cross sectional area (+17%) in healthy older adults (P<0.05). MPS and mTORC1 signaling (i.e., phosphorylation status of 4E-BP1, S6K1, and rpS6) increased following EAA ingestion (P<0.05). Basal MPS increased by 28% after RET (P<0.05). However, the amplitude of the response of MPS and mTORC1 signaling to EAA ingestion did not differ from pre-training values (P>0.05).
CONCLUSION: Aging does not inhibit the EAA-stimulation of muscle mTORC1 signaling and MPS. In addition, RET did not increase the sensitivity of muscle to amino acids. Our data indicate that anabolic resistance to amino acids is not a significant problem in healthy older adults. We suggest that future work in conditions associated with more pronounced muscle wasting is necessary to determine whether exercise training can improve muscle sensitivity to amino acids or protein. Supported by NIH/NIA R56 AG051267, P30 AG024832, NIH/NCATS UL1 TR001439.

Impact of Short-term Sedentariness on Week-to-Week Myofibrillar Protein Synthesis Rates in Physically Active Young Men

Brandon J. Shad[1], Andrew M. Holwerda[2], Yasir S. Elhassan[1], Luc J.C. van Loon[2], Janice L. Thompson, FACSM[1], Gareth A. Wallis[1]. *[1]University of Birmingham, Birmingham, United Kingdom. [2]Maastricht University, Maastricht, Netherlands.*
(No relevant relationships reported)

Sedentary behaviour has been linked to the development of cardiometabolic disease and insulin resistance but little is known about its impact on the regulation of skeletal muscle mass. **PURPOSE**: To determine the impact of short-term sedentariness on week-to-week myofibrillar protein synthesis rates. **METHODS**: Utilising a within-subject design, eight physically active young men (22±1 y) completed 7 days of habitual physical activity (HPA) followed by 7 days of increased sedentariness (SED) using a step reduction model. Two days prior to the study, participants ingested 400 mL of deuterium oxide (^2H_2O) with 50 mL ^2H_2O doses ingested daily thereafter for the remainder of the study. Daily saliva samples were collected throughout to assess body water deuterium (^2H) enrichments. Muscle biopsies were collected at the beginning of the study (D1), after 7 days of HPA (D8) and after 7 days of SED (D15) for assessment of week-to-week myofibrillar protein synthesis rates. **RESULTS**: Currently, eight participants have completed the intervention. Preliminary data indicate that step count was reduced by approximately 92% during SED (14052±797 to 1185±134 steps·d^{-1}; P < .001) and this led to a substantial increase in the contribution of sedentary behaviour to daily activity (72±3 to 90±1 %; P < .001) and decrease in the contribution of standing (17±2 to 8±1 %; P < .001) and ambulation (10.0±0.4 to 1.0±0.2 %; P < .01) to daily activity. ^2H_2O ingestion resulted in mean body water ^2H enrichments of 0.64±0.04 % during HPA and 0.70±0.06 % during SED (P < .05). Week-to-week myofibrillar protein synthesis rates decreased by approximately 26% from 1.24±0.08 %·d^{-1} during HPA to 0.92±0.14 %·d^{-1} during SED (P = .096). **CONCLUSIONS**: Preliminary data show a trend for short-term sedentariness to reduce week-to-week myofibrillar protein synthesis rates in physically active young men.

Utilizing Next Generation Sequencing to Describe Age-Related Skeletal Muscle Changes with Bed Rest

Ziad S. Mahmassani, Paul T. Reidy, Alec I. McKenzie, Chris Stubben, Robin Marcus, Paul LaStayo, Mark Supiano, Michael Howard, Micah J. Drummond. *University of Utah, Salt Lake City, UT.*
(No relevant relationships reported)

Short-term bed rest is used to simulate periods of disuse experienced during hospital visitation. In our previous reports, we found that 5d of bed rest induced a ~4% loss of skeletal muscle mass in OLD (60-79 y) but not YOUNG (18-28 y) subjects (Interaction: P < 0.001). Identifying muscle transcriptional events that underlie this consequence of bed rest will help identify therapeutic targets to offset muscle loss in vulnerable older adult populations. **Purpose**: To compare the gene transcriptome response between YOUNG and OLD skeletal muscle after bed rest and identify a transcriptional program that underlies rapid loss of muscle mass. **Methods:** RNA was isolated and sequenced (HiSeq, Illumina; DESeq, R) from muscle biopsies obtained from the vastus lateralis of YOUNG (N=9; 22.9 ± 1.1 y, 171.6 ± 2.0 cm, 65.6 ± 4.6 kg) and OLD (N=18; 67.6 ± 1.3 y, 173.7 ± 1.8 cm, 75.7 ± 2.2 kg) men and women before and after five days of bed rest (Tanner et al 2015; Reidy et al 2017). **Results:** After bed rest, 551 genes responded similarly and 61 genes were differentially regulated between YOUNG and OLD (P ≤ 0.05). Ingenuity Pathway Analysis identified the top commonly regulated pathways to be related to Actin Cytoskeleton Signaling, ILK Signaling, Calcium Signaling, and Mitochondrial Dysfunction. Out of the differentially regulated genes, 51 were altered in YOUNG (42 increased, 9 decreased) but were unresponsive in OLD after bed rest (P ≤ 0.05). On the other hand, 9 genes were altered only in OLD as a result of bed rest (P ≤ 0.05) of which 5 are protein coding (MRPL49, HIST1H2BC: increased; PXDNL, NEXN, MAGI2: decreased). These genes code for proteins related to mitochondrial function, DNA structure, oxidative stress, Z-disc stabilization, and activin signaling, respectively. **Conclusion:** Our preliminary results indicate that altered gene expression in YOUNG in response to bed rest may be indicative of a compensatory expression profile to combat muscle loss. Additional investigation of the differentially regulated gene responses in young and old adults are ongoing in efforts to further describe underlying molecular events that occur in response to bed rest. Supported by NIH Grant R01 AG050781.

Neuromotor Training in Older Adults: A Pilot Study

Natalie Barron, Michelle Perri, Joshua Guggenheimer. *St. Catherine's University, St Paul, MN.* (Sponsor: Mark Blegen, FACSM)

(No relevant relationships reported)

PURPOSE: To discover if older women have improved gait speed and ROM after participating in a neuromotor training exercise program.
METHODS: Seven independently living women (79±9 yrs) participated in our study. Subjects underwent 16 sessions of neuromotor training over an 8-week period. The program consisted of two sets of 10 repetitions of eight exercises: squats, chair dips, lunges, band row, hip flexion and extension, bicep curls, ankle plantar flexion and dorsiflexion, and one legged balance. Hip flexion and ankle arc range of motion were measured pre- and post-intervention using an Acumar digital inclinometer. Gait speed, stride length, double stance time and timed-up-and-go (TUG), were measured using the BTS G-Walk device both pre- and post-intervention.
RESULTS: TUG times were significantly reduced from 14±6 sec to 10±4 sec, (p = 0.006). Interestingly, right hip ROM was significantly reduced post-intervention (94±13 vs. 88±13, p = 0.01). While not statistically significant, there was a 14% increase in gait speed and 8% and 10% increases in left and right leg stride lengths, respectively. Moreover, double limb stance time decreased by 12% and 19% with the left and right legs leading, respectively.
CONCLUSIONS:
The importance of improved gait and ROM variables is crucial for OA in order to reduce the risk of falls. The intervention used in this study produced a significant reduction in TUG times, which may imply enhanced functional independence, as TUG performance is contingent upon lower-body strength and gait speed. Even though statistically significant improvements in ROM and gait speed were not found, practical improvements were observed. Future neuromotor interventions should continue to find exercises that prioritize the improvement of gait and ROM variables, thereby enhancing functional independence.

Dual-task Training Reduces Fall Frequency And Increases Physical Activity In Individuals With Parkinson's Disease

Amanda L. Penko[1], Jacob E. Barkley[2], Jay L. Alberts[1]. *[1]Cleveland Clinic, Cleveland, OH. [2]Kent State University, Kent, OH.*

(No relevant relationships reported)

Parkinson's disease (PD) is a neurodegenerative disease associated with motor and non-motor symptoms that increase individuals' risk of falling, which may contribute to lowered physical activity behavior. Dual-task constructs, or simultaneous performance of a motor-cognitive task, results in an increase in gait dysfunction in PD; however both single-task (separate training of gait and cognition), and dual-task training (i.e., simultaneous training of gait and cognition) have been shown to improve gait function in PD. A comparison of the effects single- and dual-task interventions on physical activity behavior, falls and motor symptoms in PD has yet to be assessed. **Purpose:** The aim of this study was to determine the effects of single- and dual-task training on physical activity, falls, and motor symptoms in PD patients with a history of falls. **Methods:** Twenty-one PD patients (age 63 ± 9 years) were randomized into single (*n* = 11) or dual-task (*n* = 10) training group. Both training groups exercised 40 minutes, three times/wk for eight weeks. Daily physical activity, 30-day fall frequency, and Unified Parkinson's Disease Rating Scale (UPDRS) were assessed during peak levodopa response (1-hr post antiparkinsonian medication administration) by a single-blinded rater at baseline and post intervention. **Results:** UPDRS scores significantly (*p* = 0.007) improved from baseline (34.90 ±11.24) to end of treatment (32.75 ±11.63) for both the single and dual-task groups. Physical activity significantly increased (*p* = 0.03) from baseline (4,942 ± 4,415 steps/day) to end of treatment (5,914 ± 5,425 steps/day) for both single and dual-task groups combined. Fall frequency decreased significantly (*p* = 0.02) in the dual-task group from baseline (2.30 ±3.02 falls) to end of treatment (0.80 ± 1.14 falls) with no change (*p* = 0.32) in falls in the single-task group (0.60 ± 0.84 falls at baseline, 0.80 ± 1.14 falls at end of treatment). **Conclusion:** Both single and dual-task training were successful in increasing physical activity.

The improvement in UPDRS scores exceeded the threshold for minimally clinically important difference. Fall frequency was reduced only in the dual-task group, which indicates dual-task training is superior than single-task training at reducing falls in PD.

A Novel Movement Ability Training Program Enhances Performance in Female Soccer Athletes

Casey Myers[1], Mike Decker[1], Kevin Shelburne[1], Matt Shaw[1], Julie Graves[2], Eric McCarty[2], Michelle Wolcott[2]. *[1]University of Denver, Denver, CO. [2]University of Colorado, Boulder, CO.*

(No relevant relationships reported)

PURPOSE: The purpose of this study was to assess the effects of a novel training program on the field-based performance testing of speed, power and movement quality.
METHODS: Twenty-five, elite female soccer athletes (13.3 ± 0.6 y; 161.9 ± 5.3 cm; 50.9 ± 4.9 kg) participated in a 7-week, training program performed with a wearable neuromuscular device (WND). The training program was directed by an exercise specialist and consisted of a three-tier progression of exercise complexity and intensity to enhance the athlete's movement ability. All athletic exposures with and without the WND were recorded and analyzed descriptively. Field-based measurements of speed, power and movement quality were performed at the start (pre) and the end (post) of the training program. Speed was measured with a stop watch during a 20 yard sprint. Power was calculated from the flight times of three, single leg maximum vertical jumps captured with a wireless inertial measurement unit attached with double sided adhesive over the sacrum. Movement quality was determined by video analysis of three drop jump landings using the original and modified Landing Error Scoring System (LESS). A one-way repeated measures ANOVA contrasted pre and post sprint times and the average number of landing errors scored by the standardized methods of the LESS and the modified LESS. A two-way (time, leg) repeated measures ANOVA was used to measure the change in average and peak single leg jump heights (p=.005).
RESULTS: Twenty-two athletes completed pre and post testing. Each athlete had an average of 11.3 ± 2.9 hours of weekly athletic exposure of which 6.9 ± 1.7 hours were with the WND. Over the course of training, speed increased 4% (pre, 3.36 ± .06 s; post, 3.22 ± .04 s; F(1,21)=10.171, p=.004), average and peak power increased 40% (pre, .125 ± .003 m; post, .175 ± .006 m; F(1,21)=59.618, p<.001) and 37% (pre, .140 ± .004 m; post, .192 ± .007 m; F(1,21)=48.482, p<.001) and movement quality increased by 20% (LESS: pre, 6.7 ± .4 errors; post, 5.3 ± .5 errors; F(1,21)=15.032, p=.001; modified LESS: pre, 7.3 ± .4 errors; post, 5.8 ± .5 errors; F(1,21)=22.353, p<.001).
CONCLUSIONS: The novel training program enhanced the field-based measurements of speed, power and movement quality in elite female soccer athletes.

Results from the Randomized Controlled Trial Cyclical Lower Extremity Exercise (CYCLE) Trial for Parkinson's disease

Jay L. Alberts, Amanda L. Penko, Anson Rosenfeldt, Nicole M. Zimmerman. *Cleveland Clinic, Cleveland, OH.*

(No relevant relationships reported)

Parkinson's disease (PD) is a neurodegenerative disease affecting approximately one million Americans. Our previous work suggested that forced exercise (FE), a mode of aerobic exercise in which voluntary exercise (VE) rate is augmented, results in global motor improvements. **Purpose:** The aim of this randomized clinical trial was to systematically evaluate the effects of voluntary and forced exercise on the motor symptoms of PD. **Methods:** A total of 100 individuals with PD (age 63 ± 8 years, *n* = 38 females) were randomized into one of three groups: VE (*n* = 40), FE (*n* = 40), or no-exercise control (*n* = 20). The VE and FE groups exercised 3x/week for 8 weeks on a stationary semi-recumbent cycle ergometer in a target heart rate range of 60-80% of heart rate reserve. The FE group exercised on a stationary cycle with the assistance of a motor that augmented pedaling rate by 35% compared to their preferred exercise rate. The MDS-Unified Parkinson's Disease Rating Scale (UPDRS) was used to characterize PD motor function. All clinical evaluations were completed while patients were 'off' antiparkinsonian medication (12 hr) at baseline, end of treatment (EOT), EOT+4 week and EOT+8 week. **Results:** UPDRS-III scores significantly decreased from baseline to the EOT for both the VE and FE groups. The VE and FE groups demonstrated significant improvements in clinical ratings following exercise. The magnitude of improvement was 5.4 and 4.5 points for the VE and FE groups (*p*<0.001) at EOT. The significant decrease in UPDRS-III was maintained for the VE (-3.5) and FE (-3.2) during the EOT+8 week follow up. The control group exhibited a slight worsening, 2.2 increase, at EOT in clinical ratings. There were no significant differences between the VE and FE groups. **Conclusion:** Improvements in global motor performance following VE and FE interventions indicate high intensity aerobic exercise is likely enhancing central nervous function (CNS) which ameliorates basal ganglia dysfunction associated to PD. The clinical rating improvement in the FE and

VE groups persisted eight weeks after ending treatment suggesting high intensity aerobic cycling may have potential in altering PD progression and efficacy as a complementary treatment to traditional approaches to PD.

Long-term Tai Chi Exercise Lead to Enhanced Resistance Postural Perturbation Among Older Adults

Jiahao Pan[1], Cuixian Liu[2], Li Li, FACSM[3]. *[1]361° (CHINA) CO., LTD,, Xiamen, China. [2]Shanghai University of Sport, Shanghai, China. [3]Georgia Southern University, Statesboro, GA.*
(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the influences of performing precision fitting task on the dynamics of postural sway among older adults. **METHODS**: Three groups (12 each) participants aged 65 to 75 years recruited for the project: habitual Tai Chi practitioners (TC, body mass (M) = 64.4 ± 9.3 kg, height (H) = 162.5 ± 6.9 cm), long term brisk walkers (BW, M = 62. 8 ± 6.6 kg, H = 163.5 ± 6.5 cm), and sedentary (SE, M = 68.3 ± 7.0 kg, H = 163.9 ± 7.0 cm). Participants were asked to stand on a force plate (Kistler 9287C, Kistler Corporation, Switzerland) with their feet forming a 30° angle and their heels 8% body height apart. Participants were required to fit a 90 * 90 mm block into three different openings (small: 100 * 100, medium: 115 *115, and large: 130 * 130 mm) with two different distances (1 and 1.3 times arm's length). The task time and base of support were recorded by optical gate and reflective markers using Vicon system (Vicon Corporation, USA) synchronized with force plate data collection. The average time-to-contact (TTC) measures were used to examine the dynamic of posture sway during fitting task. Two two-way ANOVAs were used to assess the effects of group by size for average TTC at the two reaching distances. **RESULTS**: There was no group by size interaction observed for either distance ($p > .05$). Significant differences were detected for group (close: $F_{2,99} = 11.567$, $p < .00$; far: $F_{2,99} = 13.549$, $p < .00$) and size (close: $F_{2,99} = 49.228$, $p < .00$, far: $F_{2,99} = 36.296$, $p < .00$) for both distances. LSD Post Hoc revealed that TTC for TC was significantly less than that of the SE and BW at both close (2.30±0.56 vs. 2.81±0.71 vs. 2.61±0.71 s, $p < .05$) and far distance (1.82±0.31 vs. 2.30±0.61 vs. 2.11±0.58 s, $p < .05$). Additionally, TTC of small fitting size was significantly longer than that of the middle and lager fitting sizes, while TTC of middle size also was longer than that of the larger size at both close (3.25±0.75 vs. 2.46±0.43 vs. 2.14±0.28 s, $p < .05$) and far (2.52±0.57 vs. 1.98±0.42 vs. 1.74±0.30 s, $p < .05$) distances. **CONCLUSIONS**: Small fitting opening provided greater perturbation to postural control lead to longer TTC. However, postural control of the TC revealed having greater resistance to the perturbation lead to shorter TTC. Therefore, Tai Chi training have the potential for resist postural perturbation and prevent fall among older adults.

1545   Board #6   May 31 1:00 PM - 3:00 PM

Feasibility and Effectiveness of Augmented Feedback on Landing Mechanics in Female Basketball Players Compared to Controls

Erin H. Hartigan, Kelly Coleman, Jaclyn Brooks, Hailey Frisbee, Michael Lawrence, Katie Hawke, Gwenyth Breslen. *University of New England, Portland, ME.*
(No relevant relationships reported)

PURPOSE: Improper landing biomechanics (dynamic limb valgus,[1] hard landing,[2,3] and limb asymmetries[4]) influence risk of ACL injury in female athletes.[5] An intervention to train women to land properly using minimal time and resources appears warranted.[6] This study tested the feasibility and effectiveness of implementing video feedback and task cards (written and pictorial cues) into basketball practice. Effectiveness was defined as reducing dynamic limb valgus (greater hip abduction and external rotation angles), landing softer [lesser vertical ground reaction force (vGRF), greater hip and knee flexion angles], and decreasing limb differences. **METHODS**: 16 female high school basketball players were randomly assigned to a control (n=8) or intervention (n=8) group. The intervention (I) group utilized delayed video feedback and task cards at 6 practices while the control (C) group received typical coaching. Pre and post-season data collections included 5 double and 5 single limb drop jumps [dominant (D) and non-dominant (ND) limb] from a 31 cm box onto a force plate. Motion analysis equipment and software were used to calculate peak hip and knee angles and vGRF over the first 10% of landing.[2] A RM-ANOVA was used (P<.05). **RESULTS**: The feedback paradigm did not increase practice time and cost was minimal ($8 for BaM video delay app, iPad® was borrowed). Significance for double limb landing include: a group*time interaction for hip flexion angles (p=.04; C group decreased hip flexion angles over time: Pre=55°; post=46°); main effect of time for hip abduction (ABD) angle (p=.009; pre=1.7°; post=3.2°); and a main effect of group for hip ABD angles (p=.043; I=4.6°; C=.3°). Significance for single limb landing included a time*group interaction for vGRF (p=0.04, I group decreased over time); and a time*limb interaction for hip external rotation angles [p=.016; limb differences at pre (D=5.8°; ND=.77) and not at post (D=1.5°; ND=4.3°)]. **CONCLUSION:** This intervention provided varied feedback for different learning styles[7] and may improve landing mechanics in female athletes. High team compliance with the intervention may

---

occur since it requires minimal time and resources. **References:** 1. Paterno AJSM 2010 2. Paterno CJSM 2007 3. Hewett AJSM 2005 4. Fox SM 2014 5. Munro PTS 2012 6. Sugimoto CPMRR 2015 7. Braakhuis JHSE 2015

Effects of Gait Modification on Lower Extremity Sagittal Plane Biomechanics

Oladipo Eddo[1], Bryndan Lindsey[1], Shane Caswell[1], David Hollinger[1], Jessica Pope[1], Matt Prebble[1], Ana M. Azevedo[2], Nelson Cortes[1]. *[1]George Mason University, Manassas, VA. [2]University of Lisbon, Lisbon, Portugal.*
(No relevant relationships reported)

Gait modification (GM) via real-time biofeedback (RTB) is a conservative intervention that has shown positive outcomes in post stroke and diabetic patients. Results from a recent systematic review support the effectiveness of this approach for increasing peak internal knee extension moment (iPKEM). iPKEM is a resistive moment to peak external knee flexion moment (ePKFM), which is associated with altered joint loading. Scarce information exists on the comparative effectiveness of existing GM strategies. **PURPOSE:** To compare the effectiveness of trunk lean (TL), medial knee thrust (MKT), and foot progression (FP) on iPKEM. **METHODS:** 10 healthy individuals volunteered for this study (28.4±3.8 years, 1.73±0.1 m, 75.3±12.5 kg). Mean and standard deviation (SD) for iPKEM, trunk angle, knee angle (KA), and foot angle during stance were calculated from 10 baseline trials using a motion capture system (200Hz) and force plates (1000Hz). 10 trials completed for each strategy using RTB so that joint angles fell within a determined range (1-5 SD) relative to baseline. Visual 3D (V3D) was used to project visual RTB as a line graph displaying real-time joint angle during stance. V3D was used to calculate joint angles (°) and internal moments (Nm/kgm). Participants modified their gait based on strategy so the line fell within a highlighted bandwidth representing target ranges. Repeated measures ANOVA was used to assess differences in iPKEM between strategies. Dependent t-tests were conducted to compare joint angles between baseline and modification strategy (p<0.05). **RESULTS:** A significant difference between strategies was attained for iPKEM (p=0.001). MKT (.53±.24) had higher iPKEM than all other strategies (Baseline: .31±.2, FP: .34±.12, TL: .31±1.4). No other statistically significant difference was found (p>0.05). **CONCLUSION:** MKT gait increased iPKEM despite no significant differences in KA compared to baseline. The observed increase in iPKEM during MKT gait suggests that participants were successful at attenuating ePKFM during the absorption phase of stance. Lack of significant changes in joint angles across conditions suggests that overall gait kinematics were similar for all conditions. Future research employing greater values for kinematic change is needed to further understand the effect of GM on iPKEM.

Can the Newly Learnt Gait Pattern after Running Retraining be Translated to Untrained Conditions?

Janet H. Zhang[1], Zoe Y.S. Chan[1], Ivan P.H. Au[1], Winko W. An[2], Roy T.H. Cheung[1]. *[1]The Hong Kong Polytechnic University, Kowloon, Hong Kong. [2]Boston University, Boston, MA.*
(No relevant relationships reported)

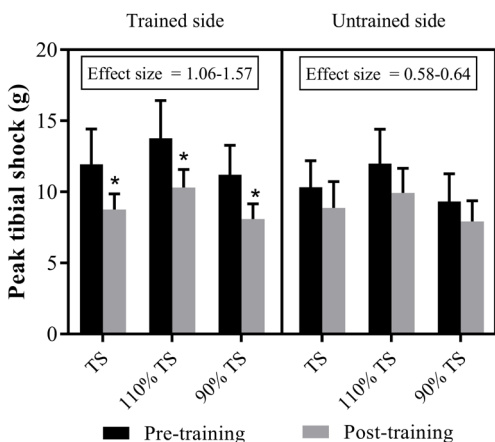
Running retraining is reported to be effective in impact loading control and injury prevention. During running retraining, biomechanics metrics, such as tibial shock, from one side of the body is usually provided while the participant is running at a controlled test speed. Whether participants are able to translate the newly learnt gait pattern to untrained conditions (e.g., untrained side of the limb and untrained speeds) remains unanswered. **PURPOSE**: To compare the tibial shock of the participants' untrained limb and at untrained running speeds before and after a course of running retraining. **METHODS**: Ten runners underwent a running retraining program as described by Crowell & Davis (2011). Before and after the program, their tibial shock from both limbs were measured using wireless accelerometers when they were running at the training speed (TS), 110% of TS and 90% of TS. The peak tibial shock during the last 20 footfalls in each 3-minute trial were extracted for analyses. **RESULTS**: The effect of gait retraining did not interact with test speeds (p=0.699) but it interacted with limb side (p<0.05). We found a reduction in the tibial shock on the trained limb at all test speeds (p=0.001-0.008; Figure 1). However, we only observed a trend of tibial shock reduction on the untrained side (p=0.074-0.098; Figure 1). **CONCLUSIONS**: The current running retraining protocol may not be fully optimized as the newly learnt gait pattern may not be completely translated to untrained conditions.


Figure 1. Peak tibial shock before and after running retraining at three speeds

TS: Training speed
* Significantly reduced compared to pre-training test

Rural-Urban Differences in Meeting Physical Activity Recommendations in Cancer Survivors in Central Pennsylvania

Scherezade K. Mama[1], Wayne Foo[2], Renate Winkels[2], Joachim Wiskemann[2], Shirley M. Bluethmann[2], William Calo[2], Joel E. Segel[1], Eugene J. Lengerich[2], Kathryn H. Schmitz, FACSM[2].
[1]*The Pennsylvania State University, University Park, PA.* [2]*Penn State Cancer Institute, Hershey, PA.* (Sponsor: Kathryn H. Schmitz, PhD, MPH, FACSM, FTOS)

(No relevant relationships reported)

PURPOSE: To examine rural-urban differences in physical activity among cancer survivors in central Pennsylvania.
METHODS: Cancer survivors residing in central Pennsylvania were identified through the Pennsylvania Cancer Registry and mailed select questionnaires based on the Behavioral Risk Factor Surveillance Survey (BRFSS). The 2013 Rural/Urban Continuum Codes (RUCC) were used to classify cancer survivors as urban/metro (RUCC codes 1-3) or rural/nometro (RUCC codes 4-9). Cancer survivors self-reported frequency and duration of aerobic physical activity and frequency of muscle-strengthening physical activity. To maintain consistency with the ACSM exercise guidelines for cancer survivors and the 2008 Physical Activity Guidelines for Americans, respondents were classified as meeting aerobic guidelines (yes/no ≥150 minutes/week), muscle-strengthening guidelines (yes/no ≥2 times/week), both aerobic and muscle-strengthening guidelines, or neither aerobic nor muscle-strengthening guidelines. A composite variable was included in multivariate models to examine the association between rural-urban residence and meeting physical activity recommendations, adjusting for cancer site, age, BMI, education, and income.
RESULTS: Rural (*n*=64, 10.9%) and urban (*n*=521) cancer survivors from 27 counties in Pennsylvania completed mailed questionnaires. The prevalence of physical inactivity was higher in rural cancer survivors (rural 39.1%, urban 30.8%), but this difference was not statistically significant (χ^2=1.8, *p*=.180). Urban cancer survivors were 1.8 times more likely to meet aerobic physical activity guidelines compared to rural cancer survivors (95% CI: 1.015, 3.25; *p*=.040); however, this was only marginally significant after adjusting for covariates (OR=1.91; 95% CI: 0.98-3.76; *p*=.057). Adjusted analyses with the composite variable confirmed that urban cancer

survivors were 2.6 times more likely than rural cancer survivors to meet the aerobic physical activity guideline compared to meeting neither guideline (OR=2.62; 95% CI: 1.08-6.31, *p*=0.03).
CONCLUSIONS: Culturally and contextually adapted interventions are needed to improve adherence with physical activity recommendations and reduce cancer health disparities in rural cancer survivors in Pennsylvania.

Breast Cancer Survivors' Psychosocial Beliefs, Physical Activity and Quality of Life

Zachary Pope[1], Nan Zeng[1], Jung E. Lee[2], Zan Gao, FACSM[1].
[1]*University of Minnesota-Twin Cities, Minneapolis, MN.*
[2]*University of Minnesota-Duluth, Duluth, MN.* (Sponsor: Zan Gao, FACSM)

(No relevant relationships reported)

PURPOSE: Physical activity (PA) among breast cancer survivors (BCS) has been associated with quicker physiological and psychological recovery following cancer treatment. Yet, little study has examined the predictive utility of psychological beliefs on BCS's quality of life (QoL) and objectively-assessed PA. Therefore, this study examined whether BCS's psychosocial beliefs predicted QoL and daily PA, energy expenditure (EE), and steps/day, with an additional examination of whether QoL differed based upon whether BCS met PA recommendations.
METHODS: Forty BCS (X_{age} = 51.2 ± 10.0 years; $X_{wt.}$ = 80.1 ± 19.7 kg) participated in baseline testing of two larger parent intervention trials. Participants completed validated surveys regarding social cognitive beliefs (i.e., self-efficacy, social support, enjoyment, outcome expectancy, and barriers) and QoL outcomes (i.e., anxiety, physical functioning limitations, fatigue, depression, sleep disturbances, pain interference/intensity, and ability to participate in social roles/activities). One-week daily sedentary behavior (SB), light PA (LPA), moderate-to-vigorous PA (MVPA), EE, and steps/day were assessed via ActiGraph GT3X+ accelerometers.
RESULTS: BCS participated in a daily average of 556.2 min, 119.9 min, and 31.3 min of SB, LPA, and MVPA, respectively, with respective daily EE and steps/day being 385.5 kcals and 4,808 steps. Stepwise multiple regression indicated self-efficacy was the only observed predictive of overall QoL—explaining 34.9% of the variance for this variable (F(1, 37) = 19.3, *p* < 0.01). Further, only outcome expectancy was found predictive daily LPA (F(1, 37) = 5.5, *p* = 0.03)—explaining 13.2% of the variance. Notably, however, independent t-tests showed no differences in any QoL outcome between BCS who met or did not meet PA recommendations.
CONCLUSIONS: Findings suggest health professionals concentrate first on increasing BCS PA self-efficacy and outcome expectancy to increase PA participation and improve QoL. Larger sample sizes might allow for broader investigations of the predictive utility of psychosocial beliefs on QoL and daily PA behavior.

A Meta-analysis Of Tai Chi/qigong On Fatigue And Quality Of Life In Cancer Patients

Xiaoyue HU, Stanley Sai-chuen HUI, FACSM. *The Chinese University of Hong Kong, Hong Kong, China.* (Sponsor: Stanley Sai-chuen HUI, FACSM)

(No relevant relationships reported)

Due to the advances in cancer treatment, 64% of the person diagnosed with cancer can expected to be alive in 5 years. Long-term cancer-related health problems for these cancer survivors becoming a public health concern. Growing evidence suggests Tai chi or Qigong as a mind-body exercise become an option for cancer patients to improve QoL and reduce the cancer related fatigue symptom (CRF).**PURPOSE**: To investigate the effects of Tai Chi /Qigong versus non-Tai Chi/Qigong treatment on cancer patients' health related QoL and CRF.**METHODS**:Studies on randomized controlled trials (RCT) of Tai Chi /Qigong as an intervention were retrieved from Medline, CINAHL, SPORTDiscus, Cochrane Library, and PubMed. Meta-analyses were performed on changes in QoL and CRF. QoL was measured by SF-36 questionnaire and cancer-specific QoL was assessed by functional assessment of cancer treatment-general (FACT-G). CRF was assessed by brief fatigue inventory (BFI) or functional assessment of chronic illness therapy-fatigue (FACIT-F). Random effects model was used to calculate the pooled mean difference (MD) with 95% confidence interval (CI).
RESULTS: A total of 14 RCTs (1,001 subjects)were included in this review. Nine RCTs (567 subjects) provided sufficient data to estimates the effect size for QoL and CRF. For QoL assessed by SF-36 questionnaire, significant differences were found in two subscales, mental health and vitality. The MD of mental health and vitality were 2.33 (95% CI: 1.71, 2.96; Z score = 7.31; *p* <0.01), 1.50 (95% CI: 0.56, 2.44; Z score = 3.14; *p* =0.002). QoL assessed by five subscales (PWB, SWB, FWB, total) FACT-G change scores were in support of Tai Chi/Qigong interventions and indicated a statistically significant effect. Their MD were 2.36 (95% CI: 1.32, 3.40), 2.91 (95% CI: 1.49, 4.32), 1.24 (95% CI: 0.03, 2.44), 2.70 (95% CI: 1.73, 3.68), and 7.74 (95% CI: 4.58, 10.91), respectively. For CRF, the standardized mean difference (SMD) was−0.51 (95% CI: −0.98, -0.04; Z score = 2.14, *p* = 0.03) indicating that Tai Chi /Qigong had

Abstracts were prepared by the authors and printed as submitted.

significant positive effects on cancer patients' CRF.**CONCLUSIONS**: This study concluded that Tai Chi/Qigong had positive effects on QoL and cancer related fatigue symptoms on cancer patients. The findings need to be interpreted with caution due to limited studies and relatively small sample size.

Does Low Volume High-Intensity Interval Training Elicit Superior Benefits to Continuous Low to Moderate-Intensity Training in Cancer Survivors?

Kellie L. Toohey, AEP. *University of Canberra, Bruce, Australia.*
(No relevant relationships reported)

PURPOSE: It is generally recommended that exercise form part of the standard of care for all cancer survivors, however, the optimal evidence-based clinical exercise guidelines for cancer survivors are currently not clear. The aim of this study was to determine the effectiveness of low volume high-intensity interval training (LVHIIT) and continuous low to moderate-intensity exercise training (CLMIT) on health outcomes in cancer survivors. **METHODS**: Sedentary cancer survivors (n = 75) within 24 months of diagnosis, aged 51 ± 12 y were randomised into three groups for 12 weeks of LVHIIT (n = 25), CLMIT (n = 25) or control group (n = 25). The LVHIIT group performed 7 x 30s intervals (≥ 85% predicted maximal heart rate), the CLMIT group performed continuous aerobic training for 20 min (≤ 55% predicted maximal heart rate) on a stationary cycle, three times per week. **RESULTS**: An interaction effect (p = 0.01) for waist circumference in the LVHIIT group was found. The LVHIIT group had larger improvements in emotional well-being compared to the other groups (p < 0.01). Participants in the CLMIT and LVHIIT group demonstrated improvements in physical and functional well-being (p < 0.01). **CONCLUSIONS**: LVHIIT elicited greater benefits in improving waist circumference and emotional well-being compared to the other groups in this study. Exercise positively impacted body composition, white blood cell count (WBC) and haemodynamic variables, without any adverse effects. Future research should explore the mechanisms involved in the changes reported in this study, so that clinicians can provide clinically relevant evidenced-based exercise prescription for cancer survivors.

1553   Board #5   May 31 1:00 PM - 3:00 PM

The Association Between Light Physical Activity and Physical Functioning Among Cancer Survivors

Elizabeth A. Fallon, Bennett McDonald, Tenbroeck Smith, Kassandra I. Alcaraz, J. Lee Westmaas, Alpa V. Patel. *American Cancer Soceity, Atlanta, GA.* (Sponsor: Melissa Bopp, FACSM)
(No relevant relationships reported)

Substantial research supports the positive effect of moderate-to-vigorous physical activity (MVPA) on physical functioning among cancer survivors. Less research has examined the association of light physical activity (LPA) and physical functioning, or the potential moderating effect of MVPA on this association.
PURPOSE: To explore the independent association between LPA and physical functioning and any moderating effect of MVPA on this association among cancer survivors.
METHODS: Self-report data from the American Cancer Society's Studies of Cancer Survivors I and II were merged. Using the Leisure Time Exercise Questionnaire, four LPA groups (0, 1-59, 60-119, and 120+ minutes/week) and three MVPA groups (0, 1-149, and 150+ minutes/week) were created. ANCOVAs assessed the independent associations of LPA and MVPA as well as the LPA by MVPA interaction on the SF-36 Physical Functioning scale. Covariates included age, time since diagnosis, race/ethnicity, cancer type by gender, cancer stage, and number of comorbidities.
RESULTS: The sample (N = 10,255) was primarily white/Caucasian (80.8%), female breast (29.5%) or male prostate cancer survivors (21.4%), with in situ/localized cancer (69.2%), 4.8 years (SD = 3.3) from diagnosis, had 1-2 comorbidities (49.9%), and mean age of 64.1 years (SD = 12.4). Almost 27% of the sample reported no leisure-time LPA or MVPA. Both LPA [F(3) = 19.93, p < 0.001] and MVPA [F(2) = 310.48, p < 0.001] were independently, positively associated with physical functioning. The LPA by MVPA interaction [F(6) = 31.34, p < 0.001] showed that among those reporting no MVPA, there is a significant difference in physical functioning between those reporting no LPA and those reporting ≥120 min/week of LPA [mean difference = 5.65 (SE = 0.3), t = 18.80, p < 0.001]. A linear trend with increasing levels of LPA was evident [t = 17.19, p < 0.001]. Among those reporting 1-149 and 150+ min/week of MVPA, there was no association of LPA and physical functioning (ps > .05).
CONCLUSIONS: Among cancer survivors reporting no leisure-time MVPA, LPA was positively associated with physical functioning. The effect was clinically meaningful at the highest level of LPA (≥120 min/week). Randomized control trials are needed to determine the impact of LPA on physical functioning among cancer survivors healthy enough to begin LPA.

1554   Board #6   May 31 1:00 PM - 3:00 PM

Diet and Eating Difficulties Affect Exercise Suitability in Head and Neck Cancer Patients Beginning Radiation

Josh N. Muhammad[1], P M. Anton, FACSM[2], K S. Courneya, FACSM[3], K A. Rao, FACSM[4], Laura Q. Rogers, FACSM[1]. [1]*The University of Alabama at Birmingham, Birmingham, AL.* [2]*Southern Illinois University, Carbondale, IL.* [3]*The University of Alberta, Edmonton, AB, Canada.* [4]*Southern Illinois University, Springfield, IL.* (Sponsor: Laura Rogers, FACSM)
(No relevant relationships reported)

PURPOSE: Determine if head and neck cancer (HNCa) patients are suitable candidates for exercise training based on macronutrient intake. Also, identify macronutrient associations with fatigue, lean mass, strength, physical functioning, and eating difficulties. **METHODS**: Cross-sectional 3-day food diary data from 23 HNCa patients initiating radiation therapy were analyzed. Self-administered survey assessed demographics. Functional Assessment of Cancer Therapy (FACT) measured eating difficulties (additional concerns subscale items) and fatigue (higher score indicated greater fatigue). Lean mass was measured by bioelectric impedance, strength by handgrip dynamometer, and physical functioning by a physical performance battery. Associations were analyzed with Spearman correlations. **RESULTS**: Participants were 60±10.8 years of age, 96% Caucasian, and 70% male with a mean body mass index of 28.75±6.5. The most frequent cancer stage was IV and site was oropharynx (61% and 70%, respectively). Difficulty swallowing, difficulty eating solid foods, and mouth pain was reported by 43%, 35%, and 48%, respectively. The mean macronutrient intake (g/day) was 249 ± 85 of carbohydrate (CHO), 81 ± 34 of fat, and 83 ± 39 of protein (PTN) with 33% reporting intake of less than 0.8 g/kg/day of PTN. Fatigue was associated with percent kilocalories from CHO (r=0.52, p=.02) and PTN (r=-0.48, p=0.03). Lean mass was positively correlated with total intake of CHO (r=0.46, p=.04), fats (r=0.54, p=.01), PTN (r=0.64, p,>.01) and kilocalories (r=0.56, p=.01). No significant correlations were observed between macronutrients and strength or physical functioning. Fat intake was positively correlated with greater ability to swallow (r=0.66, p<.01) and eat solid foods (r=0.60, p<.01) while CHO were negatively correlated with ability to swallow (r=-0.81, p<.01) and eat solid foods (r=-0.72, p<.01). PTN intake was positively correlated with ability to swallow (r=0.47, 0=.03). **CONCLUSIONS**: PTN intake sufficiency in HNCa patients beginning radiation may jeopardize exercise suitability. Macronutrient intake is associated with fatigue and lean mass. Ability to eat may serve as a marker for individuals warranting particular nutritional attention. Funding: AICR #10A048, NCI R25CA76023

Complementary and Alternative Medicine Use in Cancer Survivors in a Structured Exercise Program

Peter Smoak[1], Matthew Christensen[1], Nicholas Harman[1], Daniel Shackelford[2], Reid Hayward[1], Katie Kage[1], Jessica Brown[2], Laura Stewart[1]. [1]*University of Northern Colorado, Greeley, CO.* [2]*Carroll University, Waukesha, WI.*
(No relevant relationships reported)

INTRODUCTION: Approximately 12.7 million people are diagnosed with cancer each year and many undergo conventional treatments including chemotherapy, radiation, and surgery. Complementary medicines supplement these conventional treatments while alternative medicine refers to practices intended to replace traditional cancer treatments. Complementary and alternative medicine (CAM) practices can include, but are not limited to dietary supplementation, Chinese herbal medicine, and physical manipulation. A yearlong 2012 survey found that cancer survivors spent $4 billion on vitamins and minerals, $1.2 billion on non-vitamin or mineral natural products, and $500 million on massage. **PURPOSE:** To examine the use of CAM in cancer survivors currently participating in a structured exercise program. **METHODS:** Participants from the University of Northern Colorado Cancer Rehabilitation Institute (N=29) were given a 28-question, traditional paper and pencil, CAM survey. **RESULTS:** All respondents indicated that they were happy with the conventional medical treatments that they received, and 70% of respondents reported CAM use after their cancer diagnosis. Half of the respondents started CAM use after physician recommendation, while the other half of respondents started using CAM on their own. Also, 45% of respondents used some form of CAM while undergoing cancer treatment. Almost half of respondents (48%) claimed that CAM was very effective, while the other 52% of respondents were unsure. Only 1 one participant reported experiencing a CAM-related negative side effect. Respondents reported using dietary supplements (75%), vitamins (75%), and minerals (30%) with the most commonly used forms including Vitamins D and B, calcium, fish oil, astragalus, and ginseng. Other therapies used were massage (60%), acupuncture (25%), and cannabis (15%). **CONCLUSION:** A high percentage of cancer survivors participating in a structured exercise program reported using CAM. Consequently, cancer rehabilitation programs may want to consider providing information related to the safety and effectiveness of these products and practices to cancer survivors.

Exploring Racial/Ethnic Differences in Physical Activity and Behavioral Risk Factors among Cancer Survivors in Central Pennsylvania.

William A. Calo[1], Shirley Bluethmann[1], Wayne Foo[1], Eugene Lengerich[1], Scherezade Mama[2], Joel Segel[2], Renate Winkels[1], Joachim Wiskemann[1], Kathryn Schmitz, FACSM[1]. *[1]Penn State College of Medicine, Hershey, PA. [2]Penn State College of Health and Human Development, University Park, PA.*

(No relevant relationships reported)

PURPOSE: Racial/ethnic disparities in physical activity and behavioral risk factors are widely reported among the U.S. adult population. Little is known, however, about whether these racial/ethnic differences exist among cancer survivors. To address this gap, we examined the associations between race/ethnicity and meeting ACSM physical activity guidelines and behavioral risk factors among cancer survivors.
METHODS: We analyzed cross-sectional data from 585 cancer survivors who reside in central Pennsylvania. Survivors were identified using the Pennsylvania Cancer Registry and were mailed a survey using Behavioral Risk Factor Surveillance Survey-based items from May-September, 2017. We categorized race/ethnicity into: non-Hispanic whites (NHW; 89%), non-Hispanic blacks (NHB; 4%), Hispanics (4%), and others (3%). We classified respondents as participating in any physical activities/exercises, meeting aerobic guidelines ($\geq$150 minutes/week), muscle-strengthening guidelines ($\geq$2 times/week), or both guidelines. We also assessed whether participants were overweight/obese, current smokers, had multiple comorbid conditions, and perceived health status. Analyses were adjusted for sex, age, education, and income.
RESULTS: Sixty-seven percent reported participating in any physical activities in the past month. NHW reported higher levels of physical activity than NHB and Hispanics but these differences were not significant (p>.05). Neither race/ethnicity was associated (p>.05) with meeting aerobic guidelines, muscle-strengthening guidelines, or both. More NHB were overweight/obese than NHW or Hispanics but these differences were not significant (p>.05). Hispanics reported higher levels of smoking, however, race/ethnicity was not associated with smoking status (p>.05). All groups reported similar levels of comorbid conditions and perceived health status.
CONCLUSIONS: It was encouraging to find no evidence of racial/ethnic disparities in physical activity and behavioral risk factors in our sample. However, non-adherence to physical activity guidelines was high in all racial/ethnic groups. Future studies with more diverse samples are needed to further explore racial/ethnic differences in physical activity and their potential impact on cancer survivors' health.

D-12   Clinical Case Slide - **Cervical and Thoracic Spine**

Thursday, May 31, 2018, 1:00 PM - 2:40 PM

Thoracic Pain in a Competitive Middle-Aged Tennis Player

Stacey Bennis[1], Daniel Blatz[2]. *[1]McGaw Medical Center of Northwestern University/Shirley Ryan AbilityLab, Chicago, IL. [2]Northwestern University/Shirley Ryan AbilityLab, Chicago, IL.* (Sponsor: Joseph Ihm, MD, FACSM)

(No relevant relationships reported)

HISTORY: A 47-year-old male competitive tennis player presented to a musculoskeletal clinic with nine day history of acute right-sided mid-thoracic back pain that started after serving a tennis ball. One week later, the patient developed a thoracic rash, treated as herpes zoster by his internist. Eight months later, he returned to the musculoskeletal clinic with one week history of acute bilateral thoracic back pain and one day history of left thoracic rash. He described two prior episodes of herpes zoster (10 years prior, 8 months prior) and mild varicella zoster as a child. He denied neurologic complaints or immunocompromise.
PHYSICAL EXAMINATION: Initial examination revealed normal neurologic findings, negative lower limb dural tension tests, and right mid-thoracic paraspinal muscle tenderness exacerbated by left trunk rotation. At follow up, examination was stable except for a new erythematous vesicular rash with surrounding allodynia in dermatomal distribution at the left mid-thoracic spine.
DIFFERENTIAL DIAGNOSIS:
1. Acute recurrent herpes zoster
2. Thoracic radiculitis
3. Post-herpetic neuralgia
4. Thoracic paraspinal muscle strain
TEST AND RESULTS:
- MRI Thoracic Spine without Contrast: Multilevel degenerative changes. Moderate left foraminal stenosis at T7-8. Moderate to severe right foraminal stenosis at T9-10.
- HIV Ag/Ab: negative.
- Infectious Disease Consult: "heavy tennis playing may have resulted in re-activation of VZV."
FINAL WORKING DIAGNOSIS:
1. Acute left thoracic radiculitis due to recurrent herpes zoster reactivation from heavy tennis playing
2. Acute right thoracic radiculitis due to zoster sine herpete versus thoracic neural foraminal stenosis
3. Chronic right thoracic pain due to post-herpetic neuralgia versus thoracic radiculitis
TREATMENT AND OUTCOMES:
1. Valtrex 1000mg PO TID x7 days and 1000mg TID at onset of any future symptoms
2. Topical lidocaine patch versus capsaicin patch for treatment of post-herpetic neuralgia neuropathic pain
3. Discussed possibility of gabapentin as an alternative option for management of post-herpetic neuralgia
4. 2-3 weeks rest from tennis, and rest from tennis at onset of any future symptoms
5. Follow up after MRI (patient has not yet followed up in the office)

1561   May 31 1:20 PM - 1:40 PM

Cervical Spinal Injury: Presenting Issue —Decreased Range Of Motion Globally, Mild-to-moderate Stiffness With Chronic Pain

Zenon R. Jimenez. *Mercy College, Dobbs Ferry, NY.* (Sponsor: M. Allison Williams, FACSM)

(No relevant relationships reported)

Cervical Spinal Injury: Presenting Issue —decreased range of motion globally, mild-to-moderate stiffness with chronic painHISTORY:36 y/o retired rugby player sustained multiple collisions during his professional career is now presenting with signs and symptoms indicative of cervical spinal trauma. He reports having many concussions, after which he wouldn't recall his own memories of finishing a game and regained awareness of self many hours post event. Also, he reports that "every Sunday while he played professionally felt as if he was in a car accident" at the high level of intensity he was expected to perform.**PHYSICAL EXAMINATION**:Last seven years, individual has been waking up to both arms presenting completely numb through his hands. Last six months, symptoms have intensified; experiencing local burning into right latissimus dorsi during trunk flexion. Furthermore, right leg also experiences a local burning sensation whenever he's driving. Left arm and hand severely cramp whenever he performs any actions, which require a greater than usual amount of exertion and may limit many of his career functions. Chronic cervical pain at the base with stiffness. Occasional left drop foot that impedes ambulation**DIFFERENTIAL DIAGNOSIS**:Suspected herniated nucleus pulposusPossible cervical spinal stenosis**TEST AND RESULTS**:Exaggerated deep tendon reflexes left of midline Clonus with multiple beats with quick stretch of left foot into dorsiflexion(+) Hoffman's & Babinski sign bilaterallyInverted brachioradialis reflex on left armDecreased ROM globally in all directionsMild tenderness to palpation locally near the spinous process of C6X-ray(+) MRI HNP**FINAL / WORKING DIAGNOSIS**:Cervical spondylotic myelopathy from long standing protrusion of the C5/6 disc resulting in cord flatting.**TREATMENT AND OUTCOMES**:Physical therapy with non-significant changes from the baseline. Underwent two courses of methyl-prednisone, which alleviated complications during the admission, but shortly after the medication was discontinued, complications presented to pre medication levels. Non-steroidal inflammatory drugs were unsuccessful at ameliorating signs and symptoms.Surgery for C4/5, C5/6 disc replacement with prestige LP prosthesis, via anterior cervical discectomy with replacement instead of fusion.

1562   May 31 1:40 PM - 2:00 PM

Spinal Trauma in a Division 1 Football Player

Arjun K. Ramprasad. *Crozer-Keystone Health System, Springfield, PA.* (Sponsor: Tom Kaminski, PhD, FACSM)

(No relevant relationships reported)

CLINICAL CASE SAMPLE

HISTORY: A division 1 football player developed acute onset shortness of breath after a tackle during game play. He made a proper form tackle but was struck in the sternum by an opposing player and the side by a teammate. On the field he initially complained of difficulty breathing but his airway remained patent. He then complained of rib and upper back pain but was able to walk off the field under his own power. A sideline evaluation demonstrated thoracic spine tenderness. He was then transported to the ER via EMS.

PHYSICAL EXAMINATION: Initial on-field examination revealed no sternal or laryngeal tenderness but did show right sided posterior rib tenderness. Additional sideline exam revealed midline thoracic tenderness around T6. He was neurovascularly intact and had full active range of motion of his neck and all extremities.

DIFFERENTIAL DIAGNOSIS:
1. Laryngeal fracture
2. Sternal fracture
3. Traumatic rib fracture
4. Vertebral fracture
5. Spinal cord trauma

TESTS AND RESULTS:
CT scan of cervical spine:
— No acute cervical spine fracture
CT scan of thoracic spine:
— Acute burst type compression fracture of T6 with 4mm of retropulsion
MRI or thoracic spine
— Acute burst fracture of T6 vertebral body with approximate 25% height loss along with marrow edema. A strain of the interspinous ligaments between T-6 & T-7 is also seen

FINAL/WORKING DIAGNOSIS:
Acute traumatic burst fracture of T6 vertebrae

TREATMENT AND OUTCOMES:
1. The initial concern was for airway compromise, but his airway remained patent. Spinal cord injury was a concern due to midline thoracic tenderness but unlikely as he was ambulatory and had an intact neurological exam.
2. After admission, imaging and a discussion with orthopedics, it was decided not to use a thoracic body brace as he would need a cervical extension due to his T6 fracture.
3. He was kept overnight for observation then discharged with instructions to limit spine flexion and extension. Repeat MRI at 2 weeks showed no worsening of his fracture or ligament sprain. His pain was controlled with oxycodone and muscle relaxers.
4. The plan is to work with physical therapy to progress his movement as he heals

1563   May 31 2:00 PM - 2:20 PM

Thoracic Radiculopathy Case

Malia Cali, Jacques Courseault. *LSUHSC, New Orleans, LA.*

(No relevant relationships reported)

HISTORY: A 44-year-old male with greater than 100 miles/week biking regimen presented to clinic with symptoms of chest pain, nausea and abdominal pain associated with a 30lb weight loss over 3 months. His pain was exacerbated by flexion and prolonged sitting. Pain was relieved by remaining in an upright position. Extensive cardiac work-up and MRI of the abdomen and pelvis were performed prior to presentation in clinic and were negative. A GI consultant was unable to establish a diagnosis.

PHYSICAL EXAM: Examination of the left upper abdomen near the insertion of the rectus on the rib cage exhibited severe active myofascial trigger points. Palpation of these trigger points induced nausea, abdominal, and chest pain. There was severe tenderness of the thoracic paraspinals from T6-T10. Reflexes and upper and lower extremity strength testing was normal. Sensation was normal.

DIFFERENTIAL DIAGNOSES:
1. Thoracic Radiculopathy with Active Myofascial Abdominal Trigger Points
2. Gastritis
3. Malignancy
4. Coronary Artery Disease

TEST AND RESULTS:
1. MRI of the thoracic spine:
• Scattered small perineural cysts, the largest measuring 0.7cm in diameter in the T10-T11 foramen, as well as slight central posterior protrusion of the T6-T7, T8-T9, and T9-T10 discs.
1. EMG and NCV:
• Findings consistent with inactive, subacute multilevel mid thoracic radiculopathy.

FINAL/WORKING DIAGNOSES:
Thoracic Radiculopathy due to Tarlov cysts and posterior protrusion of discs

TREATMENT AND OUTCOMES:
1. Trigger point injections under needle EMG guidance into the thoracic paraspinals and rectus abdominis were successful for symptom relief
2. Physical Therapy
3. Lyrica
4. Avoidance of prolonged flexion activities such as the cycling position
5. Returned to most daily activities. Symptoms improved significantly after trigger point injections and physical therapy with a focus on traction and extension-based exercises.

1564   May 31 2:20 PM - 2:40 PM

Persistent Right Upper Limb Weakness: Football

Melissa Lau, Michael Baria. *Ohio State University, Columbus, OH.*

(No relevant relationships reported)

HISTORY:
Patient is a 15 year old previously healthy male linebacker presenting with the chief complaint of right upper limb weakness after tackling an opponent. He completed a form tackle, hitting his opponent with the right shoulder. Upon contact he experienced immediate right upper limb dysesthetic pain down to the hand with concomitant loss of strength of his entire right arm. Over the next 24 hours, his pain resolved but profound weakness persisted with complete inability to abduct the upper limb.

PHYSICAL EXAM:
-Neurological: Strength exam demonstrated 1/5 weakness in all shoulder movements including flexion, abduction, and external rotation. He has 3+/5 strength with elbow flexion, and 4/5 with wrist flexion and extension. Biceps reflex was depressed but present. Sensation was normal.
-Musculoskeletal: Full active range of motion in cervical spine, mild tenderness to palpation at approximately C5 but no step off appreciated. Shoulder examination demonstrated no deformity, tenderness, or range of motion impairment.

DIFFERENTIAL DIAGNOSIS:
1. Cervical spine injury with resultant spinal cord injury
2. Cervical radiculopathy
3. Cervical nerve root avulsion
4. Right upper trunk brachial plexopathy
5. Suprascapular and/or axillary neuropathy
6. Rotator cuff tear
7. Shoulder fracture / dislocation

TESTS AND RESULTS:
-XR cervical spine (flexion/extension) and XR right shoulder (AP views with internal/ external rotation and axillary views): no acute pathology with no evidence of laxity
-MRI cervical spine: Mild right foraminal disc protrusion at C5-C6 contributing to mild neural foraminal stenosis. Torg ratio 0.77
-EMG: Severe C5 and moderate C6 radiculopathy. Severe axonotmesis without neurotmesis

WORKING DIAGNOSIS:
C5 and C6 radiculopathy with axonotmesis

TREATMENT/OUTCOMES:
-Initial: C-spine precautions and R arm sling placement until cervical spine was cleared by MRI
-2 weeks post injury: Neuromuscular re-education and active assisted range of motion started
-Return To Play: No sporting activity until neurologic recovery completed. It remains controversial as to whether he should resume football or wrestling. Given the Torg ratio and the severity of his injury, there is an unquantifiable risk of recurrence if collision sports are resumed should he eventually regain full neurological function.

D-13   Clinical Case Slide - **Knee III**

Thursday, May 31, 2018, 1:00 PM - 3:00 PM
Room: CC-200F

Knee Pain - Football, Basketball

Alexandra Warrick, Julie Ingwerson, Brian Haus. *UC Davis, Sacramento, CA.* (Sponsor: Brian Davis, M.D., FACSM)
(No relevant relationships reported)

HISTORY: 16 year-old high school football and basketball athlete was referred to Sports Medicine. He could not recall a specific injury, but had 2 months of recurrent pain and swelling with high-impact activities. No neuropathic, mechanical, nor instability symptoms. No prior knee orthopedic history.
PHYSICAL EXAMINATION:
Inspection showed slight genu valgum and small right knee effusion. No pain with palpation of all bony and soft tissue landmarks of the knee. Active range of motion was pain free and symmetric for knee flexion and extension. Strength was intact at 5/5 hip flexion, knee extension and knee flexion. Provocative maneuvers showed no pain with bounce and McMurrays, firm 1+ endpoint with Lachmans, anterior drawer, and posterior drawer. He was stable and symmetric with no laxity or pain during varus and valgus stressing of the knee at 0 and 30 degrees of flexion. No pain with patellar compression and negative dial testing.
DIFFERENTIAL DIAGNOSIS: Includes meniscus pathology, plica syndrome, patellofemoral pain, osteochondritis dissecans (OCD), stress injury
TESTS AND RESULTS:
1. Standing knee xrays showed medial femoral condyle OCD with knee effusion and loose body in suprapatellar space.
2. MRI of right knee showed 1.7 x 1.3 cm osteochondral defect at the central weight-bearing surface of the medial femoral condyle with displaced osteochondral fragment in the suprapatellar bursa.
FINAL WORKING DIAGNOSIS:
Grade IV osteochondritis dissecans lesion
TREATMENT AND OUTCOMES:
1. Recommended non-weight bearing and medial unloader brace requested while physical therapy initiated.
2. Diagnostic arthroscopy for loose body removal and biopsy for matrix-induced chondrocyte implantation.
3. Low impact activities only, physical therapy and medial unloader brace with ambulation until harvested cells ready for implantation.
4. Matrix-induced autologous chondrocyte implantation was performed after 6 weeks of cell culturing.
5. Athlete treated with post-operative rehabilitation protocol.
6. MRI at 6 months demonstrated interval progression of healing medial femoral condyle OCD.
7. Athlete will continue post-operative rehabilitation protocol and will be assessed for readiness for sport progression at 12 and 18 months.

1569   May 31 1:20 PM - 1:40 PM
Knee Pain And Instability - Soccer Player

Allison N. Schroeder, Kentaro Onishi. *University of Pittsburgh Medical Center, Pittsburgh, PA.* (Sponsor: Thomas Best, FACSM)
(No relevant relationships reported)

HISTORY:
A 24-year-old male soccer player presented to an orthopedic sports medicine clinic with 7 years of left knee "looseness." He first noticed this following a soccer match. His main complaint was instability and his knee would buckle 3-4 times a week, but it would never fully give-way or cause him to fall. He had a reported history of left "grade 1-2 PCL sprain." He has been avoiding aggravating activities, including playing soccer.
PHYSICAL EXAM:
No discoloration or swelling of the left posterior knee. Full active and passive range of motion without pain at end range of motion. McMurry's, Lachman's, and anterior drawer were negative. Posterior drawer was 1+. Posterior sag was 1+. Negative dial test.
DIFFERENTIAL DIAGNOSIS:
1. PCL sprain or tear
2. Posterior lateral corner injury
3. Posterior horn of medial or lateral meniscus injury
4. Meniscofemoral ligament (ligament of Wrisberg or Humphrey) injury
5. Patellar subluxation/dislocation
6. Osteochondral defect
7. Cyst in the posterior knee
TEST AND RESULTS:
MRI revealed 8x7x6mm ganglion cyst adjacent to the posteromedial aspect of the PCL near the distal insertion on the tibia. Reverse KT1000 measurement revealed laxity of the left PCL that was 3mm greater than the right. Ultrasound of the insertional PCL visualized in long axis showed no pathology but appeared kinked at the proximal 1/3 when compared to the right. Cyst lying adjacent to the PCL in the posterior medial direction was visualized.
FINAL WORKING DIAGNOSIS:
PCL sprain and adjacent PCL ganglion cyst
TREATMENT AND OUTCOMES:
He was referred to our sports ultrasound clinic for sonographic evaluation and possible intervention. Sonographically guided intervention was performed from a distal to proximal approach with the patient supine. The cyst was fenestrated 10 times and 1mL of a 1:2:2 mixture of 50% dextrose, sterile water, and 1% lidocaine solution was injected into the cyst. An additional 2mL of the solution was injected peri-PCL. He had >50% improvement in instability at 1 month. Repeat sonographic exam showed decompression of the cyst. He reported 80% improvement in the feeling of "looseness" and KT1000 testing (completed by the same provider as the initial measurement) revealed a 1mm difference in laxity of the PCL on the left compared to the right 7 weeks after the injection. He had no limit in daily activity.

Keen Pain and a Moveable Mass in Basketball Player

James Wilcox, Robert Baker, FACSM, Keith Kenter. *Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI.* (Sponsor: Robert Baker, FACSM)
(No relevant relationships reported)

HISTORY:
A 16-year-old high school basketball player was evaluated for left knee pain and a moveable mass in his knee. He started having pain, swelling, and locking of his left knee when he played basketball. He would have to manually unlock his knee sometimes. He sat out the rest of the season, but now the pain and locking has returned, and he feels a moveable mass above his knee cap. He denied any specific injury or traumatic event. He was previously diagnosed with osteochondritis dissecans (OCD) in his right knee 2 years prior and was told to sit out of football that season, but now he is having trouble with his left knee. He denied any other joint complaints. He denied any constitutional complaints. Family history was significant only for osteoarthritis and rheumatologic disease in his mother.
PHYSICAL EXAMINATION:
Generally he is a well-nourished normal appearing 16 year old male. Examination of the left knee revealed lateral joint line tenderness and a moveable mass superior to his patella. McMurray's test was positive for clicking, and he had a trace knee joint effusion on exam. Small abrasion over the tibial tubercle. He had some general laxity of his joints, but sensation, strength, range of motion, and ligamentous testing were all normal. Normal gait, no antalgic limp. Examination of the right knee was normal.
DIFFERENTIAL DIAGNOSIS:
1. Loose chondral body 2. Lipoma arborescens 3. Bucket handle meniscal tear 4. Pigmented villonodular synovitis 5. Plica 6. Synovial osteochondromatosis 7. Juvenile Rheumatoid Arthritis 8. Synovial chondrosarcoma 9. Synovial sarcoma 10. Synovial metastases
TEST AND RESULTS:
Xray of left knee - lateral femoral condyle OCD, closed growth plates Xray of right knee - lateral femoral condyle OCD with sclerosis
MRI of left knee - small effusion with lateral femoral osteochondral defect about 2.5 cm
Arthroscopy of left knee - OCD with loose bodies and chondral defect
FINAL WORKING DIAGNOSIS:
Osteochondritis Dissecans with loose bodies
TREATMENT AND OUTCOMES:

He was treated with an arthroscopic procedure to remove the 2 loose chondral bodies. He had cartilage cobble stoning debrided and a microfracture procedure performed to help fill in the chondral defect. He then participated in 6 weeks of non-weight bearing and then a formal therapy program.

Anterior Knee Pain - Golf
Shawn D. Felton, Arie J. van Duijn, Mitchell L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchell L. Cordova, FACSM)
(No relevant relationships reported)

HISTORY:
Athlete is a 71-year-old recreational golfer. Athlete's previous medical history includes bi-lateral Achilles tendon repairs, contralateral quadriceps tendon repair and Right supraspinatus tendon repair. Athlete is borderline diabetic with developing osteoarthritis.
PHYSICAL EXAMINATION:
Athlete fell while walking on pine straw on anterior knee causing right leg to be hyper flexed under weight of the patient. The athlete was unable to move and EMS summoned for transport. Upon physical exam, individual had palpable deformity proximal to the patella. Individual unable to actively extend right leg. Individual appeared with obvious swelling. Neurological and circulatory exam WNL. No signs or symptoms of fracture. Ultrasound imaging was performed and revealed a full thickness hypoechoic area indicative of a quadriceps rupture.
DIFFERENTIAL DIAGNOSIS:
1. Anterior Knee Contusion 2. Posterior Cruciate Ligament Tear 3. Medial meniscus tear 4. Anterior Cruciate Ligament Tear 5. Quadriceps Tendon Rupture
TEST AND RESULTS:
DDX Ultrasound - Full thickness hypoechoic lesion in the quadriceps tendon was visible both on the long and short axis views of the quadriceps tendon indicating full thickness tear, with hypoechoic areas around the surrounding structures suggestive of interstitial bleeding.
MRI w/o contrast - Portion of Quadriceps tendon extensor mechanism completely torn - Superficial aspect of rectus femoris is avulsed from its patellar attachment and retracted proximally - Marked anterior swelling - Patellar tendon intact
FINAL WORKING DIAGNOSIS:
Quadriceps tendon injury, superficial aspect (rectus femoris) avulsed and retracted proximally.
TREATMENT AND OUTCOMES:
Athlete underwent surgical repair of the right quadriceps tendon. Following immobilization athlete began contemporary rehabilitation program and has made full recovery without problems or complaints. This case report demonstrates the use of ultrasound imaging in a clinical setting that was as precise of eth follow-up MRI. Furthermore, it is imperative for clinicians to ensure both long and short axis views of the quadriceps tendon to ensure proper diagnosis.

Knee Swelling in a Football Player
Daniel Evering, Jr[1], David Webner[1], Kevin DuPrey[1], A.J. Duffy, III[2]. [1]*Crozer Keystone Sports Medicine, Springfield, PA.* [2]*Widener University, Chester, PA.* (Sponsor: Dr. Thomas Kaminski, FACSM)
(No relevant relationships reported)

HISTORY: An 18-Year-Old Male Division III quarterback presented to the office with left knee swelling and pain. He was playing in a game 10 days prior in which he was sacked twice, each time landing on his left knee and medial thigh. Right after the game, he noted swelling over the superior aspect of the patella and pain with direct pressure and full flexion. He described the pain as sharp and fiery, non-radiating, 3/10, waxing and waning. He has been wearing a compression sleeve and icing his knee.
PHYSICAL EXAMINATION: Examination of the patient's Left knee revealed decreased ROM with flexion and extension to 120/0 degrees. Large, 4+, suprapatellar effusion. Strength intact. Negative patellar compression test for pain and crepitus. No patellar instability. No ligamentous laxity to anterior, posterior, varus and valgus (30°) stress testing. Negative Lachman's testing. Negative anterior and posterior drawer testing. No joint line tenderness. Negative McMurray's testing. No patellar tendon tenderness. No pes anserine bursa tenderness. The patient was otherwise neurovascularly intact.
DIFFERENTIAL DIAGNOSIS: 1. Suprapatellar Bursitis 2. Prepatellar Bursitis 3. Patella Fracture 4. Intraarticular Injury with knee effusion 5. Morel-Lavallée lesion
TEST AND RESULTS: Ultrasound exam revealed large collection of fluid in the suprapatellar and medial thigh region. X-ray showed no fracture and moderate soft tissue swelling anterior to the left patella.
FINAL WORKING DIAGNOSIS: Morel-Lavallée lesion
TREATMENT AND OUTCOMES: 1. Under US guidance 75 cc of serosanguinous fluid was aspirated from the suprapatellar bursa on the left knee on the first visit.

Compression wrap applied. 2. 75 cc of serosanguinous fluid was aspirated 3 days later. Compression continued. 3. 50 cc of serosanguinous fluid was aspirated 4 day later, 7 days after the initial visit 4. 1 week later there was only mild accumulation of fluid. No aspiration was required. He had near full ROM and no pain with activity. He was cleared to return to football at that visit and successfully returned with no issues.

Knee Injury-soccer
Ankur Verma[1], Melody Hrubes[2], Terry Nicola, FACSM[2]. [1]*University of Chicago/Schwab Rehabilitation Hospital, Chicago, IL.* [2]*University of Illinois-Chicago, Chicago, IL.* (Sponsor: Terry Nicola MD, FACSM)
(No relevant relationships reported)

HISTORY: A 17-year-old male high school varsity soccer player with a history of right knee patellar dislocation 6 months ago managed non-operatively with physical therapy and bracing with successful return to sport presented with right knee swelling, pain, and decreased range of motion after being struck on the lateral aspect of his right knee during a game yesterday. He felt a pop and had swelling. He is unable to bear weight, and is unable to fully extend or flex his knee. He has been icing. He denies numbness, tingling, or weakness.
PHYSICAL EXAMINATION: Examination revealed moderate effusion and tenderness to palpation over the medial aspect of his patella, as well as the MPFL. There was some tenderness over the MCL. He has a positive apprehension sign with positive ballottement. There was no tenderness over the LCL. There was a negative Lachman's test or posterior drawer sign. There was no joint opening with varus or valgus stress. There was no medial or lateral joint line tenderness. McMurray's was unable to be attempted because of limited range of motion. He can actively extend his knee to 20 degrees short of full extension and actively flex his knee to 90 degrees.
DIFFERENTIAL DIAGNOSIS: 1. Patellar dislocation 2. Osteochondral defect 3. MPFL tear
TEST AND RESULTS: XR Right Knee: Sunrise view demonstrated a medial patellar avulsion fracture
MRI Right Knee without Contrast: Acute lateral patellar tracking injury with medial patellar avulsion fracture, kissing contusion on the femoral condyle, and high-grade medial patellar retinaculum sprain
FINAL WORKING DIAGNOSIS: Medial patellar avulsion fracture
TREATMENT AND OUTCOMES:
Re-initiate the Lateral Patella Knee Brace for stabilization
Physical therapy for range of motion, quadriceps activation, gait biomechanics and modalities to decrease swelling
Orthopaedic Surgery referral. Surgery was recommended once swelling subsides
Plan is for surgery 3-4 months after injury

D-36   Thematic Poster - Body Composition - Sport and Physiologic Considerations
Thursday, May 31, 2018, 3:15 PM - 5:15 PM

Comparison of Bone and Body Composition in the Affected and Unaffected Arms in Breast Cancer Survivors
Ashley Artese, Rachael L. Hunt, Daniel R. Marshall, Jeong-Su Kim, Michael J. Ormsbee, Robert Moffatt, Lynn B. Panton, FACSM. *Florida State University, Tallahassee, FL.*
(No relevant relationships reported)

Following surgery and treatments, breast cancer survivors (BCS) may experience weakness, pain, and swelling in the arm next to the breast where the cancer was present (affected arm), resulting in decreased use of that arm. Treatments can also cause losses in bone mineral density (BMD), lean mass (LM), and gains in fat mass (FM). There is a lack of research on the effects of cancer treatment on BMD and body composition specifically in the affected compared to the unaffected arm. **PURPOSE:** To examine BMD, LM and FM in the affected compared to the unaffected arm in BCS. **METHODS:** Arm BMD, LM, and FM were assessed on 43 BCS (60 ± 8 yrs) using dual-energy X-ray absorptiometry. Paired t-tests were used to compare arm BMD, LM, and FM. Significance was accepted at $p \leq 0.05$. **RESULTS:** BCS were 6.6 ± 7.3 yrs post treatment. Mean values of arm BMD, LM, and FM were 0.681 ± 0.097 g/cm² 2.23 ± 0.52 kg, and 1.79 ± 0.75 kg, respectively. The affected arm had lower BMD (0.674 ±

0.095 g/cm^2) and FM (1.70 ± 0.60 kg) compared to the unaffected arm (BMD: 0.689 ± 0.104 g/cm^2; FM: 1.89 ± 0.93 kg). There was no difference in LM. **CONCLUSION:** Our findings suggest that breast cancer treatments can result in accelerated changes in BMD and FM in the affected arm, which may place BCS at a higher risk for fractures on the affected side. These findings warrant the need for exercise interventions to improve BMD and body composition in the affected arm following cancer treatments. Research supported by the ACSM Doctoral Student Research Grant and the National Strength and Conditioning (NSCA) Graduate Research Grant

Phase Angle and Body Composition in Breast Cancer Survivors Compared to Healthy Age-Matched Women

Caroline D. Deaterly, Elizabeth Evans, Takudzwa A. Madzima. *Elon University, Elon, NC.* (Sponsor: Paul C. Miller, FACSM)
(No relevant relationships reported)

Breast cancer survivors (BCS) experience well documented treatment induced alterations in body composition, particularly the loss of lean mass (LM) and bone mineral density. Less is known about the treatment-related effects on phase angle, body cell mass (BCM), extracellular mass (ECM) and the ratio of ECM/BCM. Phase angle is an objective indicator of cellular health and integrity, and BCM is a measure of the actively metabolizing component of LM that also decreases with age. A phase angle less than 5° is indicative of poorer cellular health and nutritional status. An ECM/BCM ratio less than 1.0 is optimal. **PURPOSE:** To identify any differences in measures of body composition, phase angle, BCM, ECM and ECM/BCM in BCS compared to healthy age-matched women (HC). **METHODS:** Thirty post-menopausal BCS (stages 0-III) (age: 57 ± 8yrs; BMI: 26.4 ± 4.8 kg/m^2) and 26 HC (age: 58 ± 7 yrs; BMI: 26.9 ± 5.3 kg/m^2) participated in this cross-sectional study. After an 8 hr fast, whole body bioelectric impedance analysis was used to assess measures of body composition including lean mass, fat mass, body fat (%), phase angle, BCM, ECM, and ECM/BCM. Data were analyzed via one-way ANOVA. Significance was accepted at p<0.05. **RESULTS:** There were no significant differences in lean mass (BCS: 45.7 ± 5.7; HC: 47.0 ± 7.1 kg), fat mass (BCS: 24.4 ± 8.3; HC: 25.7 ± 8.2 kg), body fat % (BCS: 34.0 ± 6.0; HC: 34.8 ± 5.7 %), BCM (BCS: 20.9 ± 3.0; HC: 21.3 ± 2.8 kg), ECM (BCS: 34.9 ± 3.1; HC: 25.2 ± 3.9 kg), ECM/BCM (BCS: 1.20 ± 0.1; HC: 1.18 ± 0.1), phase angle (BCS: 6.06 ± 0.7; HC: 6.17 ± 1.0 °). Only one BCS had a phase angle less than 5°. **CONCLUSION:** Our findings suggest that BCS that are at least five years into survivorship appear to have similar phase angle, BCM, ECM, ECM/BCM as HC. Future research should be conducted to determine the effects of cancer treatments on these phase angle, BCM and ECM/BCM in BCS that have recently completed treatment.

1645   Board #3   May 31 3:15 PM - 5:15 PM

The Influence of Body Composition and Skinfold Thickness on Skin Temperature Changes after Resistance Exercise

Martin Weigert, Nico Nitzsche, Christiane Lösch, Lutz Baumgärtel, Henry Schulz. *Chemnitz University of Technology, Chemnitz, Germany.*
(No relevant relationships reported)

Resistance exercise leads to an increase in skin temperature (T) in the area of the exercised muscle. Non-contact infrared thermography seems to be applicable to identify these primary used functional muscles with measuring T changes. In previous studies, lean men showed homogenous T patterns after standardized exercise protocols.
Purpose
To examine the influence of body fat percentage (BF%) and skinfold thickness on T patterns after resistance exercise.
Methods
38 male subjects (19-32 years, BMI 20.4-55.2 kg/m^2) participated. Means (min-max) of BF% and skinfold thickness of biceps brachii were 19.2 % (6.2-51.5) and 9 mm (2-36) respectively. After 15 min of acclimatization, the participants completed three sets with ten repetitions of unilateral biceps curl with 50 % of the individual one-repetition-maximum (two min rest between the sets). T of the exercised biceps was measured at rest (T$_{rest}$), immediately following set 1, 2 and 3 (T$_{S1}$, T$_{S2}$, T$_{S3}$) and up to 30 min post exercise (T$_1$-T$_{30}$) with an infrared camera. For statistical analysis, Δ-values to T$_{rest}$ for every measuring time point, as well as T$_{max}$, ΔT$_{max}$ (=T$_{max}$ -T$_{rest}$) and time to T$_{max}$ (min after the final set) were calculated.
Results
One-way ANOVA detected a time effect on the T-values T$_{rest}$ to T$_{30}$ (Eta^2=0.64, p<0.001). Means (min-max) of T$_{rest}$, T$_{max}$, ΔT$_{max}$ and time to T$_{max}$ were 32.3 °C (28.0-34.6), 34.0 °C (29.7-36.8), 1.7 °C (-0.3-2.8) and 8 min (2-30) respectively. BF% and skinfold thickness showed a negative correlation with T$_{rest}$, T$_{max}$, ΔT$_{max}$ and time to T$_{max}$ (r>-0.52, p<0.001). A negative correlation between BF% and skinfold thickness with the Δ-values to T$_{rest}$ was found from T$_{S2}$ to T$_{10}$ (for BF%: r>-0.49, p<0.001; for skinfold thickness: r>-0.66, p<0.001). All subjects up to a skinfold thickness of 10 mm showed a homogeneous T pattern in reaction to the exercise with a minimum ΔT$_{max}$ of 1.3

°C and a time to T$_{max}$ between 2 and 9 min. The T patterns in subjects with a higher skinfold thickness were heterogeneous and some of these subjects did not respond to the resistance exercise with an increase of T.
Conclusion
A higher BF% and a higher skinfold thickness is associated with delayed and lower increases in T after resistance exercise. In contrast to lean subjects, identifying the primary used functional muscles by infrared thermography in obese subjects seems to be challenging.

1646   Board #4   May 31 3:15 PM - 5:15 PM

Body Composition of Collegiate Baseball and Softball Athletes, Consortium of College Athlete Research (C-CAR) Study

Madeline A. Czeck[1], Christiana J. Raymond-Pope[1], Tyler A. Bosch[1], Jack W. Ransone, FACSM[2], Jonathan M. Oliver[3], Aaron Carbuhn[4], Philip R. Stanforth[5]. *[1]University of Minnesota, Minneapolis, MN. [2]University of Nebraska, Lincoln, NE. [3]Texas Christian University, Fort Worth, TX. [4]University of Kansas, Lawrence, KS. [5]University of Texas, Austin, TX.* (Sponsor: Donald R. Dengel, FACSM)
(No relevant relationships reported)

PURPOSE: To evaluate total body composition measures across player positions in NCAA Division I male baseball and female softball players using dual X-ray absorptiometry (DXA). **METHODS:** Three hundred and twenty-nine male and female (201/128) collegiate baseball and softball athletes from multiple universities (M/F: age = 20.1±0.1/20.0±0.1 yrs.; height = 1.8±0.02/1.7±0.03 m; weight = 88.6±2.4/73.1±3.03 kg; body mass index = 26.5±0.8/25.0±0.3 kg/m^2) received one whole body DXA scan. The athletes were separated into four positions: pitchers (P; M/F=92/32), catchers (C; M/F=25/13), outfielders (OF; M/F=43/39), and infielders (IF; M/F=41/44). Total fat mass (FM), lean mass (LM), bone mineral density (BMD) and abdominal visceral adipose tissue (VAT) were measured by DXA. ANOVA and Tukey's HSD assessed total differences between positions for each sex (adjusted *p*-value given). **RESULTS**: Male IF had significantly (*p*=0.003; 0.018) lower total LM (65.8±6.0 kg) than P and OF (69.6±5.7, 69.6±5.9 kg), but was not significantly different from C (69.4±5.4 kg, *p*=0.079). Additionally, male OF had significantly (*p*=0.033; 0.044) lower total FM (14.4±3.1 kg) compared to P and C (16.7±4.5, 17.7±4.6 kg) but not compared to IF (16.5±6.3 kg; *p*=0.188). No significant (*p*>0.05) differences between male P, C, OF, and IF were observed for total BMD (1.47±0.1, 1.50±0.1, 1.50±0.08, 1.46±0.10 g/cm^3) and VAT (0.28±0.22, 0.31±0.21, 0.33±0.14, 0.36±0.27 kg). Female OF had significantly (*p*=0.012) lower total FM (18.5±5.9 kg) compared to P (23.8±8.8 kg), but not compared to C and IF (20.8±40, 20.6±7.2 kg; *p*=0.544; 0.731). No significant (*p*>0.05) differences for female softball P, C, OF, and IF were observed for total LM (50.8±5.5, 49.7±4.8, 48.9±4.8, 49.3±5.8 kg), BMD (1.34±0.13, 1.34±0.10, 1.32±0.10, 1.34±0.10 g/cm^3), and VAT (0.22±0.33, 0.08±0.06, 0.12±0.16, 0.14±0.26 kg). **CONCLUSIONS:** We observed that there were more positional differences in baseball players than softball players. The greater differences within positions between sports may be related to the larger field dimensions and demands of the game. These values may be used for normative DXA data for collegiate baseball and softball players.

1647   Board #5   May 31 3:15 PM - 5:15 PM

Body Composition of Division I Collegiate Basketball Athletes, Consortium of College Athlete Research (C-CAR) Study

Anna L. Solfest[1], Christiana J. Raymond-Pope[1], Aaron Carbuhn[2], Philip R. Stanforth[3], Jonathon M. Oliver[4], Jack W. Ransone, FACSM[5], Tyler A. Bosch[1], Donald R. Dengel, FACSM[1]. *[1]University of Minnesota, Minneapolis, MN. [2]University of Kansas, Lawrence, KS. [3]University of Texas, Austin, TX. [4]Texas Christian University, Fort Worth, TX. [5]University of Nebraska, Lincoln, NE.* (Sponsor: Donald R. Dengel, FACSM)
(No relevant relationships reported)

PURPOSE: To examine measures of total body composition using dual x-ray absorptiometry (DXA) in male and female NCAA Division I collegiate basketball athletes. **METHODS:** Two-hundred and eight male and eight female (88/120) collegiate basketball athletes (M/F: age=19.8±1.4/19.9±1.3 yrs; height=1.95±0.09/1.78±0.09 m; weight=95.2±13.8/77.5±13.3 kg; body mass index=25.0±2.4/24.2±2.9 kg/m^2) received one whole body DXA scan. Athletes were classified into five positions: point guards (PG; M/F=27/32), shooting guards (SG; M/F=18/27), small forwards (SF; M/F=13/18), power forwards (PF; M/F=21/27), and centers (C; M/F=9/16). Total fat mass (FM), lean mass (LM), bone mineral density (BMD) and abdominal visceral adipose tissue (VAT) were measured by DXA. MANOVA and Tukey's HSD assessed total differences between positions for each sex (adjusted *p*=0.0125). **RESULTS:** Male C had significantly higher total FM, LM, and VAT compared to all other positions except PF. Male C and PF had significantly greater total FM (18.0±7.8; 15.6±5.6 kg) than SF

Abstracts were prepared by the authors and printed as submitted.

and SG (11.0±3.0; 10.9±3.0; p=0.001), but not PG (12.5±4.4 kg; p=0.025), and greater total LM (89.9±8.9; 84.1±5.5 kg) compared to PG, SG, and SF (68.9±6.1; 73.3±6.1; 75.6±5.2 kg; $p \leq 0.001$). Male C and PF VAT measurements (0.44±0.24; 0.43±0.1 kg) were significantly higher compared to SF, SG, and PG (0.23±0.11; 0.22±0.12; 0.26±0.12 kg; all p<0.001). Before and after adjustment for weight, males did not show significant differences in BMD across position (p=0.156; p=0.559). In females, C had significantly greater (p<0.001) total FM compared to all other positions. Female SF, PF, and C had significantly (p<0.001) greater total LM (56.6±6.3; 59.0±5.0; 60.6±5.5 kg) compared to PG and SG (48.0±3.4; 51.4±3.9 kg). After adjustment for weight, no significant differences were observed in BMD across position (p=0.276). Female C had significantly higher VAT (0.29±0.24 kg) compared to PG and SG (0.06±0.06, 0.07±0.04 kg; p<0.005) but not SF and PF (0.13±0.14, 0.19±0.18 kg; p=0.11-0.44). **CONCLUSIONS:** Within collegiate male and female basketball players FM, LM, and VAT differed by position. After adjustment for weight, BMD was not significantly different for males or females. These position-specific measurements provide normative data on male and female basketball players.

1648   Board #6   May 31 3:15 PM - 5:15 PM

Positional Body Composition of Division I Volleyball Players, Consortium of College Athlete Research (C-CAR) Study

Katie L. Bisch[1], Tyler A. Bosch[1], Aaron Carbuhn[2], Philip R. Stanforth[3], Jonathan M. Oliver[4], Jack W. Ransone, FACSM[5], Andreas Kreutzer[4], Donald R. Dengel, FACSM[1]. [1]University of Minnesota, Minneapolis, MN. [2]University of Kansas, Lawrence, KS. [3]University of Texas at Austin, Austin, TX. [4]Texas Christian University, Fort Worth, TX. [5]University of Nebraska, Lincoln, NE. (Sponsor: Donald R. Dengel, FACSM)

(No relevant relationships reported)

PURPOSE: To identify normative values for total and regional body composition by position for female NCAA Division I collegiate volleyball players using dual X-ray absorptiometry (DXA). **METHODS:** Eighty-nine female volleyball players (ages 17-23) from multiple universities received a DXA scan. Athletes were categorized by position: Middle Blocker (MB=30), Outside Hitter (OH=32), Setter (ST=9), and Libero (LB=18). Total fat mass (FM) and lean masses (LM) were measured by DXA, as well as abdominal visceral adipose tissue (VAT) and total and regional measures of bone mineral density (BMD). An ANOVA assessed the effect of position on body composition and BMD measurements. Tukey's HSD post-hoc analysis test identified significance between positions. **RESULTS:** As expected, height was statistically significant (p<0.01) between all positions: MB (185.8 ± 4.6 cm) > OH (181.7 ± 4.1 cm) > ST (174.7 ± 3.7 cm) > LB (167.8 ± 8.0 cm). Weight was significantly greater in MB and OH (80.1 ± 9.3 kg, 76.6 ± 7.8 kg) compared to LB (64.5 ± 7.6 kg, p<0.001), and MB compared to ST (69.7 ± 5.7 kg, p=0.006). Body percent fat was not statistically significant by position (mean = 25.3%). Total LM was greater in MB and OH (55.7 ± 4.6 kg, 54.1 ± 4.7 kg) compared to LB and ST (45.9 ± 4.9 kg, 48.3 ± 3.2 kg, p<0.01). Total FM was significantly greater in MB than LB (21.0 ± 6.9 kg, 16.1 ± 4.0 kg, p=0.016). VAT mass was not significantly (p>0.05) different between positions. After adjusting for weight, total BMD was significantly greater in MB (1.39 ± 0.1 g/cm³, p<0.001) and OH (1.41 ± 0.09 g/cm³, p=0.002) compared to LB (1.30 ± 0.08 g/cm³), but not ST (1.31 ± 0.07 g/cm³, p>0.05). Leg BMD was higher in MB and OH (1.54 ± 0.11 g/cm³, 1.53 ± 0.11 g/cm³) compared to LB and ST (1.39 ± 0.09 g/cm³, 1.4 ± 0.06 g/cm³, p=0.001-0.008). Spine BMD was higher in MB and OH (1.32 ± 0.15 g/cm³, 1.33 ± 0.12 g/cm³) compared to LB (1.22 ± 0.09 g/cm³, p=0.03). **CONCLUSIONS:** Total body composition measures vary significantly by position; however, the similarities in percent body fat imply differences may be influenced primarily by height. Future studies should examine the distribution of mass. BMD differences may be influenced by repeated impacts of jumping during the attacking and blocking actions of front row players. These data provide some normative DXA data for collegiate volleyball players.

1649   Board #7   May 31 3:15 PM - 5:15 PM

Body Composition of Division I Collegiate Female Equestrian Athletes

Olivia H. Dengel[1], Christiana J. Raymond-Pope[2], Jonathan M. Oliver[3], Tyler A. Bosch[2], Donald R. Dengel, FACSM[2]. [1]College of St. Benedict, St. Joseph, MN. [2]University of Minnesota, Minneapolis, MN. [3]Texas Christian University, Fort Worth, TX. (Sponsor: Donald R. Dengel, FACSM)

(No relevant relationships reported)

PURPOSE: To compare measures of total and regional body composition using dual X-ray absorptiometry (DXA) in NCAA Division I collegiate equestrian athletes to a group of age, sex and BMI matched non-athlete college students. **METHODS:** Thirty-one female collegiate equestrian athletes were matched to a population of normal, non-athlete college students by age (19.8±0.2 vs. 19.8±0.2 yrs.), body mass index (22.3±0.4 vs. 22.6±0.4 kg/m²), sex and ethnicity. Total and regional fat tissue mass (FM), lean

tissue mass (LM), bone mineral density (BMD), and abdominal visceral adipose tissue (VAT) were measured by DXA. Paired t-tests assessed total and regional differences between equestrian athletes and controls. **RESULTS:** Equestrian athletes had a lower total fat percentage (%fat) than controls (30.7±0.9 vs. 33.1±0.1%, p=0.03). There was a trend for the equestrian athletes to have lower total FM (18.4±0.8 vs. 20.0±0.9 kg, p=0.06) than controls. There were no significant differences in total LM (41.0±0.9 vs. 39.9±0.8 kg, p=0.33), total BMD (1.15±0.02 vs. 1.15±0.02 g/cm³, p=0.92) and VAT (0.13±0.03 vs. 0.16±0.03 kg, p=0.25) between equestrian athletes and controls. However, equestrian athletes, when compared to the controls, had significantly lower leg %fat (33.0±0.8 vs. 37.3±0.9%, p<0.001), leg FM (7.0±0.3 vs. 8.0±0.4 kg, p=0.01) and higher leg LM (14.1±0.4 vs. 13.2±0.3 kg, p=0.04). The greater leg lean mass in equestrian riders resulted in a smaller upper to lower body lean mass ratio (1.706 ± 0.019 vs. 1.812 ± 0.030, p=0.005) compared to controls. There was no difference in leg BMD between equestrian athletes and controls (1.19±0.02 vs. 1.21±0.02 g/cm³, p=0.46). **CONCLUSIONS:** The lower total percent body fat in equestrian athletes seems to be influenced by differences in leg composition with equestrian athletes having significantly more lean mass and less fat mass. These results are consistent with the role the legs play in horseback riding and demonstrate an effect of either training or horseback riding on body composition compared to matched controls.

D-37   Thematic Poster - Exercise Training in Cancer Patients

How Does a Supervised Exercise Program Improve Quality Of Life In Patients With Cancer?

Maike G. Sweegers. *VU University Medical Center, Amsterdam, Netherlands.*

(No relevant relationships reported)

Purpose: Previous systematic reviews and meta-analyses demonstrated beneficial effects of exercise during or following cancer treatment on quality of life (QoL). Aiming to understand how exercise contributes to a patient's QoL, we examined patients' perspectives via a process called concept mapping. This unique method provides structure and objectivity to rich qualitative data.
Methods: Patients with cancer participating in an exercise program were invited to enrol. Eleven meetings with 3-10 patients were organized in which patients generated ideas in response to the statement: 'How has participating in a supervised exercise program contributed positively to your QoL'. Next, patients individually clustered (based on similarity) and rated (based on importance) the ideas online. The online assessments were combined and one concept map was created, visualizing clusters of ideas of how patients' perceive that participating in a supervised exercise program improved their QoL. The research team labelled the clusters of ideas, and physiotherapists reflected on the clusters during semi-structured interviews.
Results: Sixty patients attended the meetings of whom one patient was not able to generate an idea in response to the statement. Forty-four patients completed the online clustering and rating of ideas. The resulting concept map yielded 6 clusters: *personalized care, coaching by a physiotherapist, social environment, self-concept, coping* and *physical fitness and health. Personalized care* was rated as most important. Overall, physiotherapists recognized these clusters in practice.
Conclusion: Patients with cancer reported that participating in a supervised exercise program improved their physical fitness and influenced social, mental and cognitive factors, resulting in improvements in QoL. These results can be used to increase the awareness of the importance of supervised exercise programs for the QoL of patients with cancer.

Exercise and The Cancer Patient: Function Improves Independent of Cardiovascular and Anthropometric Changes

Sarah R. McDowell[1], Cynthia Villalobos[1], Justin C. Brown[2], Paul D. Vosti[3], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]Harvard University, Cambridge, MA. [3]St. Joseph's Medical Center, Stockton, CA.* (Sponsor: Kathryn H. Schmitz, FACSM)
(No relevant relationships reported)

Each year, approximately 1.6 million Americans are diagnosed with cancer. The consequences of cancer and its associated treatment include elevations in cardiovascular risk, deteriorating body composition, and diminishing physical function. Exercise is an effective countermeasure; however, limitations in adherence may compromise the magnitude of improvement experienced. **PURPOSE**: To evaluate cardiovascular, anthropometric, and functional adaptations to an exercise program in cancer survivors. **METHODS**: We conducted a 10-week exercise intervention on 157 cancer survivors; 58 were retained through follow-up. At baseline, we recorded demographic, anthropometric, cardiovascular, and functional data. Anthropometric measurements were weight, body mass index (BMI), and body fat percent (BF%). Cardiovascular measurements were blood pressure and heart rate. Functional tests were VO2 max, six-minute walk, timed up-and-go, chair stand, sit-to-stand, arm curl, grip strength, Universal Machine (UM) push and pull, epic lift, sit-and-reach, functional reach, and back scratch. Paired-samples t tests measured changes from baseline to follow-up. **RESULTS**: Anthropometric variables did not change: body weight (p=0.585), BMI (p=0.477), and BF% (p=0.367). Cardiovascular variables did not change: systolic blood pressure (p=0.560), diastolic pressure (p=0.292), and heart rate (p=1.000). Improvement was detected in 11 of 13 functional tests: VO2 max (p=0.005), six-minute walk (p<0.001), timed up-and-go (p<0.001), chair stand (p<0.001), sit-to-stand (p=0.005), arm curl (p<0.001), grip strength (p<0.001), UM push (p<0.001), UM pull (p<0.001), epic lift (p=0.005), and functional reach (p=0.001). Mean values improved in sit-and-reach (p=0.321) and back-scratch (p=0.099), but pre-post comparisons were not significant. **CONCLUSION**: Exercise had no effect on anthropometric or cardiovascular profiles, but physical functioning improved in nearly every domain. In this population, maintenance of functional capacity can help preserve the ability to perform tasks of daily living, and it associates with survival. Although we found exercise to improve strength, aerobic capacity, and flexibility, the high rate of attrition is a potential limitation; further research is necessary to confirm our findings.

1653   Board #3   May 31 3:15 PM - 5:15 PM

Piloting the Effect of Aerobic Exercise during Chemotherapy Infusion in Patients with Cancer

Kate M. Edwards[1], Vanessa Thomas[1], Catherine Seet-Lee[1], Birinder S. Cheema[2], Michael Boyer[3], Michael Marthick[3]. *[1]University of Sydney, Sydney, Australia. [2]University of Western Sydney, Cambelltown, Australia. [3]Chris O'Brien Lifehouse, Sydney, Australia.* (Sponsor: Ollie Jay, FACSM)
(No relevant relationships reported)

Exercise in cancer patients is safe and can improve a range of outcomes including cancer-related fatigue, physical functioning and quality of life. Preclinical trials suggest an acute exercise bout during chemotherapy infusion may improve the treatment efficiency. It would also present an additional opportunity for supervised exercise. However, there are currently no published human trials of such an intervention. **PURPOSE:** To determine the safety and feasibility of delivering an aerobic exercise intervention to cancer patients during chemotherapy infusion. **METHODS:** A randomised crossover trial has commenced with eligible patients receiving either usual care or performing 20 minutes of low intensity cycling during infusion. Data collection includes patient uptake, physiological exercise response, perceived exertion, patient experience and a daily symptom diary for 1 week subsequent. **RESULTS:** Exercise has been safely delivered with neither adverse events nor interference to usual care reported for all subjects (N=3, Female, 52 ± 8 yrs). 60% of patients approached agreed to participate, and all reported that the exercise was no less comfortable, no more difficult, and less boring than usual care. Heart rate rose to the target 30%-40%HRR within 5-8 minutes and was steady during exercise, recovering to within 10 beats of resting rates in 4.7 ± 4.6 min. On average, systolic blood pressure rose 15% during exercise, with a maximum reading of 153mmHg, and full recovery to resting levels within 15 minutes. Oxygen saturation remained above 95% at all times. Rated perceived exertion during exercise ranged from 9-13 on the Borg scale. Reported daily symptom data was similar after both exercise and usual care. **CONCLUSIONS:** Exercise during chemotherapy infusion may be a safe and feasible addition to chemotherapy. Larger data collection is required to evaluate drug delivery efficiency, symptom reduction and opportunity for physical activity increase.

Effect of Exercise on Chemotherapy-Induced Peripheral Neuropathy Symptoms in Women with Breast Cancer

Kelcey A. Bland[1], Amy A. Kirkham[2], Josh Bovard[1], Tamara Shenkier[3], David Zucker[4], Margot K. Davis[1], Don C. McKenzie[1], Karen A. Gelmon[3], Kristin L. Campbell[1]. *[1]University of British Columbia, Vancouver, BC, Canada. [2]University of Alberta, Edmonton, AB, Canada. [3]British Columbia Cancer Agency, Vancouver, BC, Canada. [4]Swedish Cancer Institute, Seattle, WA.*
(No relevant relationships reported)

Chemotherapy-induced peripheral neuropathy (CIPN) is a common, dose-limiting side effect of taxane treatment for breast cancer. Given the limited medical or pharmacological treatment options to reduce CIPN, understanding the impact of lifestyle interventions is of interest. **Purpose:** To evaluate the effect of exercise during taxane treatment on CIPN symptoms in women with breast cancer. **Methods:** Women with early-stage breast cancer were randomized to supervised exercise (EX) or usual care (UC) during taxane treatment (~4 cycles, 2-3 weeks apart). Exercise included thrice-weekly progressive aerobic (50-75% HRR, 25-35 min), resistance (1-2 sets, 10-12 reps, 50-65% estimated-1RM) and balance training. CIPN symptoms were evaluated via: 1) the EORTC-QLQ CIPN20 subscale (scored from 0-100, with higher scores indicating greater symptom burden, and summarized as % of participants experiencing symptoms "quite a bit" or "very much") and; 2) quantitative sensory testing at the foot (vibration and pinprick). Assessments occurred at: 1) baseline (pre-taxane chemotherapy); 2) post-taxane cycle 3 and; 3) end of chemotherapy. **Results:** Twenty-seven women enrolled (UC: n=15, EX: n=12). Relative to baseline, both groups reported worse total sensory symptoms post-cycle 3 (Δ16.3, p<0.01) that progressed further by the end of chemotherapy (Δ24.3, p<0.01). At post-cycle 3, sensory symptoms were 38% lower in EX compared to UC but this was not statistically significant (UC=26.3±4.7, EX=16.3±5.4, p=0.17). The most frequently reported symptoms were tingling and numbness in both the hands and feet. Post-cycle 3, foot numbness was less prevalent (UC=50%, EX=9%, p=0.04), and foot tingling trended toward reduced prevalence (UC=43%, EX=9%, p=0.08) in the EX group. No group differences were found at the end of chemotherapy, or for hand symptoms at any time point. More UC participants had impaired vibration sense post-cycle 3 (UC=67%, EX=17%, p=0.02). There were no group differences for pinprick testing. **Conclusion:** Multi-model exercise during taxane treatment may delay CIPN symptom progression in breast cancer patients. Specifically, our findings indicate that exercise may reduce patient-reported and quantitative sensory symptoms in the feet after three taxane treatment cycles, where onset is frequently reported.

1655   Board #5   May 31 3:15 PM - 5:15 PM

Benefits of Immediate Versus Delayed Exercise in Men Initiating ADT for Prostate Cancer

Dennis R. Taaffe, FACSM[1], Robert U. Newton[1], Nigel Spry[2], David Joseph[3], Suzanne K. Chambers[4], Robert A. Gardiner[5], Prue Cormie[6], David HK Shum[4], Daniel A. Galvao[1]. *[1]Edith Cowan University, Perth, Australia. [2]Genesis CancerCare, Perth, Australia. [3]Sir Charles Gairdner Hospital, Perth, Australia. [4]Griffith University, Gold Coast, Australia. [5]University of Queensland, Brisbane, Australia. [6]Australian Catholic University, Melbourne, Australia.*
(No relevant relationships reported)

Androgen deprivation therapy (ADT) in men with prostate cancer (PCa) results in adverse effects including reduced muscle strength and physical performance, potentially compromising daily functioning. **PURPOSE:** To examine whether it was more efficacious to commence exercise at the onset of ADT rather than later in treatment to counter declines in strength and physical function. **METHODS:** One hundred and four men with PCa (68.3±7.0 years, 29.7±5.2 % fat, Gleason score 7.6±0.9) initiating ADT were randomised to immediate exercise (EX, n=54) or delayed exercise (DEL, n=50) for 12 months. EX comprised 6 months of supervised resistance/aerobic/impact exercise initiated at onset of ADT with 6-month follow-up. DEL comprised 6 months usual care followed by 6 months of resistance/aerobic/impact exercise. Muscle strength (chest press, leg press, seated row) and physical performance (6-m usual and fast walk, 6-m backwards walk, 400-m walk, stair climb, repeated chair rise) were assessed at baseline, 6 and 12 months. Data were analysed by ANCOVA using an intention-to-treat approach. **RESULTS:** There was a significant difference for all strength measures at 6 months favouring EX (p<0.001), with net differences in leg press, seated row and chest press strength of 19.9 kg (95% CI, 12.3 to 27.5 kg), 5.6 kg (3.8 to 7.4 kg), and 4.3kg (2.7 to 5.8 kg), respectively. From 6-12 months DEL increased in all strength measures (p<0.001) such that there were no differences between groups at 12 months. Similarly, physical performance improved (p<0.001) in EX compared to DEL at 6 months for the 400-m walk (-9.7 s, 95% CI -14.8 to -4.6 s), stair climb (-0.4 s, -0.6 to -0.2 s) and chair rise (-1.0 s, -1.4 to -0.7 s), with no differences between groups by 12 months. **CONCLUSION:** Exercise either

THURSDAY, MAY 31, 2018

at the onset or after 6 months ADT preserves/enhances muscle strength and physical function. However, to avoid any initial treatment-related adverse effects on strength and function, exercise should be prescribed and commenced at the onset of ADT. Supported by Cancer Australia (ID# 1029901).

1656   Board #6   May 31 3:15 PM - 5:15 PM

Effects of an Exercise Intervention on Lung Cancer Patients Who Have Undergone a Lobectomy

Nicholas Harman[1], Jessica M. Brown[2], Daniel Shackelford[2], Reid Hayward[1]. [1]*University of Northern Colorado, Greeley, CO.* [2]*Carroll University, Waukesha, WI.*
(No relevant relationships reported)

Lung cancer is the second most commonly diagnosed form of cancer, and is often treated surgically via tumor resection and lobectomy. Removal of lung tissue often impairs cardiopulmonary function, reduces activities of daily living, and lowers quality of life. Exercise interventions improve cardiopulmonary health and may attenuate the negative effects of lung cancer and its treatment. **Purpose:** To evaluate the response of lung cancer patients who had previously undergone a lobectomy to a structured, supervised 12-week exercise intervention, and compare these results with all other cancer patients completing the same exercise intervention. **Methods:** Nine male and female lung cancer survivors who had previously undergone a lobectomy, were recruited to participate in a 12-week exercise-based rehabilitation program. The program consisted of one hour sessions, three days per week, and included cardiovascular endurance, muscular strength and endurance, balance, and flexibility exercises. Subjects completed pre and post assessments of cardiopulmonary function, consisting of a graded exercise test, yielding peak oxygen consumption (VO_2 peak), and spirometry, yielding forced vital capacity (FVC) and forced expiratory volume (FEV_1). Subjects were divided into two groups: surgical resection including lobectomy (LOB, n = 9), and all other cancers (AOC, n = 205). **Results:** There were significant improvements in VO_2 peak in the LOB group (Pre: 15 ± 2 mL/kg/min, Post: 19 ± 5 mL/kg/min; +20%; p = 0.03) and no significant changes in FVC and FEV_1. There were significant improvements in VO_2 peak (Pre: 21 ± 0.5 mL/kg/min, Post: 24 ± 0.6 mL/kg/min; +13%; p = 0.00) and FEV_1 (Pre: 95 ± 1 %-predicted, Post: 97 ± 1 %-predicted; +2.2%; p = 0.02) in the AOC group. Between group comparisons yielded no significant difference in improvement to VO_2 peak for LOB vs AOC (p = 0.77). **Conclusion:** Results from this study demonstrate that lung cancer patients who have previously undergone a lobectomy can safely and effectively complete an individualized, prescriptive exercise intervention. These data also show that lung cancer survivors who have previously undergone a lobectomy are able to improve cardiopulmonary function to the same degree as all other cancer survivors completing a rehabilitative exercise intervention.

D-38   Thematic Poster - Hydration

Ad LibitumFluid Consumption off-sets Thermal and Cardiovascular Strain Exacerbated by Dehydration during Heat Waves

Connor Graham, Nathan B. Morris, Ollie Jay, FACSM. *University of Sydney, Sydney, Australia.* (Sponsor: Ollie Jay, FACSM)
(No relevant relationships reported)

Purpose: We compared the impact of different fluid replacement practices on the development of dehydration and the associated changes in thermal and cardiovascular strain throughout 3 hours of light exercise in peak heat wave conditions (40°C, 40%RH). **Methods:** Seven participants completed four separate 180-min trials, exercising at 3 METs in 40°C, 40%RH. In each trial a different hydration plan was employed; i) *ad libitum* consumption of 20°C water (ALTAP); ii) *ad libitum* consumption of 4°C water (ALCHILL); iii) no fluid replacement (NOFR); iv) full replacement of sweat loss (FULLFR). Fluid consumption (FC), resultant dehydration (%DEH), rectal temperature (T_{re}), mean skin temperature (T_{sk}), heart rate (HR), whole body sweat rate (WBSR), and local sweat rate (LSR) were measured. **Results:** Compared to NOFR, FC was greater in FULLFR (1.39±0.27 L; P<0.001), ALTAP (1.36±0.46 L; P=0.001) and ALCHILL (1.04±0.39 L; P=0.002). FC was greater in ALTAP than ALCHILL (P=0.01). %DEH was greater in NOFR (1.79±0.18%)

compared to FULLFR (0.03±0.14%; P<0.001), ALTAP (0.08±0.65%; P=0.002) and ALCHILL (0.46±0.59%; P=0.004). The rise in T_{re} from rest was greater in NOFR (1.13±0.34°C) compared to ALTAP (0.68±0.32°C; P<0.001), ALCHILL (0.72±0.34°C; P<0.001) and FULLFR (0.72±0.35°C; P<0.001). HR was higher after 180 min in NOFR (100±11 beats·min[-1]) compared to ALTAP (86±12 beats·min[-1]; P<0.001), ALCHILL (87±15 beats·min[-1]; P<0.001), and FULLFR (91±11 beats·min[-1]; P=0.003). No differences in T_{sk}, LSR or WBSR were observed between trials. **Conclusions:** No fluid consumption throughout a 3-h heat wave exposure with light physical activity exacerbated both thermal and cardiovascular strain, although differences in T_{re} were not due to difference in sweating. *Ad libitum* consumption of 4°C or 20°C water was sufficient to prevent levels of dehydration that exacerbate physiological heat strain. Preliminary findings show 4°C water seems to blunt thirst, and hence fluid intake relative to 20°C water.

1659   Board #2   May 31 3:15 PM - 5:15 PM

Energy Drink Consumption and Running Performance in a Hot Environment

Emma L. Reed[1], Lindsey N. Russo[1], Zachary J. Schlader[1], Jennifer L. Temple[1], David Hostler, FACSM[2]. [1]*University at Buffalo, BUFFALO, NY.* [2]*University at Buffalo, Buffalo, NY.*
(Sponsor: Dave Hostler, FACSM)
(No relevant relationships reported)

Energy drinks have been reported to have an ergogenic effect on exercise performance but there are few objective reports about the interaction of energy drinks and exercise in the heat in healthy, young adults. **PURPOSE**: To determine if energy drink consumption prior to a 5-km trial improves performance or alters thermoregulation when running in a hot environment.
METHODS: Experienced runners (4 males and 1 female; age: 22 ± 2.9 y; VO_{2max}: 51.16 ± 7.55 ml/kg/min) completed two 5-km trials in a double-blinded, randomized, crossover design 45 minutes after consuming a 500mL solution of a commercially available energy drink (ED) (~215 mg caffeine, ~480 mg taurine) or an equal volume of similarly flavored placebo (P). Both trials were completed on a treadmill in an environmental chamber set to 34°C and 40% relative humidity. Subjects were instructed to complete the 5-km run as fast as possible but were blinded to time, speed, and distance. Subjects were told the distance completed every 500 m. Physiological and perceptual variables were collected during the trials. **RESULTS**: There was no difference in time to complete the 5-km trial (1447 ± 296 (ED) vs. 1440 ± 264 sec (P)). Core temperature (39.27°C ± 0.33°C (ED) vs. 39.14°C ± 0.53°C (P)), skin temperature (36.2°C ± 0.4°C (ED) vs. 35.3°C ± 1.2 °C (P)), rate of perceived exertion (both 9.4 ± 0.5), and heart rate (193 ± 9 bpm (ED) vs. 193 ± 12 bpm (P)) at the end of exercise did not differ. **CONCLUSIONS**: Consuming an energy drink before running a 5-km trial in the heat did not affect thermoregulation or improve performance.

1660   Board #3   May 31 3:15 PM - 5:15 PM

100% Orange Juice Consumption on Hydration, Electrolyte, and Cardiovascular Measures Following Exercise In The Heat

Melani R. Kelly, Dawn M. Emerson, Evan J. Landes, Evan R. Barnes, Philip M. Gallagher. *University of Kansas, Lawrence, KS.*
(No relevant relationships reported)

Compared to commonly consumed carbohydrate electrolyte beverages (CEB), 100% orange juice (OJ) has a similar carbohydrate content, less sodium, and an increased amount of potassium, vitamins, and minerals, making it a possible fluid replacement option. **PURPOSE:** To investigate OJ, water (W), and CEB on hydration, electrolyte, and cardiovascular measures following exercise in the heat. **METHODS:** We used a randomized, controlled, single-blind design to determine the effects of OJ, a commercially available flavored W, and a commercially available CEB on plasma osmolality (Posm); plasma sodium (PNa+), potassium (PK+), calcium (PCa+), and chloride (PCl-); urine volume (Uvol); fluid volume (Fvol); heart rate (HR); and blood pressure (BP). Participants (n = 26, 20 male, 6 female, age: 22.1 ± 3.3 yrs; weight: 72.9 ± 10.0 kg; height: 174.3 ± 7.9 cm; VO2max: 48.8 ± 7.3 mL/kg/min) cycled 80 min at 70% VO2max in a hot, humid environment (30.1 ± 0.2°C, 51.6 ± 4.0% relative humidity) on 5 consecutive days. After exercise, participants consumed 237 mL (8 oz) of assigned beverage then rested 1 hr in an ambient environment. Dependent measures were taken pre-, during, post-, and 1 hr post-cycling. **RESULTS:** There were no significant differences between conditions at any time point for Posm, PNa+, PCa+, PCl-, Fvol, Uvol, HR, or BP. Participants began exercise euhydrated (Posm = 266.9 ± 16.6 mOsm/L) and maintained hydration to post- (266.3 ± 19.5 mOsm/L) and 1 hr post-cycling (261.9 ± 12.8 mOsm/L). PK+ post-cycling was significantly greater in OJ (4.3 ± 0.2) than CEB (4.0 ± 0.1, P = .04). PK+ 1 hr post-cycling was significantly lower in CEB (3.9 ± 0.1) than W (4.3 ± 0.2, P = .003) and OJ (4.2 ± 0.3, P = .01). Overall, pre- PK+ (3.9 ± 1.9 mmol/L) was significantly lower than post- (4.2 ± 0.2 mmol/L, P < .001) and 1 hr post-cycling (4.1 ± 0.3 mmol/L, P < .001). **CONCLUSION:** Consuming 8 oz of OJ on multiple days after moderately intense cycling in the heat

maintained fluid, electrolyte, and cardiovascular measures similar to W and CEB. Only PK$^+$ was significantly affected by OJ, with post-cycling measures being higher, but within normal limits. 100% OJ is a viable rehydration option after exercise. Funded by the Florida Department of Citrus (#STE0075600).

Rehydrating Efficacy of Maple Water After Exercise-Induced Dehydration: Potential Sex

Alexs A. Matias, Monique D. Dudar, Josip Kauzlaric, Kimberley A. Frederick, Stephen J. Ives. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Paul J. Arciero, FACSM)

(No relevant relationships reported)

BACKGROUND: Physical work, exacerbated by environmental heat stress, can induce dehydration, impairing physiological function. Therefore, understanding efficient rehydration strategies is paramount. The rehydrating effects of carbohydrate-electrolyte drinks and coconut water are well documented. To the best of our knowledge, no studies have investigated the rehydrating efficacy of maple water (MW). **PURPOSE:** Investigate the rehydrating efficacy of MW following exercise induced dehydration. **METHODS:** 26 healthy college-aged (24±1 kg/m^2, 22±1 yrs) males (n=13) and females (n=13) participated in a single blind, counterbalanced, crossover design study investigating the rehydrating efficacy of MW vs. maple flavored bottled water after exercise-induced dehydration (~2.0%Δ Body Weight [BW]) in an environmental chamber (30°C, 50% RH). Post-exercise, participants consumed either: 1L of MW or control. Assessments of hydration (BW, salivary and urine osmolality [Sosm/Uosm]), urine specific gravity (USG), urine output (UO), urine color (UC), thirst, fatigue, heart rate (HR), and HR variability (HRV) were taken at baseline, immediately post-exercise, and 0.5, 1, and 2h post-consumption. **RESULTS:** Following dehydration (p<0.05), MW had no differential (p>0.05) impact on rehydration. Thirst sensation was 12% higher in the MW condition (p<0.05). When analyzed by sex, females had lower UO (30%, p<0.05), higher ΔBW (25%, p<0.05), USG (p<0.05), and Usom (23%, p<0.05), but similar Sosm (p>0.05). Analysis of MW revealed higher electrolyte content (Ca^{2+}, K$^+$, Mg$^+$, Mn$^+$, CO$_3^{2-}$, PO$_4^-$, SO$_2^-$, Cl-, but not Na$^+$), osmolality (81 vs. 11 mOsm/kg), and antioxidant potential (AP; FRAP assay, 3.9 ± 0.0 vs. 1.0 ± 0.1), which tended to increase urine AP following MW consumption (9.4 ± 0.7 vs 7.6 ± 1.0 mmol; MW vs. control). **CONCLUSION:** MW is an equally effective rehydrating beverage to water, but has higher electrolyte concentration and osmolality which might better trigger thirst mechanisms when rehydration is performed ad libitum. Further, MW has a superior antioxidant capacity, which tended to increase urinary antioxidant capacity and might reduce free radicals associated with exercise. There are apparent sex differences in urinary (UO, ΔBW, USG, Uosm), but not salivary, based measures of rehydration and warrants further study.

Commercial Hydration Beverages Effectively Prolong Positive Fluid Balance in Older Adults Compared to Water

Megan M. Clarke, Anna E. Stanhewicz, W. Larry Kenney, FACSM. *The Pennsylvania State University, University Park, PA.* (Sponsor: W. Larry Kenney, FACSM)

(No relevant relationships reported)

Glucose-based beverages are often prescribed when mild-to-moderate dehydration is suspected because glucose-sodium cotransporters in the small intestine facilitate active transport of Na+ and resultant water diffusion. Alternatively, amino acid (AA)-based beverages use AA-sodium cotransporters to facilitate increases in vascular volume in the short-term with potentially fewer negative GI issues. **PURPOSE:** To compare effects of commercially available hydration solutions on short term fluid balance after an overnight fast. We hypothesized that (1) older subjects would stay in positive fluid balance longer after fluid ingestion due to decreased renal excretion rates, and (2) consumption of commercially-available hydration products would further delay negative fluid balance compared to water. **METHODS:** On five separate visits following an overnight fast, 12 young (Y, 23±3 yr; 7M/5F) and 12 older (O, 67±6 yr; 5M/7F) subjects consumed 1 L of distilled water, Gatorade (6% glu, 20 mmol/L Na$^+$), Pedialyte (2.5% glu, 45 mmol/L Na$^+$), Enterade (5 AA, 30 mmol/L Na$^+$), or Enterade-AD (anti-diarrheal; 8 AA, 60 mmol/L Na$^+$) over a 30-minute period. Urine samples were collected before ingestion and at 0, 60, 120, 180, and 240 min post-ingestion. Net fluid balance was calculated at each time point and time spent in positive fluid balance (g urine < g fluid consumed) was determined for each beverage by non-linear exponential decay modeling. **RESULTS:** GFR was lower in O compared to Y (71±3 vs. 94±6 ml/min, P<0.01). There was no difference among beverages for Y in time spent in positive fluid balance. Time in positive fluid balance was significantly longer for O compared to Y following ingestion of 1L of Pedialyte (234±34 vs. 140±18 min; P<0.01), Enterade (291±49 vs. 152±18 min; P<0.01), and Enterade-AD (228±27 vs. 161±25 min; P=0.04) and was significantly increased in O with Enterade compared to water (291±49 vs. 204±35 min, P=0.02). **CONCLUSIONS:** After a bolus fluid load, healthy older adults exhibit a prolonged time course for urine excretion due to

decreased GFR. Ingestion of commercially-available hydration solutions prolongs positive fluid balance compared to water ingestion in healthy older -- but not young -- adults. An AA based hydration product was the most effective short-term (0-4 h) oral hydration strategy for older adults.

Consumption of a Caffeinated Soft Drink during Exercise in the Heat Worsens Dehydration

Christopher L. Chapman, Blair D. Johnson, James R. Sackett, Mark D. Parker, Zachary J. Schlader. *University at Buffalo, Buffalo, NY.* (Sponsor: Dave Hostler, FACSM)

(No relevant relationships reported)

Chronic dehydration is linked to kidney dysfunction in workers regularly exposed to hot environments. Sugar-rich beverages, such as soft drinks, are regularly consumed on work sites. Such hypertonic drinks decrease plasma and extracellular fluid volumes during rest. Consuming a soft drink-like beverage after resting heat exposure worsens dehydration in rats. It is unknown if drinking a caffeinated soft drink exacerbates dehydration during exercise in the heat.
PURPOSE: Test the hypothesis that consuming a caffeinated soft drink during exercise in the heat increases the magnitude of dehydration.
METHODS: Twelve healthy subjects (age: 24±5 y, 3 females) completed randomized soft drink (Mtn Dew, Soda), and water control (Water) trials. Subjects completed four 1 h work-rest cycles (45 min exercise, 15 min seated rest) in a 35°C, 65% RH environment. During rest, subjects drank 500 mL of the assigned rehydration beverage (~11°C). Physiological variables, and venous blood and urine samples were taken pre-(PRE), and post-exercise (POST) after 15 min supine rest in a moderate environment. Percent changes in plasma volume were estimated from changes in hemoglobin and hematocrit. Data are reported as a change from Pre (mean±SD).
RESULTS: Increases in core temperature (Soda: 0.8±0.3, Water: 0.8±0.3°C, p=0.46) and changes in nude body weight (Soda: -0.3±0.8, Water: 0.0±0.7%, p=0.20) were not different between trials. Urine specific gravity was higher at POST (p<0.05), but there were no differences between trials (Soda: 0.006±0.013, Water: 0.007±0.009, p=0.89). At POST, plasma osmolality was elevated in Soda (2±3 mOsm/kg) and reduced in Water (-6±3 mOsm/kg, p<0.01). Urine osmolality was higher at POST (p<0.01), but there were no differences between trials (Soda: 69±368, Water: 185±311 mOsm/kg, p=0.12). Plasma volume was lower in Soda at POST (p<0.02), but there were no differences between trials (Soda: -5±6, Water: -2±7%, p=0.15). Elevations in heart rate were higher in Soda at POST (Soda: 20±12, Water: 12±12 bpm, p<0.03). Mean arterial pressure was elevated in Soda (p<0.01) at POST, but was not different between trials (Soda: 5±8, Water: 2±5 mmHg, p=0.33).
CONCLUSION: These data indicate that consuming a caffeinated soft drink during exercise in the heat worsens dehydration and elevates cardiovascular strain.

Effects of Different Water and Sodium Consumption Volumes on Fluid Retention and Hyperhydration.

David M. Morris, Elizaveta Roslanova. *University of Texas - Permian Basin, Odessa, TX.*

(No relevant relationships reported)

Previous research has shown that co-consumption of sodium and water prior to exercise is effective in promoting hyperhydration. However, optimum fluid and sodium consumption volumes for attaining hyperhydration have not been systematically studied. While consumption of larger volumes of fluid may seem to be advantageous, overconsumption of fluid may trigger excess diuresis and, thus, not provide advantages over smaller fluid doses. **PURPOSE:** To compare the effects of different water and sodium dose volumes on fluid retention.
METHODS: Urine excretion was measured during four separate 2-hr hyperhydration protocols in 13 well hydrated male subjects (24 ± 4 yr, 177.0 ± 8.9 cm, 75.2 ± 9.5 kg) who were free from known renal, digestive, and cardiovascular disease. Each protocol began with a complete bladder void and assessment of urine specific gravity (USG). Subjects then consumed water and NaCl in an isotonic mixture in four different dosing strategies: 20 mL H$_2$O · kg bm^{-1} with 94 mg NaCl · kg bm^{-1} (20), 15 mL H$_2$O · kg bm^{-1} with 70.5 mg NaCl · kg bm^{-1} (15), 10 mL H$_2$O · kg bm^{-1} with 47 mg NaCl · kg bm^{-1} (10), or 5 mL H$_2$O · kg bm^{-1} with 23.5 mg NaCl · kg bm^{-1} (5). Protocols were applied in a randomized, crossover fashion. Each treatment was divided into three equal portions and consumed at 0, 45, and 90-min of the 2 hr hyperhydration period. Total urine excretion for the two hour period was subtracted from the fluid consumed to determine total fluid retention (TFR). USG and TFR, expressed in mL · kg bm^{-1}, were compared using separate, one-way repeated-measures ANOVAs and Sidak *post hoc* analyses.
RESULTS: USGs were 1.009 ± 0.005 (20), 1.016 ± 0.028 (15), 1.010 ± 0.003 (10) and 1.009 ± 0.005 (5) (P = 0.93 - 1.00) indicating that subjects were well and similarly hydrated for each trial. TFR, expressed in mL · kg bm^{-1}, were 10.8 ± 2.7 (20), 7.5 ± 2.3 (15), 5.0 ± 2.5 (10) and 2.6 ± 1.4 (5) (P = 0.001 - 0.039).

CONCLUSIONS: The data suggest that, when consuming a water and NaCl mixture in volumes ranging from 5 - 20 mL $H_2O \cdot kg\ bm^{-1}$, fluid retention rates are approximately 50% regardless of the volume of fluid consumed. Thus, to achieve maximum hyperhydration, at least 20 mL $H_2O \cdot kg\ bm^{-1}$ should be consumed.

Dynamic Knee Hyperextension in Competitive High School Soccer Players

Stacy J. Ingraham[1], Jon-Paul W. Ciszewski[2], David W. McGehee[2], Jessica N. Schindler[2], Sarah J. Ingraham[3], William W. Newhouse[4], Daniel D. Hanson[5], Jane R. Yank[2]. *[1]Crown College, St. Bonifacious, MN. [2]Bethel University, St. Paul, MN. [3]Norwich University, Northfield, VT. [4]University of Minnesota, Minneapolis, MN. [5]Wheaton College, Wheaton, IL.*

(No relevant relationships reported)

Purpose: The purpose of this study was to explore the incidence of dynamic knee hyperextension in high school soccer athletes by sex and team level (freshman, junior varsity and varsity), as observed through high-speed photography. In addition, the data was gathered to explore if the difference of dynamic hyperextension noted between men and women was similar to the differences found in ACL injury surveillance data incidence statistics. **Methods:** Dynamic knee extension of 87 male (*n*=41) and female (*n*=46) high school soccer athletes was captured using high-speed photography while punting a soccer ball 8 times in a single session. One photo demonstrating each athlete's maximal knee extension was assessed for degree of extension, both visually and using Kinovea, a motion analysis software program. **Results:** Multinomial logistic regression regarding certainty of hyperextension with a 5-point scale by two judges showed no significant differences by sex of the player (*p*=.456) or team level (*p*=.064). The incidence of hyperextension for females and males across all skill levels was approximately 16/41 (39%) and 16/36 (44%), respectively. Results of binary logistic regression on the presence or absence of observed hyperextension showed no significant differences by sex of the players (*p*=.702) or by team level (*p*=.191). Results of categorical data analysis showed no significant differences among six player groups consisting of freshman, junior varsity, and varsity levels for both boys and girls (chi-square=3.928, *p*=.560). Interestingly, there was a marginal increased incidence of hyperextension in freshman high school athletes (p=.099). The incidence of hyperextension among all participants of this study is not congruent with published ACL injury surveillance, confirming the multifactorial nature of ACL injuries. **Conclusion:** The results indicate that with a larger sample size, a difference between team levels may emerge. The lack of difference of hyperextension between males and females suggest hyperextension incidence is not a good predictor of injury differences between sexes. More research is needed to identify the relationship between observed dynamic knee hyperextension, recoil and ACL injury.

A Novel Approach To Investigate Differences In Knee Mechanics After ACL Reconstruction Using Inertial Sensors

Jasper Reenalda[1], Erik Maartens[1], Jaap Buurke[1], Mary Lloyd Ireland, FACSM[2], Brian Noehren, FACSM[2]. *[1]Roessingh Research and Development, University of Twente, Enschede, Netherlands. [2]University of Kentucky, Lexington, KY.* (Sponsor: Brian Noehren, FACSM)

(No relevant relationships reported)

Hop testing after an Anterior Cruciate Ligament reconstruction (ACLR) is a common functional test to determine return to play status. However, hop tests are not very sport specific, as they do not capture other tasks in sports like accelerating, decelerating, cutting and turning. A figure 8 running task is proposed as an alternative, involving these sport specific movements. Knee mechanics during this task can be objectified using inertial sensors. These sensors have been used previously to objectify hop tests and showed differences in knee kinematics in ACLR patients.
PURPOSE: To investigate sagittal knee mechanics in ACLR patients during a 5 minute figure 8 running task, using inertial magnetic measurement units (IMUs).

METHODS: 5 ACLR patients (2M 3F, 20.4 ± 2.1 yrs, 164.2 ± 10.7 cm, 69.1 ± 23.5 kg) one year post ACLR, and 10 healthy controls (7M 3F, 21.8 ± 2.0 yrs, 178.3± 10.2 cm, 73.5± 14.3 kg) performed a 5 minute figure 8 running task wearing a lycra suit equipped with 8 IMUs at the feet, tibia, upper legs, sacrum and sternum. Sagittal knee mechanics were determined at the straights since this is the most standardized part of the figure 8. The absolute difference in peak knee flexion (ADPK) during stance phase was determined between reconstructed and healthy leg for the ACLR group and between both legs for the healthy (HLTH) population. An independent Mann-Whitney U-test was used to test for a statistical difference in ADPK between ACLR and HLTH. **RESULTS:** ADPK was significantly higher (p < 0.05) for the ACLR group versus the healthy population.
CONCLUSIONS: Subjects who have had an ACLR have a larger difference in peak knee flexion between their reconstructed and healthy leg (less flexion in the reconstructed knee) at the straights of a figure 8 Running task compared to healthy controls. The figure 8 test might serve as a new test to determine return to play and to assess re-injury risk. Future research should test this and include (frontal plane) knee mechanics during cutting and turning.

Table 1: Peak knee flexion (degrees) of the reconstructed and healthy leg during stance phase of the individual ACLR subjects (ACLR#) and ACLR group and for the left and right leg for the HLTH group. An asterisk denotes the statistical significant difference.

	ACLR1	ACLR2	ACLR3	ACLR4	ACLR5	ACLR (N=5)	HLTH (n= 10)
ACLR side	Right	Right	Right	Left	Right		
Reconstructed leg	27.9 ± 5.2	26.8 ± 3.1	47.5 ± 2.4	28.4 ± 5.1	44.0 ± 5.6	34.9 ± 11.4	46.3 ± 8.4
Non-injured leg	48.3 ± 5.0	48.6 ± 3.4	48.3 ± 1.7	37.4 ± 3.0	43.2 ± 3.3	45.2 ± 5.5	48.2 ± 9.5
ADPK	22.9 ± 4.9	21.8 ± 3.8	1.9 ± 1.9	9.1 ± 6.8	2.3 ± 2.5	12.0 ± 5.2 *	4.9 ± 5.2

Reductions in Peak Knee Adduction Moment in Three Previously Studied Gait Modification Strategies: Preliminary Analysis

Bryndan Lindsey[1], Oladipo Eddo[1], Shane Caswell[1], David Hollinger[1], Jessica Pope[1], Matt Prebble[1], Ana M. Azevedo[2], Nelson Cortes[1]. *[1]George Mason University, Manassas, VA. [2]University of Lisbon, Lisbon, Portugal.*

(No relevant relationships reported)

First peak knee adduction moment (PKAM) has been associated with osteoarthritis (OA) progression. Gait modification strategies using real-time biofeedback (RTB) including lateral trunk lean (TL), medial knee thrust (MKT), and reduced foot progression angle (FPA) have reduced PKAM in both healthy and OA populations. However, heterogeneity between limited study designs makes it unclear which strategy most effectively reduces PKAM. **PURPOSE:** To compare the effects of TL, MKT, and FPA strategies on PKAM in healthy individuals during gait. **METHODS:** 10 healthy individuals volunteered for this study (28.4 ± 3.8 years, 1.73 ± 0.1 m, 75.3 ± 12.5 kg). Mean and standard deviation (SD) for PKAM, trunk angle, knee angle (KA), and foot angle during stance was calculated from 10 baseline trials using a motion capture system and force plates. 10 trials completed for each strategy using RTB so that joint angles fell within a determined range (1-5 SD) relative to baseline. Visual 3D was used to project visual RTB as a line graph displaying real-time joint angle during stance. Visual 3D was used to calculate joint angles (°) and internal moments (Nm/kgm). Participants modified their gait so the line fell within a highlighted bandwidth representing target ranges. Repeated measures ANOVA was used to assess differences in PKAM between conditions. Dependent t-tests were conducted to compare joint angles between baseline and modification strategy (p<0.05). **RESULTS:** Compared to baseline (0.10±.04) only MKT (.18±.09) showed a statistically significant difference in PKAM (p=0.014). No other statistically significant difference was found (p>0.05). **CONCLUSION:** Contrary to prior studies, results showed no differences in PKAM during LTL and FPA gait. Lack of significant changes in joint angles across conditions suggest that gait modifications were too small to significantly alter PKAM. MKT gait increased internal PKAM despite no significant differences in KA compared to baseline. It is possible that reductions in PKAM during gait modification are offset due compensatory mechanisms that remain poorly understood. More research is required to identify the magnitude of kinematic change needed to reduce PKAM and understand mechanical changes occurring along the entire kinetic chain during gait modification.

1669 Board #4 May 31 3:15 PM - 5:15 PM
Lack of Association Between Clinical Measures of Symmetry and Knee Loading Mechanics After ACL Reconstruction

Lindsey K. Lepley, Julie P. Burland, Steven M. Davi, Adam S. Lepley. *University of Connecticut, Storrs, CT.*

(No relevant relationships reported)

Distance hopped in the anterior cruciate ligament reconstructed limb (ACLR) limb relative to the contralateral limb (i.e. limb symmetry index [LSI]) has been used

as a clinical criterion to help guide safe return to sport. However, it is unclear if laboratory measures of knee kinematic and kinetic loading symmetry are related to clinical symmetry. Ongoing asymmetry in knee loading mechanics may predispose the individual to recurrent injury. Identifying whether clinical symmetry is related to knee loading symmetry is important to fully understand readiness to return to sport. **PURPOSE:** To evaluate whether clinical limb symmetry, measured by distance hopped during the single leg hop for distance (SLHD) test, is associated with landing mechanics symmetry in participants with a history of ACLR. **METHODS:** Motion analysis data were collected on participants with a history of ACLR (n=10, 6f/4m, 22.4±2.1yrs, 1.6±0.8m, 65.6±12.1kg, time from surgery to test 5.8±1.9yrs). The LSI ([ACLR limb/contralateral limb] x100) was calculated for the following parameters collected during the loading phase of the SLHD: distance hopped, peak knee flexion angle at initial contact, peak knee flexion angle, peak knee extensor moment, and the area under the curve (AUC) for knee flexion angle and knee extensor moment. Spearman correlations were used to determine if symmetry in distance hopped was associated with symmetrical landing mechanics. **RESULTS:** Distance hopped symmetry (99.5±5.1%) was not associated with peak knee flexion angle at initial contact (72.8±26.9%, rho=-0.164, P=0.651), peak knee flexion angle (90.1±10.7%, rho=0.103, P=0.777), AUC knee flexion angle (88.3±14.8%, rho=-0.006, P=0.987), peak knee extensor moment (89.9±19.2%, rho=0.576, P=0.082) or AUC knee extensor moment (87.0±23.5%, rho=0.188, P=0.603) symmetry. **CONCLUSION:** Clinical symmetry was not associated with any laboratory measures of knee kinematic or kinetic loading symmetry. The lack of association between clinical symmetry and knee loading mechanics suggests that individuals with a history of ACLR use altered inter-limb biomechanical strategies to achieve the same functional outcomes. This finding suggests that additional assessment of loading mechanics may be warranted to help guide safe return to sport after ACLR.

The Effects of Wearing Knee Wraps on Total Concentric Work Performed During the Back Squat Exercise.

Cardyl Trionfante[1], Ben Kantura[2], Erica Marshall[2], Arnold G. Nelson, FACSM[1], J. Derek Kingsley, FACSM[2]. [1]*Louisiana State University, Baton Rouge, LA.* [2]*Kent State University, Kent, OH.* (Sponsor: Arnold G Nelson, FACSM)
(No relevant relationships reported)

PURPOSE: To investigate the effects of using knee wraps on vertical displacement, lifting duration, and work performed during the concentric phase of the back squat exercise. **METHODS**: Resistance-trained men performed a back squat protocol over three testing sessions, along with two training days, over a 2-week period. Each testing session involved performing six single repetition sets of the back squat with 5-min of rest. During each testing session, participants underwent 2 different treatments such that the first three sets were performed unassisted (U) and the second three sets were performed with knee wraps (W). The two training days occurred between the second and third testing sessions. On these training days, participants were randomly assigned to a back squat training group; one that trained with knee wraps (TW; n=7) (mean±SD; Age: 26±4yrs, Height: 1.81±0.06m, Mass: 88.4±13.7kg, 1RM: 144±23kg) and one that trained without knee wraps (TU; n=7) (Age: 24±5yrs, Height: 1.78±6.4m, Mass: 81.4±3.8kg, 1RM: 143±25kg). A linear position transducer was used to measure concentric vertical displacement, lifting duration, and work [Force*distance]. Repeated measures ANOVAs were used to determine differences in back squat across time (testing days 1(D_1), 2(D_2), and 3(D_3)), treatment (U vs. W), and training group (TW vs. TU). **RESULTS**: A significant main effect of time (p<0.001) was observed such that during the third back squat testing session concentric vertical displacement (D_3- 0.46±0.06m) was greater than the first two sessions (D_1- 0.43±0.08m, D_2- 0.44±0.06m) regardless of treatment or training group. Lifting duration significantly decreased (p<0.001) during the third session (D_3- 0.99±0.16s) that was also significantly different from the first two sessions (D_1- 1.06±0.23s, D_2- 1.05±0.19s) regardless of treatment or training group. Concentric work was also significantly greater (p<0.001) during the third session (D_3- 911±135Nm) compared to the first two sessions (D_1- 844±176Nm, D_2- 861±144Nm), independent of treatment or training group. **CONCLUSION**: Our data suggest that knee wraps didn't significantly alter concentric vertical displacement, duration, or work of the back squat exercise for single repetition sets.

Acute Effects of Two Hip Flexor Stretching Techniques on Knee Joint Position Sense and Balance

Hussain Aslan[1], David Suprak[2], Harsh Buddhadev[2], Jun San Juan[2]. [1]*Western Washington University, Kirkland, WA.* [2]*Western Washington University, Bellingham, WA.*
(No relevant relationships reported)

Tightness of hip flexor (THF) muscles has been recognized as a risk factor for various musculoskeletal injuries in the lower extremities. Abnormal knee joint position sense (JPS) has also been linked to several orthopedic and musculoskeletal conditions in the knee joint. **Purpose:** To examine the acute effects of two hip flexor stretching techniques on hip extension range of motion (ROM), knee JPS and dynamic balance performance (DB). **Methods:** Thirty-six healthy college age students (24 males, 11 females, mean age 22.37 ± 1.63 years, height 171.05 ± 9.64 cm, and weight 72 ± 13.70 kg) with THF participated in this study. Hip extension ROM, knee JPS and DB were measured pre- and post-stretching using a digital inclinometer, an iPod touch and the Y-balance kit, respectively. Subjects were randomly divided into dynamic stretching (DS), and hold-relax proprioceptive neuromuscular facilitation (HR-PNF) groups. Three-way mixed analysis of variance (ANOVA) was used to explore if an interaction existed between the groups (DS vs. HR-PNF), time (pre-and post) and side of hip (right vs. left) in hip extension ROM, knee JPS and DB measurements. **Results:** There was a significant effect of time on hip extension ROM in both stretching groups (pre = 9.37°, 9.64°, vs post = 0.18°, 0.27°, right and left hips, respectively; *p* < 0.001). Also, there was a significant effect of stretch type on hip extension ROM (-3.87°, -2.48 °) and (-0.90°, -0.26°) right, left, PNF versus DS group, post- stretching time points, respectively; *p* = 0.004) favoring HR-PNF over DS. There was a non-significant effect of time on mean knee JPS replication error in both groups. In DB measurement, there was a significant main effect of time and directions of reach on the Y-balance test's mean distance. The total mean distance of reach to posterolateral direction for both stretching groups (pre = 110.96 %, post = 113.48 %) was larger than the total mean distance of reach to posteromedial direction (pre = 103.82 %, post = 107.94 %) which was in turn larger than the total mean distance of reach to the anterior direction (pre = 66.49 %, post = 65.64 %; *p* < 0.001). **Conclusions:** DS and HR-PNF stretching resulted in a significant acute improvement in hip extension ROM and DB measures. However, knee JPS replication error results showed nonsignificant improvement over time in either stretching group.

Movement Efficiency Profile Affects Knee Loading Responses to a Controlled Acute Exposure to High Metabolic and Mechanical Training Load

Barnett Frank, Troy Blackburn, Steve Marshall, Claudio Battaglini, FACSM, Anthony Hackney, FACSM, Darin Padua. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Claudio Battaglini, PhD, FACSM)
(No relevant relationships reported)

Exposure to acute high training loads (HTL) induces biomechanics associated with knee joint injury. **Purpose:** Determine if individuals with high-risk (HR) and low-risk (LR) biomechanics exhibit different changes in tri-planar knee loading in response to a controlled HTL exposure. **Methods:** 43 physically active, healthy, college-aged field or court sport female athletes (n=43; age=20.5±1.6 yrs, height=167.7±7.0 cm, mass=62.8±7.1 kg) were assigned to a LR (n=21) or HR (n=22) movement profile group defined by the landing error scoring system. Peak anterior tibial shear force (ATSF ($N•N_{bw}$-1)), internal knee varus (IKVRM), and internal knee external rotation (IKERM) moments ($Nm•N_{bw}$-1$•m_{ht}$-1) were measured during a jump-landing task prior to and after a metabolically and mechanically controlled HTL exposure. Participants completed five sets of treadmill running at a speed (LR:11.1±1.2 km•h-1, HR:11.3±1.0 km•h-1, t$_{41}$=0.702, p>0.05) coincident with 110-120% of their ventilatory threshold (LR:37.1±3.6 ml•kg-1•min-1, HR:37.1±3.6 ml•kg-1•min-1, t$_{41}$=0.072, p>0.05) for five minutes and 10 jump-landings from a 30 cm box half their height from a landing target line. **Results:** A significant group-by-time interaction was observed for ATSF (F$_{1,41}$=5.000, p<0.05) The HR group experienced increases in ATSF (HR-Pre-HTL: 0.86±0.10[0.82, 0.90], HR-Post-HTL: 0.90±0.08[0.86,0.93]), whereas the LR group experienced decreases in ATSF (LR-Pre-HTL: 0.82±0.17[0.76,0.90], LR-Post-HTL: 0.79±0.13[0.74,0.85]) from pre-to-post HTL exposure. No significant group-by-time interactions were observed for IKVRM (F$_{1,41}$=0.648, p>0.05; HR-Pre-HTL: 0.41±0.23[0.31, 0.51], HR-Post-HTL: 0.42±0.22[0.33, 0.52] & LR-Pre-HTL: 0.28±0.14[0.22, 0.34], LR-Post-HTL: 0.25±0.11[0.21, 0.30]) or IKERM (F$_{1,41}$=0.083, p>0.05; HR-Pre-HTL: 0.21±0.09[0.25,0.17], HR-Post-HTL: 0.17±0.11[0.22,0.12] & LR-Pre-HTL: 0.21±0.09[0.24,0.17], LR-Post-HTL: 0.16±0.08[0.19,0.12]). **Conclusion:** Movement profile has a large effect (d=0.98) on HTL-induced sagittal plane knee loading responses linked to knee joint injury. Individuals with greater movement efficiency appear to be more biomechanically resilient to acute HTL exposure compared to individuals with high-risk biomechanics.

Effects Of Load Carriage and Step Length Manipulation on Knee Loads During Walking

Richard W. Willy[1], Paul DeVita, FACSM[2], Stacey A. Meardon[2], John D. Willson[2]. [1]*University of Montana, Missoula, MT.* [2]*East Carolina University, Greenville, NC.* (Sponsor: Paul DeVita, FACSM)
(No relevant relationships reported)

PURPOSE: Effects of load carriage on medial tibiofemoral joint (mTFJ) and patellofemoral joint (PFJ) contact forces were evaluated using preferred, 7.5% shorter

THURSDAY, MAY 31, 2018

and 7.5% longer step lengths. **METHODS:** Sixteen male Army ROTC Cadets (20.1 ±2.5 years, 77.4 ±13.4 kg) completed walking treadmill trials (1.3 m/s) with and without 20-kg load carriage. Trials were then collected with altered step lengths (±7.5%) with load carriage. Joint contact forces normalized to body weight (BW) per step and per 1-km were estimated for the mTFJ and PFJ via musculoskeletal modeling. **RESULTS:** At preferred step length, the load carriage increased peak mTFJ contact force per step by 19.3% (p<0.001, d=1.33) and mTFJ impulse per 1-km by 22% or 89 additional BW*s per km (p<0.001, d=1.49). Relative to body mass, the load carriage increased peak PFJ contact force per step by 14.2% (p<0.001, d=0.66) and PFJ impulse per km by +18.7% or 19 additional BW*s per km (p<0.001, d=0.69). There was a 1:2 relationship between the load carriage and absolute peak mTFJ contact force increase versus a more modest 1:1 relationship between load carriage and absolute peak PFJ contact force increase. Compared with preferred step length with load carriage, a short step with load carriage did not alter mTFJ or PFJ contact forces (all p>0.05). In contrast, a long step magnified the effect of load carriage on all metrics of mTFJ and PFJ contact forces. Specifically, a long step with load carriage increased peak mTFJ contact force by 9.0% (p<0.004, d=0.63) and mTFJ impulse per 1-km by 6.6% or 32.8 additional BW*s per km (p=0.001, d=0.48). A long step increased peak PFJ contact force by 26.6% (p=0.004, d=0.68) and PFJ impulse per 1-km by 22.7% or 27.1 additional BW*s impulse per km (p=0.001, d=0.48) compared with preferred step length with load carriage. A long step with load carriage resulted in 1:3.2 and 1:2.4 relationship between added load weight and absolute increases in peak mTFJ and PFJ contact forces, respectively. **CONCLUSIONS:** The added load carriage was preferentially borne by the mTFJ with a smaller increase in PFJ contact forces. A short step was not an effective strategy to reduce mTFJ and PFJ loads. A longer than preferred step length, often observed in shorter individuals during formation marching, increased both mTFJ and PFJ contact forces with greatest increases noted in the PFJ.

D-40   Thematic Poster - **Step it Up! Walking Toward Health**

Trends In The Prevalence And Volume Of Transportation And Leisure Walking Among U.S. Adults, 2005-2015

Emily N. Ussery[1], Susan A. Carlson[1], Geoffrey P. Whitfield[1], Kathleen B. Watson[1], David Berrigan[2], Janet E. Fulton, FACSM[1]. *[1]Centers for Disease Control and Prevention, Atlanta, GA. [2]National Cancer Institute, Bethesda, MD.* (Sponsor: Janet Fulton, FACSM)

(No relevant relationships reported)

Promotion of walking is an important strategy for increasing physical activity levels in the US, as highlighted in *Step It Up! The Surgeon General's Call to Action to Promote Walking and Walkable Communities*. Public health monitoring of walking behaviors can guide future efforts to promote walking. The proportion of adults who walk for transportation or leisure has increased in recent years, but trend data on walking for specific purposes is limited.
PURPOSE: To examine trends in the prevalence and volume of self-reported walking for transportation and leisure among US adults from 2005 to 2015.
METHODS: The 2005, 2010, and 2015 National Health Interview Survey assessed participation in and time spent walking for transportation and leisure in the past week among adults (n=83,933). For each year, the prevalence and mean volume (minutes/week) of walking were calculated for those reporting any transportation walking, any leisure walking, and both transportation and leisure walking. Trends were evaluated using logistic (prevalence) and linear (volume) regression.
RESULTS: The prevalence of transportation walking increased steadily from 2005 to 2015 (linear: p<0.05). Leisure walking prevalence increased overall, but slowed between 2010 and 2015 (linear and quadratic: p<0.05). Reported transportation and leisure walking volume decreased from 2005 to 2015, with no change between 2010 and 2015 (linear and quadratic: p<0.05). The prevalence of walking for both transportation and leisure increased steadily from 2005 to 2015 (linear: p<0.05); walking volume also decreased in this group, with no change between 2010 and 2015 (linear and quadratic: p<0.05).
CONCLUSION: Transportation and leisure walking prevalence increased over the last decade, but time spent walking decreased. Encouraging walking for multiple purposes may increase participation in and time spent walking. Promotion efforts could benefit from a better understanding of factors explaining these trends.

Measure	2005			2010			2015		
	n	Estimate	(95% CI)	n	Estimate	(95% CI)	n	Estimate	(95% CI)
Prevalence of walking (%)									
Any transportation	8,302	28.4	(27.5-29.3)	7,582	29.2	(28.4-30.1)	9,895	31.7	(30.8-32.5)b
Any leisure	11,775	42.1	(41.2-42.9)	12,059	49.9	(49.0-50.8)	15,744	52.2	(51.2-53.1)b,c
Both transportation and leisure	4,506	15.5	(14.9-16.2)	4,516	17.6	(17.0-18.3)	6,353	20.6	(19.9-21.3)b
Mean volume of walking (minutes/week)a									
Any transportation	8,302	75.3	(73.3-77.4)	7,582	58.3	(56.4-60.2)	9,895	59.1	(57.5-60.9)b,c
Any leisure	11,775	90.2	(88.3-92.1)	12,059	79.8	(78.3-81.5)	15,744	79.3	(77.6-81.0)b,c
Both transportation and leisure	4,506	199.2	(193.5-205.2)	4,516	164.0	(159.1-169.0)	6,353	165.0	(160.4-169.7)b,c

Estimates are weighted and age-standardized to the 2000 US standard population.

a Walking volume was calculated by multiplying the number of walking bouts in the past week by the average minutes per bout among those reporting walking participation.

b Significant linear trend from 2005 to 2015 (p<0.05).

c Significant quadratic trend from 2005 to 2015 (p<0.05).

Association Between Walkable Community Design Features and Walking Among U.S. Adults — 2015

Geoffrey Whitfield[1], Susan Carlson[1], Emily Ussery[1], Kathleen Watson[1], David Berrigan[2], Janet Fulton, FACSM[1]. *[1]Centers for Disease Control and Prevention, Atlanta, GA. [2]National Institutes of Health, Bethesda, MD.* (Sponsor: Janet Fulton, FACSM)

(No relevant relationships reported)

Step It Up! The Surgeon General's Call to Action to Promote Walking and Walkable Communities calls for community design that makes it safe and easy to walk for people of all ages and abilities. Determining which community design features are associated with walking at the national level can inform strategies to improve and monitor walkability in the U.S.
PURPOSE: To document the associations between walking and walkable supports and destination types among U.S. adults.
METHODS: Adult respondents (n=29,925) to the 2015 National Health Interview Survey reported the presence of two near-home walkable supports (roads, sidewalks, paths, or trails; sidewalks on most streets) and four destination types (shops, stores, or markets; bus or transit stops; movies, libraries, or churches; places that help one relax, clear one's mind, and reduce stress). Stepwise logistic regression was used to identify features significantly associated with self-reported walking for leisure or transportation in the past week. From the resulting model, the prevalence of walking was calculated for each combination of features.
RESULTS: When combined in a single model, one support and three destination types were associated with walking: roads, sidewalks, paths, or trails (prevalence ratio [PR], present vs. absent [95% confidence interval]: 1.11 [1.07-1.16]); transit (1.07 [1.04-1.10]); movies, libraries, or churches (1.07 [1.04-1.11]); and places to relax (1.39 [1.34-1.44]). For specific combinations of the four, 7.4% reported absence of all features, 36.5% of whom reported any walking. In comparison, 32.5% reported presence of all features, 73.7% of whom reported any walking (PR: 2.02 [1.82-2.22]). The prevalence of walking was generally higher among adults who reported a greater number of features (p<0.001 for linear trend).
CONCLUSIONS: Among U.S. adults, one near home walkable support (roads, sidewalks, paths, or trails) and three walkable destination types (transit; movies, libraries, churches; places to relax) were associated with walking. Walking was two times more common among adults who reported all four features versus no features. These results support the idea that multiple built environment features may combine to influence walking and designing communities with these features may help improve walkability in the U.S.

Walkability, Health Behaviors, And Body Mass Index In Twins

Glen E. Duncan[1], Ally Avery[1], Philip M. Hurvitz[2], Anne Vernez-Moudon[2], Siny Tsang[3], Eric Turkheimer[4]. [1]*Washington State University - Health Sciences Spokane, Spokane, WA.* [2]*University of Washington, Seattle, WA.* [3]*Columbia University, New York, NY.* [4]*University of Virginia, Charlottesville, VA.*
(No relevant relationships reported)

Built environments (BE) may influence health behaviors and subsequently obesity. However, most research in the BE literature has been fraught by methodological problems including self-selection bias and structural confounding. Twin studies provide a quasi-experimental approach to address these issues. **PURPOSE**: This study examined relationships among BE walkability, health behaviors, and body mass index (BMI) between and within twin pairs, and how these relationships differ when considering walkability of the home neighborhood and each twins' full activity space. **METHODS**: Geocoded home addresses and continuous physical activity data from accelerometers and GPS loggers were obtained in 144 identical twin pairs over 2 weeks. Dietary energy density (DED) was assessed by food frequency questionnaire, and BMI was derived from measured height and weight. Walk Score™ (WS) was used to estimate walkability; home WS refers to walkability of the home neighborhood and GPS WS refers to the mean of individual WS values matched to every GPS point collected by each participant, reflecting the walkability of each twins' activity space. **RESULTS**: Home WS was related to GPS WS between-pairs (r = 0.52; 95% CI: 0.38, 0.63); the relationship was attenuated but significant within-pairs (r = 0.25; 95% CI: 0.08, 0.41). DED was related to GPS WS but not home WS (r = -0.20; 95% CI: -0.36, -0.04) between-pairs; this relationship was not significant within-pairs. Moderate-to-vigorous physical activity (MVPA) performed outside of the home neighborhood, defined using both 833 and 1,666m buffers, was related to GPS WS between-pairs (both r = 0.22; 95% CI: 0.06, 0.38); the relationship was attenuated but significant within-pairs (both r = 0.18; 95% CI: 0.00, 0.35). BMI was related to GPS WS but not home WS (r = -0.23; 95% CI: -0.36, -0.04) between-pairs; this relationship was not significant within-pairs. BMI was related to walking bouts and MVPA performed within the 1,666m home neighborhood buffer between-pairs (both r = -0.23; 95% CI: -0.38, -0.06), but not within-pairs. However, BMI was not related to DED levels either between or within-pairs. **CONCLUSIONS**: Twin studies support the concept that aspects of the BE are indirectly associated with BMI through its influence on health behaviors, particularly physical activity. Supported by R01AG042176.

Physical Activity and Biological Aging: Is Walking Enough? An NHANES Investigation

Larry A. Tucker. *Brigham Young University, Provo, UT.*
(No relevant relationships reported)

PURPOSE: Research indicates that high levels of total physical activity are predictive of lower levels of biologic aging. However, research has never studied the extent to which walking alone contributes to reduced cellular aging. The principal objective of the present study was to determine the extent to which walking accounts for differences in leukocyte telomere length (LTL) in a large random sample of U.S. men and women. Another purpose was to assess the extent to which multiple demographic and lifestyle covariates affect the relationship between walking and LTL. **METHODS**: A total of 5,823 adults from the National Health and Nutrition Examination Survey (NHANES) were studied cross-sectionally. The quantitative polymerase chain reaction method was employed to compare LTL to standard reference DNA. Adults were divided into three walking groups based on self-reported minutes of walking per week: No Walking (< 10 minutes of walking per wk), Some Walking (10-149 min. of walking per wk) and Achieved Guidelines (≥ 150 min. of walking per wk). Participation in 61 physical activities other than walking was also measured and total MET-minutes of activity other than walking was calculated based on the frequency, duration, and intensity of each activity. Non-walking activity (i.e., other activity) was controlled statistically, with the other covariates. **RESULTS**: Telomeres were 15.5 base pairs shorter for each year of chronological age (F=723.2, P < 0.0001). After adjusting for age, sex, race, marital status, and income (F=4.9, P=0.0153), adults who met the PA Guidelines by walking ≥ 150 min per week had significantly longer telomeres than those reporting No Walking and also those reporting Some Walking. Differences in LTL remained significant after controlling for smoking, BMI, and other physical activity along with the demographic covariates (F=3.6, P=0.0406). Adults with ≥ 150 min of walking per week were estimated to have a biologic aging advantage of 6.6 years (102.8 base pairs ÷ 15.5) over Non-Walkers. **CONCLUSIONS**: Evidently, adults who engage regularly in ≥ 150 min per week of walking tend to have longer telomeres, accounting for years of reduced cellular aging, compared to adults who do not walk regularly and also those who accumulate less than 150 minutes per week of walking.

Daily Step Counts in Service Members with Lower Limb Amputation

Elizabeth Russell Esposito[1], Barri L. Schnall[2], Bradford D. Hendershot[2], Jason M. Wilken[1]. [1]*Brooke Army Medical Center, Ft. Sam Houston, TX.* [2]*Walter Reed National Military Medical Center, Bethesda, MD.*
(No relevant relationships reported)

Lower limb amputation can be a life-altering event given the critical role the lower limb plays in transferring, standing, and walking. The physical impairments an individual may experience can decrease his or her ability to function in the free-living environment. It has been reported that, on average, civilians with lower limb amputations of all levels walk only 2,000-3,000 steps per day. Although potentially not surprising that they are less active than able-bodied individuals, the magnitude of the activity gap is remarkable. **PURPOSE**: To quantify physical activity in Service Members with lower limb loss in the months following amputation. **METHODS**: Activity data were collected on 27 Service Members who received amputations during the recent military conflicts (N=16 unilateral transtibial, N=7 unilateral transfemoral, N=1 bilateral transtibial, N=3 bilateral transfemoral) using a StepWatch3 (Orthocare Innovations, Oklahoma City, OK) secured to the prosthesis and worn for one week. **RESULTS**: Service Members with lower limb amputations fell substantially below the recommended 10,000 steps per day to maintain an active lifestyle and averaged only $3,142 \pm 1,308$ steps per day. The individuals included in this data set were tested during their rehabilitation at the Center for the Intrepid and Walter Reed Military Medical Center and had been walking with a prosthetic limb for an average of 7.3 ± 3.6 months (range 2 to 12 months). There were no indications that individuals farther along in the rehabilitative process walked more steps per day than those in the earlier stages of rehabilitation (R^2=0.008). **CONCLUSION**: Although these young and previously highly active Service Members have extensive access to rehabilitative care and prosthetic technology, these data raise considerable concern about activity levels after amputation. These low activity levels indicate high risk for progressive declines in overall physical health. One limitation of this study was that these individuals may have been engaging in strength training or other exercises without a prosthetic limb as part of physical therapy, or recovering when not in therapy. It is unknown if their step counts are representative of activity once discharged from rehabilitation. Funding: Military Amputee Research Program W81XWH-06-2-0073

Leisure-time Physical Activity, Work-related Walking and Incidence of Kidney Stones In Japanese Workers: The Niigata Wellness Study

Susumu S. Sawada, FACSM[1], Yuko Gando[1], Ryoko Kawakami[2], Minoru Tashiro[3], I-Min Lee, FACSM[4], Steven N. Blair, FACSM[5], Motohiko Miyachi[1], Hirohito Sone[6], Kiminori Kato[6]. [1]*National Institutes of Biomedical Innovation, health and Nutrition, Tokyo, Japan.* [2]*Waseda University, Saitama, Japan.* [3]*Niigata Medical Association of Occupational Health, Niigata, Japan.* [4]*Harvard Medical School, Boston, MA.* [5]*University of South Carolina, Columbia, SC.* [6]*Niigata University, Niigata, Japan.*
(No relevant relationships reported)

Limited data are available on the relationship of physical activity (PA) with the incidence of kidney stones. **PURPOSE**: The purpose of this study is to investigate the independent and joint effects of leisure-time PA (LTPA) and work-related walking (WRW) on the incidence of kidney stones among Japanese workers in the Niigata Wellness Study. **METHODS**: A cohort of 16,458 Japanese men [median (IQR) age 49 (43-53) years] and 7,140 women [median (IQR) age 48 (43-52) years] free of kidney stones completed a medical examination, and reported on LTPA and WRW in 2001. The participants were divided into three categories (0 min/week; LTPA-none, 1-119 min/week; LTPA-M$_1$, ≥120 min/week; LTPA-M$_2$) based on LTPA, and also divided into two categories based on existence of WRW (no; WRW-no, yes; WRW-yes). The development of kidney stones during follow-up from 2002 to 2006 was based on self-reports from questionnaires at another medical examination in 2006. Odds ratios and 95% confidence intervals (95%CI) for the incidence of kidney stones were obtained using logistic regression models while adjusting for sex, age, body mass index, cigarette smoking (5 categories), and alcohol intake (3 categories). **RESULTS**: During the 5 year follow-up period, 169 participants developed kidney stones. In regards to the independent effects of LTPA and WRW. Using LTPA-none as reference, odds ratios and 95% CIs for LTPA-M$_1$ and LTPA-M$_2$ were 0.72 (0.44-1.17) and 0.64 (0.40-1.02) (P for trend=0.034). Also, using WRW-no as reference, odds ratios and 95% CIs for WRW-yes was 0.85 (0.62-1.17). With regards to the joint effects of LTPA and WRW, using the LTPA-none and WRW-no group as reference, odds ratios and 95% CIs were 0.72 (0.42-1.24) for the LTPA-M$_2$ and WRW-no group, 0.39 (0.16-0.97) for LTPA-M$_2$ and WRW-yes group, respectively. **CONCLUSIONS**: These results suggest that there

---

Abstracts were prepared by the authors and printed as submitted.

is an independent effect of LTPA on the incidence of kidney stones. Also, there is a strong joint effect of LTPA and WRW on the incidence of kidney stones in Japanese workers.

HealtheSteps Lifestyle Prescription Program Can Increase Physical Activity and Decrease Blood Pressure in At Risk Adults

Robert J. Petrella, FACSM[1], Dawn P. Gill[1], Wendy Blunt[1], Roseanne W. Pulford[1], Adam Gavarkovs[2], Narlon C. Boa Sorte Silva[1], Cassandra Bartol[1], P Karen Simmavong[1], Ashleigh De Cruz[1], Guangyong Zou[1]. *[1]Western University, London, ON, Canada. [2]Harvard University, Cambridge, MA.*
(No relevant relationships reported)

Approximately 30% of Canadian adults have one or more chronic diseases. This number is expected to grow as the Canadian population ages and risk factors for chronic disease continue to climb.
PURPOSE: 1) To evaluate the effectiveness of HealtheSteps (HeS), a 6-month lifestyle prescription program, on increasing physical activity (PA) and decreasing systolic blood pressure (SBP) in adults at-risk for chronic disease; 2) To explore long-term maintenance of these outcomes.
METHODS: Pragmatic randomized controlled trial where adults from 5 primary care settings in Ontario, Canada (N = 118; mean age 57 (SD=12) years; 76% female) with ≥1 chronic disease risk factor (metabolic syndrome or type 2 diabetes; body mass index >25 kg/m²; exercise <150 min/wk; sit ≥3 hr/d; eat <8 servings of fruit and vegetables/d) were randomized to intervention (HeS) or comparator (wait-list control; WL). Over 6 months, HeS included 4 bi-monthly coaching sessions (setting lifestyle prescriptions and strategies to achieve goals) and access to eHealth technologies (phone coaching; social network; smartphone apps; website). From 6 to 12 months, in-person coaching was removed but participants could access all eHealth technologies. By 12 months, participants only had access to publically available technologies. We examined *within* and *between* group differences in mean steps/day (Yamax Digi-Walker SW-200 pedometers) and SBP (BP-Tru BPM-100 automated BP monitors) using linear mixed models adjusted for age, sex and site.
RESULTS: By 6 months, HeS increased their steps/day more than WL [mean change (95% CI); p-value for difference – HeS: 1646 (786, 2507); WL: -1486 (-2312, -659); p<0.001]. By 12 months, the increase in PA was still evident *within* HeS [mean change from baseline (95% CI): 1890 (888, 2892)]. Although there were no differences between groups (p=0.93), both groups decreased their SBP (mmHg) over 6 months [mean change (95% CI) – HeS: -6.38 (-10.43, -2.33); WL: -6.61 (-10.52 to -2.70)]; HeS maintained this to 18 months [mean change from baseline (95% CI): -6.58 (-11.35, -1.81)].
CONCLUSION: HeS was effective in improving physical activity over 6 months, compared to usual care, in adults at risk for chronic disease; these improvements were maintained 1-year later. Results also suggest that HeS may reduce SBP in both the short and long-term.

The Effect of 2 Walking Programs on Hba1c in Sedentary Employees During a 10 Week Intervention

Mynor G. Rodriguez-Hernandez, James R. McDonald, David D. Pascoe, FACSM, Michael D. Roberts, Danielle D. Wadsworth. *Auburn University, Auburn, AL.* (Sponsor: David D. Pascoe, FACSM)
(No relevant relationships reported)

Physical activity is related to many benefits for metabolic impairments such as type 2 diabetes. However, it remains unclear whether different physical activity programs affect blood glucose in the same way. **PURPOSE**: The present study examined changes on HbA1c in sedentary employees exposed to two different walking programs during 10-week intervention. **METHODS**: 67 sedentary employees were enrolled in a 10-week walking intervention. Participants were randomly assigned to one of three groups: intermittent walking (Age = 46±9, BMI= 30.33±5.79 kg/m²), continuous walking (Age = 48±9, BMI= 30.53±6.17 kg/m²), or a no intervention control group (Age = 42±10, BMI= 27.66±5.11 kg/m²). Notably, the two walking groups were instructed to complete a program time and intensity matched. A1cNOW+ was used to test HbA1c from finger prick blood and accelerometer assessed physical activity. **RESULTS**: Statistically significant changes were observed in HbA1c as the overall analysis $F(1,64) = 4.229$, $p=.044$) with a medium size effect of $n^2=062$. Bonferroni Post-Hoc test shows that the continuous walking group was significantly affected, F=8.463, p=.009, with a large size effect $n^2=.297$. There were no changes within the multiple break group or control group (p>0.05). Accelerometry showed a main effect of time by group interaction $F(4,124) = 5.091$, $p=.001$) with a large effect size $n^2= .14$, the Post-Hoc indicated that the continuous walking group took significantly longer bouts at moderate to vigorous intensity at week-6 compared to pre-test (p=0.009). There were no changes in the length of bouts in the intermittent or control groups

(p>0.05). **CONCLUSIONS**: As preventive strategy, blood glucose may be better controlled by a continuous moderate intensity walking program compared to an intermittent walking program for sedentary office employees.

The Impact of Physical Activity Level on the Oral Microbiome: A Cross-Sectional Investigation

Stephanie P. Kurti[1], Jacob M. Allen[2], Javier Abello[3], Lucy J. Mailing[2], Jeffrey A. Woods, FACSM[2], Sara K. Rosenkranz[3], Craig A. Harms, FACSM[3]. *[1]James Madison University, Harrisonburg, VA. [2]University of Illinois, Champaign-Urbana, IL. [3]Kansas State University, Manhattan, KS.* (Sponsor: Craig A. Harms, FACSM)
(No relevant relationships reported)

Previous research indicates that the composition and diversity of the gut and lung microbiome is associated with many autoimmune and inflammatory diseases. However, aerobic exercise has recently been shown to preferentially shift the composition of the gut microbiome. The physiological significance of these changes is not well understood, and currently there are no published data exploring whether physical activity may impact the composition and diversity of the oral microbiome. **Purpose:** We conducted this exploratory analysis to determine whether the composition of the oral microbiome was impacted by habitual physical activity (PA) level. **Methods:** Sixteen young adults between the ages of 18- 35 years (n=8 physically inactive (PI) subjects accumulating <30 minutes of planned exercise per week; n=8 trained athletes (TA) >150 minutes of moderate-to-vigorous PA per week) visited the laboratory after an overnight fast and without using any toothpaste or antibacterial mouthwash for 24 hours. Upon arrival to the laboratory, body composition assessment and PA questionnaires were administered, followed by saliva and sputum sample collection. Processing and DNA extraction was performed on samples within 48 hours of collection, and the bacterial 16S rNA gene was amplified followed by sequencing. Subjects were given an accelerometer to wear around their waist for one week to verify chronic PA level. Principle components analysis followed by linear regression was used to compare oral microbial taxonomy across PA levels. **Results:** PI and TA had significantly different chronic PA levels (PI: 240±26 METS/wk, TA: 3810±1656 METS/wk) ($p<0.01$). The amount of vigorous PA that subjects accumulated in METS/week explained 19.69% of the composition in the oral microbiome. Of particular interest, *Veillonella spp.*, *Streptococcus spp., Gemella spp.* and *Enterococcus spp.* were significantly higher in PI versus TA ($p<0.05$, respectively), which have been associated with various types of lung diseases, including chronic obstructive pulmonary disease and asthma. **Conclusion:** These data indicate that: (1) habitual PA level differentially impacts the oral microbiome and (2) that the amount of vigorous activity accumulated per week explains a significant portion of the variance in the oral microbiota composition.

Respiratory Infections in Young Elite Female Gymnasts

Jan G. Bourgois[1], Jan Boone[1], An Mariman[2], Liesbeth Delesie[2], Els Tobback[2], Dirk Vogelaers[2], Jasmien Dumortier[1]. *[1]Ghent University, Ghent, Belgium. [2]Ghent University Hospital, Ghent, Belgium.*
(No relevant relationships reported)

PURPOSE: Immune function can be suppressed during periods of hard training and competition with Upper Respiratory Tract Infections (URTI's) as a possible consequence. The main aims of the study were (1) to map the incidence of URTI's in a non-endurance sport as gymnastics, and (2) to determine to which extent Immunoglobulin A (IgA) can be associated with URTI in young elite female gymnasts. **METHODS**: This study included 17 elite female gymnasts from the High Performance School Artistic Gymnastics in Ghent (Belgium) (age: 16.6 ± 3.4 years; body mass: 46.5 ± 6.7 kg; height: 153.9 ± 6.5 cm; VO2MAX: 52.09 ± 4.63 ml·min-1·kg-1). Before the first training of every week (after a minimum of 36h without training) for a period of 56 weeks, every gymnast completed an URTI and fatigue (VAS scale) questionnaire and donated 1 ml of unstimulated whole saliva for its assessment (saliva flow rate,

IgA secretion rate, absolute IgA and relative IgA (= mean values when URTI/Mean values when no URTI)). The saliva was analyzed using an ELISA assay kit (Salivary Secretory IgA Enzyme Immunoassay Kit, Salimetrics, USA). After normality checks through Shapiro-Wilk tests, Spearman rank correlations were used for the evaluation of relations between URTI, immune parameters and fatigue. **RESULTS**: Over the 56 weeks, gymnasts had 2.3 ± 2.8 URTI episodes and 99.5 ± 82.5 URTI symptoms with a mean fatigue score of 5.5 ± 0.6. During this period, 632 saliva samples were collected and analyzed, resulting in 1.00 ± 0.42 ml $\cdot$ min[-1] for saliva flow rate, 130.40 ± 39.05 μg $\cdot$ ml[-1] for absolute IgA concentration, 119.17 ± 49.83 μg $\cdot$ min[-1] for IgA secretion rate and 101.10 ± 5.03 % for relative IgA values. A significant correlation was found between URTI symptoms and relative IgA concentration (R=-0.733, P=0.003*). **CONCLUSIONS:** Values for amount of URTI's and immunological parameters of young elite gymnasts were similar to those of adult sailors (Neville et al., MSSE. 2008; 40: 1228-36), with relative IgA concentrations being associated with the development of URTI symptoms. Thus, young athletes are as prone as adult athletes to develop URTI's. However, since these athletes exercise indoor in contrast to an outdoor sport as sailing, environment may have an impact on the prevalence of URTI's.

The Percentage Of Non-classical Monocytes In Obese Individuals Is Reduced By High-intensity Interval Training

Fabiano T. Amorim[1], Mariana Aguiar de Matos[2], Bruna C. Chaves Garcia[2], Kaio C. Pinhal[2], Vanessa O. Fernandes[2], Denia V. Vargas[2], Flávio de Castro Magalhães[2], Etel Rocha-Vieira[2]. [1]University of New Mexico, Albuquerque, NM. [2]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brazil. (Sponsor: Dr. Ann Gibson, FACSM)

(No relevant relationships reported)

Obesity is associated with both metabolic and inflammatory disturbances. Exercise training represents an efficacious strategy to modulate these deleterious aspects of obesity. **PURPOSE:** To evaluate the effects of high-intensity interval training (HIIT) in monocyte subtypes distribution patterns of obese individuals. **METHODS:** Nine lean control (CON, BMI = 20.8 ± 1.7 kg•m[-2]), nine obese insulin sensitive (OBS, BMI = 35.1 ± 3.8 kg•m[-2]) and nine obese insulin resistant (OBR, BMI = 37.8 ± 4.6 kg•m[-2]) subjects were used in this study. The OBS and OBR underwent 8 weeks of HIIT, 3 x/week, using a cycle ergometer, with progressive increases in intensity and volume (8 to 12 bouts of 1 min at 80 to 110% of the maximum power output separated by 1 min active recovery at 30 W). Insulin resistance was defined as homeostasis model assessment index (HOMA-IR) ≥ 2.71. Venous blood was collected after 12 hours fasting, before and after HIIT for the quantification of monocyte subtypes (classics, intermediaries and non-classics) and metabolic parameters (insulin, glucose, triglycerides and cholesterol fractions). β-pancreatic cell function (HOMA-β) were also calculated. Volunteers also underwent an oral glucose tolerance test (OGTT). Body composition was evaluated using dual-energy X-ray absorptiometry (DXA). **RESULTS:** Pre-training blood triglycerides, VLDL-cholesterol, HOMA- β and insulin concentration were higher (p<0.05) in OBR compared to OBS and CON. OBR also had higher mass of visceral adipose tissue compared to OBS and CON (1,785 ± 754, $1,153 \pm 431$ and 149 ± 80 g, respectively). Both OBS and OBR individuals had increased (p<0.05) percentage of non-classical monocytes (11.0 ± 5.5 and 12.2 ± 5.9%, respectively), compared to CON (4.8 ± 2.2%). The percentage of non-classical monocytes was positively correlated to BMI, fat percentage, HOMA-β and OGTT. After 8 weeks of HIIT, the frequency of non-classical monocytes was reduced (p<0.05) by almost 40% in OBS and OBR (12.1 ± 5.6 and 8.7 ± 3.2%, pre- and post-HIIT, respectively). Although training had no effect on BMI and body fat, HOMA- β was improved (p<0.05) after HIIT (267 ± 166 and 183 ± 109, pre- and post-HIIT, respectively). **CONCLUSION:** HIIT reduces inflammation and improve metabolic parameters in obese insulin sensitive and insulin resistant individuals.Supported by CAPES, CNPq, FAPEMIG

Inflammatory Cytokine Production is Elevated in MAIT Cells Following Acute Exercise

Erik D. Hanson[1], Eli Danson[1], William S. Evans[1], William A. Wood[1], Samy Sakkal[2], Claudio L. Battaglini, FACSM[1]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC. [2]Victoria University, Melbourne, Australia. (Sponsor: Claudio Battaglini, FACSM)

(No relevant relationships reported)

Mucosal associated invariant T (MAIT) cells occupy a unique niche within human immunity yet little is known regarding the effects of exercise on activation or cytokine production. **PURPOSE:** To determine if exercise alters MAIT cell proinflammatory cytokine production and early activation markers after submaximal aerobic exercise. **METHODS:** 17 healthy young males [age 22 (4y), VO_2max 51.6 (10.2 mL/kg/min), %fat 18.0 (5.0%)] performed a graded exercise test on a cycle ergometer until

volitional exhaustion. Participants cycled for 40 min at 86% of ventilatory threshold following an overnight fast. Peripheral blood mononuclear cells were isolated from blood samples obtained at rest, 0h and 1h after submaximal exercise. Following a 4h stimulation with phorbol 12-myristate 13-acetate and ionomycin, MAIT cells counts and intracellular interferon gamma (IFNγ), tumor necrosis factor alpha (TNFα) and interleukin 17 (IL-17) production were quantified using flow cytometry. Data were analyzed using one-way ANOVA and are expressed as mean (SD). **RESULTS:** Stimulated Vα7.2[+]CD161[+] MAIT cells were 2.3 (1.2%) of all T cells at rest and increased to 3.2 (2.2%) at 0h but this did not reach significance (p=0.134). MAIT cells expression of CD69 was 76.0 (13.4%) and remained constant with exercise. TNFα expression significantly increased with exercise before returning to baseline [rest: 71(18%), 0h: 79 (13%), 1h: 65 (19%); p=0.017] whereas IL-17 and IFNγ were unchanged. The total number of circulating cells significantly increased at 0h for MAIT cells [73.4 (85.6%); p=0.003] and MAIT cells expressing TNFα [89.4 (139.9%); p=0.018], IL-17 [275.4 (370.5%); p=0.026], but not IFNγ [64.5 (127.5%); p=0.061] with all counts returning to baseline at 1h. **CONCLUSIONS:** Submaximal aerobic exercise transiently increased the percentage and total number of MAIT cells expressing TNFα, which may aid in activation and recruitment of additional immune cells. The total number of MAIT cells positive for IL-17 and IFNγ are higher but are driven by the exercise-stimulated lymphocytosis. The increase in proinflammatory cytokine production is part of the enhanced immune response seen immediately following vigorous exercise and suggests that MAIT cells may play an important role within this response.

1688   May 31 4:15 PM - 4:30 PM

Environmental Mobilization Of Hematopoetic Stem Cells With Exercise, Compression, And Cooling

Adam W. Anz, Danielle R. Hansen, Christopher S. Warrell, Ronna S. Parsa, Hillary A. Plummer, Jan M. Stelly, Nicole K. Rendos. *Andrews Research & Education Foundation, Gulf Breeze, FL.*

(No relevant relationships reported)

Hematopoetic stem cells (HSC) have recently been studied to improve healing and rehabilitation from musculoskeletal injury. HSC are currently collected using invasive bone marrow aspiration and peripheral harvest after pharmaceutical mobilization. Animal studies show environmental stresses including heat, hypoxia, and cold mobilize HSC. HSC have also been mobilized to peripheral circulation (PC) with exercise. We hypothesized that the combination of environmental stress and exercise can mobilize HSC to PC. Mechanisms for environmental mobilization will aid in understanding healing and rehabilitation mechanisms and may provide a more convenient method to harvest HSC. **PURPOSE:** To determine if the combination of compression and cooling during exercise can mobilize HSC in PC. **METHODS:** Ten healthy, active males (height $1.78 \pm .06$ m, weight 85.1 ± 13.3 kg, age 30.4 ± 4.7 y) completed a 20-min exercise protocol on the Vasper™ recumbent cross trainer. The protocol entailed a 7-min warm up and 6 sprints alternating between 30s and 60s in duration with 90s recoveries. Compression cuffs were placed around the upper arms and thighs and inflated to 40 and 65 mmHg, respectively. Subjects sat on a cooling pad and wore a cooling vest to decrease body temperature. Blood samples were collected via forearm vein access prior to exercise and at 20 (T20), 30, 60, 90, 120, 150, 180 min and 24h post exercise. A complete blood count with differential and flow cytometry was performed on each sample. A linear mixed model analysis was used to evaluate differences in each variable. **RESULTS:** A spike in white blood cell (WBC) count was seen between baseline and T20 ($M_{diff} = 1.740$, $SE = .48$, $p = .004$). The WBC differential revealed a decrease in neutrophils (M_{diff} 4.13, $SE = 1.52$, $p = .015$) and eosinophils ($M_{diff} = .42$, $SE = .13$, $p = .009$), and an increase in lymphocytes ($M_{diff} = 4.51$, $SE = 1.62$, $p = .014$) from baseline to T20, with no change in basophils, monocytes, or immature granulocytes. Flow cytometry indicated an increase in CD34(+), a cell surface marker for HSC, from baseline to T20 ($M_{diff} = 1.25$, $SE = .48$, $p = .028$) with no change in the viability of the WBCs. **CONCLUSION:** The Vasper™ consistently mobilizes HSC to PC when used to a high level of exertion. Further study is required to determine if these cells can be consistently harvested from PC after mobilization.

Effects of Acute Eccentric Exercise on Immune Responses to Vaccination in Young and Aged Mice.

Yi Sun, Jeffrey A. Woods, FACSM. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Jeffrey Woods, FACSM)

(No relevant relationships reported)

Several published studies suggest that acute eccentric exercise can improve vaccination responses in humans. However, whether this strategy can improve sub-optimal vaccine responses in the aged is unknown. While it has been suggested that such damaging exercise acts as an inflammatory adjuvant, the mechanism behind the effect is unknown. **Purpose**: To determine the effects of acute eccentric exercise on primary

antibody and cell-mediated immune responses in young and aged mice. **Methods**: C57BL/6 male mice, aged 6-8 week (n=19) and 27 months (n=16) were randomized into either eccentric exercise (Y-ECC, A-ECC) or sedentary (Y-SED, A-SED) groups. For the Y-ECC and A-ECC groups, mice were exercised at 17m/min at -20% grade for 45 min on a treadmill. Y-SED and A-SED mice remained in their home cages. All mice were inoculated in the gastrocnemius with 100μg of OVA and 200 μg aluminum hydroxide (a suboptimal dosage based on titration experiments) immediately after the exercise. Blood was collected prior to, and one, two and four weeks after vaccination. ELISA was performed to analyze anti-OVA IgG. At three weeks post exercise, all mice were injected with 100μg OVA into the dorsal side of the right pinnae to determine the delayed-type hypersensitivity (DTH) response. Left pinnae were treated as controls. Ear thickness was measured immediately before and every 24h after intradermal injection. **Results**: Acute eccentric exercise did not improve primary antibody responses in either young (p=0.06) or aged (p=0.76) mice, compared to their sedentary control groups. We did not find significant differences between Y-ECC and Y-SED in their DTH responses (p=0.25). However, acute eccentric exercise enhanced DTH responses in aged mice, especially at 1 day post intradermal injection (p=0.001). We also documented a significant immunosenescent effect in antibody (p< 0.001), but not cell-mediated (p=0.813), immune responses to vaccination. **Conclusion**: Our results suggest that acute eccentric exercise improved the cell-mediated immune response to OVA vaccination in aged, but not in young mice and failed to affect the anti-OVA antibody response in young or aged mice.

Association Between Body Composition and Physical Activity Behaviors

Pedro J. Benito[1], Eliane A. Castro[2], Daniel Dos Santos[2], Rocío Cupeiro[1], Ana B. Peinado[1]. *[1]Universidad Politécnica de Madrid, Madrid, Spain. [2]Universidade de Franca, São Paulo, Brazil.*
(No relevant relationships reported)

Evidence has shown that replacing sedentary time with equivalent amounts of light-intensity physical activity (LIPA) or moderate-to-vigorous intensity physical activity (MVPA) yielded associated health benefits on body composition. Therefore, because time is finite, to know these associations is relevant for physical activity promotion strategies.
PURPOSE: To analyze the effect of the sedentary and active times proportions on body composition in overweight and obese subjects.**METHODS**: Ninety-six (46 males and 50 females) overweight and obese participants (body mass index 25-34.9 kg/m²), aged 18-50 years, participated in this study. Body composition was assessed by DXA and physical activity was measured by accelerometry. Pearson correlations were used to determine the association between body composition and physical activity behaviours. Sedentary time (≤1.5 METs), LIPA (>1.5 - <3.0 METs) and MVPA (≥3.0 METs) were expressed in percentage of the daily time.
RESULTS: Significant correlations were found between sedentary time and fat mass ($r = 0.36$; $p < 0.001$), android fat mass ($r = 0.23$; $p = 0.03$) and lean body mass ($r = -0.36$; $p < 0.001$). In the same way, MVPA was correlated with these variables (fat mass: $r = -0.39$; $p < 0.001$; android fat mass: $r = -0.21$; $p = 0.04$ and lean body mass $r = 0.39$; $p <0.001$). LIPA only was correlated with body weight ($r = -0.28$; $p = 0.01$).
CONCLUSIONS: Our results highlight the importance of reducing sedentary time and promoting MVPA, which may improve body composition in overweight and obese people. LIPA seems to have less impact in the body tissues distribution.**Supported by Spanish Government Grant DEP2008-06354-C04-01.**

1692   May 31 3:30 PM - 3:45 PM
Change in Energy Intake and Health Eating Index in Response to Exercise During Weight Maintenance

Lauren T. Ptomey, Anna M. Gorczyca, Amanda N. Szabo, Felicia S. Steger, Ron Krebill, Matthew S. Mayo, Debra K. Sullivan, Richard A. Washburn, FACSM, Joseph E. Donnelly, FACSM. *University of Kansas Medical Center, Kansas City, KS.*
(No relevant relationships reported)

PURPOSE: It is hypothesized that energy intake increases and diet quality improves in response to increased exercise energy expenditure, thus diminishing the impact of exercise for weight loss and maintenance. The purpose of this analysis was to examine the impact of 3 levels of recommended exercise on energy intake and diet quality during weight maintenance. **METHODS**: Overweight/obese adults (n=175, age= 43 yrs., BMI~32 kg•m²) who lost ≥ 5% of their initial body weight in response to a 3-mo. weight loss intervention which included energy restriction, increased exercise (100 min•wk⁻¹) and weekly behavioral counseling, completed a 12 mo. weight maintenance intervention. All participants were prescribed a weight maintenance diet (estimated RMR x 1.4), asked to attend biweekly behavioral sessions, and were randomized to one of 3 levels of exercise (150, 225, 300 min•wk⁻¹), with a minimum of 3 exercise sessions•wk⁻¹ completed under supervision. Exercise minutes across 12 mos. were obtained from direct observation or heart rate monitors for supervised and unsupervised sessions, respectively. Energy intake (3-day food records) was assessed at randomization (mo. 0), 6 and 12 mos. Energy intake and diet quality (Healthy Eating Index-2010 (HEI)) were calculated using the Nutrition Data System for Research 2014. **RESULTS:** Energy intake at mo. 0 was 1337 ± 309, 1284 ± 25, and 1344 ± 317 kcals•day⁻¹, and total HEI scores were 59.0, 57.9, and 60.8 in the 150, 225, and 300 min•wk⁻¹ groups, respectively. Average exercise across 12 mos. was 120, 147, and 170 min•wk⁻¹ in the 150, 225, and 300 min•wk⁻¹ groups, respectively. As expected with a weight maintenance diet, energy intake (kcals•day⁻¹) increased from 0-12 mos. in the 150 (319 ± 523), 225 (164 ± 441), and 300 min•wk⁻¹ groups (266 ± 454). However, the between group difference for change in energy intake (0-12 mos.) was not significant (p=0.18). There was no significant difference for change in HEI (0-12 mos.) between the 150 (+0.93), 225 (-2.38), and 300 min•wk⁻¹ groups (-2.60, p=0.29). Exercise min•wk⁻¹ was not associated with energy intake (r= 0.01, p= 0.94) or HEI (r=0.11, p=0.15). **CONCLUSION:** There was no impact of the volume of exercise (min•wk⁻¹) on energy intake or HEI in initially overweight/obese adults completing a weight maintenance intervention.

1693   May 31 3:45 PM - 4:00 PM
Vo2max Is Associated With Energy Expenditure Measures, Including Diet Induced Thermogenesis, Under Sedentary Conditions

Takafumi Ando, Paolo Piaggi, Jonathan Krakoff. *National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ.*
(No relevant relationships reported)

Low cardiorespiratory fitness predicts subsequent weight gain independently of physical activity. However, the physiological mechanisms underlying this relationship have not been fully explained. One hypothesis is that VO2max is related to measures of energy expenditure, in particular diet induced thermogenesis. Results from previous studies exploring these associations have been mixed. However, these studies may have been limited by methodological issues regarding the adjustment for energy expenditure (EE) by confounding factors and small sample size.
PURPOSE: To determine the association between VO2max and measures of 24-h thermogenesis under predominantly sedentary condition and in particular awake fed thermogenesis (AFT) a measure of diet induced thermogenesis. **METHODS:** Two hundred twenty-nine American Indians from the southwest (132 men, 97 women) had measures of body composition by hydrodensitometry, resting metabolic rate (RMR) by the ventilated hood method, and then performed the intermittent treadmill run test for assessment of VO2max. On a separate day, they spent 24 hours in a whole-room calorimeter for assessment of 24-h EE, AFT, sleeping metabolic rate (SMR), and spontaneous physical activity (SPA) by radar system. As we have reported previously, AFT was calculated as the intercept of EE vs. SPA at zero activity minus SMR. **RESULTS:** After adjustment for fat free mass, fat mass, age and sex, multiple regression analysis showed that a higher VO2max (L/min) was associated with a higher RMR (beta = 45.9 kcal/day per L/min, standardized beta = 0.184, p = 0.010, n = 181) and 24-h EE (beta = 62.1, standardized beta = 0.125, p = 0.028, n = 229) and including additional adjustment for energy intake higher AFT (beta = 65.8, standardized beta = 0.334, p = 0.012, n = 179). Neither SMR (p = 0.64) nor SPA (p = 0.80) were associated with VO2max. **CONCLUSION:** VO2max was associated with RMR, AFT and 24-h EE. In particular the association with AFT indicates a possible common mechanism regulating both processes and that the protective effect of higher VO2max on weight change reflect its association with measure of 24-h thermogenesis.

Weight Loss is Associated with Change inLeftVentricular Mass in Adults with Obesity: The Heart Health Study

Renee J. Rogers, Erik B. Schelbert, Yaron Fridman, Meghan R. Maher, John M. Jakicic, FACSM. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John M. Jakicic, FACSM)

Reported Relationships: R.J. Rogers: *Contracted Research - Including Principle Investigator; Weight Watchers International, Inc..*

Greater left ventricular mass (LVM) has been associated with incidence of cardiovascular events in cohort studies. LVM has been shown to be associated with larger body mass index (BMI), which may partially explain the association between obesity and cardiovascular disease (CVD). However, despite the importance of cardiorespiratory fitness (CRF) to lower CVD, few studies have examined how CRF contributes to LVM within the context of weight loss. **PURPOSE**: To examine the change in weight, cardiorespiratory fitness, and LVM in response to a behavioral weight loss intervention, and to examine the association between change in body weight, CRF and LVM in relation to a behavioral weight loss intervention. **METHODS**: Data were examined from sedentary adults (N=290; BMI: 32.2±3.8 kg/m^2) that engaged in a 12-month behavioral weight loss program. All participants received weekly in-person intervention sessions for months 1-6, with combined in-person and telephonic sessions for months 7-12. Participants were prescribed weight loss through diet or diet + physical activity. Diet was prescribed at 1200-1800 kcal/day and physical activity was progressively increased to 150-250 min/wk. Assessment of body weight, CRF expressed as time to termination from a graded exercise test (GXT) and oxygen uptake, along with LVM using cardiac magnetic resonance imaging were assessed at both baseline and 12 months. **RESULTS**: There was a significant change in body weight (90.4±13.9 to 80.2±13.5 kg; p<0.001), CRF (22.6±4.5 to 25.6±5.1 ml/kg/min; p<0.001), GXT termination time (7.8±3.0 to 9.7±3.5 min; p<0.001) and LVM (88.5±21.3 to 84.1±20.0 g; p<0.001). Weight loss was correlated with reduced LVM (r=0.263; p<0.001), but the reduced LVM was not correlated with the increase in CRF (r=-0.07; p=0.10) or increase in GXT termination time (r=-0.04; p=0.35). **CONCLUSIONS**: LVM may be associated with poor cardiovascular health outcomes. It appears that weight loss reduces LVM, suggesting that a lifestyle intervention for inducing weight loss may be effective in reducing cardiovascular disease risk.

1695   May 31 4:15 PM - 4:30 PM

Attenuation of Excessive Weight Gain One Year Post Pediatric Obesity Treatment Initiation

Kate A. Heelan, FACSM, Holly Bower, Bryce M. Abbey, Roderick T. Bartee. *University of Nebraska - Kearney, Kearney, NE.*

(No relevant relationships reported)

In the United States, the prevalence of obesity among 6 to 11 year-old children is 18.4% (Hales et al., 2017). Over the past 30 years, family-based pediatric obesity treatment programs have been implemented demonstrating both short-term and long-term results (Epstein et al., 1998). Building Healthy Families (BHF) was adapted from Epstein's efficacious family-based weight control treatment program and implemented for 6-12 year-old obese children in a rural mid-western community. Fifty-eight families including 69 obese children (BMI percentile 96.5 ± 3.9%) participated in BHF; a 12-week nutrition, physical activity and lifestyle modification program. Child health outcomes included a clinically and statistically significant reduction in child BMI z-score (-0.27 ± 0.22) at 12-weeks. **PURPOSE:** To determine long-term weight loss success by assessing body mass and stature one-year post BHF initiation and compare to a match control group that participated in yearly health screenings at school. **METHODS:** BHF participants (n=69, age: 9.30 ± 1.84 years) and 70 match control (age: 9.43 ± 2.08 years) were measured for body mass and stature at baseline and one year later. BMI, BMI percentile, and BMI z-scores were calculated based on age and gender. **RESULTS:** After one year, BHF participants grew 5.72 ± 2.46 cm and gained 3.48 ± 6.89 kg resulting in a BMI z-score change of -0.22 ± 0.40. In comparison, the match control group grew 5.97 ± 2.67 cm (p>0.05), gained 6.12 ± 5.01 kg (p<0.05) resulting in a BMI z-score change of -0.07 ± 0.21 (p<0.05). **CONCULUSION:** The match control group gained 43% more body mass in one year compared to the BHF participants (p<0.05). Previous data have suggested normal weight children of the same age gain approximately 3.2 ± 1.5 kg per year (Holt et al., 2009) suggesting that BHF participants demonstrated an attenuation in excessive weight gain. A BMI z-score change of -0.22 ± 0.40 in one year presents clinically significant changes that may enhance health. Family based intensive treatment programs are time consuming, expensive, and require family commitment; but appear to have long-term positive influence on growth and maturation among participants.

1696   May 31 4:30 PM - 4:45 PM

Association Between Family Health Behaviors and Obesity Severity: Does Weight Metric Matter?

Karissa L. Peyer[1], Joani Jack[2], Gregory W. Heath, FACSM[1]. [1]*University of Tennessee at Chattanooga, Chattanooga, TN.* [2]*University of Tennessee College of Medicine Chattanooga and Children's Hospital at Erlanger, Chattanooga, TN.*

(No relevant relationships reported)

PURPOSE: Family behaviors regarding physical activity (PA), nutrition and screen time are associated with increased risk for obesity. With increased levels of severe obesity in American youth, the association of these factors with extremely high weight status should be evaluated. The purpose of this study was to examine potential difference in screen, nutrition, and PA activity behaviors among children attending a youth obesity clinic.
METHODS: Subjects included 484 youth (mean age = 11.5) attending their first visit at a Childhood Healthy Eating and Active Living clinic. Height, weight, and age assessed and used to calculate sex- and age-reference Body Mass Index Percentile (BMI%) as well as percent over the 50th (BMI50) and 95th (BMI95) percentiles. Parents completed a behavioral survey including questions about a number of health behaviors including whether their child consumed second helpings (rarely, sometimes, or always), had a TV in the Bedroom (yes/no), or ate with the TV on (yes/no). Parents also reported typical screen (< 2 hours, 2-4 hours, 5+ hours) and PA (< 30 minutes, 30-60 minutes, ≥ 1 hour per day) behaviors. Analysis of Variance and T-tests were used to examine differences in BMI variables based on reported behaviors. All analyses were performed using SAS Enterprise Guide 7.1 with alpha set at 0.05.
RESULTS: Average BMI% was over 99 while BMI50 and BMI95 median splits were 185% and 137%, respectively. BMI50 and BMI95, but not BMI% were significantly higher in children obtaining ≥ 1 hour of PA compared to those obtaining < 30 minutes per day (p < 0.04). BMI50 and BMI95, but not BMI%, were significantly higher for children who had a TV in the bedroom than for those who did not (p < 0.0001 and 0.002). Only BMI50 was significantly lower among Screen Time categories (p = 0.0104). All BMI variables were significantly higher for children who ate with the TV on compared to those who did not (p < 0.001) and for children who always asked for seconds compared to those who rarely did (p < 0.05).
CONCLUSIONS: Among obese children/youth, commonly targeted health behaviors resulted in differences in weight status, although the extent of these relationships depends on the weight metric being used. Further analysis should examine the influence of interventions to alter these behaviors and the change captured by these weight metrics.

1697   May 31 4:45 PM - 5:00 PM

Outdoor Time and Metabolically Healthy Obesity in Children: Results from the Canadian Health Measures Survey

Brittany V. Rioux, Neeru Gupta, Danielle R. Bouchard, James Dunbar, Martin Sénéchal. *University of New Brunswick, Fredericton, NB, Canada.*

(No relevant relationships reported)

A large proportion of children are recognized as metabolically healthy obese (MHO) and present a favorable cardio-metabolic profile. However, the contribution of outdoor time physical activity (PA) to the MHO phenotype is unknown.
PURPOSE: To investigate the association between outdoor time PA and the MHO phenotype in children. **METHODS**: An analysis of overweight and obese children aged 6-14 (n=386) from the Canadian Health Measures Survey (cycles 3-4) was performed. Outdoor time PA (hours/week) was self-reported using a series of questions in relation to the school schedule, such as: "during the past month, on an average school day, how much time did you usually spend outside?" Participants were given a score of 0-5 based on their response: 0 min. (0); 1 to <15 mins. (1); 15 to <30 mins. (2); 30 to <1 hour (3); 1 to <2 hours (4); and ≥2 hours (5). Then, a computed score, ranging from 0-25, was created for outdoor time PA. MHO status was determined based on the absence of cardio-metabolic risk factors including: triglycerides, HDL-cholesterol, systolic or diastolic blood pressure, and glucose (MHO: 0 cardio-metabolic risk factors; non-MHO: ≥1 cardio-metabolic risk factors). Multiple logistic regression analyses for the likelihood of MHO were adjusted for age, sex, socioeconomic status, and moderate-to-vigorous PA (MVPA) intensity. **RESULTS**: The proportion of MHO children was 58.5%. No significant differences were observed between MHO and non-MHO according to outdoor time PA, sedentary time, or MVPA (*p*>0.05). Logistic regressions indicated that outdoor time PA was not significantly associated with the MHO phenotype (OR: 0.99, 95% CI=0.92-1.05; *p*=0.69), while MVPA was significantly associated with the MHO phenotype (OR: 1.01, 95% CI=1.00-1.02; *p*=0.03). **CONCLUSIONS**: Outdoor time PA is not associated with the MHO phenotype. Children are more likely to be MHO with greater amounts of MVPA, regardless of whether these activities are completed outdoors or indoors.

1698   May 31 5:00 PM - 5:15 PM
Anthropometric Changes in Elementary School Children Receiving Varying Amounts of Obesity Prevention Programming

Abigail E. Duffine, Emily N. Werner, Brianna D. Higgins, Dorothy Hanrahan, Kristen Kochenour, Patricia A. Shewokis, Stella L. Volpe, FACSM. *Drexel University, Philadelphia, PA.* (Sponsor: Stella L. Volpe, FACSM)

(No relevant relationships reported)

PURPOSE: To assess the change in body mass index (BMI) and waist circumference of elementary school students receiving varying amounts of obesity prevention programming during the first year of a multi-year, ecological school-based health intervention.
METHODS: These data were collected from 214 students enrolled in the fourth grade of four schools. The intervention included programs focused on improving nutritional intake and increasing physical activity. Two schools received a high amount of programming (HP) (> 40 programs/year), while two schools received a low amount of programming (LP) (< 20 programs/year). Height, body weight and waist circumference were measured at baseline and post-intervention.
RESULTS: At baseline, BMI (± standard deviation [SD]) in HP and LP schools were 18.9 ± 4.7 kg/m^2 and 19.4 ± 3.6 kg/m^2 (p=0.319), respectively. Post-intervention BMI for HP and LP schools were 19.3 ± 4.4 kg/m^2 and 19.4 ± 3.5 kg/m^2 (p=0.775), respectively. Waist circumference (± SD) at baseline in HP and LP schools were 63.3 ± 4.7 cm and 67.5 ± 10.2 cm (p=0.002), respectively. Post-intervention waist circumference were 64.4 ± 9.8 cm and 66.8 ± 10.0 cm (p=0.081) for the HP and LP schools, respectively.
CONCLUSIONS: The high and low program schools both exhibited increases in BMI after program implementation; though, there were no significant differences between the groups over time. However, BMI alone is not the most effective assessment of adiposity in children; utilizing waist circumference may provide additional information. At baseline, the HP schools had a significantly lower waist circumference compared to the LP schools. Although there was a slight increase in waist circumference in the HP schools and a slight decrease in the LP schools at post-intervention, these were not significantly different. Though the difference in programming did not significantly influence BMI or waist circumference, assessing the changes in anthropometric measures throughout the larger, multi-year intervention may reveal more meaningful impact on the change in adiposity in children.
This study was funded by Independence Blue Cross Foundation

D-43   Clinical Case Slide - **Head**
Thursday, May 31, 2018, 3:15 PM - 4:55 PM
Room: CC-200E

Different Strokes for Different Folks - Football

Tu Dan Nguyen[1], Mark Chassay, FACSM[1], Jocelyn Szeto[1], Noor Alzarka[2]. *[1]University of Texas Health Science Center at Houston, Houston, TX. [2]Memorial Family Medicine Residency, Sugar Land, TX.*

(No relevant relationships reported)

History:
22-year-old D1 University Football Long Snapper presents to the training room for migraines. He's had migraines for 6-7 years and 4 concussions since HS. The night prior he had a migraine in the temporal region associated with transient left-sided vision loss & left arm numbness for 30-40 minutes. A diffuse headache lasting for 4-5 hours followed. Sumatriptan relieved the pain. He's had increased migraine frequency for the past 6 months. Episodes were described to his neurologist. MRI of the Brain & Cervical Spine were ordered.

Physical Examination:
AF VSS. NAD, well appearing. PERRLA, EOMI, NCAT
Cranial nerves intact, no nystagmus, normal face symmetry, tongue & palate midline
Sensation intact
Strength/tone normal bilaterally
Reflexes 2+
Coordination and gait intact
Differential Diagnosis:
Migraine (hemiplegic/retinal) with brainstem aura
Transient Ischemic Attack or Cerebrovascular Accident
Cerebral Aneurysm
Intracranial space-occupying lesion
Dissection Syndrome
Tests & Results:
MRI Brain w/o contrast: small subacute infarct in the right cerebellum. No mass effect or ICH.
MRI C-Spine: mild degenerative changes. No canal stenosis
Admitted to the hospital further work up. Labwork negative.
US LE w/ doppler - No DVT
CTA head/neck: Normal vessels. No dissection
MRA Neck: Common and internal carotid arteries w/ normal caliber and contour. Normal vertebral arteries. Left vertebral a. is dominant. No flow-limiting stenosis.
TTE: Small right to left shunt on agitated saline contrast study suggestive of a patent foramen ovale.
Transcranial Doppler US Bubble Study: Right to left shunting, showering bubbles
Final / Working Diagnosis:
Cryptogenic subacute right cerebellar infarct secondary to a PFO
Treatment and Outcomes:
Aspirin & Clopidogrel started inpatient. Discharged after workup.
PFO closure and transseptal left heart catheterization completed with Cardiovascular Surgery.
Continue ASA and Clopidogrel for 6 months post-op; ASA lifelong.
Retired from the football team.
Repeat TTE: well seated closure device.
Cardiac rehabilitation for first 2 months post-op.
4 months post-op: running about 1 mile daily, 6 days/week. Endurance and circuit training with low weights.
He's been migraine free since 2 months post-op. He takes Indomethacin as needed. Follow up scheduled for 6 months post-operation.

1703   May 31 3:35 PM - 3:55 PM
Head Injury - Trampoline

Michael J. Cools, Jason Mihalik, Kevin Carneiro. *University of North Carolina, Chapel Hill, NC.* (Sponsor: Kevin Guskiewicz, FACSM)

(No relevant relationships reported)

HISTORY: A 14-year-old boy was jumping on a trampoline when he struck his right mastoid on a netting support pole. He did not lose consciousness or have other symptoms at that time. He had a small abrasion at the impact site, but no visible hematoma. The following day, he noted a droop on the right side of his face and inability to close his right eye. He also noted that sounds in his right ear were much louder than sounds in his left.
PHYSICAL EXAMINATION: He presented to a sports concussion clinic the following week. Examination of the patient's head demonstrated a small abrasion on his right mastoid. No other signs of traumatic injury were noted. Neurologic examination demonstrated a right-sided facial droop (House-Brackmann grade 4). Hearing was now symmetric. No abnormalities were noted when examining the other cranial nerves. The rest of his neurologic examination was normal and he exhibited no signs or symptoms of a concussion.
DIFFERENTIAL DIAGNOSIS:
1. Bell's Palsy
2. Temporal bone fracture
3. Facial nerve edema
TEST AND RESULTS:
Head and temporal bone computed tomography (CT) scan:
— No acute intracranial process
— No temporal bone fracture
Magnetic Resonance Image (MRI) with focus on the facial nerve:
— No facial nerve abnormality
— No evidence of microfractures within the temporal bone.
FINAL WORKING DIAGNOSIS:
Traumatic facial nerve edema without temporal bone fracture
TREATMENT AND OUTCOMES:
He was placed on valacyclovir and prednisone taper. He was instructed to use eye lubricant frequently and tape his eye closed at night to prevent corneal abrasions. He was referred to an otolaryngologist, who saw him 1 month later. At that time, his facial nerve function had returned to normal.

1704   May 31 3:55 PM - 4:15 PM
Head And Neck Injury-Soccer

Tracy Bras. *Evergreen Sports Medicine Fellowship, Augusta, ME.* (Sponsor: Jim Dunlap, FACSM)
(No relevant relationships reported)

HISTORY A 16-year-old male soccer player twisted his neck awkwardly while heading a ball. He continued to play despite neck soreness. Six days later he headed the ball several more times during a game and developed worsening pain and swelling. The next morning, he had a headache, dizziness and photophobia. He felt very tired, sleeping more than usual. He was seen by his pediatrician and referred to sports medicine with concern for concussion and cervical strain. When evaluated 13 days after the initial injury, symptoms included intermittent headache, pressure in his head, earache and occasional dizziness. He reported good sleep, but still felt tired. He denied cognitive or emotional symptoms. Neck pain and swelling was the most concerning symptom. He endorsed odynophagia but had no difficulty breathing. He denied radicular or neurologic symptoms. He denied fevers. He had one prior concussion 5 months ago. Symptoms included memory problems, difficulty concentrating, and headache. Recovery time was two weeks. **PHYSICAL EXAMINATION** Well appearing. Pupils equal and reactive to light. No nystagmus. Normal accomodation. Negative VOMS Cervical spine: Cervical spine ROM normal, painful with side bending and rotation. Paraspinals and sternocleidomastoids are tender to palpation, right worse than the left. Bilateral posterior chain lymphadenopathy noted. Spurling's negative. Upper extremity strength and sensation are intact. Abdomen: No hepatosplenomegaly. **DIFFERENTIAL DIAGNOSIS** Concussion, cervical strain, cervical spine fracture, infection, hematologic malignancy **TESTS AND RESULTS**. Ultrasound right sternocleidomastoid : No evidence of hematoma or disorganized muscle architecture. There was a large lymph node just posterior to the muscle measuring 2.5 cm in diameter with a mixed echogenic appearance. Labs: WBC 9.7, Hemoglobin 13.7, Hematocrit 40, Platelets 130, Basic Metabolic Panel normal, ALT 148, AST 87, Alkaline Phosphatase 131, albumin 4.0, Bilirubin 0.5, ESR 5, EBV IgM Positive, EBV IgG Positive **FINAL WORKING DIAGNOSIS** Infectious Mononucleosis **TREATMENT AND OUTCOMES** Patient was held from sports participation for two additional weeks. Symptoms improved over that time period. He was seen by his pediatrician and was cleared to return to contact sports and increase activity level as tolerated.

1705   May 31 4:15 PM - 4:35 PM
Vision and Vestibular Problems: A Bumpy Ride

Olivia E. Podolak, MD, Fairuz Mohammed, MPH, Christina L. Master, MD, CAQSM. *Children's Hospital of Philadelphia, Philadelphia, PA.*
(No relevant relationships reported)

HISTORY: A 16-year old female with hypermobility experienced a whiplash injury on a flight due to sudden turbulence and immediately developed headache and nausea. She subsequently suffered from persistent headaches, dizziness, motion sickness, nausea, and fatigue for weeks following the incident. A full laboratory workup was within normal limits. The family worried her symptoms were due to a concussion and sought evaluation by a Sports Medicine Physician.
The patient's medical history revealed congenital cataract of the right eye and glaucoma. She underwent surgical removal of the cataract as an infant, which resulted in amblyopia. Since childhood, she suffered from strabismus of the right eye and underwent patching for nine years with residual exophoria.
As a result of the concussion, the exophoria and glaucoma progressed. Corrective lenses for her exophoria began to overcompensate, resulting in esotropia.
PHYSICAL EXAMINATION: Initial presentation was 97 days post-injury. Her self-reported Post-Concussion Symptom Inventory (PCSI) score was 108 compared to a pre-injury symptom score of 1.
A vestibular/ocular exam revealed abnormalities with smooth pursuits, saccades, vestibulo-ocular reflex, visual motion sensitivity, near point of convergence (NPC) and accommodation tests. The exam provoked headache, dizziness, nausea, fogginess, and diplopia symptoms. The patient's NPC was assessed but she reported discomfort with drifting of the eye. Assessment for monocular accommodation of the right eye was unsuccessful due to diplopia.
DIFFERENTIAL DIAGNOSIS:
1. Concussion
2. Natural progression of amblyopic strabismus
3. Vestibular migraine
WORKING DIAGNOSIS:
- Concussion with post-concussive monocular esotropia of the right eye requiring surgical intervention.
TEST AND RESULTS:
- Clinical examination and PCSI survey at both the initial and follow up visits.
TREATMENT AND OUTCOMES:
1. Surgical correction of strabismus.
2. 18 days after initial presentation and following surgical intervention:
a. PCSI score decreased to 100.

b. Primary complaints of motion sickness and diplopia resolved.
c. Symptoms and performance on clinical examination improved.
d. No esotropia was present during NPC assessment.
e.Assessment for monocular accommodation of the right eye was successful.

1706   May 31 4:35 PM - 4:55 PM
Sustained Post-concussive Learning Disorder And Severe Emotional Dysregulation In A Pediatric Patient

Mary Daley. *Tufts Medical Center, Boston, MA.*
(No relevant relationships reported)

HISTORY: 10-year-old female with persistent emotional dysregulation and learning disorder after sustaining a mild head injury in a motor vehicle accident at age 5. She was evaluated in the ED but had no head imaging at the time. In the immediate aftermath of the injury, she developed headache, neck and shoulder pain, and generalized fatigue. These symptoms gradually resolved within several months. However, she also developed depression, irritability, and aggressive behaviors, all of which began within weeks of the accident and represented a drastic change of personality. She developed a regression in counting and language skills, and began struggling with inverting numbers and letters. She exhibited impairments in language processing, working memory, and concentration. In addition to sustained emotional dysregulation and excessive irritability, learning and memory difficulties have persisted for more than four years.
PHYSICAL EXAM: 10-year-old girl with mildly restricted affect. Cooperative but with latency of speech. The remainder of the physical and neurological exam, including cranial nerves, gait, coordination, strength, reflexes, and sensation was within normal limits.
DIFFERENTIAL DIAGNOSIS:1. Post-concussive syndrome
2. Post-traumatic stress disorder
3. Specific learning disorder in reading; dyslexia
4. Attention deficit hyperactivity disorder; inattentive type
TESTS AND RESULTS:1. MRI Brain obtained at age 6 - normal for age. 2. Neuropsychological Evaluation - consistent with severe dyslexia as well as ADHD, inattentive type, notable understood as *secondary* to her learning disability and exacerbated by emotional factors.
FINAL/WORKING DIAGNOSIS:1. Traumatic brain injury
2. ADHD, Inattentive Type 3. Dyslexia 4. Dyscravia (voicing substitution dysgraphia)
TREATMENT AND OUTCOMES
1.IEP implemented with minimal improvement academically.
2.Stimulant trial resulted in mild improvement in attention difficulties, but was discontinued after 5 months due to intolerable side effects.
3.Currently treated with alpha-agonist with moderate improvement in irritability and aggressive behaviors.
4.Patient continues with significant learning disorder including severe dyslexia and dyscravia, as well as sustained impairments in working memory.

D-44   Clinical Case Slide - **Leg**

Thursday, May 31, 2018, 3:15 PM - 5:15 PM
Room: CC-200F

1710   May 31 3:15 PM - 3:35 PM
Right Distal Thigh Pain - Water Polo

Erin M. Conlee[1], Brett J. Kindle[2], Jay Smith[1]. *[1]Mayo Clinic, Rochester, MN. [2]Andrews Institute, Gulf Breeze, FL.* (Sponsor: Karen L Newcomer, MD, FACSM)
(No relevant relationships reported)

HISTORY: A 15 year old male experienced spontaneous onset of distal lateral thigh pain during his water polo season without preceding event. Symptoms, including an ache and hypersensitivity, responded to activity modification but recurred immediately

Abstracts were prepared by the authors and printed as submitted.

upon activity resumption, with knee extension even against gravity. He noted no mechanical symptoms, swelling or discoloration. Patient had been receiving physical therapy for presumed distal quadriceps tendinosis but was soon unable to tolerate even topical treatments to the region.
PHYSICAL EXAMINATION: Exam revealed tenderness localized to the superior pole of the patella and the vastus lateralis-retinacular interface without nodularity. No knee effusion was present, and all provocative maneuvers of the knee were negative. Give-way weakness of the right quadriceps was present as was skin hypersensitivity.
DIFFERENTIAL DIAGNOSIS: 1. Proliferative synovial disorder 2. Vascular malformation 3. Chronic musculotendinous strain of the vastus lateralis-retinacular region 4. Malignancy
TEST AND RESULTS: Femur radiographs were negative but contrast MRI of the distal thigh revealed a T2 hyperintense lobulated mass deep to the vastus lateralis and quadriceps tendon, separate from the suprapatellar recess. CT guided biopsy showed benign fibrovascular tissue consistent with an arteriovenous malformation (AVM).
FINAL WORKING DIAGNOSIS: Slow flow arteriovenous malformation
TREATMENT AND OUTCOMES: The patient underwent percutaneous sclerotherapy with 2cc of absolute alcohol. He reported complete resolution of pain within 1-2 weeks and returned to all previous competitive activity.
1711 May 31 3:35 PM - 3:55 PM
Anterior Thigh Pain - Shot put/Discus

Casey Muir, Edward Laskowski, FACSM. *Mayo Clinic, Rochester, MN.*
(No relevant relationships reported)

History: A 17 year-old male who was a first year participant in shot put and discus events presented with gradual onset aching left hip pain for 3 weeks. He denied any precipitating trauma or injury prior to symptom onset. His pain localized primarily to the left proximal anterior thigh. Hip flexion and abduction aggravated the pain. He tried intermittent ice without improvement. He denied radicular pain, weakness, sensory, or mechanical hip symptoms. After 1 physical therapy session, the pain progressed to a 10/10 intensity, constant throbbing, sharp pain in the proximal anterior thigh. **Physical Examination:** Antalgic gait with shortened stance phase on the left. Focal tenderness to palpation at the AIIS and proximal hip flexor tendons. Range of motion was full and symmetric. Pain was elicited at the extremes of left hip flexion, internal rotation, and external rotation. No weakness with manual muscle testing, but he had pain with resisted hip flexion. Stinchfield elicited hip flexor and AIIS pain. FABER and FADIR aggravated left anterior hip pain. **Differential Diagnosis:** 1. Proximal Left Hip Flexor Muscle Strain 2. Traction Apophysitis 3. Labral Tear or other intra-articular hip pathology 4. Femur Stress Fracture 5. Abscess/infection **Tests and Results:** Left Hip X-ray - Negative left hip. Left Hip MRI - Partial thickness tearing of direct/indirect heads of rectus femoris tendons with extensive surrounding edema. Between the direct/indirect heads, lateral to AIIS, a 2 cm x 1.5 cm oval mass-like lesion heterogeneously dark and bright on T2 and intermediate to minimally dark on T1 with suggestion of a rim of decreased T1/T2 signal. Minimal periosteal reaction with bone marrow edema. Normal articular cartilage. **Final/Working Diagnosis:** Myositis Ossificans **Treatment and Outcomes:** 1. Crutches given with instructions to weight bear as tolerated. 2. Naproxen BID started after MRI findings. 3. Continued therapy with only range of motion initially. 4. Instructed to avoid impact exercises/activities. 5. Repeat left hip x-ray six weeks later revealed calcification in soft tissues lateral to left hip consistent with heterotopic ossification. 6. Therapy program was advanced. Eight weeks later reported no symptoms during over 85% of activity. 7. Returned to football in the fall and completed outstanding season, no hip region pain.

1712 May 31 3:55 PM - 4:15 PM
Atypical Leg Pain in a Chi Runner

Jennifer Oberstar. *University of Minnesota, Minneapolis, MN.*
(Sponsor: Steven Stovitz, FACSM)
(No relevant relationships reported)

General Medicine- Chi Running
HISTORY:
A 67-year-old white male, using Chi running to treat bilateral calf pain presented with worsening pains over the past month. He exercises for 30 minutes, 3 times/week, and has sharp cramping pain in both calves exacerbated by running. After increasing the intensity of runs, his right leg goes to sleep. Gait modifications have helped reduce pain slightly. The patient's history included the following: shin splints and chondromalacia patella since age 30, non-smoker, non-diabetic, no cardiac history, and treatment for hypertension and hyperlipidemia. Family history included coronary artery disease. The patient was sent to Interventional Radiology (IR) for an ankle-brachial index (ABI) and was started on aspirin. No mechanical or structural cause of pain was identified, but moderate peripheral arterial disease (PAD) was discovered in the right leg. CT angiogram of the pelvis and lower extremities was recommended. Results of the CTA lead to the patient's direct admission.
PHYSICAL EXAMINATION:
BMI: 34.91, CONSTITUTIONAL: Healthy, HEENT: normocephalic, LUNGS: clear, CV: RRR, no bruits, GI: soft, NT/ND, SKIN: No rashes, NEURO: intact sensory and motor function of the lower extremities, VASCULAR: No bruits
DIFFERENTIAL DIAGNOSIS:
1. Claudication
2. Abnormal gait
3. PAD
TEST AND RESULTS:
Ultrasound ABI Doppler with Exercise-
Right: Resting ABI of 0.84, Positive exercise study
Left: Resting ABI of 1.29, Negative exercise study
CT angiogram of the pelvis and bilateral lower extremity-
Abdominal aorta Large fusiform infrarenal AAA 8.6 x 7.5 cm. Dilated right and left common iliac arteries 2.4 and 2.8 cm. Focal fusiform aneurysmal dilatation of the mid to distal main trunk of the left internal iliac artery 3.2 cm.
Right leg elongated thrombus within the right popliteal artery appearing to attach to the arterial wall proximally resulted in high-grade stenosis
FINAL WORKING DIAGNOSIS:
1. Large fusiform infrarenal AAA
2. Left internal and bilateral common iliac aneurysms
3. Popliteal artery embolism
TREATMENT AND OUTCOMES:
1. Evaluation: IR, Vascular surgery, and Cardiology
2. AAA repair: left internal and bilateral common iliac aneurysms and right popliteal embolectomy
3. Walking 3-4 miles with mild pressure but no pain in his calves at 5 weeks postoperatively

1713 May 31 4:15 PM - 4:35 PM
Unilateral Quadriceps Weakness

Jacqui Stone. *University of Calgary, CALGARY, AB, Canada.*
(No relevant relationships reported)

HISTORY: 17-year-old male athlete presenting with insidious onset of isolated, painless, unilateral quadriceps weakness and wasting. PHYSICAL EXAMINATION: Significant unilateral quadriceps atrophy with relative rectus femoris sparing. Strength was mildly reduced on the affected side, but much less than would be expected given his level of atrophy. There were no other sensory or focal neurologic deficits on examination. DIFFERENTIAL DIAGNOSIS: Monomelic Amyotrophy, Amyotrophic Lateral Sclerosis, Cord compression, Nerve root/plexopathy TESTS AND RESULTS: Nerve conduction studies, EMG, and MRI findings consistent with final diagnosis FINAL WORKING DIAGNOSIS: Monomelic Amyotrophy (quite rare) TREATMENT AND OUTCOMES: Observation and long-term follow up, conservative management with physiotherapy. Typically clinical deficit remains stable and isolated, but follow-up is required to ensure it is not a different diagnosis. In this clinical case presentation, we review the natural history, epidemiology, diagnosis, differential considerations, prognosis and management of this rare entity.

1714   May 31 4:35 PM - 4:55 PM

Say It Aint Sew: A Unique Cause of Calf Pain in Marathoner

Matthew D. Sedgley, MD FAAFP CAQSM. *MedStar Sports Medicine, Ellicott City, MD.* (Sponsor: Nailah Coleman, MD, FACSM)

(No relevant relationships reported)

HISTORY: 53 year old female who is a marathoner presents with a chief complaint of calf pain. Located near the gastrocnemius muscle on the left leg. Mechanism of injury was she is training for a marathon in order ot qualify for Boston Marathon. It is worse with fast running. Better with rest. There is no numbness.
PHYSICAL EXAMINATION: General: Fit appearing masters level runner WNWD, NAD ENT: NCAT, normal teethSkin: No rashes or ulcersCardiac Vasc: normal capillary refill, no cyanosis and palpable pulses distally at dorsalis pedis bilaterallyNeuro: normal sensation, no tremors, symmetric knee and ankle reflex +2 bilaterally, negative slump signPsyche: nervous that she will not BQ in qualifying race, no depressionMSK: Inspection: no atrophy, swelling or bruisingPalpation: tender gastrocnemius on the left leg only, no defect ROM: ankle dorsiflexion -15 degrees bilaterally and plantar flexion 40 degrees bilaterallyStrength: 5 out of 5 dorsiflexions, plantar flexion, inversion and eversion and FHL and EHL bilaterally.Special Testing: negative slump sign, negative homans sign, negative Thompson test.
DIFFERENTIAL DIAGNOSIS: Tennis calf/muscle strainLumbar radiculitisMTSS vs stress fractureCECSPAESPeripheral neuritis/entrapment
TEST AND RESULTS: Xray left tibia and fibula 2 views: possible foreign object in calf muscleMSK ultrasound: on long and short axis a sewing needle is seen in the gastrocnemius muscle deep fibers.
FINAL WORKING DIAGNOSIS: Foreign object in muscle
TREATMENT AND OUTCOMES: Anke surgeon consulted. Opted for watchful waiting instead of surgery. Patient qualified for Boston and chose after hearing benefits and risks to avoid surgery.

1715   May 31 4:55 PM - 5:15 PM

Leg Pain in Recreational Runner with Parkinson's Disease - Running

Timothy M. Dekker, George G.A. Pujalte, FACSM. *Mayo Clinic, Jacksonville, FL.*
(No relevant relationships reported)

HISTORY: A 76-year-old male, with known Parkinson's disease since 15 years ago, presented due to left posterior thigh pain that started a week prior. He was running and felt a "tug," sharp pain and weakness. At rest it was a pulling sensation, 5/10 in intensity. Running and prolonged sitting made it worse. He denies any back pain, numbness or tingling. He had been trying to walk/run about 2 miles a day, and strength training. He had a very similar pain on the right side a year ago and with a hamstring strain, given a methylprednisolone dose pack, and physical therapy focusing on his hamstrings. He was able to run pain-free until this injury. He was very distressed that he was unable to run as he believed exercise has been essential in managing his Parkinson's.
PHYSICAL EXAMINATION: No leg swelling or ecchymosis. Normal hip and knee range of motion. Normal strength. Pain with resisted hamstrings testing. Right-favoring antalgic gait, but takes small steps. Tenderness to palpation of left proximal hamstring. Straight leg test caused mild pain in left hamstring.
DIFFERENTIAL DIAGNOSIS: Hamstring strain Piriformis syndrome Lumbar radiculopathy
TEST AND RESULTS: X-ray of left thigh: Mild pelvic enthesopathy at hamstrings' tendinous origins along bilateral ischial tuberosities Hips and knees with mild degenerative changes.
FINAL WORKING DIAGNOSIS: Recurrent proximal hamstring strains, in a Parkinson's disease sufferer intent on running recreationally.
TREATMENT AND OUTCOMES:
The challenge is that the patient insists on running, but gait changes caused by Parkinson's make it difficult.
Physical Therapy initiated special program starting with light stretching and submaximal strengthening, progressing to increased resistance training. Refrained from running initially; after weeks of therapy, was able to walk/run again. Patient made to understand gait effects of Parkinson's; continues therapy, wants to run in spite of condition.

D-45   Clinical Case Slide - **Medical Issues III**

Thursday, May 31, 2018, 3:15 PM - 4:55 PM
Room: CC-Mezzanine M100F

(No relevant relationships reported)

1719   May 31 3:15 PM - 3:35 PM

Seizure - Running

Vanessa Franco. *Kaiser Los Angeles Medical Center, Los Angeles, CA.*
(No relevant relationships reported)

HISTORY: A 13-year-old boy was running laps when he began convulsing. He was brought to the Emergency Department (ED) where vital signs, basic labs, CT brain, and EEG were normal. An EKG was read by the ED physician as normal, but the QTc was 491ms. The patient was discharged with neurology follow-up. Two months later, the patient was playing basketball when he developed convulsions and collapsed. Paramedics noted the patient to be pulseless. En route to the ED, he received 1 minute of CPR followed by 1 shock and 2 minutes of CPR. He then achieved return of spontaneous circulation.
PHYSICAL EXAMINATION: Examination of the patient on his 1st ED visit was normal. During his second ED visit, the patient's Glasgow Coma Scale was 1-1-1. The patient was hypotensive with a blood pressure of 91/47. His pulse was 80 and he was saturating 100% on BVM. He had abrasions to his chin and neck. His pupils were equal and reactive to light bilaterally.
DIFFERENTIAL DIAGNOSIS:
1. Intracranial process such as traumatic brain injury, hemorrhage, tumor, infection.
2. Toxicologic etiology such as cocaine use, alcohol or benzodiazepine withdrawal, or overdose of buproprion or a tricyclic antidepressant.
3. Metabolic abnormality such as hypoglycemia, hyponatremia, or hypernatremia.
4. Cardiac process such as arrhythmia, ischemia, or total anomalous coronary artery.
5. Pulmonary embolism.
TEST AND RESULTS:
Labs 1st visit: Normal, 2nd visit: HCO3 18, Glucose 257, BUN 19, Cr 0.9, Na 137, K 3.7, CO2 16, AG 19, Ca 8.1, CK 209, BNP 110, Lactate 4.4, Mg 1.9, Trop 0.03, TSH 6, WBC 8.9, Hbg 13, plt 267, INR 1.3
Urine drug screen 2nd visit: neg
Chest xray 1st and 2nd visit: mild cardiomegaly.
EKG 1st visit: LVH and QTc of 491ms, 2nd visit: LVH and dagger-like Q waves, QTc of 504ms.
Bedside Cardiac Ultrasound 2nd visit: Focal hypertrophy of the interventricular septum to 23 mm.
FINAL/WORKING DIAGNOSIS:
Hypertrophic Cardiomyopathy
TREATMENT AND OUTCOMES:

The patient was intubated, resuscitated, and transported by helicopter to the nearest Pediatric Intensive Care Unit. Seizure-like activity is often thought to reflect a primary brain disorder; however, poor cardiac function and arrhythmias can decrease perfusion to the brain and cause convulsions. Seizure-like activity during exercise should increase suspicion of a cardiac etiology.

1720   May 31 3:35 PM - 3:55 PM

Primum Non Nocere - A Case Of Medication Overuse

Sahil Shah, Shaun Knox, Andrew Martin. *Campbell University School of Osteopathic Medicine, Lillington, NC.*

(No relevant relationships reported)

HISTORY: 19 year old female college track athlete (100, 200 sprints) with past medical history significant for familial hypercholesterolemia acutely developed right posterior thigh pain during practice, 8 months prior to initial presentation to the clinic. Medications included oral contraceptive pills and simvastatin. She was seen at a different physician office and was diagnosed with a hamstring strain via MRI. Treatment course outlined at that time included rest, acupuncture. This was not completed and she presented to the sports medicine clinic for evaluation and continued treatment due to persistent pain. **PHYSICAL EXAMINATION**: Stable vital signs and general physical examination, including no rash in the affected area. Musculoskeletal exam revealed full AROM, strength 5/5 and pain at the myotendinous junction of the right biceps femoris. **DIFFERENTIAL DIAGNOSIS**: 1. Hamstring strain 2. Iliotibial band syndrome 3. Statin side effect 4. Meralgia paresthetica
TEST AND RESULTS: Vitamin D level - 34.4 Lipid panel (on simvastatin): Total - 206, TG - 110, HDL - 42, VLDL - 22, LDL - 142 Lipid panel (off simvastatin): Total - 215, TG - 93, HDL - 46, VLDL - 19, LDL - 150
FINAL WORKING DIAGNOSIS: Right biceps femoris strain Familial Hypercholesterolemia
TREATMENT AND OUTCOMES:
1. She was taken off her statin medication as this may have been contributing to muscular pain, and was not likely providing benefit for preventing cardiovascular disease at this point. 2. Percutaneous/transcutaneous electric nerve stimulation to the local area. 3. Range of motion exercises, eccentric strengthening of the affected area 4. Modified practice until able to perform event pain free, then return to full activity.

1721   May 31 3:55 PM - 4:15 PM

Preparticipation Physical Exam: More Than a Hernia Check.

Joshua Priddle DO[1], Michael Goodlett MD[2], Siraj Abdullah DO[1], Joseph Edison DO[1]. *[1]VCOM-Auburn, Auburn, AL. [2]Auburn University, Auburn, AL.*

(No relevant relationships reported)

HISTORY: A 17 year old male NCAA Div 1 football player presents for his intake physical exam with the complaint of right medial knee pain. He had a recent history of a right MCL sprain two weeks prior. He has a significant past medical history of a right nondisplaced fracture of his proximal tibia repaired by ORIF at the age of 12. The hardware was removed 3 months later. The patient has no other complaints.
PHYSICAL EXAMINATION: His vital signs were within normal limits. The HEENT, CV, Respiratory, and Skin exam were unremarkable. On musculoskeletal exam of his right knee he was tender to palpation over the right medial tibial plateau, medial joint line, and over his MCL. He had no obvious effusions. His right knee opens 1+ to valgus stress testing. He had a 1 cm shorter leg length discrepancy on the right compared to the left. He had full range of motion. His knee was otherwise stable to varus stress. He had a stable anterior and posterior drawer and he was neurovascularly intact.
DIFFERENTIAL DIAGNOSIS: 1. MCL Sprain, 2. Tibial Bone Bruise, 3. Tibial Fracture, 4. Medial Meniscal Injury.
TEST AND RESULTS: X-ray obtained for evaluation of his right knee pain demonstrated a multiloculated cystic bone lesion with sclerotic and thin margins abutting the articular surface of the proximal tibia. MRI confirmed a 3.7 X 3.6 X 6.9 cm multiloculated mass in the medial metaphysis of the right tibia extending to the subchondral surface. There was no enhancement of the ACL, PCL, MCL, or LCL.
SECONDARY DIFFERENTIAL DIAGNOSIS: 1. Giant Cell Tumor, 2. Aneurysmal Bone Cyst, 3. Chondromyxofibroma, 4. Osteosarcoma
Orthopedic oncology performed an open bone biopsy of the lesion and the patient was subsequently diagnosed with a simple bone cyst.
FINAL WORKING DIAGNOSIS: Simple Bone Cyst
TREATMENT AND OUTCOMES: Curettage and bone grafting were performed. The patient was discharged and kept on 50% weight bearing with no ROM restrictions with progression of crutches for 6 weeks. At his 6 week post op appointment the patient was off crutches and doing well. He was ambulating without assistance. X-rays obtained at that time showed improvement and new bone growth. At his 3 month follow up he was pain free. X-rays showed bone growth and no interval growth of the lesion. At that time he was cleared for full practice and sport participation.

1722   May 31 4:15 PM - 4:35 PM

18yo Female Lacrosse Player with Abdominal Pain

Kyle H. Yost, Valerie Cothran, Paul Goleb. *University of Maryland, Baltimore, MD.*

(No relevant relationships reported)

History:
An 18yo college lacrosse player was injured when she was struck in the abdomen with a lacrosse stick early in practice. She developed epigastric abdominal pain and reported her symptoms to her athletic trainer. Five months prior, she sustained a splenic laceration during lacrosse and was instructed to wear an abdominal pad during lacrosse activities. She was wearing an abdominal pad when she sustained this abdominal injury. She reported her symptoms a 4/10 and that it was different than her previous splenic injury. She was then sent to the emergency room of a community hospital. In the emergency room she had a CT scan performed, which showed physiological fluid without evidence of abdominal or pelvic organ injury. She was then transferred to a level one trauma hospital for observation. Overnight her pain remained minimal and the next day she was going to be discharged. Before she was discharged her pain increased and it was determined she would have an exploratory laparotomy.
Physical Exam:
Constitutional: Well-developed and well-nourished. No distress.
Cardiovascular: Normal rate and rhythm.
Pulmonary: Lungs clear to auscultation.
Abdominal: Soft, non-distended. Diffusely tender over the abdomen with the pain concentrated over the epigastric area. Normal bowel sounds.
Differential Diagnosis:
1. Abdominal muscle contusion.
2. Pancreatic laceration/contusion.
3. Splenic laceration.
4. Liver laceration/contusion.
Tests and Results:
CT 9/19/17: Pelvic peritoneal free fluid within the pelvis most likely physiologic, without specific evidence of abdominal or pelvic organ injury.
Exploratory Laparotomy 9/20/17: Contusion to mid to distal body of the pancreas, no other intra-abdominal pathology identified.
Final working diagnosis:
1. Pancreatic contusion secondary to blunt abdominal trauma.
Treatments and Outcomes
1. Admitted to the surgical ICU.
2. Post op day five her peri-pancrearic drains removed and nocturnal jejunal feeds were stopped.
3. Post op day six she was discharged from the hospital with GJ tube in place.
4. Eight weeks post op her GJ tube will be removed.
5. She will resume sports activities at 3 months post op with contact starting at 6 months post op.

1723   May 31 4:35 PM - 4:55 PM

General Medicine - Ultramarathon Runner

Kristin Schwarz, Laura Moretti, Kathryn Ackerman, FACSM. *Boston Children's Hospital, Boston, MA.*

(No relevant relationships reported)

HISTORY:
19-yo male ultramarathoner presents for performance advice. He runs 20 hr/wk, avg 120 mi/wk. 100-mi race avg pace is 8:30 min/mi. Follows vegan, gluten-free, raw food diet. Refuses to use vitamins/supplements. Does not feel he needs to gain weight. Minimal sexual interest, absence of morning erections. PMH: Low weight, 1 prior fracture. Fam Hx: Sister -celiac disease, Neg for osteoporosis or eating disorders.
PHYSICAL EXAMINATION:
Temp: 36.6° C. Refuses Ht and Wt. BP Lying: 110/70, P 54; Standing 106/64, P 65 A&Ox3 and no acute distress; Eyes: PERRLA, +Conjunctival pallor; CV: RRR, No murmurs, rubs, gallops; Lungs: Clear; Thyroid: Normal; Skin: No rashes or lesions.
DIFFERENTIAL DIAGNOSIS:
1. Malabsorptive disorder
2. Hypogonadism
3. Hypothyroidism
4. Relative Energy Deficiency in Sport (RED-S)
TESTS AND RESULTS:
EKG: sinus bradycardia, 48 bpm
DXA: BMI 17.6. Lumbar spine Z-score -2.3 (*-6.6%), Fem neck Z-score -0.6 (*-9.8%), total hip Z-score -0.2 (*-10.5%), % Fat Z-score -1.0
*(*Change from DXA 3 yr prior)*
Labs: WBC 3200/uL (L), MCV 101.2 fL (H), Ferritin 15 ng/mL (L), Iron 82 mcg/dL, TIBC 325 mcg/dL, B12 334 pg/mL (L), Folate wnl; Free testosterone 44 (L), Total testosterone 32 ng/dL (L), SHBG 44 nmol/L (wnl); 25-OH Vit D 20 ng/mL (L). TSH 2.14 mIU/L (wnl), Free T4 1.1 ng/dL (wnl), T3 2.2 pg/mL (L); IGF1 wnl, prolactin wnl; AST 23, ALT 7 (L), TTG IGA and Total IgA wnl; ESR and CRP wnl.
FINAL/WORKING DIAGNOSIS:

-Relative Energy Deficiency in Sport (RED-S)
-Secondary to: Inadequate energy intake, eating disorder
TREATMENT AND OUTCOMES:
1. Nutrition Evaluation:
-Dietary recall: 2700 to 3000 kcal/d (protein: 1.4 g/kg/d, carb: 8 g/kg/d, fat 0.5 g/kg/d). 1000-1500 kcal deficit/d.
Goal= 4,000+ kcal/d. Diet insufficient in macronutrients. Initial goal: begin with small change- increase fat to 1 g/kg/d.
Recommended: Vit D, Iron, and B12 supplements (patient refused).
2. Refused anthropometrics for months - contracted that weights required for medical/nutrition appts.
3. Top finish in national ultramarathon. 2d later: Lying: BP 104/62, P 52; Standing 110/60, P 72 (+Orthostasis); EKG: sinus bradycardia. Recommended: higher level of care, but patient refused.
4. Sports Psych Referral: Felt he was "hitting a wall" in training. Went from pre-contemplative to contemplative stage regarding dietary changes.
5. Close follow-up.

1740   Board #1   May 31 2:00 PM - 3:30 PM

The Association of Asymmetry in Hopping Tests and Non-contact Injuries in Division I Female Student-athletes

Meghan Warren[1], Monica Lininger[1], Craig A. Smith[2], Adam Copp[1], Nicole J. Chimera[3]. *[1]Northern Arizona University, Flagstaff, AZ. [2]Smith Performance Center, Tucson, AZ. [3]Daemen College, Amherst, NY.*

(No relevant relationships reported)

PURPOSE: Limb differences in hopping for distance tests (single, triple, and crossover) are commonly used for return to play readiness after anterior cruciate ligament (ACL) injury. Females athletes are at high risk of ACL injury and risk factor identification and early prevention is critical. No study has been conducted to assess the ability of these three tests to identify high-risk athletes. To determine the association between asymmetry in hopping tests and non-contact and overuse injuries in Division I female basketball, soccer, and volleyball student-athletes. **METHODS**: 65 female student-athletes (SA; 19.1±1.1 yrs, 171.1±8.8 cm, 68.5±9.6 kg), injury-free at testing (prior to the season) were included in the study. The order of the clinical tests was randomized for each SA, and included the single, triple, and crossover hop for distance, and isometric hip strength and jumping tests. Any injury that caused the SA to report to the athletic training room was abstracted from the medical record. Only the first injury for each SA was recorded. Contact injuries were excluded. ROC curves and area under the curve (AUC) were calculated using absolute values of the difference between the right and left leg for each hopping test to determine the optimal cut-point. Logistic regression determined the odds of non-contact or overuse injury with each hopping test using the cut-point determine from ROC curve. History of previous injury was assessed for confounding. **RESULTS**: 53 athletes were injured during their sport season. The cut-point for single hop was 6 (sensitivity = 0.55, specificity = 0.67, AUC = 0.51), and triple and crossover hop was 12 (sensitivity = 0.74 and 0.66, specificity = 0.75 and 0.58, AUC = 0.42 and 0.41, respectively). After adjusting for previous injury, a statistically significant association was found with the triple hop and the odds for non-contact injuries (odds ratio = 7.43 [95% confidence interval 1.72 - 32.17]). No significant association was found with single or crossover hop after adjusting for previous injury. **CONCLUSIONS**: Using a clinically relevant injury definition, the triple hop showed the strongest predictive ability for non-contact and overuse injuries. This hopping test may be a clinically useful tool to help identify increased risk of injury in female athletes playing high-risk sports.

1741   Board #2   May 31 2:00 PM - 3:30 PM

The Association of Proximal Hip Strength and Non-Contact Injury in Division I Female Student-Athletes

Nicole J. Chimera[1], Monica R. Lininger[2], Craig A. Smith[3], Adam Copp[2], Meghan Warren[2]. *[1]Daemen College, Amherst, NY. [2]Northern Arizona University, Flagstaff, AZ. [3]Smith Performance Center, Tucson, AZ.*

(No relevant relationships reported)

Rehabilitation progress has been measured using jump performance and strength testing. However, there remains a paucity of research examining the relationship between strength performance and future injury. If strength tests are able to determine which athletes are at an increased risk of injury, then education and targeted injury-prevention programs can be implemented. **PURPOSE**: To determine the association between proximal hip strength and non-contact and overuse injuries in Division I female basketball, soccer, and volleyball student-athletes. **METHODS**: 68 female student-athletes (SA; 19.1 ± 11 yrs, 171.3±8.7 cm, 68.4± 2.5 kg), recruited over 3 years, injury-free at the time of testing (prior to their respective seasons) were included in the study. Clinical tests were randomized for each SA, and included isometric hip abduction, external rotation, and extension using a handheld dynamometer, as well as hopping and jumping tests. The first non-contact injury that caused the SA to report to the athletic training room was abstracted from the medical record. Contact injuries were excluded. Strength was adjusted for body weight and categorized into tertiles. Logistic regression determined the odds of non-contact or overuse injury with each clinical test. History of previous injury was assessed for confounding. **RESULTS**: 54 SA were injured during their sport season. No statistically significant association was found between injury and hip abduction (weakest vs. strongest odds ratio: 1.52 (95% confidence interval 0.31-7.50), middle tertile vs. strongest: 0.70 (0.18-2.82)), external rotation (weakest vs. strongest odds ratio: 3.87 (95% confidence interval 0.67-22.36), middle tertile vs. strongest: 0.95 (0.24-3.71)), or extension (weakest vs. strongest: 1.15 (0.25-5.23), middle tertile vs. strongest OR = 0.80 (0.18 - 3.62)). **CONCLUSIONS**: None of the strength tests were associated with non-contact and overuse injury in this group of Division I female SA. Type II error cannot be ruled out for the findings.

1742   Board #3   May 31 2:00 PM - 3:30 PM

Wearable Contour Sensors to Assess Neuromuscular Control During Repeated Unilateral Partial Squat Task

Shannon E. Linderman[1], Donna Moxley Scarborough[2], Eric M. Berkson[1], Mary M. Eckert[1], Nan-Wei Gong[3]. *[1]Massachusetts General Hospital, Boston, MA. [2]MGH Institute of Health Professions, Charlestown, MA. [3]Figur8 Inc, Boston, MA.*

Reported Relationships: S.E. Linderman: *Salary; figur8, Inc.*

PURPOSE: Improved quantification of muscle balance and symmetry, key facets of neuromuscular control, could aid sports medicine clinicians' assessment of injury risk and readiness to return-to-sport. This proof-of-concept study evaluates a body contouring sensor network for assessment of neuromuscular control via intra-subject test-retest and intra-limb symmetry testing of peak quadriceps (Quads) and hamstring (HS) muscle contraction during a repeated unilateral partial squat (RUPS) task. **METHODS:** Wireless contour stretch sensors were placed bilaterally across the Quads and HS muscle bulks of 5 healthy females (23 ± 4.3 years) who exercise regularly (4.6 ± 0.96 times/week). Subjects performed 3 trials of the RUPS activity. Total Quads and HS muscle bulk displacements were collected for 3 squat repetitions during the 3rd RUPS trial. Four subjects performed same day re-testing sessions. Statistical analyses included ICC 2-way mixed effects consistency model evaluation of intra-subject test-retest reliability (n= 4) and paired t-test analysis of limb symmetry (n= 5). **RESULTS:** Both measurements of Quad and HS total muscle displacement displayed excellent correlation during test-retest reliability, $ICC_{2,1}$=0.91 (0.18-0.99) and $ICC_{2,1}$=0.97 (0.58-0.99). Quad and HS muscle contraction displacement differed significantly between dominant and non-dominant limbs, p = 0.026 and p = 0.041, respectively (Table 1). A significantly greater Quad/HS total displacement ratio was observed for the dominant limb, p = 0.014. **CONCLUSIONS:** The wearable contour-sensor demonstrated consistent Quad and HS peak muscle displacement detection during the RUPS task. We observed differences in muscle ratios and peak muscle displacement between limbs among a small sample of healthy females. These findings demonstrate proof of concept for further investigation of this on-body contour sensor system for assessment of neuromuscular control.

THURSDAY, MAY 31, 2018

Table 1: Average peak muscle displacement of 3 partial squats during repeated unilateral partial squat (RUPS) activity.

Measure (n = 5)	Right limb Mean ± standard deviation (% sensor stretch)	Left limb Mean ± standard deviation (% sensor stretch)
Quadriceps Peak displacement	**3.047 ± 0.742**	**2.877 ± 0.764**
Hamstrings Peak displacement	**5.025 ± 0.754**	**6.195 ± 0.906**
Quadriceps/Hamstrings Ratio	**0.630 ± 0.218**	**0.487 ± 0.200**

1743 Board #4 May 31 2:00 PM - 3:30 PM

Knee Extension Strength Asymmetry does not affect Peak Power or Fatigue during the Wingate Test

Stuart Best, Reiley Bergin, Scott Royer, Joshua Winters, Kathleen Poploski, Nicholas Heebner, John Abt, FACSM, Scott Lephart, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: John Abt, FACSM)
(No relevant relationships reported)

PURPOSE: Peak and mean power during the Wingate test is associated with knee extensor strength, however it is unknown if knee extensor asymmetry affects this relationship. We hypothesized that increased muscle asymmetry would be associated with decreased peak and mean power during the Wingate test in healthy subjects. **METHODS**: 206 highly active male subjects (27 ±4 yrs, 84 ±9 kg) completed individual limb isokinetic strength testing on a dynamometer ($60° \cdot sec^{-1}$), as well as a 30 second Wingate anaerobic test in a seated position. Strength testing included maximal knee extension strength (% Body Weight). Knee extension asymmetry ratio between legs (A_{ext}) was calculated as $A_{ext} = E_{min}/E_{max}$, where E_{max} = strongest leg, E_{min} = weakest leg. Subjects were later classified as High Symmetry (HS, $A_{ext} \geq 0.95$, n=76), Moderate Symmetry (MS, $0.90 \leq A_{ext} < 0.95$, n=60), Moderate Asymmetry (MA, $0.85 \leq A_{ext} < 0.90$, n=35) or High Asymmetry (HA, $A_{ext} < 0.85$, n=35). Wingate data ($W \cdot kg^{-1}$) were analyzed for peak power (P_{peak}), mean power (P_{mean}), as well as power output at 5 second intervals. **RESULTS**: There were significant differences in E_{min} (HS > MA, p=0.012; HS > HA, p<0.001; MS > HA, p=0.044) but not E_{max} between groups. No significant differences in P_{peak} (12.89 ±0.68, 12.74 ±0.63, 12.71 ±0.52, 12.87 ±0.79 $W \cdot kg^{-1}$), P_{mean} (9.26 ±0.81, 9.05 ±0.82, 9.15 ±0.78, 9.32 ±1.08 $W \cdot kg^{-1}$) or any other power variables were found between the HS, MS, MA and HA groups respectively (all p>0.055). When all subjects were combined, knee extensor asymmetry (A_{ext}) was not associated with any power variables (all p>0.133). P_{peak} and P_{mean} respectively were positively associated with E_{max} (r=0.414, p<0.001; r=0.464, p<0.001) and E_{min} (r=0.397, p<0.001; r=0.420, p<0.001). Although all relationships were significant, the associations between strength variables (E_{min} and E_{max} respectively) and power decreased from 5 seconds (r=0.490, p<0.001; r=0.490, p<0.001) to 30 seconds (r=0.265, p<0.001; r=0.331, p<0.001). **CONCLUSIONS**: Greater knee extensor strength imbalance between legs is not associated with decreased power throughout a 30 second Wingate test. These data suggest that for bilateral tasks in which the legs do not move independently, such as cycling, training focused only on improving strength symmetry between legs may not improve peak power production.

1744 Board #5 May 31 2:00 PM - 3:30 PM

Cardiorespiratory Fitness of Otherwise Healthy Obese Women

Vipa Bernhardt[1], Dharini M. Bhammar[2], Rubria Marines-Price[3], Tony G. Babb, FACSM[3]. *[1]Texas A&M University Commerce, Commerce, TX. [2]University of Nevada-Las Vegas, Las Vegas, NV. [3]Institute for Exercise and Environmental Medicine, Texas Health Presbyterian Hospital and UT Southwestern Medical Center, Dallas, TX.* (Sponsor: Tony G Babb, FACSM)
(No relevant relationships reported)

PURPOSE: Cardiorespiratory fitness (CRF) is used as a diagnostic and prognostic health indicator for all-cause and cardiovascular disease mortality (Lee et al, 2010). Thus, properly quantifying and interpreting CRF is important for accurate diagnoses. The current EACPR/AHA Scientific Statement includes peak oxygen uptake (VO₂peak) both in ml/min/kg and as percent of predicted (Guazzi et al, 2016).We have previously shown, in a small cohort of otherwise healthy obese women (n = 26), that obese adults have normal or slightly reduced CRF (~85% of predicted), depending on the prediction equation used (Lorenzo & Babb, 2012). Here, we wanted to validate our earlier findings in a larger sample of women. **METHODS:** Obese women underwent hydrostatic weighing to assess body fat percentage, fat mass, and lean body mass. They then completed an incremental cycling test to exhaustion to determine VO₂peak. Prediction equations from Riddle et al (R; 1980), Wasserman et al (W; 2005), and Gläser (G; 2010) were used to assess CRF as previously described. Differences between percent predicted VO₂peak values derived from the three equations were analyzed using repeated measures ANOVA. **RESULTS:** Data from 121 women (34 ± 7 yr, 36 ± 4 kg/m² BMI, 46 ± 5% body fat, 44 ± 9 kg fat mass, 52 ± 6 kg lean body mass, mean ± SD) were analyzed. VO₂peak (ml/min/kg) was low (18.9 ± 3.0 ml/min/kg) and decreased with increasing body mass, severely penalizing heavier individuals. In fact, applying the current ACSM CRF classification, 113 women would be considered "very poor" and 8 as "poor" (all below the 25th percentile). Mean values of % predicted VO₂peak were significantly different between equations R and W, and W and G, but not between R and G (R: 92 ± 14%, W: 91 ± 14%, G: 92 ± 14%, p < 0.01). Using a cutoff for low CRF of < 84% of predicted VO₂peak, only 27-32% of women fell into this category, depending on the equation used. **CONCLUSIONS:** The commonly used method of evaluating VO₂peak based on body weight (ml/kg/min) is not appropriate in obese individuals; VO₂peak as percent of predicted is a better alternative when assessing CRF. Similar to our previous data in a small cohort of otherwise healthy obese women, the current data show that the majority of obese women have normal CRF, independent of the prediction equation used.

1745 Board #6 May 31 2:00 PM - 3:30 PM

A Cluster Analysis and Validation of Health-related Fitness Tests in College Students

You Fu[1], Ryan D. Burns[2], Timothy Brusseau[2], Nora Constantinon[1]. *[1]University of Nevada, Reno, Reno, NV. [2]University of Utah, Salt Lake City, UT.*
(No relevant relationships reported)

PURPOSE: Because health-related fitness consists of several domains, understanding clustering of scores from a testing battery can help practitioners derive exercise programs. The purpose of this study was to explore the clustering of health-related fitness test scores in college students and to validate the solution against criterion measures. **METHODS**: Participants were college students (Mean age = 19.2 0.6 years; N = 523; 342 females, 181 males) recruited from a university in the southwestern U.S. The health-related fitness assessments consisted of BMI, estimated VO₂ Peak from the Astrand-Ryhming cycle ergometer test, and standard push-ups. Criterion measures consisted of DXA-assessed percent body fat (%BF), measured VO₂ Peak from a maximal treadmill test, and a 1-Repetition Maximum (1-RM) bench press score. A hierarchical cluster analysis was performed to derive groupings. One-way ANOVA tests were used to explore the differences among the derived cluster groups on each criterion measure. **RESULTS**: Six cluster groups were formed representing various fitness "phenotypes" (Pseudo-F = 179.7). The cluster groups differed in %BF (F(5, 517) = 44.6, p < 0.001, eta-squared = 0.31), measured VO₂ Peak (F(5, 517) = 49.7, p < 0.001, eta-squared = 0.33), and 1-RM bench press scores (F(5, 517) = 17.0, p < 0.001, eta-squared = 0.12), providing validation evidence. **CONCLUSIONS**: Six cluster groups were formed from a health-related fitness test battery in college students that were validated against criterion measures of health-related fitness. The cluster groups can be used to inform current fitness status and for the derivation of exercise programs.

1746 Board #7 May 31 2:00 PM - 3:30 PM

Work Performed Above The Respiratory Compensation Point Is Not Equivalent To W′

Jeffrey A. Leo[1], Surendran Sabapathy[1], Michael J. Simmonds[1], Troy J. Cross[2]. *[1]Griffith University, Gold Coast, Queensland, Australia. [2]Mayo Clinic, Rochester, MN.*
(No relevant relationships reported)

The hyperbolic power-time relationship for severe-intensity cycling exercise is defined by two physiological parameters: (i) the asymptote, critical power (CP); and (ii) the curvature constant, $W′$. Recently, we reported that the respiratory compensation point (RCP) displays poor measurement agreement with the CP. However, it is unknown whether the amount of supra-RCP mechanical work ($RCP′$) performed during ramp-incremental cycling is similar to that performed above the CP (i.e., $W′$). **PURPOSE:** We sought to determine the measurement agreement between $W′$ and $RCP′$ obtained during incremental cycling of varying ramp slopes. **METHODS:** Twelve male cyclists completed three separate ramp-incremental cycling protocols, where the work rate increment was slow (SR, 15 $W \cdot min^{-1}$), medium (MR, 30 $W \cdot min^{-1}$), or fast (FR, 45 $W \cdot min^{-1}$). Initially, the RCP (adjusted for mean response time) was obtained using the ventilatory equivalent for CO_2 method. To assess $RCP′$, we calculated the power–time integral between the RCP and the instantaneous power output observed at exercise termination for each ramp-incremental test, separately. $W′$ was determined via Morton's model for ramp-incremental exercise. The assumption that $W′$ and $RCP′$ occur at equivalent kilojoule (kJ) values was assessed by one-way repeated-measures ANOVA and by evaluating the concordance correlation coefficient (CCC) and typical error (root-mean-square error [RMSE]) for each ramp-incremental test, separately. **RESULTS:** $RCP′$ decreased with increases in the ramp-incremental slope ($P < 0.05$). $RCP′$ in SR (21.5 ± 6.5 kJ), MR (16.8 ± 5.6 kJ) and FR (13.3 ± 4.3 kJ) were not

different from W' (15.7 ± 6.9 kJ). The degree to which the relationship between W' and RCP' approximated the line of identity was poor for SR (CCC = -0.09 and RMSE = 11.3 kJ), MR (CCC = 0.23 and RMSE = 7.5 kJ) and FR (CCC = 0.37 and RMSE = 6.5 kJ).

CONCLUSION: Our data demonstrate that RCP' is lower when the ramp-incremental slope is increased. Furthermore, despite occurring at similar kJ values, we observed poor measurement agreement between W' and RCP', as evidenced by the low CCC and the large RMSE values, irrespective of the ramp-incremental protocol. Together, these findings indicate that RCP' obtained during ramp-incremental cycling is not equivalent to W'.

Effectiveness of Preseason Conditioning on Vo$_{2max}$ in College Athletes Assessed via Ift and Gxt

Kallie LaValle, Jordan Nieuwsma, Joseph D. Ostrem. *Concordia University - St. Paul, St. Paul, MN.*
(No relevant relationships reported)

Developing a greater aerobic capacity is essential for successful performance in college athletics (Helgerud, Engen, Wisloff & Hoff, 2001). Specifically, the preseason training program can be utilized for aerobic capacity improvement to optimize performance throughout the competitive season (Castagna, et al. 2013). Moreover, accurately assessing aerobic capacity is important to quantify the effectiveness of an aerobic training program.
PURPOSE: The purpose of the study was to determine the aerobic capacity changes via Intermittent Fitness Testing (IFT) and Graded Exercise Testing (GXT) in Division II collegiate athletes following a preseason conditioning program.
METHODS: Fourteen college athletes (male = 7; age = 19±1 yrs) participated in the study. Subjects performed the 30-15 IFT (Buchheit, 2007), an interval running assessment with progressively increasing speed until maximal effort is reached, and a modified Balke GXT assessment on a treadmill to failure. Aerobic fitness was assessed before and after an 8-week preseason interval training program. Paired t-tests evaluated mean differences within IFT and GXT assessments for pre- and post-training variables. Independent t-tests compared the IFT and GXT assessments between genders. Correlations between IFT and GXT assessment were reported via Pearson's correlation coefficients.
RESULTS: The measured VO$_{2max}$ via GXT (45.1 vs. 48.9 ml/kg/min, P<0.001) and estimated 30-15 IFT VO$_{2max}$ (46.7 vs. 48.9 ml/kg/min, P<0.001) both significantly increased over the 8-week preseason training period. Heart rate (HR) at 2 min post-GXT was significantly lower (150bpm vs. 141bpm, P=0.019) following preseason training. GXT measured VO2max and 30-15 IFT estimate VO2max displayed a strong correlation before and after preseason interval training (r=0.84, P<0.001 vs. r=0.77, P<0.001). Weight was significantly lower in post testing (1.5±2kg, P=0.019).
CONCLUSIONS: Preseason interval training produced positive aerobic capacity improvements and were similarly detected with IFT and GXT. Further studies could investigate the relationship between in-season athletic performance and preseason aerobic capacity changes.

Comparison of Non-Maximal Tests for Exercise Prescription and Outcome Assessment

Reem A. Alajmi, Carl Foster, FACSM, John P. Porcari, FACSM, Kim Radtke, Scott T. Doberstein. *University of Wisconsin-La Crosse, La Crosse, WI.*
(No relevant relationships reported)

Introduction Although maximal incremental exercise tests (GXT) are the gold standard for outcome assessment and exercise proscription, they are not widely available in either fitness or clinical exercise programs. **Purpose** This study compares the prediction of VO$_2$max in healthy, sedentary volunteers using a non-exercise prediction (Matthews), RPE extrapolation to 19 & 20 and the Rockport Walking Test (RWT) and of VT using the Talk Test and RPE @ 13,14,15. **Methods** Subjects performed treadmill GXT with gas exchange, submaximal treadmill with RPE and Talk Test, the RWT and Matthews **Results** All methods provided reasonable estimates of both VO$_2$max and VT, with correlations >0.80 and SEE ~1 MET. VO$_2$max was best estimated with extrapolation to RPE=19. VT was intermediate between the TT Last Positive & Equivocal stages and between RPE 13 & 14. **Conclusion** Non-maximal evaluation can be used in place of maximal GXT with gas exchange to make reasonable estimates of both VO$_2$max and VT.

Normative Benchmark Workout Scores Forcrossfit® Athletes

Gerald T. Mangine[1], Brant Cebulla[2], Yuri Feito, FACSM[1]. [1]*Kennesaw State Univeristy, Kennesaw, GA. [2]University of California at Berkeley, Berkeley, CA.* (Sponsor: Yuri Feito, FACSM)
(No relevant relationships reported)

PURPOSE: To provide normative reference values for the five most common benchmark workouts for male (M) and female (F) CrossFit® athletes competing in the teen (T), individual (I), and masters (MS) divisions The CrossFit Games®.
METHODS: Five-hundred uniform resource locators were scraped from a publicly-available online database and yielded 133,857 user profiles that contained self-reported anthropometric and performance data. Profiles were sorted by sex and age (i.e., T, I, or MS) and then screened for errors. Profiles were eliminated from the analysis if they: 1) contained data points that exceeded four standard deviations (i.e., < 0.001% of all values) from their respective mean; or 2) did not contain more than one completed benchmark workout (i.e., Fran, Grace, Helen, Filthy-50, and Fight-Gone-Bad). Subsequently, a randomly-selected sample was used to calculate the mean, standard deviation, and normative percentiles (in deciles) for each workout in I$_M$ (n = 500; 178.7 ± 7.4 cm; 86.1 ± 10.1 kg), I$_F$ (n = 500; 164.0 ± 6.7 cm; 64.2 ± 7.3 kg), MS$_M$ (n = 500; 178.8 ± 7.4 cm; 87.1 ± 10.6 kg), and MS$_F$ (n = 500; 164.7 ± 6.7 cm; 64.3 ± 7.7 kg). Due to limited user profiles, the entire populations were assessed for T$_M$ (n = 285; 175.8 ± 8.5 cm; 73.7 ± 11.6 kg) and T$_F$ (n = 136; 163.7 ± 7.1 cm; 61.6 ± 9.1 kg).
RESULTS: Separate norms were calculated for each sex and age category for Fran (T$_M$: 314.6 ± 142.5 sec; T$_F$: 250.0 ± 109.4 sec; I$_M$: 300.2 ± 125.2 sec; I$_F$: 361.3 ± 129 sec; MS$_M$: 330.2 ± 138.4 sec; MS$_F$: 363.1 ± 145 sec), Grace (T$_M$: 212.8 ± 76.8 sec; T$_F$: 257.3 ± 97.9 sec; I$_M$: 178.8 ± 86.5 sec; I$_F$: 207.4 ± 80.5 sec; MS$_M$: 213.4 ± 95.4 sec; M$_F$: 242.4 ± 114.8 sec), Helen (T$_M$: 9.8 ± 1.8 min; T$_F$: 12.0 ± 1.9 min; I$_M$: 9.5 ± 2.0 min; I$_F$: 10.9 ± 1.9 min; MS$_M$: 10.1 ± 2.0 min; MS$_F$: 11.3 ± 2.2 min), Filthy-50 (T$_M$: 24.3 ± 6.1 min; T$_F$: 29.2 ± 6.6 min; I$_M$: 24.9 ± 5.5 min; I$_F$: 26.8 ± 6.3 min; MS$_M$: 26.9 ± 6.7 min; MS$_F$: 27.4 ± 5.6 min), and Fight-Gone-Bad (T$_M$: 291 ± 50 reps; T$_F$: 269 ± 48 reps; I$_M$: 331 ± 60 reps; I$_F$: 284 ± 60 reps; MS$_M$: 314 ± 60 reps; MS$_F$: 283 ± 51).
CONCLUSION: This study presents norms for the five most common benchmark workouts for male and female athletes participating in The CrossFit Games® across the three major divisions. The norms can be used to assess competency in these sport-specific challenges within these populations.

Assessment And Application Of The 'bunkie Test' In College Students

Natalie Tamjid[1], Jamie DeRevere[1], Elizabeth O'Neill[2], Kimberly Kostelis[1]. [1]*Central Connecticut State University, New Britain, CT. [2]Springfield College, Springfield, MA.* (Sponsor: Sean Walsh, FACSM)
(No relevant relationships reported)

In an attempt to improve athletic performance and assess potential dysfunction of core fascial lines, the 'Bunkie test' is a functional performance test consisting of five different plank positions. There is no current literature that establishes appropriate rest intervals for in-between plank positions, as well as no established termination criteria.
PURPOSE: The current study was conducted to examine the rest interval duration and test termination criteria for the Bunkie test. interval duration and test termination criteria for the Bunkie test **METHODS:** Forty college students from two universities volunteered to participate in the study. Participants completed three sessions separated by at least 48 hours, which consisted of 5 plank positions held bilaterally. Positions included the anterior power line (APL), lateral stabilizing line (LSL), posterior power line (PPL), posterior stabilizing line (PSL), and medial stabilizing line (MSL). The plank positions were held for as long as possible with proper form. Each session utilized a different rest interval of either 30s, 1min, or 2min between each of the plank positions.

Abstracts were prepared by the authors and printed as submitted.

RESULTS: A repeated measures ANOVA revealed significant differences bilaterally among rest intervals for APL (p=.009; p=.001) whereas, no significant differences (p<.05) were observed for PPL. LSL and MSL and PSL had significant differences among rest intervals on one side (LSL left, p=.002; MSL right, p=.006; PSL right p=.005)). Post hoc analysis with a Bonferroni adjustment revealed less variability among times between the 1min and 2min rest intervals between plank positions **CONCLUSIONS**: The results of the current study revealed that utilizing a shorter rest interval time frame (30s) appears to create greater variability in performance outcomes. Since no differences were found between using a 1 min or 2 min rest interval for both the final hold times and tension times, a rest interval of at least 1 min will allow for more dependable data.

Worker's Cardiorespiratory Fitness Evaluation Using a 3-min Step Test with Daily Physical Activity Assessments

Tomoaki Matsuo, Rina So. *National Institute of Occupational Safety and Health, Japan, Kawasaki, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)

(No relevant relationships reported)

As measuring VO_{2max} in the workplace can be burdensome, the development of time-efficient, safe, and validated cardiorespiratory fitness (CRF) evaluation methods would be effective. Although step tests can be used to estimate VO_{2max}, their validity is not sufficient. Recently, precise physical activity (PA) information has been obtained from sophisticated wearable devices. **PURPOSE:** We developed a new CRF measurement procedure using a 3-min step test along with daily PA assessments. This study investigated the validity of the new method. **METHODS:** Our study subjects included 80 Japanese workers (45 men and 35 women, aged 30 to 59 years). We measured our subjects' VO_{2max} by the Bruce protocol using treadmill exercise and an indirect calorimeter. The subjects completed two types of step test: the Chester step test (CST) for ≥6-min, and the JNIOSH step test (JST). The latter was newly developed by our institute and consists of a 3-min (60, 80, 100 BPMs) stepping exercise followed by a 1-min rest. Daily PA levels were assessed by subjects wearing a 7-day accelerometer, and also a questionnaire which measured three types of workers' PA levels: during working time, non-working time on workdays, and non-workdays. We performed multiple regression analyses using VO_{2max} as the dependent variable, and age, sex, BMI, heart rates from step tests, time (min) spent in given PA levels from the accelerometer, and scored points on the questionnaire, as the independent variables. **RESULTS:** The correlation coefficients of the step tests and VO_{2max} were 0.65 (R^2 = 0.42) in the CST and 0.64 in the JST (0.41). In addition to age, sex, and BMI, the time spent in vigorous (>6.0 METs) PA and PA intensity points on the questionnaire were observed as significant independent variables ($P<0.05$). Multiple regression analyses showed that the adjusted R^2 increased to 0.73 when age, sex, BMI, heart rates during the JST, time spent in vigorous PA, and the questionnaire's PA intensity points were included as independent variables. **CONCLUSION:** Our study suggests that this procedure can potentially be used to assess CRF at workers' health check-ups when VO_{2max} measurements are not available. Supported by the Industrial Disease Clinical Research Grants from the Ministry of Health, Labour and Welfare, Government of Japan (150903-01).

Investigating The Effects Of Obesity On Fitness Among Community-dwelling Older Adults In Taiwan

Chueh-Ho Lin[1], Liang-Hsuan Lu[2], Wen-Hsu Sung[3], Shang-Lin Chiang[2], Po-Jung Chen[3]. *[1]Master Program in Long-Term Care, Taipei Medical University, Taipei, Taiwan. [2]Tri-Service General Hospital, Taipei, Taiwan. [3]National Yang-Ming University, Taipei, Taiwan.*

(No relevant relationships reported)

Obesity is a critical health issue, increasing the risk for chronic diseases, including hypertension, diabetes mellitus, and coronary artery disease, in the elderly. However, the impact of obesity on physical fitness, which is important for functional performance of daily activities among the community-dwelling elderly, has not been evaluated.
PURPOSE: We investigated obesity-related changes in physical fitness among community-dwelling elderly individuals.
METHODS: Sixty-nine elderly individuals (67 women and 2 men; age, 73.26±6 years) were recruited and classified into the obese (BMI ≥27.0 kg/m², n=17) or non-obesity (BMI <27.0 kg/m², n=52) group. Weight, height, and waist girth were measured for all individuals. The following physical fitness tests were evaluated: back scratch, sit-and-reach, 30-s sit-to-stand, 2-min leg lift, single leg balance, and the timed up-and-go (8 feet walk distance). Between-group differences were evaluated using independent sample *t*-tests, with a p-value <0.05 denoting statistical significance (SPSS statistical software, version 19.0).

RESULTS: The prevalence of obesity was 24.6% in our study group. Weight and waist girth were lower in the non-obese than in the obese group: 19% ($t_{(67)}$ =5.492, p<0.01) and 13% ($t_{(67)}$ = 3.443, p=0.001), respectively. Performance on the back scratch test and single leg balance was better for the non-obese than for the obese group: back scratch (-22.9±15.3 cm *versus* -10.1±16.1 cm, respectively, p=0.005) and single leg balance (12.4±14.8 s *versus* 26.1±31.7 s, respectively, p=0.018). Performance for the non-obese and obese group was comparable on the sit-and-reach test (7.9±13.7 cm *versus* 7.0±8.0 cm, respectively, p=0.790), 30-s sit-to-stand (19.3±5.3 repetitions *versus* 18.1±3.5, respectively, p=0.412) and 2-min leg lift (131.9±36.9 repetitions *versus* 114.7±25.5, respectively, p=0.079).
CONCLUSIONS: We identified some effects of obesity among community-dwelling elderly individuals, such as single leg balance, which could lead to restriction in activities of daily living and an increased risk of falling.

Relationship Between Body Mass Index, Core Strength, and Balance in Adults

Brian B. Parr, Samuel R. LaMunion, Allison P. Jolley, Andrew G. Hatchett. *University of South Carolina Aiken, Aiken, SC.* (Sponsor: Michael J. Turner, FACSM)

(No relevant relationships reported)

Previous research suggests that obesity is associated with physical function limitations and poor balance, which may interfere with activities of daily living and lead to an increased risk of falls and injuries. Impaired balance has been attributed to low core strength in obese individuals. **PURPOSE**: To determine the relationships among body mass index (BMI), core strength, and balance in normal (BMI 18.5-24.9 kg•m⁻²), overweight (25.0-29.9 kg•m⁻²), and obese (≥30.0 kg•m⁻²) adults. **METHODS**: Seventeen adults (mean±SD: age, 39.4±9.8 y; BMI 28.3±5.3 kg•m⁻²), completed two assessments: a timed plank test, in which the time a subject could hold a static plank position was measured, and the Star Excursion Balance Test (SEBT), in which the distance is measured while a subject stands on one foot and reaches as far as possible at eight different angles with the opposite foot. **RESULTS**: There was a significant relationship between BMI and plank time (r=0.66, p=0.004), but not between plank time and SEBT performance (r=0.39, p=0.12) or BMI and SEBT (r=0.19, p=0.46). Mean plank time was significantly higher (p<0.001) in normal (85.3±6.5 s) compared to the overweight (56.8±10.8 s) and obese (51.1±11.2 s) subjects. The reach distance for all SEBT angles were lower in the obese subjects compared to the normal and overweight groups, although these differences were not statistically significant (all p>0.05). **CONCLUSIONS**: There is a significant relationship between BMI and core strength. Additionally, plank time is significantly lower in obese subjects indicating reduced core strength. There are also small, but non-significant, differences in balance among BMI groups. These findings suggest that obesity is associated with core strength and balance deficits that should be addressed in a fitness program.

Inertial Load Influences Power Measures during the Wingate Test

JohnEric W. Smith[1], David D. Pascoe, FACSM[2], Benjamin M. Krings[1], Matthew J. McAllister[1], Junfeng Ma[1]. *[1]Mississippi State University, Mississippi State, MS. [2]Auburn University, Auburn, AL.* (Sponsor: David D. Pascoe, FACSM)

(No relevant relationships reported)

The Wingate Test is a commonly used assessment of anaerobic capacity and power during cycling. Wingate Protocol involves participants reaching maximal pedal cadence prior to resistance being added to the cycling flywheel. **PURPOSE:** The purpose of this study was to create a method to correct power measures to account for the influence of inertial load during a Wingate Test. **METHODS:** This study was performed using a Velotron ergometer and the Velotron Wingate Software. Ergometers were pedaled up to three different cadences (130, 150, and 170 revolutions per minute) at five different loads (3.75, 5.25, 6.75, 8.25, and 9.75 kp). Pedaling force was removed immediately before resistance was added to the flywheel. Data were collected for a full 30-seconds as utilized in a standard Wingate Test. **RESULTS:** Peak power resulting from inertial load ranged from 482-1615 W. Average power resulting from inertial load over the first portion of the test varied between 282-735 W based on flywheel resistance and initial cadence while no work was performed. Statistical modeling allowed the development of a regression curve (r^2 = 0.986) accounting for second by second predictions of the influence of inertial load on power output readings. **CONCLUSION:** The Wingate Test can be valuable tool in a participant's work assessment. However, caution needs to be taken in the interpretation and application of power output as this study has demonstrated.

Comparison of 3 Alternative Systems for Measuring Vertical Jump Height

Scott T. Staiger, Eric T. Wahl. *Dakota State University, Madison, SD.*
(No relevant relationships reported)

Muscular power is a skill-related component of physical fitness and is most often associated with athletic performance. A simple and effective way to measure lower body muscular power is the vertical jump test. **PURPOSE:** To compare 3 different vertical jump measurement devices and to determine the reliability of the 3 devices. **METHODS:** A convenience sample of 30 college students (16 males and 14 females; mean age 20.7 ± 3.3 years), volunteered to participate in this study. The vertical jump heights were determined by the 3 devices (Just Jump™ mat, Vertec™, and the Vert™ device) simultaneously. The Just Jump™ mat was placed on the ground next to the Vertec™, and the subject wore the Vert™ device, clipped to their waist, while jumping. The subjects completed a brief, dynamic warm-up prior to performing the counter movement vertical jumps. Each subject was allowed 2 submaximal effort practice jumps prior to performing 5 maximum effort vertical jumps. After each jump, the 3 measurements were recorded. Each subject completed a 2nd series of 5 jumps 2-3 days after the first testing session. The protocol for the 2nd day was exactly the same as the first day. An ANOVA was used to determine differences between vertical jump heights between the 3 measurement devices and a paired T-test was used to compare vertical jump measurements between the 2 testing days on each device. Significance was defined as $p < .05$ for all statistical calculations. **RESULTS:** There was no significant difference in vertical jump heights measured between the 3 devices on either day (Day 1 - Just Jump™ mat: 21.2 ± 6.2 in.; Vertec™: 21.0 ± 6.2 in.; Vert™: 20.1 ± 4.9 in.; $p = 0.227$; Day 2 - Just Jump™ mat: 21.2 ± 6.0 in.; Vertec™: 21.1 ± 6.2 in.; Vert™: 20.2 ± 4.9 in.; $p = 0.233$). In addition, there were no significant differences between the vertical jumps between the 2 days for any of the devices (Just Jump™ mat: $p = 0.616$; Vertec™: $p = 0.141$; Vert™: $p = 0.897$). **CONCLUSION:** The results of this study indicated that the Vert™ device recorded values approximately 1 inch lower than the Vertec™ and the Just Jump™ mat, however, the difference was not statistically significant. In addition, all 3 devices recorded similar measurements on both days of testing. Based on these results, any one of the 3 devices would be adequate to provide consistent and reliable vertical jump results in a field setting.

Comparison of Anaerobic Power Tests During Cycle and Non-Motorized Treadmill Ergometry at Optimized Loads.

Rasmus Rooks, Brian M. Kliszczewicz, Cherilyn N. McLester, Emily E. Bechke, Cassie M. Williamson, John R. McLester, FACSM. *Kennesaw State University, Kennesaw, GA.* (Sponsor: John R. McLester, FACSM)
(No relevant relationships reported)

Electromagnetically braked cycle ergometers (CE) have been the standard modality for maximal anaerobic power (AP) testing in applied research settings; however, modern non-motorized treadmill (NMT) ergometers may prove a viable alternative for testing. **PURPOSE:** To compare performance markers derived from a 30-s maximal sprint on CE and NMT under optimized loads **METHODS:** Recreationally active men ($n = 5$; 24.8 ± 4.4 yrs) and women ($n = 6$; 21.3 ± 3.4 yrs) volunteered for the study. First visit consisted of a force-velocity-power test on the CE and NMT to determine optimal resistance for peak power production. Remaining two visits were performed in a randomized crossover order, consisting of a single 30-s maximal AP test on the CE or NMT. Peak power (PP), mean power (MP), minimal power (Pmin), and fatigue index (FI) were averaged over three revolutions on the CE and three strides on the NMT. Rating of perceived exertion (RPE), maximal heart rate (HRmax) and blood lactate concentration (BLa) were collected as a measure of intensity. All markers were analyzed using paired samples t-tests and Pearson product correlation coefficients. **RESULTS:** PP, MP and Pmin were higher (P < 0.001) on NMT (924.44 ± 297.72 W, 636.90 ± 309.55 W and 364.34 ± 123.20 W, respectively) than CE (501.90 ± 154.20 W, 309.55 ± 115.28 W and 178.11 ± 58.93 W, respectively). Significant correlation was found between PP ($r = 0.938$, $p < 0.001$), relative PP ($r = 0.871$, $p < 0.001$), MP ($r = 0.859$, $p = 0.001$), relative MP ($r = 0.721$, $p = 0.012$), Pmin ($r = 0.824$, $p = 0.02$) and relative Pmin ($r = 0.779$, $p = 0.05$). FI was not significantly different on the NMT $= 59.9 \pm 9.6\%$ compared to the CE $= 63.9 \pm 6.7\%$, $p = 0.172$, although they were not significantly correlated, $p > 0.05$. HRmax was higher on the NMT than CE (184.1 ± 11.0 bpm and 177.7 ± 11.0 bpm, $p = 0.001$, respectively). BLa (NMT $= 11.6 \pm 2.5$ mmol/l; CE $= 10.4 \pm 2.4$ mmol/l) and RPE (NMT $= 17.6$; CE $= 17.1$), ($p > 0.05$), were not significantly different. Optimal braking force on the NMT was $20.8 \pm 4.3\%$ for males and $14.5 \pm 1.9\%$ for females. Optimal torque factor on the CE was 0.76 ± 0.25 Nm/kg for males and 0.52 ± 0.08 Nm/kg for females. **CONCLUSION:** There is a strong relationship between CE and NMT in assessing AP at optimized loads, however higher power output and maximal heart rates were observed on a NMT. Further research is necessary to clarify FI relationship.

1757   Board #18   May 31 2:00 PM - 3:30 PM

Stride Time Variation and Resilience in Healthy Young Adults during a Graded Exercise Task

Nikki E. Barczak[1], Matthew W. Wittstein[2], Nicholas A. Hadgis[2]. *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC. [2]Elon University, Elon, NC.*
(No relevant relationships reported)

Trait level of ego-resilience is how well individuals can adapt and be open to events as they occur. Cardiac and locomotor behaviors during exercise may represent physiological manifestations of resilience in an individual. Resilience has been related to parasympathetic activity, which may predict changes in heart rate during a graded exercise task. The prediction of performance during an exercise task has implications towards training as well as injury. Gait fluctuations have been previously associated with fall risk and trained runners tend to demonstrate smaller variability of stride time intervals than untrained runners. **PURPOSE:** The purpose of this study was to investigate the association between ego-resilience scores and physiological characteristics during a graded exercise test in young, healthy adults. **METHODS:** 30 young, healthy participants (21.73 ± 1.88 yrs) completed a valid and reliable online questionnaire assessing ego-resilience and demographic information. Prior to the task, blood pressure, using a sphygmomanometer, and resting heart rate, using electrocardiogram (ECG) were collected. Each participant then completed a graded exercise protocol on a treadmill. The protocol began with a 3-minute warm-up at 4.0 mph and 0% grade followed by 90-second stages of increasing speed (+0.5 mph) at 3% grade until the person reached exhaustion or until the 10th stage was completed. From the trial, cardiac and locomotor rhythms were measured using ECG and digital video, respectively. **RESULTS:** Ego-resilience was not significantly related to blood pressure, resting heart rate, total time spent on the exercise task, or average change in heart rate ($p > .05$). The coefficient of variation of stride time during recovery was significantly positively related to ego-resilience score ($r = .38$, $p < .05$). **CONCLUSION:** Higher ego-resilience was associated with more variance in stride time throughout the exercise task. Increased variability in stride time may reflect a more robust, or resilient, running behavior. In this study, cardiovascular measures did not demonstrate significant relationships with ego-resilience. However, the data do suggest that ego-resilience may have behavioral manifestations, such as more robust movement patterns.

1758   Board #19   May 31 2:00 PM - 3:30 PM

Using Vertical Shoulder Press To Find The Occurrence Of Bilateral Deficit In Recreationally Trained Participants

Arthur J. Burley, James L. Ramsey, Shel Levine, John W. Carbone, Rebecca W. Moore. *Eastern Michigan University, Ypsilanti, MI.* (Sponsor: Lanay Mudd, FACSM)
(No relevant relationships reported)

Bilateral deficit (BLD) is an occurrence where the unilateral sum in force output is higher than the bilateral force output in the upper or lower limbs. Maximal bilateral and unilateral lifts can be used to determine if a BLD is present. BLD can often have negative effects on performance and daily activity due to an uneven force output per limb in bilateral movements. This is important for health and fitness professionals because it can help them to recognize and reduce the occurrence of BLD. **PURPOSE**: To determine if there was a difference between a combined maximal unilateral lift (cMUL) and a maximal bilateral lift (MBL) for vertical shoulder press (VSP) and to determine if BLD was present in recreationally trained participants. It was hypothesized that the cMUL will be significantly greater than the MBL. **METHODS**: Thirty participants (19 male, 11 female) were recruited for this study. Participants engaged in three separate visits which were each 72 hours apart. The first visit consisted of a movement screening that assessed biomechanical functionality when performing the VSP. This was accomplished by observing efficiency in a set of 8 to 10 repetitions at 30% of their one repetition maximum (1RM) for the VSP. Participants were then randomly assigned for visit 2 to either a MUL or MBL testing condition and completed the other condition during visit 3. In each testing condition, participants performed 6 to 8 repetitions at 50% 1RM. Participants then proceeded to lift one repetition at 70% 1RM, which was increased by 10% after a successful lift. This pattern was followed until volitional fatigue was present. Unilateral values for the left and right limbs were combined (cMUL). A paired samples t-test was used to determine if there was a difference between cMUL and MBL ($p < 0.05$). **RESULTS**: Participants were 22.96 ± 3.72 years old, 170.1 ± 9.3cm tall, and weighed 73.7 ± 11.50kg. Although 15 participants presented a BLD, a significant difference was not observed between the MBL (99.0 ± 36.4 lbs) and cMUL (98.3 ± 32.3 lbs). **CONCLUSIONS**: The results did not support the hypothesis that the cMUL would be greater than the MBL. This could be due to the training status of the participants. Future studies are needed to assess training programs and their effect on the occurrence of BLD.

Does a Push-Up Using the Spyder 360 ™ Elicit More Muscle Activation Compared with a Standard Push-up?

Kent D. Johnson, FACSM, William Vantrease. *Lipscomb University, Nashville, TN.*

(No relevant relationships reported)

The conventional push-up is a common method for assessing a person's muscular endurance or as an exercise to improve muscle performance in the upper extremities or trunk. Many organizations encourage using the push-up as a test to assess muscular endurance (including the American College of Sports Medicine). A relatively new device called the **Spyder 360 ™** is being promoted as a method to maximize muscle activation during a push-up due to its unstable platform on wheels. **PURPOSE:** To compare muscle activation in select muscle groups during a standard push-up activity with and without the **Spyder 360 ™. METHODOLOGY:** Twelve healthy male subjects volunteered for the study (age=26.67±5.74yrs; WT=85.58±9.40kg; HT=182.14±6.04cm; Percent Fat=13.78±5.40; BMI=25.87±3.28). Volunteers reported to the laboratory and were randomly assigned to test first using either stable push-up handles (PUH) or **Spyder 360 ™** (PU360). EMG electrodes were placed over the following muscles to determine muscle activation: 1) clavicular fibers of the pectoralis major (PM); 2) middle triceps (TR); 3) middle latissimus dorsi (LD); 4) middle portion of the rectus abdominus (RA); and 5) anterior deltoid (AD). Subjects were asked to perform 5 push-ups each using the PUH and PU360. The maximal one push-up EMG data was used for comparison between the two interventions (PUH or PU360). **RESULTS:** Results indicate that the PU360 elicits significantly more muscle activation during a push-up activity in the pectoralis major (29%; $p<0.001$); triceps brachii (42%; $p=0.0086$); latissimus dorsi (26%; $p=0.0157$); and rectus abdominus (32%; $p=0.0054$). There was no significant difference in the anterior deltoid (8%; $p=.1653$). **CONCLUSION:** These results demonstrate that the PU360 elicits more muscle activation in the PM, TR, LD and RA compared with PUH for the subjects in this study.

Lifespan Physical Fitness Analysis In A University-Sponsored, Guided Exercise Program

Chris Dondzila, Amy Campbell, Vanessa DeLeo. *Grand Valley State University, Allendale, MI.* (Sponsor: Stephen Glass, FACSM)

(No relevant relationships reported)

BACKGROUND: Professional guidance is integral to assist individuals adopting an active lifestyle to enhance physical fitness, yet there is clarity lacking regarding which aspects of exercise programming (aerobic and resistance training) should be targeted across the lifespan. PURPOSE: To provide a lifespan, descriptive analysis of aerobic and muscular fitness in individuals seeking guidance in initiating an exercise program through a University program. METHODS: Upon registering in a University sponsored, guided exercise program, participants (N=991) received a comprehensive health analysis, measuring variables largely influenced by aerobic training (predicted VO_2 from the YMCA cycle test and skinfold body fat percentage) and resistance training (hand grip strength and push ups). One sample t-tests were used to compare mean data with 50th percentile ranking/good ranking (ACSM), stratified by the following age groups: 20-29 years (n=615), 30-39 years (n=178), 40-49 years (n=62), 50-59 years (n=98), ≥60 years (n=38). RESULTS: Regarding outcomes largely influenced by aerobic exercise, VO_{2max} values were lower in the male 20s (40.0±12.8 ml/kg/min) and 30s groups (33.7±11.3 ml/kg/min) and the female 20s group (33.8±9.7 ml/kg/min, all p=.000), yet higher in the female 50s group (28.8±5.3 ml/kg/min, $p<.05$); body fat percentage was higher in the female 20s (27.0±6.6%), 30s (28.0±8.9%), and 40s groups (34.4±8.9%, all p=.000). For outcomes largely influenced by resistance training, grip strength was significantly lower in the male 20s (86.8±24.4 lbs) and 30s (66.0±30.2 lbs, both p=.000) groups, whereas the 60s female group was significantly higher (57.6±12.0 lbs, $p<.05$); for pushups men performed significantly worse in the 30s (14.0±10.9 repetitions) and 40s (11.2±4.6 repetitions, both $p<.05$) groups, whereas women performed better in the 20s (19.8±10.9 repetitions), 40s (18.5±10.6 repetitions), and 50s (13.3±8.1 repetitions, all p=.000) groups. CONCLUSION: Aerobic fitness was markedly low in the early lifespan for men and women. Specific to genders, muscular fitness was low in men through the 30s and body fat percentage high in women through the 40s. Focus should be placed on enhancing all physical fitness values early in the lifespan to more effectively raise and maintain throughout older adulthood.

Chinese Collegiate Fitness Index Report Based on the Supporting Active Lifestyle Perspective

Yi Liu[1], Xiaolei Liu[2], Mingxi Guan[3], Hao Guo[4], Yan Peng[5], Ming Yang[1], Jindong Chang[1]. [1]*Southwest University, chongqing, China.* [2]*High School Affiliated to Southwest University, chongqing, China.* [3]*Chongqing Business Vocational College, chongqing, China.* [4]*Chongqing College of Humanities,Science & Technology, chongqing, China.* [5]*Sichuan Aerospace Vocatinal College, Chengdu, China.*

(No relevant relationships reported)

PURPOSE: Physical activity of college students was heavily influenced by individual interest, educational policies, social support, and the physical environment (including the built environment). The purpose of this study was to assess the status of Chinese collegiate fitness and to develop a promotion strategy from the supporting active lifestyle perspective.
METHODS: Drawing on National Academy of Kinesiology released the National Collegiate Fitness Index Report 2015 (NCFI) to develop Chinese collegiate fitness index (CCFI). The advisory committee members used the Delphi method to rate the importance of the fitness factors of CCFI. Finally, three domain was included in the CCFI and named transportation, exercise facilities, and physical education policies and services. A total of 789colleges and universities were surveyed, 386 were recovered, and 245 were valid questionnaires. The missing data that schools with incomplete responses were filled with the mean by SPSS24.0. The domain score was calculated by the rank of each group.
RESULTS: Finally, 245 colleges and universities came from 29 Provinces, Municipalities, Autonomous Regions and Hong Kong Special Administrative Region joining in the survey. Three groups were identified according to the difference of the attribution, the difference between public and private, as well as the different institutions and vocational institutions. Among the 245 colleges and universities, 48 were recognized as the subordinate universities, 152 were determined as the provincial universities, and 45 were defined as the public vocational or private colleges. The top three of universities are (1) Tsinghua University (74.7); (2) Beijing Normal University (72.1); (3) South China University of Technology (72.0).
CONCLUSIONS: There are obvious regional differences in the fitness index of Chinese collegiate ($p=0.009<0.05$); The fitness index of the subordinate universities was significantly higher than other two group universities ($p=0.000<0.05$).

Unsupervised Home-based Intermittent Walking Effectively Improves Physiological and Psychological Health

Carrie Ferguson, Rosalind E. Lancaster, Shaunna Burke, Gemma K. Lyall, Karen M. Birch, FACSM. *University of Leeds, Leeds, United Kingdom.*

(No relevant relationships reported)

Laboratory-based intermittent exercise (IE) improves exercise tolerance and other independent cardiovascular disease (CVD) risk factors in a range of populations. For IE to be truly effective this must translate to the unsupervised home environment, and overcome key perceived barriers to exercise participation. This requires that the exercise be achievable, but of a sufficient intensity to drive physiological adaptations, and also promote increases in health-related quality of life (HRQoL). **PURPOSE** To investigate whether unsupervised home-based IE walking presents an achievable, but sufficient, physiological stimulus to reduce perceived barriers to exercise, CVD risk and, as a consequence, increase HRQoL in an overweight, but otherwise healthy population. **METHODS** 25 participants (45 ± 10 yr; 32 ± 3.8 kg/m²; 10 m, 15 f) undertook 12 weeks of home-based IE walking, completing 3 sessions/week and 32 min/session of IE$_{SHORT}$; 60 s of fast walking interspersed with 60 s recovery, or IE$_{LONG}$; 4 min of fast walking interspersed with 4 min recovery. Pre- and post-IE training, perceived barriers to exercise, maximal oxygen uptake (VO_{2max}), body mass, blood pressure (BP), resting heart rate (HR), blood biomarkers, and HRQoL were all measured using standard techniques. **RESULTS** Perceived barriers to exercise were reduced following IE ($p < 0.05$), this was largely driven by reductions in IE$_{LONG}$ (IE$_{LONG}$ vs. IE$_{SHORT}$: 11 ± 13 vs. 3 ± 15 % reduction). Body mass index and resting HR were both reduced following IE ($p < 0.05$); however, blood biomarkers and BP were unchanged. VO_{2max} increased following IE ($p < 0.05$; pre-post increase ιν VO_{2max}; IE$_{LONG}$ 2.7 ± 3.7; IE$_{SHORT}$ 1.6 ± 2.6 ml·kg^{-1}·min^{-1}). HRQoL increased following IE, with this a consequence of an increase in IE$_{LONG}$ (IE$_{LONG}$ vs. IE$_{SHORT}$: 23 ± 22 vs. 7 ± 15 % increase; $p < 0.05$). It is also noteworthy that adherence to IE$_{LONG}$ was greater than IE$_{SHORT}$ (78 ± 24 vs. 58 ± 36 %; $p < 0.05$). **CONCLUSION** Home-based IE walking was achievable and provided a sufficient exercise stimulus to improve physiological

THURSDAY, MAY 31, 2018

and psychological markers of health in an overweight, but otherwise healthy population. IE_{LONG} may be more effective than IE_{SHORT} for reducing barriers to exercise, CVD risk and increasing HRQoL. Support: Heart Research UK RG2631

Examination of the Relationship between Handgrip Strength and Upper Body Muscular Endurance in College-age Females

Cassandra E. Forsythe[1], Matthew Orange[1], James W. Krieger[2]. [1]CCSU, New Britain, CT. [2]Weightology LLC, Issaqua, WA. (Sponsor: Sean Walsh PhD, FACSM)
(No relevant relationships reported)

Knowledge regarding upper body muscular endurance and strength measures in college-age females is limited due to a relative lack of investigation. Since the implementation of Title IX, a large number of females regularly participate in strength and muscular endurance activities, and as such, more observational, descriptive fitness data on this population is needed. **PURPOSE:** While push-ups are traditionally a measure of muscular endurance, many females lack the upper body strength to perform a single standard push-up. This study seeks to determine the correlation between performance of push-ups from the standard position and a standard measure of upper extremity isometric strength, handgrip. **METHODS:** Healthy, non-pregnant females were recruited from the student population at CCSU. Subjects were excluded if they had uncontrolled asthma or any other medical condition that would prevent them from participating in strenuous physical activity. Following a short warm-up, subjects completed standard push-ups to exhaustion and completed a right-left maximum handgrip assessment using a dynamometer. **RESULTS:** Our 60 subjects had a mean age of 20.6 years (SD ± 2.5, range 18-27), and performed an average of 11.7 push-ups (SEM ± 1.30, range 0-47). Their average right and left handgrip was 35.1 kg (SEM ± 0.63) and 32.8 kg (SEM ± 0.62), respectively. Both Spearman rank and Kendall's Tau correlations showed no signification relationship between push-up performance and handgrip strength for either hand (Left hand: $r = 0.17$, $p = 0.27$; Right Hand: $r = -0.04$, $p = 0.78$). **CONCLUSIONS:** Our results demonstrate that college-age females are capable of performing standard push-ups to exhaustion, but that upper extremity isometric strength is a poor predictor of push-up performance in this population.

Effects Of A 12-minute Daily Physical Activity Intervention On Health Measures Of Office Workers

Maria Konstantaki, Georgina Colgate. *Buckinghamshire New University, High Wycombe, United Kingdom.*
(No relevant relationships reported)

Office workers are known to sit for 65-75% of their working hours. Prolonged sedentary behaviour is linked to chronic disease. Physical activity programmes offered at the worksite tend to be generally attended only by the fitter or highly motivated office workers and are still unsuccessful in the long-term.
PURPOSE: To investigate the effects of a six-week 'bite size' physical activity intervention (3 x 4 minutes daily) on health measures and exercise adherence of office workers.
METHODS: Forty office workers employed in administrative positions (age range 24 to 59 yrs) performed a series of physiological measurements including body mass (BM; kg), body fat (BF; %), blood pressure (BP; mmHg), resting heart rate (HR; bpm), waist to hip ratio (WHR), upper and lower body endurance test (number of push ups and timed wall squat), and core endurance (timed plank; s) at baseline and at the end of the study. For the bite size intervention, participants worked in small groups andcompleted nine stretch and strengthening exercises in approximately 4 min, three times a day, for 6-weeks. Participants also completed a Wellness questionnaire pre- and post-intervention and recorded their adherence to sessions in a self-administered log.
RESULTS: The bite size intervention significantly improved muscular endurance of the upper body (pre: 11.6 ± 3.5 v post: 20.1 ± 2.6 push ups), lower body (8.36 ± 4.2 s v 22.7 ± 5.6 s; p=0.001) and core (43.2 ± 6.1 s v 50.8 s ± 4.8 s; p=0.005). No significant effects were found for BM, BF% or WHR, HR or BP (all at p>0.05). Wellness questionnaire results showed improved mood, sleep quality and reduction in stress levels and fatigue post-intervention. Adherence rate was 67.5%, as only 13 participants completed the intervention. **CONCLUSIONS**: The improvements in upper/lower and core endurance shown in this study could be beneficial in improving posture and alleviating low back pain often experienced by office workers due to prolonged sitting. Bite size exercise in just four minutes 3x a day might be a time saving and effective alternative to previous methods aiming to improve the health and well being of office workers.

1765   Board #26   May 31 2:00 PM - 3:30 PM

Bone Strength Differences According to Peak Power Norm Table Categories

Rebekkah J. Reichert, Maria G. Alvarez, Andrew Denys, Kimberly D. Espartero, Priscilla Franson, Arianna M. Mazzarini, Vanessa R. Yingling, FACSM. *California State University, East Bay, Hayward, CA.* (Sponsor: Vanessa R. Yingling, FACSM)
(No relevant relationships reported)

Purpose: To determine if a commonly used peak power (PP) norm table (Patterson & Peterson, 2004) discerns differences in bone strength between PP categories. Fractures become more prevalent with age due to bone strength losses. Bone strength is a predictive factor of fracture risk (Clark et al., 2006; Schuit et al., 2004) and previous research has shown muscle strength is significantly correlated to bone strength variables (Frost, 2003; Yingling, 2017). An accessible field measure of PP that detects differences in bone strength may be an important step in optimizing bone strength, thus preventing fracture later in life. **Methods**: 114 participants, 62 F and 52 M (age (yrs) 21.1∓3.3) performed a maximal vertical jump test. PP was calculated from vertical jump height (Sayers, 1999) and categorized into the following groups: Well Above Average, Average, and Well Below Average. Moment of Inertia (J), Cortical Area (Ct. Ar), cortical Bone Mineral Density (cBMD), and Strength-Strain Index (SSI) were measured using peripheral Quantitative Computed Tomography (pQCT) to quantify bone strength at the 50% tibia site. A one-way ANOVA and a Tukey post hoc test assessed differences between PP categories at a significance level of $p<0.05$ (Graphpad Prism). **Results**: Bone strength variables were significantly different between PP norm table categories, except cBMD in males. Females: SSI (*p=0.0001*), J (*p=0.0001*), Ct.Ar (*p=0.0001*), cBMD (*p=0.0063*). Males: SSI (*p=0.0457*), J (*p=0.0101*), Ct.Ar (*p=0.0226*). Post hoc testing revealed a significant difference between the Well Above Average and Well Below Average groups for both genders. **Conclusion**: Current PP norm table categories show a significant difference between Well Above Average and Well Below Average. This indicates that those in the Well Below Average category for PP could benefit from exercise prescription targeted for bone strength optimization.

1766   Board #27   May 31 2:00 PM - 3:30 PM

Aerobic And Anaerobic Parameters Of A Three-minute All-out Test Are Associated With Rowing Performance

Gabrielle A. Mori, Emily M. Casper, Alec R. Dickson, Kyle L. Sunderland. *High Point University, High Point, NC.*
(No relevant relationships reported)

Critical power can be estimated utilizing a three-minute all-out exercise test. The 2000-m rowing test is utilized by US rowing as a standard test for all of their rowers. Critical power has been reported to predict 2000-m rowing performance, however the three-minute all-out test has not been used to predict 2000-m rowing performance.
PURPOSE: The purpose of this study was to examine the relationship between 2000-m rowing performance and the parameters of a three-minute all-out rowing test in collegiate club rowers.
METHODS: Ten (F=6, M=4) collegiate rowers (mean ± SD; age 19.3 ± 1.2 y; height 176.7 ± 10.0 cm; weight 75.6 ± 19.5 kg) completed a peak power test to determine peak power output (PPO) and a one-minute all-out test, a three-minute all-out test to determine end-power (EP) and work done above end-power (WEP), and a 2000-m time trial on a rowing ergometer. Testing days were separated by 72 hours and began with a five-minute warm-up on the rowing ergometer. The peak power, one-minute, and three-minute tests were all completed on a damper setting 10 whereas the 2000-m time trial was completed at a self-selected damper setting. Repeated measures ANOVA was used to compare PPO for all the tests and Pearson's product moment correlations were conducted to measure the relationships between 2000-m time and the parameters of the all-out rowing tests.
RESULTS: The strongest relationship with 2000-m time was average power for the 3-minute test ($r = -0.968$, $p <0.001$). Additionally, 2000-m time was significantly correlated with EP ($r = -0.931$, $p <0.001$), average power during 1-minute test ($r = -0.784$, $p <0.01$), and PPO ($r = -0.762$, $p = 0.01$). Work above end-power (WEP) was significantly related to PP of all the tests. There were significant differences between PP for all tests ($p < 0.01$).
CONCLUSIONS: These results suggest that a single 3-minute all-out rowing test can predict both peak power output and 2000-m time, therefore rowing coaches could use this test to more efficiently assess rowers.

Counting Talk Test Measurements and the Relationship to Heart Rate for Exercise Prescription

Morgan Johnson, Randi Lite. *Simmons College, Boston, MA.* (Sponsor: John Porcari, FACSM)
(No relevant relationships reported)

BACKGROUND: Exercise is commonly prescribed using various heart rate (HR) methods (e.g., %HRreserve, %HRmax). Exercise can also be described using the Counting Talk Test (CTT). Studies analyzing the correlation between exercise HR and CTT are limited, as well as data supporting the validity of the CTT as a method of exercise prescription. **PURPOSE**: To investigate whether CTT results are associated with exercise HRs and can therefore be used as a valid method of exercise prescription. **METHODS:** This study included 26 women with a mean age of 20.5 ± 1.6 years. Subjects performed exercise testing on a Stages ergometer once a week for three consecutive weeks. Data was collected at rest, during five stages of self-selected exercise intensities corresponding to RPE values of 8, 10, 12, 14 and 16 based on the Borg 6-20 scale, and during recovery. Data collection included measurements of Heart Rate, CTT Number, CTT Duration, average watts, and average RPM. Calculations were performed after testing to determine the subjects' %CTT using the equation (exercise CTT/ resting CTT) x 100. Pearson Correlation Coefficients were calculated to analyze the relationship between Heart Rate and CTT Number, Heart Rate and CTT Duration, as well as between %HRmax and %CTT. **RESULTS:** A statistically significant inverse correlation was found between HR and CTT number (r= -0.4188, p< 0.05) as well as between HR and CTT Duration (r= -0.5675, p< 0.05). A statistically significant inverse relationship was also found between %HRmax and %CTT (r= -0.5211, p< 0.05). A statistically significant positive correlation was found between CTT number and CTT duration (r= 0.6866, p< 0.05). **CONCLUSION:** Heart Rate was inversely associated with both CTT number and CTT duration. There was also an inverse relationship between %HRmax and %CTT. This data supports the idea that CTT is a possible alternative method of exercise prescription. Using CTT as exercise intensity prescription may improve patient adherence, making the monitoring of exercise intensity more accessible to the general population. More research is needed to ensure proper exercise prescription using the CTT in practice.

1768   Board #29   May 31 2:00 PM - 3:30 PM

Effects of Eight Weeks of Self-Determined Training on Cardiorespiratory Fitness in Recreationally Trained Females

Anthony J. Bull, Julia Lauzon, Kaitlyn DiMarco. *Colorado College, Colorado Springs, CO.* (Sponsor: Terry J. Housh, FACSM)
(No relevant relationships reported)

Maintaining or increasing cardiorespiratory fitness (CRF) throughout a training season can be challenging for recreationally trained endurance athletes. Even if athletes intend to increase training during a training season, variables such as the total number of minutes they train per week (min·wk⁻¹) and/or the min·wk⁻¹ of moderate to high intensity training (MHIT) they participate in may affect these athletes' ability to maintain or increase CRF. **Purpose:** The purpose of this study was twofold: 1) to examine changes in CRF over 8 weeks of self-determined training in recreational female endurance athletes who indicated they planned to increase training min·wk⁻¹; and 2) to examine changes in minutes of total training and MHIT per week from self-reported exercise logs from weeks 1 and 8. **Methods:** Fourteen recreationally trained female endurance athletes (cyclists (n=4) and runners (n=10)), all of whom had a baseline $VO_{2max} \geq 80^{th}$ percentile for their age, completed incremental running or cycling trials to exhaustion to determine VO_{2max}, and provided 7 d exercise training logs at weeks 1 and 8. Runners completed incremental trials on a motorized treadmill, cyclists completed trials on an electronically braked cycle ergometer, and expired gases were measured with a metabolic system during all trials. To record training, athletes were instructed on the use of the Borg RPE scale (15-grade scale) to estimate exercise intensity (*I*), and were asked to record exercise min and *I* independently for all phases of exercise sessions. MHIT was considered to be any exercise $I \geq$ an RPE of 13 (Somewhat Hard to Maximal Exertion on the Borg scale). **Results:** There was no significant change in mean VO_{2max} values in weeks 1 vs. 8 (p=0.062, 46.50 ± 3.68 vs. 45.87 ± 4.21 mL·kg⁻¹·min⁻¹). There was also no significant change in mean total training minutes (p=0.32, 601.8 ± 221.4 vs. 551.9 ± 194.2 min·wk⁻¹) or mean total MHIT minutes (p=0.38, 272.5 ± 193.3 vs. 334.5 ± 218.1 min·wk⁻¹) in weeks 1 vs. 8. **Conclusions:** On average, CRF was maintained during the 8 weeks of self-determined recreational training. In addition, we found that average total training min and MHIT min did not change for this group in weeks 1 vs. 8, even though these recreational endurance athletes intended to increase their training during this 8-week period.

1769   Board #30   May 31 2:00 PM - 3:30 PM

The Impact of Exercise on Stress Management in Federal Officers

Scott R. Richmond[1], Thomas S. Altena[2], Amanda M. Perkins-Ball[3], Riley Galloway[2], Sam D. Enright[2]. [1]*Lindenwood University, St. Charles, MO.* [2]*Missouri State University, Springfield, MO.* [3]*Rice University, Houston, TX.*
(No relevant relationships reported)

Many Federal Officers (FO) serve in a high-stress, yet highly sedentary position. This combination places FO at greater risk for a variety of health issues. **PURPOSE**: The purpose of this descriptive study was to examine the level of physical fitness in FO and determine the relationship between exercise (EX) on Quality of Life (QoL) scores. **METHODS**: A total of 19 FO participated in this study (10 males and 9 females; mean $\pm$ SD age = 39.1 ± 8.1y, height = 172.1 ± 8.6cm, weight = 75.9 ± 15.3kg, and BMI = 25.5 ± 3.8kg/m²). The Cooper's Test of physical fitness (1.5mile run, 1-min max push-ups, 1-min max sit-ups, and vertical jump) as well as a 150m shuttle run and max grip strength were performed before and after six-months of unsupervised, voluntary exercise. In addition, subjects completed weekly online surveys indicating EX type, weekly total EX time, feelings of well-being, and a 10-point questionnaire on weekly stress (QoL). **RESULTS**: Time reported performing cardiorespiratory and resistance training was slightly below ACSM recommendations (cardio = 129.5 ± 20.3 min/week, resistance = 81.0 ± 18.5 min/week). A paired-samples t-test showed no significant changes in any anthropometric scores after 6-months of unsupervised training. Baseline vs 6-month Cooper's Test fitness results showed no significant changes with the exception of performance on the Sit-&-Reach (pre = 34.5 ± 9.2cm, 6-month = 41.9 ± 8.8cm, p<0.05). There was little to no correlation between QoL scores and amount or type of EX (average r² = 0.03). During follow up interviews, some participants indicated they were less likely to respond to weekly surveys if they did not exercise that week. The average response rate ranged from 36% to 80%. **CONCLUSIONS**: While EX is an important element for overall health and well-being, in FO there was little connection between amount of type of EX and overall QoL.

Measured Fitness and Self-Reported Exercise and Stress in Law Enforcement Officers: A Longitudinal Study

Riley Galloway[1], Thomas S. Altena[1], Scott R. Richmond[2], Amanda M. Perkins-Ball[3], Zachary Burt[1]. [1]*Missouri State University, Springfield, MO.* [2]*Lindenwood University, St. Charles, MO.* [3]*Rice University, Houston, TX.*
(No relevant relationships reported)

The job duties of law enforcement officers (LEO) are highly sedentary and stressful. **PURPOSE**: The purpose of this year-long descriptive study was assess physical activity levels in LEO and to determine if self-reported stress indicators were related to exercise. **METHODS**: Twelve LEO completed a 12-month unsupervised exercise program (7 males and 5 females; age = 38.5 ± 7.6y, height = 171.4 ± 9.2cm, weight = 77.2 ± 16.4kg, body fat % = 25.7 ± 6.1, BMI = 26.0 ± 4.2kg/m²). Participants completed the Cooper's Test of physical fitness as well as a 150m shuttle run and max grip strength at baseline, at 6-months and again at 12-months. Participants also completed an online survey indicating EX type, weekly total EX time, feelings of well-being, and a 10-point questionnaire on weekly stress. **RESULTS**: Survey response rates ranged from 36% to 80% over the course of the study. Reported cardiorespiratory and resistance training exercise levels were slightly below ACSM recommendations (cardio = 145.0 ± 34.4 min/week, resistance = 58.4 ± 15.7 min/week). Time was significantly lowered (p=0.002) in the 1.5 mile run over a 12 month period. No significant changes were observed in body weight (p=0.149) or BMI (p=0.447); however, body fat percentage was significantly reduced by 2.61% (p=0.47). Total 12 month volume of exercise in LEO did not meet ACSM recommendations and was ineffective in changing self-reported stress (r=-0.037, p>0.05). In addition, some subjects indicated reduced weekly response rate because they did not exercise that week. **CONCLUSIONS**: The overall level of fitness among the tested sample of LEO was in the fair category. A 12-month, unsupervised training program of this particular volume was sufficient in maintaining fitness parameters but did not influence self-reported stress in this law enforcement population.

Association Between Anthropometric Characteristics And Aerobic Capacity In Firefighters

Crystal Hajek[1], Cassie Schillero[1], Jacquelyn Zera[1], Elizabeth Nagle, FACSM[2]. *[1]John Carroll University, University Heights, OH. [2]University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Elizabeth Nagle, FACSM)
(No relevant relationships reported)

Firefighting is a physically demanding profession with high requirements for aerobic capacity (VO_{2max}). However, this population has a high rate of obesity, consistent with the general population. Previous research in general populations has identified a relationship between VO_{2max} and anthropometrics, specifically the impact of body weight and lean body mass. Moreover, research suggests an association between increased percent body fat (%BF) and decreased aerobic and strength measures in similar tactical populations such as military. However, this relationship has not been thoroughly examined in firefighters. **PURPOSE:** To determine the association between anthropometric characteristics and VO_{2max} of firefighters. **METHODS:** Eighteen healthy firefighters (Age= 39.9 ± 11.0 years; Body Mass Index (BMI)= 28.0 ± 3.4kg/ m²; %BF= 27.1 ± 8.7%; Waist to Hip Ratio (WHR)= 0.88 ± 0.04; VO_{2max}= 41.2 ± 7.5ml/kg/min) completed measurements of anthropometry (height, weight, bioelectrical impedance analysis, waist and hip circumferences) and a treadmill graded exercise test (GXT) to determine VO_{2max} utilizing open circuit spirometry. Normality was assessed, and Pearson correlation and Spearman coefficients were used when appropriate to determine the associations between VO_{2max} and anthropometric characteristics (BMI, %BF, WHR). **RESULTS:** Data revealed a significant moderate correlation (r= -0.636; *p= 0.005*) between %BF and VO_{2max}, indicating that higher levels of body composition are related to lower VO_{2max}. No relationship was found between BMI and VO_{2max} (r= 0.05; *p= 0.845*), and the association between WHR and VO_{2max} approached significance (r=-0.462; *p=0.053*). **CONCLUSION:** Results of the current investigation suggest %BF may be associated with maximal aerobic capacity. Additionally, data revealed no significant relationship between BMI and VO_{2max}, suggesting that total body weight may not have a significant impact on aerobic capacity. Future research should continue to investigate the effects that maintaining an ideal body composition have on work performance and injury risk, including the negative effects of obesity on thermoregulation in job specific tasks for firefighters.

Validity of Hit & Turn Tennis Test in Estimating Aerobic Capacity with Amateur Players

Bo Li, Jianrong Zhong, Xinxin Wang, Xiaotian Li, Lu Jin, Yuchao Cao, Lv Miao, Yongming Li. *Shanghai University of Sport, Shanghai, China.*
(No relevant relationships reported)

Validity of Hit & Turn Tennis Test (H&TTT) in Estimating Aerobic Capacity with Amateur Players
The Hit & Turn Tennis Test (H&TTT) is an acoustically controlled on-court test designed for evaluating tennis-specific endurance. Performance levels achieved during this test has been proposed to estimate the peak oxygen uptake (VO_{2peak}), but the validity of the regression equations warrant further investigation.
Purpose: To evaluate the validity of H&TTT in estimating VO_{2peak}.
Methods: Sixteen collegiate tennis players (age: 22.2 ± 1.7 yrs; height: 175 ± 5 cm; mass: 69.2 ± 6.1 kg; tennis training experience: 2.3 ± 0.8 yrs) volunteered to perform H&TTT on an indoor synthetic field. A portable spirometric system (K4b², Cosmed, Italy) was utilized to measure the ventilatory activities to calculate VO_{2peak} during the test. VO_{2peak} was also estimated with a H&TTT regression equation (VO_{2peak}=[Level*2+30]ml/min/kg). Additionally, for the directly measured ventilator activities two smoothing methods (5 vs. 3 successive points) were utilized to process VO_2 data, and five different methods (the highest consecutive 5 points vs 5s vs 10s vs 15s) were utilized to calculate VO_{2peak}.
Result: The levels subjects achieved in H&TTT were 14.6 ± 3.4. The estimated VO_{2peak} were 59.3 ± 6.7ml/min/kg using the regression equation. The calculated VO_{2peak} using different smoothing methods and criterion ranged between 53.5 ± 5.1 and 57.7 ± 6.0 ml/min/kg. No significant correlation was found between estimated and calculated VO_{2peak} (r < 0.3, p > 0.05). Significant differences were found for calcualted VO_{2peak} using different smoothing methods and criterion (p<0.01).
Conclusion: Inconsistent with the literature, the validity of H&TTT in estimating VO_{2peak} was not supported by this study. Caution should be paid when this test is utilized. In addition, a fixed method of data processing is recommended when calculating VO_2 from direct measurements.

D-57   Free Communication/Poster - **Resistance Training**

Ambulation and Physical Function after Eccentric Resistance Training in Adults with Incomplete Spinal Cord Injury

Whitley J. Stone[1], Sandra L. Stevens[2], Dana K. Fuller[2], Jennifer L. Caputo[2]. *[1]University of Central Missouri, Warrensburg, MO. [2]Middle Tennessee State University, Murfreesboro, TN.* (Sponsor: Kevin Finn, FACSM)
(No relevant relationships reported)

Strengthening the lower extremities positively influences walking mechanics for people with a neurological deficit. Eccentric resistance training (ERT) is a potent stimulus for the development of muscular strength characterized by low metabolic demand. This mode of training may serve to benefit those with incomplete spinal cord injuries (iSCI) seeking to improve ambulatory capacity.
PURPOSE: Determine the effect of ERT on walking speed, mobility, independence, and at-home function in those with iSCI. A secondary goal was to evaluate the relationship of daily step activity to ambulation and physical function variables.
METHODS: Training intervention with pre-, mid-, post-assessments. Adults (N = 11) with longstanding (> 1 year) iSCI, with no concurrent musculoskeletal injuries or lower extremity strength training, trained twice a week for 12 weeks on a motor driven, eccentrically biased recumbent stepper. Walking speed (10 meter walk test; 10MWT), mobility (timed up and go; TUG), independence (Walking Index for Spinal Cord Injury; WISCI), and at home function (Spinal Cord Independence Measure; SCIM) were assessed at baseline, after 6 weeks, and after 12 weeks of ERT. **RESULTS:** There were improvements in walking mobility ($p = .034, d = 0.62$), speed ($p = .005, d = .23$), and independence ($p = .004, d = .73$) after 12 weeks of ERT. At home function was unchanged ($p = .10, d = .12$). The TUG and 10MWT were correlated with step activity at mid- and post-test whereas the WISCI was significantly related at mid-test. **CONCLUSION**: The ERT improved walking function in the absence of gait training. Training on an isokinetic ergometer to improve eccentric strength promoted independence and, may potentially improve exercise self-efficacy. Additionally, this mode of ERT may diminish therapist burden in programs designed to improve ambulatory capacity or strength in those with iSCI.

Preservation Of Explosive Force In Long-term Strength Trained Elders Is Determined By Neural Adaptations

Lucas B. R. Orssatto[1], Matheus J. Wiest[2], Bruno M. Moura[1], David F. Collins[3], Fernando Diefenthaeler[1]. *[1]Universidade Federal de Santa Catarina, Florianópolis, Brazil. [2]Toronto Rehabilitation Institute, Toronto, ON, Canada. [3]University of Alberta, Edmonton, AB, Canada.*
(No relevant relationships reported)

Preservation of explosive force in long-term strength trained elders is determined by neural adaptations
PURPOSE: To understand the effects of long-term strength training in the neural and contractile properties of explosive force in young adults and elders. **METHODS:** 54 healthy males were divided in four groups: untrained young control (YC - n=14; 26 ± 4 yrs), untrained elder control (EC - n=14; 66 ± 3 yrs), strength trained young (YT - n=14; 27 ± 3 yrs), and strength trained elder (ET - n=12; 64 ± 4 yrs). Knee extension isometric torque was recorded during: 1) maximum voluntary isometric contractions (MVIC; peak torque); 2) explosive voluntary contractions (rate of torque development – RTD at 0 -50 and -150 ms); and 3) supramaximally-evoked octets (8 pulses at 300 Hz; torque at 50 and 75 ms). Surface electromyography (sEMG; 0-50, 50-100 ms) of the quadriceps muscle was recorded during explosive contractions and was normalized to the MVIC sEMG root mean square (RMS) data. The skeletal muscle index (SMI) was estimated using DXA. One-way ANOVA (Tukey post hoc) was used to compare groups. **RESULTS:** Displayed in table 1.
Table 1. SMI, MVIC and octets torque, RTD and sEMG (mean ± SD).

Variables		EC	ET	YC	YT
SMI (kg/height²)		8.9 ± 1.0[A]	10.0 ± 1.3[B]	9.3 ± 0.9[AB]	11.5 ± 0.7[C]
MVIC peak torque (N·m)		212 ± 39[A]	245 ± 50[AB]	290 ± 55[B]	358 ± 67[C]
RTD (N·m·s⁻¹)	0-50 ms	981 ± 219[A]	1340 ± 252[B]	1396 ± 483[B]	1938 ± 493[C]
	0-150 ms	870 ± 182[A]	1125 ± 195[B]	1255 ± 291[B]	1545 ± 276[C]
Octets torque (N·m)	50 ms	52 ± 18[A]	62 ± 12[A]	77 ± 13[B]	95 ± 18[C]
	75 ms	72 ± 29[A]	85 ± 17[A]	112 ± 19[B]	136 ± 26[C]
sEMG (% RMS)	0-50 ms	39 ± 13[A]	83 ± 24[B]	35 ± 14[A]	72 ± 16[B]
	50-100 ms	95 ± 28[AB]	119 ± 25[C]	80 ± 25[B]	106 ± 18[AC]

Different letters within the same factors are significantly different (p < .05).
CONCLUSIONS: Strength training optimizes the RTD through different mechanisms. YT benefited from adaptations in the neural (increased activation capacity - sEMG) and intrinsic contractile (i.e. increased octet torque) properties of the neuromuscular system. ET showed higher RTD due to adaptations in the neural (sEMG: ET > EC and YC) but not in the intrinsic contractile (Octet torque: ET = EC) properties. YC showed greater intrinsic contractile capacity than ET; however, the lower magnitude of muscle activation during the explosive contractions limited YC RTD, resulting in similar performance compared to ET. Thus, long-term strength training preserves explosive force in elders mainly due to positive neural adaptations.

Suspended Weight Training During Squats: Does It Improve Balance More Than Traditional Squats?

Bryan K. Christensen[1], Samuel P. Thielen[2], Kyle J. Hackney[1], Jeremiah T. Moen[3]. [1]North Dakota State University, Fargo, ND. [2]Sanford Power Center, Fargo, ND. [3]Mayville State University, Mayville, ND.
(No relevant relationships reported)

Unstable surface training has been popular in physical rehabilitation settings for decades. A more recent training technique in strength and conditioning is to create instability by using a suspended weight during resistance training exercises. Suspend weights could create a greater challenge for the core and potentially improve balance. **PURPOSE:** To determine if a 6 week training program using suspended weights during squats will lead to improvements in balance. **METHODS:** As part of their 6 week off-season strength and conditioning program 38 collegiate baseball players were randomly assigned to one of two groups. A group that completed the squats in the traditional fashion and a group that completed the squats while weights were suspended below the barbell. The subjects were tested pre and post for balance using a four direction Star Excursion Balance Test (SEBT). The results for each subject were normalized to a percent of their individual leg length. Difference scores were calculated between the percent of leg length scores pre-test and post-test. An independent samples t-test was conducted between these difference scores. Finally, a paired samples pre and post t-test was conducted within groups to see if there were any significant improvements within each group. **RESULTS:** The mean percent change of both the control (2.13±4.42%) and treatment (0.60+6.37%) groups improved slightly from pre-test to post-post but there were no significant differences (t = 0.79, p= 0.44) between the two groups. The paired samples t-test were not significant for the traditional squat (pre mean = 99.80 ± 8.30%, post mean = 101.93 ± 7.11%, t = 1.92, p= 0.074) or the suspended loaded squat (pre mean = 99.70 ± 6.86%, post mean = 100.30 ± 7.94%, t = .375, p= 0.71), indicating that neither technique significantly improved balance. **CONCLUSION:** The results of this study indicate that completing traditional or suspended weight squats as part of an overall 6-week strength and conditioning program will not lead to significant improvements in balance in highly trained college athletes.

Male And Female Fatigue Responses To Heavier- And Lighter-load Lumbar Extension Resistance Training

James P. Fisher, James Steele, Charlotte Stuart. Southampton Solent University, Southampton, United Kingdom.
(No relevant relationships reported)

The literature has suggested higher endurance levels in females compared to males, allowing them to withstand fatigue for a longer period. Though these gender disparities are well supported research is specific to muscle groups, and disparity in fatigue between sexes are less significant when load of resistance increases. PURPOSE: To determine force and fatigue differences in the lumbar extensors between males and females following heavy- (HL) and light-load (LL) exercise conditions. METHODS: A sample of 17 recreationally active participants (9 males; 23.8 yrs, and 8 females;

21.3 yrs) were tested for maximal voluntary isometric torque (MViT) of the lumbar extensors before, and immediately following 3 conditions; dynamic lumbar extension exercise at 80% (HL) and 50% (LL) of MViT and a non-exercising control condition (CON). The three conditions were performed in a randomised order with no less than 72 hours between conditions. Fatigue comparisons between sex and condition were made using ANOVA with repeated measures. RESULTS: Analyses revealed a significant effect by condition for absolute change in strength ($p<0.001$), furthermore there was a significant interaction effect ($p<0.016$). Independent t-tests revealed differences in decrement in maximal force between males and females for heavy ($p=0.04$; males = -18.7%, females = -12.0%) and light-load ($p=0.005$; males = -29.3%, females = -25.9%).
CONCLUSION: Fatigue responses in the lumbar extensors differ based on exercise load and sex of participant. Women showed either a more immediate recovery, or a smaller decrement in maximal force production compared to males, following fatiguing exercise at both heavy- and light-loads. This lends practical support to previous research reporting a greater number of slow twitch muscle fibres in the lumbar musculature of females compared to males.

Effects of Vibration Resistance Training on Bone Mineral Density of Postmenopausal Females

Li Peng[1], weimo zhu, FACSM[2]. [1]College of Physical Education, South-West University, Chongqing, China. [2]University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: weimo Zhu, FACSM)
(No relevant relationships reported)

PURPOSE: To determine the effects of vibration resistance training on bone mineral density (BMD) of postmenopausal females, and to compare the results of different resistance trainings.
METHOD: Forty eight postmenopausal females (66.1±0.9 yrs) were randomized into two groups. One group participated in a conventional resistance training (CRT), and another completed a vibration resistance training (VCT) on lower limbs 40 min one day, 3 days a week for 24 weeks. BMD at spine, femur neck and greater trochanter were determined before and after trainings. Data were compared and analyzed using 2-way repeated measures ANOVA.
RESULTS: There was no obvious before-after change in BMD at spine (1.06±0.04 vs. 1.07±0.05 g/cm²; p > 0.05, ES=1.92, but a positive change at femur neck (0.82±0.05 vs.0.86±0.04 g/cm²; p<0.05, ES=26.50) and greater trochanter (0.73±0.03vs. 0.78±0.03 g/cm²; p<0.05, ES=17.52) of postmenopausal females in CRT group. BMD at spine (1.07±0.05 vs. 1.10±0.03 g/cm², p<0.05, ES=7.91), femur neck (0.83±0.04 vs. 0.93±0.03g/cm², p<0.05, ES=19.26) and greater trochanter (0.73±0.04 vs. 0.80±0.06 g/cm², p<0.05, ES=4.88) were elevated significantly in VRT group after training. BMD at each part was increased greater in CRT group than those in VRT group.
CONCLUSIONS: While CRT on lower limbs was more effective in improving BMD of the femur region in postmenopausal females, VRT showed a more significant improvement at both spine and femur regions. Therefore, VRT may be a more effective intervention for promoting core strength and balance ability, as a result for reducing fall frequency of postmenopausal females. The effectiveness of a combined CRT and VRT should be examined.

1778   Board #39   May 31 2:00 PM - 3:30 PM

Impact of a Restricted Breathing Mask on Proteolytic Activity Post Resistance Training

Thomas Andre[1], Joshua Gann[2], Emily Ziperman[3], Paul Hwang[3], Darryn Willoughby, FACSM[3]. [1]Clayton State University, Morrow, GA. [2]Louisiana Monroe University, Monroe, LA. [3]Baylor University, Waco, TX.
(No relevant relationships reported)

Circulating glucocorticoids are elevated during stressful situations and act as an inhibitor of protein synthesis through varied mechanisms. Evidence suggests the stimulation of glucocorticoids on muscle proteolysis also occurs with activation

of the UPS, the lysomal system (autophagy), and the calcium-dependent calpain system. **PURPOSE:** To define the impact a restricted breathing mask (RBM) has on serum cortisol and proteolytic genes during resistance exercise. **METHODS:** In a counterbalanced cross-over design, ten resistance trained male participants (20.3 ± 1.3 years) performed two separate testing sessions, RBM and No Mask, consisting of squat, leg press, and leg extension. Muscle samples were obtained at baseline, 3hr, 6hr, and 24hr post-exercise. Blood samples were obtained at baseline, 30min, 3hr, 6hr, and 24hr post-exercise. From each muscle sample, glucocorticoid receptor-DNA (GR-DNA) binding and mRNA expression of Atrogin-1, Foxo1, MuRF1, MAFbx, Myostatin, and REDD1 were determined. Two-way repeated-measures analyses of variance (ANOVA) were performed with condition and time as main effects ($p \leq 0.05$). **RESULTS:** No significant interactions between session and time for Atrogin-1, Foxo1, MuRF1, MAFbx, Myostatin, and REDD1. There was no main effect for session for serum cortisol. There was a significant interaction between session and time for GR-DNA binding. For the RBM session, compared to baseline GR-DNA binding was significantly elevated at 3-hr ($p = .007$), 6-hr ($p > .001$), and 24-hr ($p = .002$) post-exercise. **CONCLUSION:** The use of a RBM failed to affect serum cortisol or alter the mRNA expression of proteolytic genes. However, there was an increase in delta change GR-DNA binding during the RBM compared to the no mask session.

Comparative Responses To Squats Done With Free Weights And An Exoskeleton.

Lily J. Vargas, Matthew K. Daunis, Tyler Bayers, Ling Bai, Thorburn B. Symons, John Caruso. *University of Louisville, Louisville, KY.*
(No relevant relationships reported)

PURPOSE: To compare physiological, performance and perceptual responses to the squat exercise done with a barbell, to those using an exoskeleton (Institute of Human and Machine Cognition; Pensacola FL) designed for use during manned space flight. **METHODS**:Subjects (n = 15) made four laboratory visits, which began with two familiarization sessions on the exoskeleton, followed by two squat workouts in which the exercise mode (exoskeleton, barbell) was administered in a randomized sequence. Per workout they performed four repetitions each against progressively heavier (23, 34, 45.5 and 57 kg) loads separated by 90-second rests. A series of physiological, performance and perceptual data from the final two laboratory visits were collected before, during and after workouts. Per workout, we collected the same dependent variables. Z-scores were used to identify outliers, which along with its paired value from the other workout, were eliminated from further analyses. To assess data validity, dependent physiological, performance and perceptual variables from each workout were compared with paired t-tests and Cohen's d. **RESULTS**: All subjects completed each workout (100% compliance). Z-scores results show less than 0.5% of our total data were deemed outliers. Average t-test and Cohen's d values were 0.68 and 0.25 respectively. **CONCLUSIONS**: Prior research suggests t-test and Cohen's d values less than 1.0 and 0.4 respectively denote acceptable degrees of data similarity. Based upon these guidelines, current results denote an acceptable degree of data validity derived from exoskeleton squats. We conclude exoskeleton squats yield physiological, performance and perceptual responses like those done with a barbell, and warrant continued inquiry involving microgravity simulation in human subjects.

1780   Board #41   May 31 2:00 PM - 3:30 PM

A Comparison Between Bench Press and Overhead Press Concentric Velocity and Power

Christopher A. Fahs[1], Julia C. Blumkaitis[1], Lindy M. Rossow[1], Chad M. Kerksick, FACSM[2]. *[1]Lindenwood University Belleville, Belleville, IL. [2]Lindenwood University, St. Charles, MO.*
(No relevant relationships reported)

Measuring average concentric velocity (ACV) during barbell exercises can be used for autoregulation of training loads; however, research is needed to clarify the load-velocity relationship for different barbell exercises. Training age, frequency, relative strength and limb length may influence the ACV on an individual basis. PURPOSE: To compare the ACV of the bench press and press over a spectrum of relative loads and to determine the influence of training age, frequency, relative strength, and limb length on ACV for the bench press (BP) and overhead press (OHP). METHODS: BP and OHP one-repetition maximum (1RM) was assessed in fifty-one individuals (33 males, 18 females). Height, body mass, and humerus length were measured while training age and frequency were obtained via questionnaire. ACV was measured during warm-up sets and 1RM attempts using a TENDO Power and Speed Analyzer. Relative 1RM was calculated as the 1RM divided by body mass. Average power (AP) was calculated as the load (kg) multiplied by 9.81 m/s2 multiplied by the ACV. Paired samples t-tests were used to determine differences in ACV and AP between the BP and OHP at loads 35-100% 1RM. Pearson's product moment correlations were used to determine relationships between variables. RESULTS: ACV values were significantly ($p<0.05$) greater for the OHP compared to the BP at all submaximal loads (35-95% 1RM) as well as the 1RM (0.24 ± 0.09 vs. 0.18 ± 0.07 m/s; $p<0.01$). AP values were significantly

greater ($p<0.05$) for the BP compared to the OHP at loads ≤85% 1RM but similar at 95% 1RM (228 ± 113 vs. 219 ± 118 watts; $p=0.405$) and the 1RM (156 ± 81 vs. 146 ± 78 watts/kg; $p=0.371$). Neither BP nor OHP 1RM ACV were significantly ($p>0.05$) related to humerus length, training age, or training frequency. Only BP 1RM AVC was significantly related to relative strength ($r=-0.399$; $p=0.003$). CONCLUSIONS: These data suggest velocity ranges used for prescribing training loads should not be used interchangeably for the BP and OHP; OHP velocity ranges should be greater than BP velocity ranges for the same relative loading. Velocity ranges for the BP may need to be reduced as a trainee's relative strength increases.

1781   Board #42   May 31 2:00 PM - 3:30 PM

A Comparision Between Squat And Deadlift Concentric Velocity And Power

Lindy M. Rossow[1], Abigail Boushard[1], Kathryn Blomenkamp[1], Julia C. Blumkaitis[1], Christopher A. Fahs[1], Chad M. Kerksick, FACSM[2]. *[1]Lindenwood University - Belleville, Belleville, IL. [2]Lindenwood University, St. Charles, MO.*
(No relevant relationships reported)

The average concentric velocity (ACV) of barbell exercises can be used to adjust training loads (autoregulation). The velocity ranges used for autoregulation can vary and research is needed to clarify the load-velocity relationship for each exercise. Anthropometric factors and training history may also affect the load-velocity relationship. **PURPOSE**: To compare the ACV of the squat and deadlift over a spectrum of relative loads and to determine the influence of training age, training frequency, limb length, and relative strength on ACV for the squat and deadlift. **METHODS**: One-repetition maximum (1RM) for the squat and deadlift was assessed in fifty-one individuals (33 males, 18 females). Height, body mass, and femur length were measured while training age and frequency were obtained via questionnaire. ACV was measured during warm-up sets and 1RM attempts using a TENDO Power and Speed Analyzer. Relative 1RM was calculated as the 1RM divided by body mass. Average power (AP) was calculated as the load (kg) multiplied by 9.81 m/s^2 multiplied by the ACV. Paired samples t-tests were used to determine differences between the squat and deadlift. Pearson's product moment correlations were used to determine relationships between variables. **RESULTS**: ACV values were significantly ($p<0.05$) greater for the squat compared to the deadlift at loads ≥55% 1RM including the 1RM (0.26 ± 0.08 vs. 0.22 ± 0.10 m/s; $p=0.004$). AP values were significantly greater ($p<0.05$) for the deadlift compared to the squat at loads ≤55% 1RM but similar at loads ≥65% 1RM including the 1RM (321 ± 134 vs. 317 ± 141 watts/kg; $p=0.844$). Squat 1RM AVC was significantly related to relative strength ($r=-0.297$; $p=0.033$). Deadlift 1RM AVC was significantly related to relative strength ($r=-0.308$; $p=0.028$) and training frequency ($r=-0.489$; $p<0.001$). **CONCLUSION**: These data suggest velocity ranges used for autoregulating training loads should not be used interchangeably for the squat and deadlift; Deadlift velocity ranges should be lower than squat velocity ranges for the same relative loading. Velocity ranges for both exercises may need to be reduced as a trainee's relative strength increases.

Unilateral Strength Training Changes Direction Of Strength Asymmetry But Not Magnitude In Healthy Individuals

Joshua C. Carr[1], Xin Ye[2], Nathan Wages[3], Michael Bemben, FACSM[1]. *[1]The University of Oklahoma, Norman, OK. [2]University of Mississippi, University, MS. [3]Ohio University, Athens, OH.* (Sponsor: Dr. Michael G. Bemben, FACSM)
(No relevant relationships reported)

Unilateral strength training is now recognized as an effective exercise intervention that can attenuate strength asymmetries in clinical conditions (i.e., fracture, neurological damage). The magnitude and direction of muscle strength asymmetry following unilateral strength training may provide insight regarding the adaptability of the central nervous system and further guide rehabilitation programs. **PURPOSE**: To determine the influence of unilateral isometric strength training of the non-dominant elbow flexors on strength asymmetry between limbs. **METHODS**: Ten volunteers (8 male, 2 left hand dominant) completed twelve training visits of the non-dominant elbow flexors across four weeks. The training protocol required the subjects to complete five sets of five, five-second isometric contractions at 80% of their MVIC force. Strength asymmetry of the dominant and non-dominant limbs were determined at baseline and following the training intervention with the equation: (dominant arm - non dominant arm)/stronger arm x 100. The resulting score reflects the magnitude of strength asymmetry and its direction (i.e., negative values favor the non-dominant limb). A paired samples t-test was used to compare the mean strength asymmetry scores before and after the training intervention. **RESULTS**: There was a significant ($P = 0.031$) mean difference in the direction of strength asymmetry post-training (mean ± SD: $-2.21 \pm 5.83\%$, range: $-9.8 - 4.5\%$) compared to baseline (mean ± SD: $2.12 \pm 5.34\%$, range: $-5.9 - 9.7\%$). However, the magnitude of asymmetry was unchanged ($P = 0.875$). **CONCLUSIONS**: The mean strength asymmetries were relatively small

before and after training. Nevertheless, the mean strength asymmetry shifted from the dominant limb at baseline to the trained, non-dominant limb following the training intervention. However, the individual responses were highly variable, as the magnitude of strength asymmetry decreased (40%), increased, (40%), or was relatively unchanged (20%). Collectively, these data show that unilateral non-dominant limb training reversed the direction of muscle strength asymmetry yet maintained its magnitude.

An Examination of Performance and Cognitive Outcomes following Lower-Body Resistance Training in Males

Hayden Gerhart, Mitchell Moyer, Amy Fiorentini, Ruby Pressl, Mark Sloniger, FACSM, Pao Ying Hsiao, Madeline Bayles. *Indiana University of Pennsylvania, Indiana, PA.*

(No relevant relationships reported)

PURPOSE: The purpose of the present study was to investigate physiological and cognitive changes following a 6-week lower-body resistance training protocol. **METHODS:** Eight healthy men volunteered to participate in a 6-week resistance training protocol using the back squat (BS) and conventional deadlift (DL). Each participant went through a 1-week pre-testing period consisting of anthropometric measurements, vertical jump performance, 1-repetition maximum (1RM) testing of BS and DL, maximal aerobic capacity (VO_2max), cognitive performance, and total mood disturbance (TMD). Participants were then randomly placed into one of two experimental groups. The two groups were 90-seconds (90s) rest between sets (n= 5) and 3-minutes (3m) rest between sets (n= 3). Each group came into the lab for testing sessions twice per week, separated by at least forty-eight hours. In each session, the participants performed 3 sets of 5 repetitions using eighty-five percent of the previously determined 1RM for DL and BS. **RESULTS:** Analysis of variance (ANOVA) revealed a main effect of time for BS ($p = 0.026$), and main effect of group for vertical jump ($p = 0.041$). The 3m group increased BS performance ($p = 0.020$), while the 90s group improved vertical jump ($p = 0.031$). Group by time interactions were observed for two measures of cognitive performance: Interference score ($p = 0.048$) and Word-Color score ($p = 0.050$). Additionally, a group by time interaction was also observed for TMD ($p = 0.004$). Despite the trending increase of executive function in the 3m group, a worsened TMD score post-intervention was observed ($p = 0.008$). **CONCLUSION:** Minimal rest improved power within the 90s group while the 3m group significantly improved lower body strength. Cognitive function only appeared to improve in the 3m group. Despite no increase in strength for the 90s group, it appears minimal rest is advantageous for athletes looking to enhance power performance, although further research is necessary.

The "Unregulated" World Of Strength And Conditioning: Are CSCCa Coaches The Most Effective?

Forrest Scott, Jordynne Ales, Andreas Stamatis. *SUNY Plattsburgh, Plattsburgh, NY.* (Sponsor: Peter W. Grandjean, FACSM)

(No relevant relationships reported)

When designing training protocols, safety and effectiveness are the ultimate goals, with safety being a prerequisite of effectiveness (a protocol cannot be effective if not safe first). However, in January 2017, three Pacific-12 Conference football athletes were hospitalized with rhabdomyolysis. The affected players were supervised by a strength and conditioning coach (SCC), certified by the U.S. Track and Field and Cross Country Coaches Association (USTFCCCA). The National Collegiate Athletic Association (NCAA) only requires a nationally-accredited strength and conditioning certification program and USTFCCCA is one of them. This revived the debate about the effectiveness of several SCC certifications. Among them, the Collegiate Strength and Conditioning Coaches association (CSCCa), the only SCC certifying organization that includes a two-part practical in their exam, claim they are the only ones devoted to meeting the unique needs of the collegiate SCC. We used 2016-17 NCAA DI-III championship data to determine coaching effectiveness.**Purpose**: To investigate retrospectively the relationship between NCAA national championship data and CSCCa-certified SCCs.**Methods**: Championship data was retrieved from NCAA archives. All SCCs, who won national championships in any sport within the past year/season, were recruited via email/phone in order to acquire information regarding certification. The response rate was 60%. We identified the number of CSCCa-certified coaches who worked in 2016-17 for NCAA programs that (a) did not win a championship and (b) won a championship. Using z-score for proportion (one-tailed hypothesis, significance level at 0.05), we tested for statistical significance. **Results**: Last season/year, CSCCa-certified coaches worked for 2.7% of NCAA non-championship teams and for 15.5% of championship teams. The z-score is 5.9979. The p-value is 0.0001. The result is significant at p<0.05.**Conclusion**: The SCC credential is essential for most NCAA teams. The regulation of the strength and conditioning

world is crucial to prevent future incidents of unsafe and therefore, ineffective exercise prescription. Without accounting for other factors, the process of obtaining a CSCCa certification could be a potential solution to increase the effectiveness of SCCs.

The Effects Of An Acute Bout Of Resistance Training On College-aged Male 24hr Rmr

Connor Saker, Chad Witmer, Shala Davis, FACSM, Gavin Moir. *East Stroudsburg University of Pennsylvania, East Stroudsburg, PA.* (Sponsor: Dr. Shala Davis, FACSM)

(No relevant relationships reported)

It has been demonstrated that increasing caloric expenditure through exercise participation is one mechanism by which to modify caloric balance in favor of weight loss. While chronic resistance training (RT) has been demonstrated to elevate resting metabolic rate (RMR) due to increased lean mass, there has been less research on the acute effects of a single bout of resistance training on RMR. **PURPOSE:** To determine the effects of an acute bout of resistance training on the 24 h RMR of college-aged males. **METHODS:** Ten healthy men aged 18-24yr performed 8 exercises (2 sets, 10 repetitions, 2 min recovery, 70% 1RM & 8RM) following ACSM Guidelines for RT. Subjects reported for testing following a 12 h fast and engaged in 7, 30 min RMR measurements over the next 24 h. Subjects completed both an experimental (RT) and control (no exercise) day separated by 1 week. **RESULTS:** RMR (kcal) data was analyzed using a 1 way ANOVA with repeated measures on 2 factors (group and time). Statistical analysis revealed that there was no significant main effect for group (2179.58 ± 44.82 kcal vs. 2143.16 ± 44.82 kcal; F = .330, p = .567) or group x time interaction (F =.592, p =.736, Table 1). There was a significant main effect for time (F = 5.126, p < .001, Table 2). **CONCLUSION**: We conclude that an acute bout of RT, following ACSM guidelines, did not significantly impact RMR in RT males 24 hrs post-exercise.

Table 1.
Mean 24-hour RMR Values by Group

Cluster Sets Attenuate Power Loss at Higher Intensities During the Back Squat Exercise

Will Jennings[1], Jason D. Stone[1], John D. Mata[1], J. Craig Garrison[2], Shiho Goto[2], Margaret T. Jones, FACSM[3], Andrew Jagim[4], Adam King[1], Jonathan M. Oliver[1]. *[1]Texas Christian University, Fort Worth, TX. [2]Texas Health Sports Medicine, Fort Worth, TX. [3]George Mason University, Fairfax, VA. [4]Lindenwood University, St. Charles, MO.* (Sponsor: Margaret Jones, FACSM)

(No relevant relationships reported)

Cluster sets (CLU), a training method in which a brief rest is inserted between a group of repetitions, attenuates the loss in power typically observed in traditional set (TRD) configurations during resistance training. Training studies report greater gains in strength and power when using CLU at lower intensities. However, few data exist on the kinetics and kinematics of CLU at higher intensities (>80%). **PURPOSE**: To compare the kinetics and kinematics during TRD and CLU at a high intensity. **METHODS**: Eight resistance trained men (23.9±3.3y; 177.2±7.9cm; 82.7±11.0kg; 11.9±3.5% body fat) had body composition and one-repetition maximum (1RM) back squat assessed. After at least 48 hours, in a randomized crossover, participants completed 4 sets 6 repetitions (TRD) with 180 seconds inter-set rest or 4 sets 2 clusters

of 3 (4 x [2 x 3]) (CLU) with 30 seconds intra-set rest and150 seconds inter-set rest, both configurations at 80% 1RM separated by 72 hours. Data were collected using a bilateral force plate and motion capture system, and smoothed using a 4th order Butterworth filter (12 Hz cutoff). Data were analyzed by a repeated measures ANOVA (p ≤ 0.05). **RESULTS**: A significant CONDITION x SET (p = 0.038) interaction was observed, with lower power outputs during TRD for SET 2 (p = 0.008), 3 (p = 0.019) and 4 (p = 0.002) compared to SET 1. Only SET 4 was significantly lower than SET 1 (p = 0.006) in CLU. A significant CONDITION x REP interaction (p < 0.001) was also observed. Compared to REP 1, significantly lower power outputs were observed for every subsequent repetition during TRD. In contrast, reduced power output was not observed until later in the set when performing CLU. The greater mean power was attributed to velocity, as no main effect or interactions were observed for mean force (p ≤ 0.05). A CONDITION x SET interaction approached significance (p = 0.069) for velocity, while the CONDITION x REP interaction effect was significant (p < 0.001), mirroring the pattern observed in mean power. **CONCLUSION:** These data demonstrate that the greater power observed during resistance exercise at lower intensities is also observed at higher intensities, and is attributed to higher velocities. Long-term training studies at higher intensities are warranted to determine the adaptations resulting from consistent CLU training.

Hypertrophic Responses Do Not Completely Explain Increases in Strength After 12 Weeks of Resistance Training in Previously Untrained Young Men

Christopher G. Vann, Cody T. Haun, C. Brooks Mobley, Matthew A. Romero, Paul A. Roberson, Petey W. Mumford, Wesley C. Kephart, Shelby O. Osburn, Michael D. Roberts. *Auburn University, Auburn, AL.*
(No relevant relationships reported)

Purpose: It has been suggested that resistance training-induced increases in lean mass are related to increases in strength metrics. We aimed to examine if increased lean mass was related to increased strength in untrained young men after 12 weeks of resistance training. **Methods:** 72 young male subjects performed 12 weeks of supervised resistance training (RT). Ultrasound, dual x-ray absorptiometry (DXA), 3 repetition maximum (RM), isometric mid-thigh pull (IMTP), and isokinetic dynamometry testing were performed before and after the intervention. Training was completed 3 days weekly and consisted of squat, bench press, trap bar deadlift, and barbell rows within an undulated program design. **Results:** While DXA lean mass increased by 4.7%, squat 3RM increased by 48.2% and IMTP increased by 11.7%, on average. Changes in lean mass and 3RM squat were moderately correlated (r^2=0.102, p=0.005) while changes in lean mass and IMTP were not significantly associated (r^2= 0.04, p=0.08). **Conclusion:** While studies have reported that increases in lean mass in trained individuals are seemingly related to increases in strength, we report herein that increases in lean mass do not seem to sufficiently explain changes in strength in previously untrained young men. Effect of Nine Months of Resistance Exercise on Glycemic Levels and Macrosomia in Pregnant Women

Bruna A. Zandoná[1], Luis H. Boiko Ferreira[1], André C. Smolarek[1], Luis P. G. Mascarenhas[2], Samuel C. Perin[1], Alan C. Utter, FACSM[3], Steven R. McAnulty[4], Brad J. Schoenfeld[5], Tácito P. Souza-Junior[1]. *[1]Universidade Federal do Paraná, Curitiba, Brazil. [2]Universidade Estadual do Centro-Oeste, Irati, Brazil. [3]Texas Woman's University, Denton, TX. [4]Appalachian State University, Boone, NC. [5]CUNY Lehman College, Bronx, NY.* (Sponsor: Alan C. Utter, FACSM)
(No relevant relationships reported)

Resistance training is considered a beneficial strategy to reduce the impact of high glycemic levels in patients with diabetes mellitus (DM). Gestational diabetes mellitus (GDM) is considered one of the most common pathologies during pregnancy, affecting pregnant women and their children both during the pregnancy and after birth. High glycemic index and type 2 diabetes (DM2) are also associated with macrosomia during and after pregnancy. **PURPOSE**: Analyze the chronic effect of 9 months of resistance training on glycemic levels and macrosomia incidence in 54 pregnant women. **METHODS**: Fifty-four pregnant women without any complications related to DM and who were completely inactive before the study were recruited. Participants were randomized into two groups: a control group (CG) who remained inactive during the 9 months of pregnancy or an intervention group (IG) who performed resistance training (60% of 1 RM x 3 times per week). Training was progressively increased every two weeks to sustain the intensity of training. Glucose levels were analyzed before and after the training protocols and two months after pregnancy. The APGAR score was used to determinate the health of the newborn and the incidence of macrosomia. The weight gained during the pregnancy was used to compare CG to IG. **RESULTS**: A

significant difference between CG and IG was observed on glycemic levels during the last 3 months of intervention (122 ± 8.5 to 105 ± 7.2 mg/dl p=0.012). Weight gain was significantly lower in IG compared to CG (21% less, p<0.05). Fetal macrosomia incidence was significantly lower in IG compared to CG (4.32 ± 1.2 to 13.19 ± 3.9 p=0.001). **CONCLUSION**: Regular resistance exercise appears to be a good strategy to avoid GDM, eliciting positive outcomes during the pregnancy and afterwards. The reduction of glycemic levels were significantly correlated in reducing the risks related to macrosomia.

One Set to Failure per week Increases Strength More Effectively than Traditional Resistance Training

P. Gage Murphy, Danny Dominguez, Murat Karabulut. *University of Texas at Rio Grande Valley, Brownsville, TX.*
(No relevant relationships reported)

PURPOSE: To determine the efficacy of the current recommendations for increasing strength compared to other, less time consuming programs in untrained sedentary and recreationally active females. **METHODS:** Forty-six female subjects (age = 22.7±4.1 yrs) were randomly assigned to one of four groups that determined the resistance training program they would follow for 6 weeks. All resistance training programs utilized the same two exercises on the same equipment: leg extension and leg curl. The four training groups included: a traditional group (HIGH), two blood flow restriction (BFR) groups (BFR-1 and BFR-2), and a minimalist group (MIN). HIGH group followed ACSM guidelines for increasing strength, which was comprised of 3 sets of 10 repetitions 3x/wk at 50% of 1RM. BFR-1 program consisted of 4 sets of 30, 15, 15, 15 reps 1x/wk at 20% of 1RM. BFR-2 program consisted of 4 sets of 30, 15, 15, 15 reps 2x/wk at 20% of 1RM. MIN program consisted of 1 set to failure 1x/wk at 75% of 1RM. Weight was added each week if subject completed the previous weeks program with proper form. Prior to and following 6 week training period subjects were tested for 1RM strength on leg extension and leg curl exercises. All subjects were at least 8 hours fasted as well as hydrated (determined using clinical urine refractometer) for pre- and post-testing. **RESULTS:** One-way ANOVA found no between-group differences in any of the outcome measures of interest at baseline. Repeated measures ANOVA found a significant time main effect for 1RM (p < 0.01) with all groups improving in strength for leg extension and leg curl. There was also a significant condition difference (p < 0.01) for the MIN group in the 1RM for the leg extension, representing that increases in leg extension 1RM by MIN group was significantly greater than all other conditions. **CONCLUSION:** All training programs were effective at increasing 1RM strength for the leg extension and leg curl. Strength increases by the MIN group for the leg extension were significantly greater than all other groups. These results indicate that a less frequent, more time efficient program is more effective than the current recommendations for increasing strength and it may be an alternative training approach for those who want to minimize the time spent for training but still maximize benefits.

Using Velocity Loss for Monitoring Resistance Training Effort in a Real World Setting

Paulo Gentil[1], Martim Bottaro[2], Vítor A. Marques[1], Josaphat P. P. Neto[1], Anna C. G. Santos[1], James Steele[3], James Fisher[3], Antonio Paoli[4], Pablo Prudente[1]. *[1]Universidade Federal de Goias, Goiania, Brazil. [2]Universidade de Brasília, Brasilia, Brazil. [3]Southampton Solent University, Southampton, United Kingdom. [4]University of Padova, Padova, Italy.*
(No relevant relationships reported)

Previous studies demonstrated the importance of analyzing movement propulsive velocity (MPV) loss during resistance training as an estimate of intensity of effort. However, these studies involved sets performed with maximal intended velocity and used special devices, which is not usual for most people practicing resistance training**PURPOSE**: The purpose of the present study is to evaluate the changes in MPV during resistance training with different loads while the trainees are attempting to move the load at a pre-determined repetition duration. **METHODS**: Twenty-one resistance-trained men (age: 25.7 ± 5 years; height: 177.0 ± 7.2 cm; mass: 85.4 ± 13.56 kg) participated in the study. Participants performed two tests sessions. The first to determine 1 repetition maximum (1RM) load, and the second to evaluate MPV loss during a set to momentary muscle failure (MF) performed at 75% and 50% of 1RM using a 2 second concentric and 2 second eccentric repetition duration controlled by a mobile app metronome. **RESULTS**: Mean one-repetition maximum 1RM load was 98±21.6 Kg, with a relative strength of 1.15±0.2, obtained by ratio of the load of 1RM relative to body mass. The average number of repetitions performed at 75% of 1RM was 7.5±1.7 and 13.7±2,8 for 50% of 1RM. With 75% of 1RM there was a significant difference among repetitions MPV. Post hoc analysis revealed that MPV in the last repetition was lower than in the preceding three. Similarly, MPV during the penultimate repetition was lower than during the antepenultimate and the 4th from last. However, there was no difference in MPV between the 4th last and the antepenultimate repetition. Velocity loss from

the antepenultimate to the penultimate repetition was 5.33%, from the last to the penultimate was 22.11% and the accumulated loss from the last to the 4th last was 25.4%. ANOVA for MPV values obtained at 50% 1RM load showed no significant effects, which suggested the same predetermined velocity pattern was maintained until reaching MF
CONCLUSIONS: Acessing MPV loss during resistance training using simple methods can be an important tool for standardize the intensity of effort employed during submaximal training with high loads, but not with light loads. This can be specially useful in clinical conditions where maximum exertions are contraindicated.

Comparison of Different Eccentric Phase Tempo of Knee Extension Resistance Exercise on Hypertrophy Response

Joao P. Botero[1], Mateus Guidugli Oliveira[1], Brad Schoenfeld[2], Paulo Henrique Silva Marques de Azevedo[1]. *[1]Federal University of São paulo, Santos, Brazil. [2]City University of New York City, New York, NY.*
(No relevant relationships reported)

Regarding resistance training objectives, muscle hypertrophy and strength are primary goals. The movement velocity appears to be important to improve muscle mass and strength. Eccentric exercises have been attributed to greater gains in muscle cross-sectional area, mainly because of a greater time under tension, inducing more stress to muscle fibers and greater adaptation. Therefore, manipulation of the eccentric phase tempo may have different implications to results in resistance training.**PURPOSE**: Evaluate the effects of two different velocities of eccentric phase in isotonic contractions on muscle hypertrophy and strength of the quadriceps femoris in healthy adults.
METHODS: Ten healthy adults underwent in a training program consisting of knee extensions unilaterally, where each leg was allocated in a different pattern of movement. These consisted of two groups Isotonic contractions of one second in concentric phase, 0 seconds in a transition phase and 2 seconds in eccentric phase (G2S); Isotonic contractions of 1 second in concentric phase, 0 seconds in a transition phase and 4 seconds in eccentric phase (G4S). Each protocol consisted of 5 series of exercise until volitional failure, with 70% of 1 maximal repetition and 3 minutes of rest between series, 2 times a week. **RESULTS**: We observed muscle hypertrophy response over time for all muscles (Rectus Femoris (RF), $P = 0.00$; Vastus Lateralis (VL), $P = 0.00$ and Vastus Medialis (VM), $P = 0.00$; the difference between treatments was observed only for VM ($P = 0.022$). The effect size was: RF, 0.78 and 0.82; VL, 1.05 and 0.8; VM, 0.59 and 1.08; for G2S and G4S, respectively. Both groups improved strength over time ($P = 0.00$), with the effect size for G2S of 0.63 and G4S 0.55, with Hedge's g approach; however, there was no difference ($P < 0.05$) between treatments. Time Under Tension (TUT) was different between groups (G2S=1300.6±356 and G4S=2535.6±654).
CONCLUSIONS: Our results suggest that the different eccentric phase tempo is not able to produce differences in strength and muscle hypertrophy for knee extensors, except for the Vastus Medialis, although the time under tension was greater in G4S.

Impact of Explanations onStrength Exercises and Daily Movements

Julia C. Blumkaitis, Christian Espitia Betancourth, Christopher A. Fahs. *Lindenwood University Belleville, Belleville, IL.*
(Sponsor: Chad Kerksick, FACSM)
(No relevant relationships reported)

Research is needed to clarify if an explanation or technique descriptions may have an impact on biomechanics of individuals, especially in major strength exercises and daily movements such as squat (SQ), sit-stand up (SS), overhead dumbbell press (DBP), and overhead barbell press (OHP). **PURPOSE:** To determine if peak velocity and peak acceleration of SQ, SS, DB, and OHP are influenced by written descriptions and explanations. **METHODS:** Twenty-one subjects (14 males, 7 females) attended two visits with 48-72h separation. At each visit they performed four different exercises (SQ, SS, DBP, OHP) in the same order and with the same resistance during which movement was recorded with the Iron Path Pro Application Version 2.2. Additionally, the app recorded velocity, acceleration, bar distance, and force. At the second visit subjects were randomized to either receive a description on correct SQ and OHP technique or not. Height, body mass, humerus and femur length were measured and resistance training experience and frequency were reported via survey. Two-way mixed ANOVA with repeated measures was used to determine differences between the first and second visit (time) and explanation and non-explanation (condition). **RESULTS:** The subjects had the following descriptive statistics: age of 21.4±1.6 yrs, body mass of 79.38±23.71 kg, height of 1.77±0.10 m, femur length 0.45±0.05 m, humerus length 0.35±0.05 m, lifting experience of 4.68±3.45 yrs, and lifting session 2.6±1.63 days per week. No significant (p>0.05) condition, time, or condition x time effects were found for either peak velocity or peak acceleration for the SS, SQ, DBP, and OHP.

CONCLUSION: These data show that neither repeated trials (time) or condition had a significant impact on peak velocity and peak acceleration in SS, SQ, DBP, or OHP in this sample of young, resistance trained subjects.

The Effect of Dietary Nitrates on Exercise Capacity in Chronic Kidney Disease

Meghan G. Ramick[1], Danielle L. Kirkman[2], Joseph M. Stock[2], Bryce J. Muth[2], David G. Edwards[2]. *[1]West Chester University, West Chester, PA. [2]University of Delaware, Newark, DE.*
(No relevant relationships reported)

PURPOSE The purpose of this study was to test the hypothesis that an acute dose of 12.6mmol dietary nitrate in the form of concentrated beetroot juice (BRJ) would improve exercise capacity and skeletal muscle mitochondria function in adults with moderate to severe chronic kidney disease (CKD). **METHODS** 12 individuals with moderate to severe CKD participated in this study (61±4 yrs; 9 males; eGFR 47.8ml•min^{-1}•1.73m^2). Participants reported to the laboratory and a baseline blood sample was obtained for determination of NO metabolites (NOm; Nitrate, nitrite, s-nitrosothiols and metal bound NO). Participants were then randomized to ingest 12.6mmol of BRJ or a nitrate depleted placebo (PLA). Exercise testing began 2.5 hours post beverage ingestion to coincide with peak plasma nitrite levels. Skeletal muscle mitochondrial oxidative function testing was performed using near infrared spectroscopy (NIRS) followed by a symptom limited graded exercise test (GXT) on a cycle ergometer for determination of peak oxygen consumption (VO$_2$ peak). Participants repeated the entire protocol in the other condition a minimum of 7 days later. **RESULTS** Plasma NOm values were significantly increased in the BRJ condition 2.5 hours post ingestion compared to BRJ baseline as well as PLA at 2.5 hr (2.5 hr: PLA 30.2±6.6uM vs BRJ 973±261uM, p>0.05). We did not observe an improvement in mitochondrial oxidative capacity or VO$_2$ peak in the BRJ condition compared to PLA (p>0.05). The amount of work performed and total exercise time was significantly increased after BRJ compared to PLA (Work: PLA 39.5±9.9 vs BRJ 44.7±10.7kJ; Exercise Time: PLA 627±86 vs BRJ 674±85 seconds; p<0.05 for both). VO$_2$ at the ventilatory threshold (VT) was significantly greater in the BRJ condition compared to PLA (PLA 0.79±0.08L/min vs BRJ 0.95±0.09 L/min; p<0.05). **CONCLUSION** An acute dose of 12.6mmol dietary nitrate significantly improved VO$_2$ at VT, work performed, and total exercise time in adults with moderate to severe CKD. This research was supported by an ACSM Foundation Research Grant from the American College of Sports Medicine Foundation and NIH grant HL113514.

The Kidney As A Hub For Ph Modulation: Interrelationship Of Lactate, Pulse, And Blood Pressure

Roman C. Musselman[1], J. Mark VanNess[1], Greg Roberts[2], Jonathan M. Saxe[2], Lewis E. Jacobson[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.*
(No relevant relationships reported)

Following the pioneering work of Hill and Meyerhoff, in 1933, Margaria and colleagues published a compelling relationship between pH and lactate in the blood. In 1976, Sahlin and colleagues detected and presented that same relationship in skeletal muscle. These events helped make lactate metabolism one of the most famous and misunderstood phenomena in exercise physiology. We now know that rates of ATP hydrolysis and hydrogen ion clearance are fundamental to exercise-induced metabolic acidosis; however, the role of the kidney in modulation of blood lactate and pH still requires further elucidation in athletic and ill populations. **PURPOSE:** To better understand the determinants of blood pH by examining the interrelationship between lactate, pH, and cardiovascular parameters in a patient population. **METHODS:** We analyzed a sample of 248 patients who were admitted to a Midwestern U.S. hospital for acute trauma. All patients were assessed for predictors of pH based on complete blood count and other measurements collected during intake. Multiple linear regression tested the effect of demographic, anthropometric, and metabolic variables on blood pH. **RESULTS**: Subjects were 63.3% male with a mean age of 50.5 ± 21.6 years, normal blood pH (7.3 ± 0.4), and slightly elevated lactate (2.0 ± 1.7 mmol/L). Mean arterial pressure (98.5 ± 18.5 mmHg) and heart rate (90.7 ± 18.1 bpm) were also slightly elevated. The variables that predicted significant reductions in pH were

lactate (p<0.001) and pulse rate (p=0.040). The variables that predicted significant increase in pH were mean arterial blood pressure (p=0.001), temperature (p=0.010), and pregnancy status (p=.026). Sex (p=0.316), age (p=0.714), obesity (p=0.195), and blood alcohol content (p=0.624) were not statistically significant. Injury severity score was a trending predictor (p=0.057). **CONCLUSIONS:** The strong association between lactate and pH may indicate a need to re-examine components of the lactate/pH framework. The associations between blood pressure, pulse, and pH implicate the kidney; further work needs to be done in outlining renal function and its role in modulation of pH and cardiovascular function.

Home-based Exercise Improves Heart Contractility Determined by 2D Speckle Tracking Strain in Renal Transplant Recipients

Laura Stefani[1], Riggs Klika, FACSM[1], Gianni Pedrizzetti[2], Chiara Ingletto[1], Benedetta Tosi[1], Stefano Pedri[3], Giorgio Galanti[1]. [1]University of Florence, Firenze, Italy. [2]University of Trieste, Trieste, Italy. [3]ESAOTE, Firenze, Italy. (Sponsor: Riggs J. Klika, FACSM)
(No relevant relationships reported)

PURPOSE: Renal transplant recipients (RTR) are at high risk for adverse cardiovascular events due to potential cardiotoxic effects of multiple drug therapies and often sedentary behavior. Moderate intensity exercise has been shown to decrease the risk of these potential events. The purpose of this study was to evaluate the changes in myocardial function using global longitudinal strain (GLS), mean strain (Lo) and ejection fraction (EF) determined from 2D speckle tracking strain (STS) before and after participation in a home-based aerobic and strength training program in RTR and to determine if there was a sex difference in the response.
METHODS: A group of 30 RTR's (12 females and 18 males, aged 47.9 ± 12.3 y, BMI: 24.4 ± 3.9, average age at transplant 38.6 ± 13.1 y) participated in an exercise program for 12 months. Individualized exercise programs were created based on the results of a cycle ergometer test, hand grip dynamometry, bioelectrical impedance and skinfold analysis with the goal of achieving 150 minutes*wk^{-1} of activity at moderate intensity (minimal levels were set at 3x*week^{-1} with a goal of at least 30 minutes*session^{-1}. Subjects completed 2D echocardiographic examination at T_0, T_6, and T_{12} months. Repeated measure ANOVA and a two-way mixed ANOVA with Tukey post-hoc analysis were used to detect differences across time and sex differences.
RESULTS: GLS and Lo increased significantly from T_0 to T_6 and remained high at T_{12} (GLS: -17.9 ± 3.3 vs -20.4 ± 3.2 and -20.5 ± 3.8 and Lo: -18.3 ± 3.8 vs -20.4 ± 3.3 and -20.4 ± 3.0) with no changes in EF over time (EF % 60.4 ± 5.3 vs 61.8 ± 6.9 and 64.3 ± 6.2). Men were significantly older at time of transplant (33.8 ± 12.6 vs, 45.7 ± 11.4, p < 0.05) with lower cardiac function at T_0 (-17.1 ± 3.7 vs -19.2 ± 2.2), p < 0.05) than women and accounted for a majority of the improvement in cardiac function in this sample. **CONCLUSIONS**: A moderately intense exercise program was well tolerated by RTR's and significantly improved heart function in men during the initial 6 months of the program. More than EF, 2D ST analysis appears more sensitive in detecting training adaptations. Future studies should investigate the potential role of GLS in the assessment of cardiac function following unsupervised exercise training.

Combined Effects of Hypohydration, Muscle Damage, and Exertional Hyperthermia on Biomarkers of Acute Kidney Injury

Cory L. Butts, Aaron R. Caldwell, Samantha A. Mohler, Matthew S. Ganio, FACSM, Nicholas P. Greene, Stavros A. Kavouras, FACSM, Brendon P. McDermott, FACSM. *University of Arkansas, Fayetteville, AR.* (Sponsor: Dr. Brendon P. McDermott, FACSM)
Reported Relationships: C.L. Butts: *Consulting Fee; Gatorade Sports Science Institute.*

Dehydration, exertional hyperthermia, and muscle damage commonly occur in athletic, military, and occupational settings, yet, their combined effects on biomarkers of acute kidney injury are not well understood. **PURPOSE:** Investigate the combination of dehydration, muscle damage, and exercise in the heat on biomarkers of renal stress. **METHODS:** Six male participants (age 24±5 y, body mass 74.9±6.3 kg, body fat 14.5±4.1%) completed two trials, one euhydrated (EU; fluid replacement ≤2% body mass loss) and one hypohydrated (HY; fluid restriction 24-h prior to and throughout exercise), separated by ≥28 days. Trials consisted of muscle damaging unilateral eccentric knee flexion, 60 minutes of treadmill running (~60% VO$_2$max) in the heat (33 °C, 54% RH), and 30 minutes of passive recovery. Participants were provided a rehydration protocol in both trials and returned 24-h later for a follow-up visit. **RESULTS:** Urine osmolality when HY was greater pre- (HY 1045±102, EU 612±142 mOsm/kg; P <0.01) and post-trial (HY 1007±105, EU 503±205 mOsm/kg; P <0.01), but not 24-h post (HY 543±310, EU 545±404 mOsm/kg; P = 0.98). Serum osmolality was also different pre-trial (HY 301±5, EU 290±5 mOsm/kg; P = 0.02), but was

---

similar 24-h post (HY 295±4, EU 293±3 mOsm/kg; P = 0.25). Isometric strength was reduced regardless of condition immediately after eccentric exercise (grand mean Δ = -33.6±27.9 N·m, P = 0.03). Rectal temperature increased to a greater degree when HY (2.11±0.60 °C) compared to EU (1.65±0.44 °C; P = 0.01). Plasma neutrophil gelatinase-associated lipocalin (pNGAL) increased independent of condition (grand means: pre- 59.9±7.3, post-exercise 77.6±12.0 ng/mL, P <0.01), but was not different between trials (P = 0.84). However, percent changes from baseline in pNGAL were greater, regardless of time, when HY (19.1±7.5%) compared to EU (6.1±11.2%, P < 0.01). **CONCLUSION:** Exercise in the heat with muscle damage increased renal strain when HY and resulted in greater changes in pNGAL, a biomarker of acute kidney injury. These preliminary findings suggest that improper fluid consumption prior to and during exercise may augment renal stress, yet the long-term consequences of these detriments require further investigation.

Associations of Physical Activity, Diet, and Kidney Function in Pre-diabetic Early Stage Chronic Kidney Disease

Faatihah Niyi-Odumosu[1], Thomas Yates[2], Joseph Henson[2], David J. Stensel[1], Alice C. Smith[2], Melanie J. Davies[2], Nicolette C. Bishop[1]. [1]Loughborough University, Loughborough, United Kingdom. [2]University of Leicester, Leicester, United Kingdom.
(No relevant relationships reported)

Purpose Early-stage chronic kidney disease (CKD) is prevalent in pre-diabetes. A healthy lifestyle is promoted in those at high risk of developing type 2 diabetes (T2DM) yet any relationships between physical activity and nutritional intake on kidney function in these individuals is unknown. This study aimed to quantify the independent associations that may exist between changes in physical activity, dietary fats and fibre, and estimated kidney function in individuals with pre-diabetic stage-2 CKD. **Methods** The study analysed data from a subset of adults at high risk of T2DM recruited to a lifestyle education programme (Yates et al. Diabet Med. 34:698-707, 2017). At baseline and 24 months, 126 (84 male) pre-diabetic CKD stage 2 (mean(SD) baseline estimated glomerular filtration rate (eGFR) 76.7(8.0) ml/min/1.73 m², age 66(6) years, BMI 31.6(5.1) kg/m²) provided dietary data via the Dietary Instrument for Nutrition Education food frequency questionnaire and physical activity and steps by 7-day accelerometry. Linear regression examined the independent associations of baseline and change at 24 month in eGFR and average number of steps, moderate to vigorous physical activity (MVPA), total fat and unsaturated fat, and dietary fibre against 95% level of significance (p≤0.05). **Results** Between baseline and 24 months eGFR decreased by -3.04(9.4) ml/min/1.73 m². There were no changes in MVPA, steps, fat and fibre intake but responses were highly variable between individuals. Baseline and change in eGFR at 24 months were positively associated with baseline MVPA (Pearson correlation, r=0.182, p=0.02 and r=0.160, p=0.04 for baseline eGFR and change in eGFR respectively), but not change in MVPA. There was a positive association between change in eGFR and average number of steps at baseline (r=0.140, p=0.059). However, after adjustment for known confounders (including age, sex, BMI, smoking status, ethnicity), these associations disappeared. There were no associations between eGFR and dietary fats (total and unsaturated), and fibre. **Conclusions** Higher MVPA and average number of steps were associated with (but not predictive of) higher eGFR in a group of adults with pre-diabetic stage-2 CKD. Therefore, a healthy active lifestyle should be encouraged in pre-diabetes to prevent decline in kidney function.

Aerobic Exercise Improves Subclinical Cardiopulmonary Abnormalities in Chronic Kidney Disease

Danielle L. Kirkman, Bryce J. Muth, Joseph M. Stock, David G. Edwards. *University of Delaware, Newark, DE.*
(No relevant relationships reported)

PURPOSE Subclinical cardiopulmonary abnormalities have been reported in patients with mild-moderate CKD that may predispose these individuals to overt cardiovascular disease (CVD). This randomized controlled trial investigated whether 12 weeks of moderate to vigorous intensity aerobic exercise could improve cardiopulmonary measures in Stage 3-5 non-dialysis CKD patients.
METHODS 36 Stage 3-5 CKD patients (eGFR, 44±2 ml/min/1.73m²) with no CVD history were randomized to an Exercise Training (EXT) or Control (CON) arm. EXT consisted of 3x45 minutes of supervised exercise per week at 60-85% HRR for 12 weeks. CON received routine care. Cardiopulmonary exercise testing (CPX) was carried out at baseline and after 12 weeks. CPX was performed on a cycle ergometer with workload increased by 15W every minute until volitional fatigue. Breath by breath expired respiratory gas analysis was carried out with an automated gas analyzer and averaged over 10 second intervals.
RESULTS EXT significantly improved exercise capacity as shown by an increase in VO$_2$peak compared to CON (EXT: 17.89±1.21 *vs.* 19.98±1.59; CON: 18.29±1.73

Abstracts were prepared by the authors and printed as submitted.

vs. 17.36±1.60 ml/kg/min; *p*<0.01). Cardiopulmonary reserve improved following EXT as indicated by an increased oxygen uptake efficiency slope (EXT: 1.76±0.13 *vs.* 1.93 ± 0.12; CON: 1.76±0.14 *vs.* 1.68±0.15 AU, *p*<0.01). Relative O_2 pulse improved following EXT, suggestive of improved left ventricular function (EXT: 0.12±0.01 *vs.* 0.14± 0.01; CON: 0.14±0.01 *vs.* 0.14±0.01 ml/beat/kg; *p*=0.03). Ventilation perfusion mismatching (V_E/VCO2) was still evident following EXT (EXT: 32±2 *vs* 33±0.9; CON: 32±2 *vs* 34±1 AU; *p*=0.1). EXT had no effect on the ventilatory cost of oxygen uptake (V_E/VO_2; EXT: 40±2 *vs.* 42±2; CON: 37±2 *vs.* 41±2 AU; *p*=0.5). EXT had no effect on autonomic function assessed by maximal heart rate (EXT: 149±8 *vs.* 143±8; CON: 131±5 *vs.* 129±5 bpm; *p*=0.4) and 1 minute heart rate recovery (EXT: 15±1 *vs.* 16±2; CON: 14±1 *vs* 13±1 %; *p*=0.2).
CONCLUSION Aerobic exercise improved exercise capacity, cardiopulmonary reserve and oxygen delivery in CKD patients. Despite these improvements, CPX measures were not fully restored to those observed in matched sedentary healthy individuals. Additional interventions coupled with exercise may be required enhance cardiopulmonary adaptations to exercise training in CKD.

Using an Accelerometer to Predict Mechanical Load of Physical Activities in Adults

Shelby L. Francis, Kathleen F. Janz, FACSM, Jacob E. Simmering. *University of Iowa, Iowa City, IA.* (Sponsor: Kathleen F. Janz, FACSM)
(No relevant relationships reported)

PURPOSE: The accepted method for quantifying impact forces on the lower skeleton involves force plates to quantify ground reaction forces (GRF) in a lab. This method is not feasible in free-living situations. Developments in accelerometer (accel) technology may provide the ability to evaluate the effects of mechanical loading on bone. Technology is preferred over a compendium approach since the GRF of activities such as jumping, jogging depend on the actual execution of the movement. The purpose of this project was to validate an accel for the prediction of mechanical load by comparing its output to GRF. **METHODS:** Participants (n=20 males, 20 females; 18 to 39 yr) completed 10 repetitions of 9 activities (stand, walk, jog, run, 15 cm jump, step down from curb, drop down from curb, forward hop, side hop) on a force plate with an accel on their right hip. The activities were categorized as standing, ambulation, and jumping and used with 59 accel variables to predict mechanical load. Models were fit using the randomForest package in R using 10-fold cross-validation. Model performance was assessed using coefficient of determination (R^2) and median absolute error. **RESULTS:** The percentage of variation explained by the models ranged from 0.32 to 0.78 with median absolute errors ranging from 0.20 to 0.49. The best model (Model 2) contained the known activity categories and accel variables, but is not realistic for free-living situations where activity categories will not be known. The best free-living model was Model 5, which used derived activity categories and accel variables.

Results from Five Random Forest Models to Predict Mechanical Load.		
Model	R^2	Median Absolute Error
1. Known Activity Categories	0.44	0.43
2. Accel Variables	0.65	0.27
3. Known Activity Categories + Accel Variables	0.78	0.20
4. Derived Activity Categories	0.32	0.49
5. Derived Activity Categories + Accel Variables	0.66	0.23
Known Activity Categories=standing, ambulation, jumping.		
Accel Variables=59 possible accel variables related to measures of central tendency, variability of accel signal, and change in direction.		

CONCLUSION: Models containing the accel variables performed better than those containing only activity categories. The accel data can be used to predict categories and GRF. Accels provide valuable objective information when evaluating mechanical loading on bone and should be used when examining bone-strengthening physical activity in free-living situations.

To Investigation Of The Alignment Abnormality In Pelvic Girdles In One Leg Standing X-ray Examination

Masanori Takemura[1], Kenichi Ichihashi[1], Arijit Banerjee[2], Junzo Tsujita[3]. *[1]Ichihashi Clinic, Kobe, Japan. [2]Amagasaki-city Board of Education, Amagasaki, Japan. [3]Institute of Health & Sports Medical Science, Osaka, Japan.*
(No relevant relationships reported)

Urinary incontinence is often considered a disorder by pelvic floor dysfunction in post-partum women. Thus we think a lack of care during the puerperal period also influences instability of the pelvic girdle as well as pelvic floor dysfunction. A lumbar X-ray examination was performed as diagnostic imaging for low back pain, and alignment abnormality in the pelvic girdle was often found. At our clinic, diagnostic imaging with a simple load as one leg standing was performed in addition to the above cases to emphasize abnormality in pelvic girdle.**PURPOSE**: To investigate alignment abnormality of pelvic girdles, in particular symphysiolysis, in one leg standing X-ray of the pelvic girdle in post-partum women, and to examine the relationship with alignment abnormality in pelvic girdles and the cross-sectional areas (CSA) of the psoas major.
METHODS: Participants were 30 parous women (61.5±14.5yr, 154.6±6.74cm) who consulted us with low back pain at our clinic. Lumbar X-ray, one leg standing X-ray, and a lumbar MRI were conducted. The difference in the height between right and left superior pubis ramus (the malalignment in pelvic) was measured from a one leg standing X-ray. The CSA of the psoas major was measured from a lumbar MRI at L4-L5, and the difference between right and left CSA was calculated. Analysis of the relationship between the malalignment in pelvic and the CSA of the psoas major was performed using Spearman's rank correlation coefficient.
RESULTS: The malalignment in pelvic measured from a one leg standing was 1.64±1.39 mm (mean ± SD). These malalignment in pelvic varied between right leg standing and left leg standing. The amount of variation between right leg standing and left leg standing was 1.41±0.894. The CSA of psoas major was 711.5±146.6 mm². The difference in CSA between right and left was 13.0±7.31 %. The relationship between the malalignment in pelvic and the CSA of psoas major was not statistically significant (rs = 0.213, p>.05), but the relationship became significant by increasing number of experiments (power analysis; n = 77).
CONCLUSIONS: The alignment abnormality in pelvic girdles could be estimated by a one leg standing X-ray examination. These results suggest that lack of care during the puerperal period influences alignment abnormality in pelvic girdle, and may lead to a future orthopedic disease.

1801   Board #62   May 31 3:30 PM - 5:00 PM

A Comparison of pQCT Versus B-Ultrasound for Lower Leg Muscle Size Assessment in Young Adults

Samuel R. Buchanan, Robert E. Hight, Breanne S. Baker, Christopher D. Black, Michael G. Bemben, FACSM, Debra A. Bemben, FACSM. *The University of Oklahoma, Norman, OK.* (Sponsor: Debra Bemben, FACSM)
(No relevant relationships reported)

The current gold standards for assessing muscle cross-sectional area (mCSA) are magnetic resonance imaging and computed tomography, both expensive and largely unavailable methods. **PURPOSE:** The purpose of the investigation was to examine the precision of ultrasound (US) in measuring muscle thickness (MTH) and peripheral quantitative computed tomography (pQCT) for measuring mCSA in the dominant (DOM) and non-dominant (ND) gastrocnemius (GST) muscle group of college-aged males and females (n=4). **METHODS:** pQCT (XCT 3000, Stratec) and B-mode ultrasound (UF-750XT) imaging were performed on both lower legs at the tibia 66% site before and after four weeks of dominant leg plantar flexor strength training. GST muscle thickness was assessed in the lateral head by measuring the distance from fat tissue to the fibula. Two-way repeated measures ANOVAs (leg x time) were performed to detect differences in muscle size between legs across time within each imaging technique. As expected, there were no significant leg or time effects for either device (Table 1), thus, the data were collapsed by leg for correlation analysis. The relationship between mCSA and muscle thickness was determined by Pearson's r. Intraclass correlation coefficients (ICC), coefficient of variation % (CV%), and least significant change (LSC) were calculated to determine precision. **RESULTS:** The ICCs for ND mCSA and ND MTH were 0.999 and 0.967, respectively. The ICC for DOM mCSA was 0.993 and 0.894 for MTH. CV%s for ND mCSA was 1.08% and 3.1% for MTH, and for DOM was 1.59% for mCSA and 7.83% for MTH. LSCs at 95% confidence for ND mCSA and ND MTH were 20.5 cm² and 0.25 cm, respectively. LSCs for DOM mCSA was 37cm² and 0.65 cm for MTH. There was a moderate correlation between mCSA and MTH (r=0.7, p<0.01). **CONCLUSION:** Precision values were comparable between imaging techniques, thus, US may be a viable alternative to measuring muscle size in the gastrocnemius muscle.

Table 1. pQCT and US Measures for Dominant (DOM) and Non Dominant (ND) Lower Legs (means ± SD)						
Variable	DOM (n=4)			ND (n=4)		
pQCT mCSA						
Pre (cm²)	743.36	±	180.76	740.26	±	193.54
Post (cm²)	741.96	±	183.46	748.32	±	193.52
US MTH						
Pre (cm)	2.39	±	0.79	2.43	±	0.49
Post (cm)	2.19	±	0.53	2.46	±	0.61

Measurement Of Nitrate And Nitrite In Biopsy-Sized Muscle Samples

Andrew R. Coggan, FACSM, Ashley D. Troutman, Mary Beth Brown, FACSM. *Indiana University Purdue University Indianapolis, Indianapolis, IN.*
(No relevant relationships reported)

Studies of rats have demonstrated that skeletal muscle plays a central role in whole-body nitrate (NO_3^-)/nitrite (NO_2^-)/nitric oxide (NO) metabolism. The small size of human muscle biopsy samples, however, presents an analytical challenge in this context. Indeed, a recent study by Nyakayiru et al. (J Appl Physiol 2017; 123:637-644) reported that NO_2^- was below the limit of detection (LOD) using the "gold standard" chemiluminescent method even when assaying 40 mg of tissue. **PURPOSE**: To develop a method to precisely and accurately quantify the NO_3^- and NO_2^- content of biopsy-sized muscle samples. **METHODS**: NO_3^- and NO_2^- were extracted from rat soleus muscle samples using methanol combined with mechanical homogenization + ultrasound, bead beating, pulverization, or pulverization + 0.5% Triton X100. After centrifugation to remove precipitated proteins, NO_3^- and NO_2^- were measured using a dedicated high performance liquid chromatography analyzer with a LOD of <0.5 pmol. **RESULTS**: Mechanical homogenization + ultrasound resulted in the lowest NO_3^- content (62±16 pmol/mg), with high variability (CV >50%) across samples from the same muscle. NO_2^- content (1.00±0.18 pmol/mg) was also elevated, suggestive of NO_3^- reduction during tissue processing. Bead beating or pulverization yielded higher NO_3^- and lower NO_2^- levels, but reproducibility was still poor. Pulverization + 0.5% Triton X100 provided the highest NO_3^- (97±15 pmol/mg) and lowest NO_2^- (0.59±0.16 pmol/mg) contents, with the least variability (CV ~15%). These values are consistent with literature data from larger rat muscle samples analyzed using the chemiluminescent approach. **CONCLUSIONS**: We have developed a method capable of measuring NO_3^- and NO_2^- in muscle samples as small as 10 mg. The theoretical limit is even lower, i.e., 1 mg for both NO_3^- and NO_2^- and 5 ng for NO_3^- alone. This method should prove highly useful in investigating the role of skeletal muscle NO_3^-/NO_2^-/NO metabolism in both healthy and diseased subject populations, in response to exercise and dietary interventions, etc.

2D Ultrasound-Based Characterization of Achilles Tendon Micromorphology in Runners Using Spatial Frequency Parameters

Ari L. Baquet[1], Kai-Yu Ho[2], Yu-Jen Chang[3], Abbigail Fietzer[1], Michelle Evers[2], Caleb Strassberg[1], Greg Bashford[4], Kornelia Kulig[1]. *[1]University of Southern California, Los Angeles, CA. [2]University of Nevada, Las Vegas, Las Vegas, NV. [3]West Virginia University, Morgantown, WV. [4]University of Nebraska-Lincoln, Lincoln, NE.*
(No relevant relationships reported)

Achilles tendinopathy is a common overuse condition in runners, and if degenerative can be a precursor to rupture even in absence of symptoms. Ultrasonography and spatial frequency analysis are capable of detecting impaired collagenous organization and tensile strength in Achilles tendons, often not plainly visible. These tools, along with basic clinical tests and athletic history, may help characterize the traits and risk factors for sub-clinical Achilles tendinopathy. **PURPOSE**: To characterize athletic history, waist-to-hip ratio, BMI, ultrasonography findings, heel raise endurance, and composite dorsiflexion associated with symptomatic and asymptomatic Achilles tendons in runners. **METHODS**: 48 self-identified runners (16 F, 42 ± 9.8 years) with 9 ± 7.6 years of running experience were examined. Heel raise endurance and knee-to-wall composite dorsiflexion were assessed. Height, weight, and waist and hip circumferences were taken, and participants filled out a VISA-A and activity questionnaire. Achilles ultrasound images were analyzed for peak spatial frequency radius (PSFR), P6 width (an indirect measure of collagen bundle size), and Q6 (ratio of PSFR to P6) with

MATLAB code developed for prior tendon research. Data were sorted by PSFR into 4 ascending groups (1.50-1.69, 1.70-1.89, 1.90-2.09, 2.10-2.29), and 1-way ANOVA with post-hoc analyses was used to detect and compare between-group differences. **RESULTS**: One-way ANOVA revealed statistically significant differences for knee-to-wall (p=0.043) and BMI (p=0.038). Post-hoc analyses showed that knee-to-wall was higher at PSFR of 1.50-1.69 when compared to PSFR of 1.90-2.09 (p=0.032). Decreased BMI was found at PSFR of 1.50-1.69 versus 1.70-1.89 (p=0.001). **CONCLUSIONS**: In tendons with decreased PSFR (impaired collagenous organization), increased ipsilateral composite dorsiflexion was found. Lower PSFR has been linked to degraded mechanical properties of tendons. Although Achilles tendon stiffness is not the sole factor affecting ankle ROM, findings from this study depict the relationship between the two variables. Where PSFR was at or below the low end of previously-established healthy ranges (1.8-2.4), lower BMI was found with lower PSFR.

1804   Board #65   May 31 3:30 PM - 5:00 PM

Test-Retest Reliability of Muscle Cross Sectional Area and Echo Intensity in Upper Extremity Muscles

Brett Pexa[1], Joseph B. Myers[2], Hayden Giuliani[1], Eric D. Ryan[1]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC. [2]Tampa Bay Rays Baseball Organization, St. Petersburg, FL.* (Sponsor: Brian Pietrosimone, FACSM)
(No relevant relationships reported)

Ultrasonography has become a popular tool to simultaneously examine muscle size and quality due to their important role in muscle function. These variables demonstrate excellent reliability in the lower extremity but have yet to be assessed in upper extremity.
PURPOSE: To determine the test-retest reliability of US-derived cross sectional area (CSA) and echo intensity (EI) in the infraspinatus, supraspinatus, and flexor carpi ulnaris.
METHODS: Twenty two shoulders and forearms were scanned with a brightness mode US one week apart (n=11, age: 19.9 ± 0.94 years; height: 180 ± 6.73cm, mass: 78.37±12.17kg). Shoulder muscles were panoramically assessed at 1/3 the distance from the root of the spine of the scapula and the acromial angle. The flexor carpi ulnaris was assessed 4 cm distal to the medial epicondyle. Images were reduced in ImageJ to assess CSA and EI in each muscle. Relative and absolute consistency were assessed with intraclass correlation coefficients (ICC) and standard error of measurement (SEM), respectively. Minimal detectable change (MDC) scores were determined to identify a difference or change that can be considered real.
RESULTS: Infraspinatus CSA ($ICC_{(2,1)}$=0.960) and EI ($ICC_{(2,1)}$=0.850) demonstrated the highest relative consistency among the three muscles (supraspinatus CSA: $ICC_{(2,1)}$=0.717, EI: $ICC_{(2,1)}$=0.762; flexor carpi ulnaris CSA: $ICC_{(2,1)}$=0.954, EI: $ICC_{(2,1)}$=0.676). Infraspinatus CSA and EI (CSA: SEM=3.28%, MDC=9.09%, EI: SEM=9.40%, MDC=26.05%) also demonstrated the lowest SEM and MDC, expressed as a percentage of the mean values (supraspinatus CSA: SEM=15.83%, MDC=43.89%, EI: SEM=12.99%, MDC=36.01%; flexor carpi ulnaris CSA: SEM=13.56%, MDC=37.61%, EI: SEM=9.90%, MDC=27.45%).
CONCLUSIONS: Of the upper extremity muscles examined, the infraspinatus muscle had the highest relative consistency, and the lowest absolute consistency and MDC scores for CSA and EI. Furthermore, as the primary stabilizer of the glenohumeral joint, future studies may consider examining infraspinatus CSA and EI to assess upper extremity muscle morphology following an intervention, treatment, and/or condition.

Assessment of Muscle Injury Using Diffusion Kurtosis MRI and[1] H MRS

Richard M. Lovering, Shama R. Iyer, Jiachen Zhuo, Steven Roys, Wenjun Zhu, Su Xu. *University of Maryland School of Medicine, Baltimore, MD.* (Sponsor: E.G. McFarland, FACSM)
(No relevant relationships reported)

Muscle strain injuries are typically diagnosed based on physical exam and patient history, although muscle strain injuries can be detected by T_2-weighted magnetic resonance imaging (MRI) and Diffusion Tenser Image (DTI). Proton MR spectroscopy (^{1}H MRS) enables the study of metabolic changes *in-vivo*, such as fat content stored inside fibers as droplets (intra-myocellular lipids, IMCL) or in adipocytes between myofibers (extra-myocellular lipids, EMCL). Diffusion kurtosis imaging (DKI) is a novel technique that allows *in-vivo* characterization of diffusion of water in muscle. **PURPOSE:** To determine the effects of injury on IMCL and EMCL *in vivo*, and if variables calculated from DKI would serve as an earlier and more sensitive marker of damage after muscle strain injury in rats. **METHODS:** The tibialis anterior muscles (TAs) of anesthetized Sprague-Dawley rats (N=3, 300 ± 5 g) were injured by 50 lengthening contractions. DTI and DKI were acquired over the same region as axial T_2 images. A Point-RESolved Spectroscopy pulse sequence was used for MRS data acquisition from TA muscle. LCModel package (Provencher 2001, Version 6.3) was used for quantification of the MRS data. TA imaging was compared to functional

changes, and BODIPY 495/503 staining of TA cross-sections sections was used to identify lipid depositions. **RESULTS:** Injury was confirmed by a significant loss of isometric torque (70 +/- 2% loss). There was a significant lactate accumulation (>= 68 mM) with corresponding reductions of EMCL and total creatine (tCr) at 4 hours post injury. The complicated metabolic patterns were expected during muscle regeneration, remodeling, and maturation. BODIPY staining confirmed the changes quantified by the ^{1}H MRS findings. For DTI, mean diffusion (MD) and fractional anisotropy (FA) values varied little and returned to normal by the time of functional recovery (day 21). Mean kurtosis (MK), however, was significantly different at all time points and remained high, even after recovery. **CONCLUSIONS:** These data suggest that DKI may be a useful indicator of overall muscle health. Furthermore, EMCL and IMCL levels, determined from ^{1}H MRS, can be used as biomarkers of metabolic alterations following muscle injury and subsequent recovery.

Near-Infrared Spectroscopy Derived Total Heme vs. Assay Derived Total Heme

Kaylin D. Didier, Shane M. Hammer, Kelsey J. Phelps, John M. Gonzalez, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.*

(No relevant relationships reported)

PURPOSE: The primary aim of this study was to compare frequency-domain multi-distance (FDMD) Near-Infrared Spectroscopy (NIRS) derived total heme concentration (hemoglobin + myoglobin) to the total heme derived during a chemical assay. The secondary aim of this study was to explore the influence of adipose tissue thickness on NIRS measurements of mammalian muscle. We hypothesized that the total heme measured by the FDMD NIRS would not be significantly different from the assay values.
METHODS: Five swine were transported to the Kansas State University Meats Laboratory for harvest under federal inspection. Carcass measurements were taken on the same day as harvest. Immediately post draining of the carcass the NIRS probe was placed along the belly of the *deltoideus* (DT), *triceps brachii lateral head* (TLH), *tensor fasciae latae* (TFL), *longissimus dorsi* (LD), *biceps femoris* (BF), and *semitendinosus* (ST) muscles and a measurement was taken for 1 min. The position of the probe was marked to accurately assess the same region of exposed muscle after processing. After the carcass was processed the muscles were exposed (removal of the skin and adipose tissue layer). The NIRS probe was placed on the exposed muscle and data was collected for 1 min. The muscles were then excised for chemical analysis.
RESULTS: The NIRS total heme signal with the skin intact was significantly less than the assay derived total heme (p<0.05). The NIRS total heme signal during the direct muscle condition was not significantly different from the assay derived total heme for BF, DT, ST, TFL, and TL (p>0.05), but was significantly less than the assay derived total heme for the LL muscle group (p=0.012). The NIRS total heme signal directly on the muscle was significantly correlated with the assay derived total heme concentration (r²=0.56, p<0.0001). The NIRS total heme signal was significantly less for the intact skin compared to direct muscle conditions for BF, DT, ST, TFL, and TL (p<0.05), but not for the LL (p=0.922).
CONCLUSIONS: The similar total heme derived between the assay and the FDMD NIRS (during direct muscle measurements) indicates that the NIRS provides an accurate quantification of the total heme in the muscles, including myoglobin. However, when skin and adipose tissue are intact the signal is attenuated and should be taken into consideration.

Comparison between Dual X-ray Absorptiometry and Magnetic Resonance Imaging for Visceral Fat Assessment in Athletes

Hiroko MURATA[1], Tomoyoshi YAGI[1], Taishi MIDORIKAWA[2], Suguru TORII[1], Eri TAKAI[1], Motoko TAGUCHI[1]. [1]*Waseda University, Tokorozawa, Japan.* [2]*Obirin University, Machida, Japan.*

(No relevant relationships reported)

PURPOSE: Heavyweight athletes, e.g., linemen reportedly have excess body fat mass, increased cardiometabolic risk, and insulin resistance, compared to non-heavyweight athletes. Visceral fat is related to cardiometabolic risk. Visceral adipose tissue (VAT) mass is usually assessed with magnetic resonance imaging (MRI). However, this method is labor- and time-intensive. VAT measurement using dual X-ray absorptiometry (DXA) takes less time to scan and analyze findings than MRI. Moreover, DXA can accurately measure abdominal VAT in average-weight individuals. However, this method has not been validated in athletes with a wide range of body habitus. This study compared VAT volume measured by DXA (DXA-VAT) and MRI (MRI-VAT).
METHODS: The study included 30 male collegiate athletes (height 173.3±6.7 cm, weight 90.4±21.3 kg, body mass index 29.9±6.0 kg/m², waist circumference 90.9±16.4 cm) from the following sports: judo, American football, sumo, skiing, and weight

lifting. Paired measurement of VAT was performed using MRI and DXA. MRI-VAT volume was calculated by integrating six 65-mm single MRI slices corresponding to the level of DXA-VAT volume measurement. Data were compared using a paired *t*-test and a Bland-Altman plot was used to assess systematic error.
RESULTS: DXA and MRI-VAT volume differed significantly (p<0.01). Regression analysis showed a linear relationship between DXA and MRI-VAT volume (r=0.90). The fit line for the relationship between MRI and DXA-VAT volume was calculated as follows: DXA-VAT volume = MRI-VAT volume + 97 (cm³). Bland-Altman analysis showed DXA-VAT volume overestimation by 94±53 cm³ compared with MRI-VAT volume, with no systematic error (p=0.203). Less subcutaneous abdominal fat in athletes than in nonathletes may cause overestimation of DXA-VAT volume.
CONCLUSIONS: DXA-VAT volume was overestimated compared with MRI-VAT volume, with strong correlations for a wide range of values. A new equation may be needed to assess DXA-VAT in athletes.

Utilizing Ultrasound Imaging to Evaluate Acute Doppler Flow Adaptions of the Medial Elbow

Arie J. van Duijn, Shawn D. Felton, Kevin P. Lynch, Mitchell L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchell L Cordova, FACSM)

(No relevant relationships reported)

The use of musculoskeletal ultrasound imaging (MSKUI) has been rapidly gaining use and application in the orthopedic clinical setting. An emerging feature of MSKUI is power Doppler imaging quantification (PDIQ) that can be used to quantify circulation in MSK tissues and provide a measure of tissue perfusion and/or inflammation.
PURPOSE:
To examine the use of PDQI for evaluation of tissue perfusion of the ulnar collateral ligament (UCL) following an in-game performance in collegiate pitchers.
METHODS:
Ten Division I collegiate baseball pitchers (mean age 20.4 ± 1.4 yrs and mean body fat percentage 18.6 ± 3.9%). with no history of significant upper extremity injuries participated. MSKUI imaging was obtained with a GE LOGIQe ultrasound unit for each athlete prior to and immediately following (< 15 minutes) the pitching performance during his first game of the season. Post-imaging PDQI ratios were calculated to assess the maximum level of tissue perfusion of the UCL in the throwing arm.
RESULTS:
Differences in maximum UCL PDQI ratios pre and post the first pitching outing of the season were analyzed through paired sample t-tests. There was no significant difference (t(9) =-1.37, p≥0.5) between the PDQI ratios before (mean max ratio .082 ± .06) and after pitching (mean max ratio: .22 ±.29). Assessment of the following control variables: pitch count (F$_{1,7}$ = 0.73, p=.42) and innings pitched (F$_{1,7}$ = 0.37, p=.56) indicated no significant effect on the PDQI ratios.
CONCLUSIONS:
No statistically significant difference in perfusion of the UCL, as expressed by PDQI ratios was found after a single pitching outing. However, a numerical increase in the mean PDQI ratio post pitching was seen. Upon further exploration of the data, it was noted that there was significant variability in ratio changes among the subjects, which may be improved upon by increasing the sample size and number of pitching outings. Further research is needed to evaluate the clinical significance of immediate perfusion changes during throwing.

1809   Board #70   May 31 3:30 PM - 5:00 PM

The Use of Dual Energy X-Ray Absorptiometry For the Identification of Knee Osteoarthritis

Katie R. Hirsch[1], Malia NM Blue[1], Kara C. Anderson[1], Eric T. Trexler[1], Hope C. Davis[1], Brittney A. Luc-Harkey[2], Brian Pietrosimone, FACSM[1], Abbie E. Smith-Ryan, FACSM[1]. [1]*University of North Carolina at Chapel Hill, Chapel Hill, NC.* [2]*Brigham and Women's Hospital, Boston, MA.* (Sponsor: Abbie Smith-Ryan and Brian Pietrosimone, FACSM)

(No relevant relationships reported)

Knee osteoarthritis (KOA) severity is currently determined by the presence and magnitude of tibiofemoral osteophytes and joint space width (JSW) narrowing upon weight-bearing radiography. Newer dual-energy x-ray absorptiometry (DEXA) models have a specialized knee scan feature that could serve as a low-radiation, cost effective alternative to radiographic diagnosis. **Purpose**: To 1) evaluate the relationship of DEXA-derived JSW with patient-reported pain and physical function and 2) evaluate the reliability of a semi-automatic knee analysis software for measuring JSW from DEXA-derived images. **Methods**: Eleven adults (6 females; 5 males) with radiographically defined KOA (Mean ± SD: Age= 60.0 ± 9.0 yrs, BMI= 29.0 ± 3.7 kg/m², WOMAC pain=8.3 ± 2.8; WOMAC function=27.4 ± 6.7) completed scans of the involved and uninvolved knees using the GE Lunar iDXA orthopedic application for the knee. Medial and lateral JSW was analyzed using semi-automatic knee analysis

software (OASys 1.0, Optasia Medical, Cheadle, UK). Pain and physical function were evaluated using the respective Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) subscales. **Results**: Despite the non-weight bearing nature of the DEXA scan, greater medial JSW narrowing of the involved knee was significantly correlated with greater WOMAC pain scores (Spearman correlation; R= -0.815; p=0.002). There were no significant correlations with lateral JSW of the involved knee, medial or lateral JSW of the uninvolved knee, and WOMAC subscales (p>0.05). There was strong test-retest reliability for involved lateral (intraclass correlation coefficient [ICC]= 0.95; standard error of the measurement [SEM]= 0.22 mm) and medial (ICC= 0.99; SEM= 0.15 mm) DEXA-derived JSW using the semi-automatic software. **Conclusions**: The strong relationship between WOMAC pain and DEXA-derived JSW suggests potential use of DEXA as a practical tool for tracking severity and pain associated with KOA. Semi-automatic knee analysis software designed to evaluate radiographic images can reliably evaluate JSW from a DEXA-produced image. Further validation of DEXA-derived images of the knee for KOA diagnosis is warranted. Supported by: NIAMS (1R21AR067560 -01) and the Rehabilitation Research Resource to Enhance Clinical Trials (1P2CHD086851-01).

Evaluating Near Infrared Spectroscopy Signals From Skeletal Muscle

ADEOLA A. SANNI, Kevin K. McCully. *UNIVERSITY OF GEORGIA, Athens, GA.*

(No relevant relationships reported)

Near Infrared Spectroscopy (NIRS) uses the relative absorption of light at 850 and 760nm to determine skeletal muscle oxygen saturation. There are currently disagreements in the literature over how to report oxygen saturation and the relative contributions of hemoglobin and myoglobin. **Purpose:** 1) Compare the separate 850nm (HbO2) and 760nm (HHb)signals during rest, ischemia, and reperfusion, and 2) test whether electrical stimulation to increase metabolic rate changes oxygen saturation values during 5-6 minutes of complete ischemia. **Method:** Ten participants ages = 20-29 years were measured. NIRS measurements were made in the forearm flexor muscles at rest, after 30 seconds of 6 Hz electrical stimulation, during and after 5-6 minutes of complete ischemia produced by arterial occlusion preceded by 30 seconds of 6 Hz electrical stimulation. After 5-6 minutes of ischemia 30 seconds of 6 Hz electrical stimulation was performed. **Results:** Six Hz stimulation for 30 s increased metabolic rate for HbO2 and HHb; 6.2 ± 3.1 and 5.5 ± 2.7 fold over rest, respectively. Six Hz stimulation during cuff ischemia did not change either the HHb or HbO2 values (p>0.05). There was significantly greater (p<0.05) pulsitility associated with heart rate in the HbO2 ($0.78\pm0.41\%$ range) compared to HHb ($0.16\pm0.09\%$ range). Pulse size increased during reperfusion; HbO2 ($2.37\pm0.38\%$ range) compared to HHb ($0.96\pm0.32\%$ range). **Conclusions:** The difference in the magnitude of pulsitility between HbO2 and HHb signals suggests different anatomical locations for these signals, further suggesting that using various ratios of HbO2 and HHb signals should be performed with caution. Increasing metabolic rate with electrical stimulation during complete ischemia did not further change the NIRS signals, suggesting complete ischemia is obtained with 5-6 minutes of complete cuff occlusion.

Measuring Thigh Cross-sectional Areas From CT Scans: Validation Of NIH Image J And SliceOmatic Methods

Richard A. Dennis[1], Alejandro G. Villasante Tezanos[2], Reid D. Landes[3], James N. Wise[3], Kalpana P. Padala[1], Philip A. Kern[2], Kimberly K. Garner[1], Prasad R. Padala[1], Marcas M. Bamman[4], Dennis H. Sullivan[1], Charlotte A. Peterson[2], Douglas E. Long[2]. *[1]Central Arkansas Veterans Healthcare System, North Little Rock, AR. [2]University of Kentucky, Lexington, KY. [3]University of Arkansas for Medical Sciences, Little Rock, AR. [4]University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Brian Noehren, FACSM)

(No relevant relationships reported)

PURPOSE: Muscle and fat areas in thigh CT scans are important outcomes in aging and exercise research. NIH Image J and SliceOmatic software programs are often used to quantify these areas but three methodological issues commonly exist between references: the tissue density range used to define muscle and fat varies between studies, areas of intermediate density are omitted, and the handling of areas of matching density (i.e. skin and bone marrow) is unreported. Thus, the purpose of this analysis was to validate methods for using these programs while assessing the effects of these three issues on the results. **METHODS**: CT scans of the mid-thigh were analyzed for two cohorts based on gender (57F, 65-86 yrs v. 44M, 64-91 yrs) and

the effects of resistance exercise training (12 wks, 26M, 62-77 yrs) and detraining (26 wks, subset 16M, 62-75 yrs). The total thigh was segmented into seven regions based on Hounsfield Units range: fat of normal (NDF) and high-density (HDF); muscle of low (LDM), normal (NDM), high (HDM), and very high density (VHDM); and bone. **RESULTS** (mean, SD, cm²): In the first cohort, male thigh total area was smaller (207 ± 27 v 223 ± 42, P=0.02) and contained less NDF (54 ± 19 v 118 ± 38, P<0.0001) but more muscle of all densities (e.g. NDM 108 ± 19 v 69 ± 14, P<0.0001) than female thigh. These results were from Image J and the effect of skin was not considered. However, the results were strongly correlated (R²=0.99) with those from SliceOmatic even if skin was included as subcutaneous fat. In the second cohort, resistance training (pre v post) increased thigh size (220 ± 32 v 229 ± 30, P<0.0001) and muscle content of all densities (e.g. NDM 107 ± 20 v 111 ± 22, P=0.02) except VHDM. Detraining (trained v detrained) decreased thigh size (230 ± 34 v 222 ± 39, P=0.0007) and content of NDM (115 ± 24 v 106 ± 21, P<000.1) and HDM (2.5 ± 1.8 v 1.8 ± 1.6). These results were from SliceOmatic and were not affected by skin fat and bone marrow. **CONCLUSIONS**: Image J and SliceOmatic generate similar results for measurement of muscle and fat of all densities in the thigh. SliceOmatic is the more capable program but Image J is sufficient if areas with density similar to muscle and fat are constant and do not affect the results. Funding: VA RRD Merit RX001203 (RAD) and NIH NIA R01 AG046920 (CAP and MMB).

Common Muscle Tests As Related To Trabecular Bone Strength In Division II Athletes.

Kimberly D. Espartero, Andrew Denys, Maria G. Alvarez, Priscilla Franson, Arianna M. Mazzarini, Rebekkah J. Reichert, Vanessa R. Yingling, 94501, FACSM. *California State University, East Bay, Hayward, CA.* (Sponsor: Vanessa R Yingling, FACSM)

(No relevant relationships reported)

High impact repetitive loading, associated with most sports is beneficial to the skeleton. The mechanostat theory illustrates a dependence of bone strength on muscle strength. Therefore, a field measure of muscle function that can approximate bone strength is important to optimize bone strength in educational and recreational settings. Recent studies reporting significant correlations between muscle power and bone strength (Janz, 2015, Yingling, 2017) have focused on cortical bone sites. Trabecular bone is a common site of stress and osteoporotic fracture. **PURPOSE:** To investigate the relationship between common muscle function tests (Relative Grip Strength, 1 Rep Max of Leg Extensors, Peak Power-vertical jump) and bone strength in the trabecular bone of the distal tibia of Division II athletes. **METHODS:** Eighty-six Division II athletes, 56 females and 30 males (age 20.2 +/- 1.7, height (m) 1.7 +/- 0.1, body fat % 17 +/- 7.4) performed a relative grip strength (RGS) test using a hand dynamometer, a one repetition maximum leg extension test (1RM) and a vertical jump test using a Vertec. PP was calculated from vertical jump height (Sayers, 1999). Trabecular Bone Mineral Content (vBMC.tb), Trabecular Bone Mineral Density (vBMD.tb), Total Area (T.Ar.tb), and Bone Strength in compression (BSIc) were measured using peripheral Quantitative Computed Tomography (pQCT) at the 4% tibial site. Linear regressions were run to relate muscle function and trabecular bone strength. **RESULTS:** All three muscle function measures significantly predicted trabecular bone strength parameters in the distal tibia. However, the R² values for PP were much higher than the values for RGS and 1RM. PP explained 41% of the variance in BSIc compared to 30% for 1RM and 13% for RGS. Similar results were found for vBMC.tb (PP [R²=0.5272], RGS [R²=0.1216], 1RM [R²=0.2818]) and T.Ar.tb (PP [R²=0.4996], RGS [R²=0.1242], 1RM [R²=0.1560]). The R² values for vBMD.tb were low for all muscle function variables. **CONCLUSION:** PP is a predictor of trabecular bone strength parameters. Muscle function seems to have the greatest effect on the strength (BSIc) geometry (T.Ar.tb) and amount of the trabecular bone (vBMC.tb) and is less related to the density of the trabecular bone (vBMD.tb). Lower limb muscle power could provide a means to monitor trabecular bone health.

Difference in Attentional Involvement and Respiratory Complexity During Static Balance Between Older and Young Adults

John P. Manning[1], Luis Hernandez[1], Shuqi Zhang[1], Paul Wright[1], David Benner[1], Li Li, FACSM[2]. *[1]Northern Illinois University, DeKalb, IL. [2]Georgia Southern University, Statesboro, GA.*
(No relevant relationships reported)

Balance system requires multiple bodily systems working in tandem. Sample entropy (SE), indicator of attentional involvement in balance, measures time series complexity, high values indicating high complexity. In older adults (OA), balance is documented as deteriorating as aging progresses. As such we hypothesized attentional investment on balance is higher among OA, leading to lower SE. **Purpose:** Investigate 1) effects of group and breathing conditions on attentional involvement (AI) in balance 2) group effect on respiratory complexity (RC) and AI in balance between OA and YA. **Methods:** Participants were recruited and placed into 2 groups, OA (n=6) and YA (n=6). Participants were asked to stand on force plate for 2 minutes (Accusway, AMTI, Watertown, MA) with feet apart at 15º one fist apart at heels. Balance tests conducted under 3 breathing conditions, neutral breathing (NB), chest breathing (CB), abdominal breathing (AB). Raw data of CoP were filtered by 4th order low-pass Butterworth filter with cutoff-frequency 10Hz in R software (R software, The R Foundation, Austria). SE of CoP was calculated in mediolateral-direction (SE_x), anteroposterior-direction (SE_y), chest RC (SE_{Ch}), abdominal RC (SE_{Ab}) in R. Factorial MANOVA was used to test the effects of group and breathing conditions (independent variables) on SE_x, SE_y, SE_{Ch}, SE_{Ab} (dependent variables). ANOVA and post-hoc tests used when needed. **Results:** MANOVA showed significant difference in group and breathing condition (Wilks' λ<.000). Older adults exhibited higher means (p<.05) in SE_x (OA:0.149±0.052; YA:0.108±0.040) and SE_y (OA:0.271±0.106; YA:0.142±0.062). A significant interaction was observed between groups and breathing conditions (Wilks' λ<.000). ANOVA showed significant interactions in SE_{Ch} and SE_{Ab} (p<.000). Post-hoc tests showed YA AB (0.013±0.004) was significantly higher than all conditions and OA AB (0.006±0.002) was significantly higher than YA CB (0.010±0.003) with respect to SE_{Ch} (p<.05); YA NB (0.011±0.005) and YA CB were significantly higher than OA NB (0.006±0.001), OA CB (0.006±0.001), OA AB, and YA AB with respect to SE_{Ab}. **Conclusion:** Breathing condition significantly affected attention on balance with significant group effect between RC and AI, OA and YA. YA group exhibited highest combined complexity for both SE_{Ch} and SE_{Ab}.

Mobility And Balance Performance Is Associated With Health-related Quality Of Life In Community-dwelling Older Adults

Lauren Graham[1], Allison M. O'Halloran[1], Trishia T. Yada[1], Jane E. Freund[1], Chitra Lakshmi K. Balasubramanian[2], Srikant Vallabhajosula[1]. *[1]Elon University, Elon, NC. [2]University of North Florida, Jacksonville, FL.* (Sponsor: Stephen Bailey, FACSM)
(No relevant relationships reported)

Safe and successful mobility maybe essential to maintain quality of life in independently living community-dwelling older adults. These are high functioning individuals who may encounter precarious situations during their community ambulation increasing their risk for falling and loss of mobility. Loss of mobility in these individuals may have a dramatic impact on their quality of life. Though there are many ways to measure balance and fall-risk in older adults, the Community Balance and Mobility (CB&M) assessment is shown to alleviate the ceiling effects and suggested to be a preferred assessment for balance and mobility in independently living community-dwelling older adults. It is important from a clinical perspective to determine if performance on such a challenging assessment like CB&M is related to having a higher quality of life. **PURPOSE:** To assess how quality of life is related to mobility and balance performance in community-dwelling older adults. **METHODS:** An ongoing study of 20 older adults (mean age: 74.1±6.4 years; 10 females) who were living independently in the community participated. Health-related quality of life was measured with 36-Item Short Form Health Survey (SF-36). SF-36 is a patient-reported survey measuring health status with subscales consisting of physical functioning, role limitations due to physical health, role limitations due to emotional problems, energy/fatigue, emotional well-being, social functioning, pain, and general health. Mobility and balance was measured with CB&M, a performance measure consisting of 13 challenging tasks evaluating mobility and balance performance. Correlation analysis was performed between SF-36 and CB&M scores. **RESULTS:** The physical function subscale (r = 0.572; p = 0.008) and general health subscale (r = 0.520; p = 0.019) showed significant moderate positive correlations with mobility and balance performance, as assessed by the CB&M. **CONCLUSIONS:** Community-dwelling older adults with a higher CB&M score attained higher scores on the SF-36 subscales, suggesting that, greater mobility and balance ability is associated with a higher quality of life in independently-living community-dwelling older adults. If dynamic balance can be improved or maintained in older adults, they are more likely to sustain a better health-related quality of life.

Relationship between Cognition and Exercise Capability in Community-dwelling Older Adults

Chunmei Cao[1], Yu Liu[2], Jingmin Liu[1], Weimo Zhu, FACSM[3], Weimo Zhu, FACSM[3]. *[1]Tsinghua University, Beijing, China. [2]Peking University, Beijing, China. [3]University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
(No relevant relationships reported)

Several studies found that both cognition and exercise capability (EC) were risk factors related to older adults' falls. However, there is limited information about the performance of cognition and EC in old adults.
Purpose: To investigate the relationship between components of cognition and EC in older adults.
Method: Sixty-six old adults (aged 65-80 yr., 31 males and 35 females) volunteered performing a battery of four physical test (Hand force, 30-s chair-stand test, Eyes closed standing and The timed "Up & Go") evaluating EC. Four psychological tasks (Stroop task, N-back task, More_oddshifting task and working memory) were used to assess EF, and 2-Choice Reaction Time (CRT) to processing speed, dual task walking to attention. Person correlation coefficient (r) was used to determine the relationship between cognition and EC.
Result: Some low-to-moderate correlations were found between cognition and EC, which are summarized in the table below:

	Stroop task	N-back task	More_oddshifting task	Working memory	CRT	Dual task
Hand force,	.11	.10	.09	.11	-.16**	-.41*
30-s chair-stand test	.20*	.22	.18*	.18	-.26**	.25
Eyes closed standing	.32**	.19*	.29**	.12	-.15**	-.40*
The timed "Up & Go"	-.27**	-.21*	-.31**	-.25*	.39**	.24*

Note: *=p<.05, **=p<.01.
Conclusion: The cognition does have low-to-moderate relationship with some EC, which means that we may promote one through training another one.

Greater Stance Time Variability is Associated with Lower Step Activity in Older Adults

Trishia T. Yada[1], Lauren E. Graham[1], Allison M. O'Halloran[1], Jane E. Freund[1], Chitra Lakshmi K. Balasubramanian[2], Srikant Vallabhajosula[1]. *[1]Elon University, Elon, NC. [2]University of North Florida, Jacksonville, FL.* (Sponsor: Stephen Bailey, FACSM)
(No relevant relationships reported)

Previous research has shown that older adults with greater gait variability are at a higher risk for falling. Falls increase fear of falling and may subsequently result in mobility disability manifesting as decreased physical activity. Physical activity is commonly gauged from continuous step activity monitoring. While decreased step activity has been associated with impaired gait, the associations between gait variability and step activity are not understood. **PURPOSE:** To examine the relationship between gait variability and step activity in older adults. **METHODS:** Spatiotemporal gait parameters were recorded for 19 healthy older adults (mean age 74.5 ± 6.3 years; 9 males/ 10 females) walking at a normal walking speed across a GAITRite walkway for 5 trials. Step activity (# of steps) was collected using a research-grade step activity monitor for 7 consecutive days. Average number of steps for the 7 days was used. Coefficient of variation (defined as % of SD over mean) of gait speed, stride length, step width, swing time, stance time and double support time were calculated. Pearson's and Spearman's correlation coefficients were used based on normality to determine the relationship between gait variability and step activity. **RESULTS:** Stance time variability showed significant moderate inverse correlation with step activity (rho = -0.482, p = 0.036). Swing time variability showed moderate inverse correlation with step activity with a trend towards significance (r = -0.451, p = 0.052). Variability of gait speed (rho = -0.349, p = 0.143), stride length (r =

-0.3, p = 0.212), step width (rho = -0.088, p = 0.721), and double support time (rho = -0.249, p = 0.304) showed weak inverse but not significant correlation with step activity. **CONCLUSION:** In general, gait variability seems to be inversely related to step activity in older adults meaning those with greater gait variability showed lower step activity. In particular, stance time variability has earlier shown to be critical in identifying older adults with mobility disability and those older adults at risk for future disability. Our finding of decreased step activity in those older adults with increased stance time variability suggests that step activity monitoring could provide surrogate and complimentary measures to identify mobility disability in older adults.

Elevated Bmi Impairs Balance Among Older Adults With Vestibular Disorders

Alexis C. King[1], J Mark VanNess[1], Toni J. Oliver[2], Courtney D. Jensen[1]. [1]University of the Pacific, Stockton, CA. [2]San Luis Sports Therapy, Templeton, CA.
(No relevant relationships reported)

Each year, more than 2.5 million geriatric patients are admitted to emergency departments for fall-related injuries. Identifying variables that predict fall risk may help manage this problem. Physical activity and body composition are potential predictors. The average elderly fall risk patient walks <2,200 steps per day and is commonly advised to minimize physical activity owing to elevated risk of injury. Limiting exposure can be effective in the short term but the chronic anthropometric consequences may exacerbate risk in the future. **PURPOSE:** To evaluate the effect of body mass index (BMI) on balance in geriatric patients who are at risk of falling. **METHODS:** We enrolled 24 patients (12 men, 12 women) with a diagnosed vestibular disorder who were ≥65 years of age. Patients were excluded if they had a history of injury precluding participation or currently participated in an exercise program. We collected demographic, anthropometric, and balance data at baseline. Balance was assessed using a CSMi HUMAC System Balance Board. After baseline testing, subjects were randomized to either a fatigue intervention (modified Bruce treadmill protocol) or a mild walking intervention (2 mph, 0% incline, 4 minutes). Following exercise, patients repeated the balance assessment. Linear regression tested the effects of age, sex, obesity, and group assignment on the change in balance score. **RESULTS:** The regression model explained 78% of the variance in the change in balance score (p<0.001). Holding all other predictors constant, performing the fatigue protocol associated with a greater loss of balance (3.9 percentage points; p=0.044); for each 1-point increase in BMI, patients experienced an additional loss of 0.7 percentage points. When evaluating obesity as a binary variable, being classified as obese associated with a loss in balance of 5.0 percentage points (p=0.011). **CONCLUSIONS:** The relationship between fall risk and level of activity is complex. In our sample, obesity associated with a greater deterioration of balance following physical activity. When patients who are at risk of falling are advised to avoid physical activity, that advice may result in chronic compromise of balance, elevating the risk of future falls. Conversely, exercise performed in a safe, controlled environment may have therapeutic potential.

The Effect of Mental Fatigue on Postural Stability in Young and Older Women

Amanda J. Morris, Garrett Lindsey, Anita D. Christie. *University of Oregon, Eugene, OR.* (Sponsor: David Gabriel, FACSM)
(No relevant relationships reported)

Allocation of attentional resources is required for maintaining postural stability. Fewer attentional resources are available for balance control when individuals perform a dual task paradigm involving concurrent performance of a cognitive task. However, these effects have not been studied under conditions of mental fatigue. **PURPOSE** To determine if mental fatigue influences postural stability and if there are age differences in stability in response to mental fatigue. **METHODS** Center of pressure (COP) displacement in response to standing platform perturbations was recorded at the beginning and end of 20 minutes of the psychomotor vigilance task (PVT; mental fatigue condition) and 20 minutes of watching a nature video (control condition) in 16 young (22.4 ± 3.72 years) and 16 older females (72.6 ± 6.50 years). The PVT is a sustained attention task that induces mental fatigue, as indicated by increases in reaction time (RT) to visual stimuli. **RESULTS** Older adults had a significantly longer RT (325.17 ± 30.90 ms) than young (287.95 ± 29.53 ms) at baseline (p=0.002). Both groups had significantly longer RTs by the end of the PVT task (young 11% increase, p=0.002; older 7% increase, p=0.03), indicating the presence of mental fatigue in the mental fatigue condition. Older adults had a significantly larger anterior-posterior (AP) COP displacement (7.37 ± 0.75 cm) than young adults (5.77± 1.67 cm) at baseline (p =0.001). Nine young and 8 old adults had increases of 0.7-54% in AP COP displacement after the mental fatigue condition. However, there was no significant main effect of condition (p=0.12) nor an interaction of age and condition (p = 0.85) for the percent change in AP COP from the beginning to the end of the session.

CONCLUSION These results indicate that although postural control and reaction time performance was worse in older than young at baseline, there was no significant effect of mental fatigue on postural stability in either group.

Electrical Nerve Stimulation Elicits Intensity-dependent Changes in Force Steadiness in Young and Older Adults

Diba Mani, Daniel F. Feeney, Roger M. Enoka. *University of Colorado, Boulder, CO.* (Sponsor: Robert Mazzeo, FACSM)
(No relevant relationships reported)

When individuals attempt to match a submaximal target force by performing a steady isometric contraction, the fluctuations in force are often quantified as force steadiness (coefficient of variation [CV] for force) to provide an index of the neural drive to muscle. **PURPOSE:** To compare force steadiness of the wrist extensors during evoked and voluntary submaximal contractions in young and older adults. **METHODS:** Thirteen young (5 men, 25 ± 4 yrs) and 12 older (7 men, 78 ± 5 yrs) adults participated in a 1-hr protocol that involved maximal voluntary contractions (MVCs) and voluntary and evoked isometric contractions to match a 10% MVC target force. Force steadiness during the voluntary contraction was compared with that evoked by wide, high-frequency (1 ms pulses at 100 Hz) and narrow, low-frequency (0.2 ms pulses at 50 Hz) neuromuscular electrical stimulation (NMES), and a voluntary contraction with superimposed submotor transcutaneous electrical stimulation (TENS). CV for force was compared between age groups with unpaired t-tests and within age groups by paired t-tests. **RESULTS:** CV for force was less for young adults (1.82 ± 0.43%) than older adults (2.80 ± 1.08%) during the voluntary contraction with the wrist extensors (p<0.03). Force steadiness did not differ between age groups during the evoked contractions. However, older adults were steadier during both types of NMES (wide: 2.01 ± 0.67%, p<0.04; narrow: 1.69 ± 0.62%, p<0.02) than during the voluntary contractions (2.80 ± 1.08%). Concurrent TENS did not influence force steadiness for older adults, but young adults were less steady during TENS (2.41 ± 1.02%, p<0.03) than during the voluntary contraction by itself (1.82 ± 0.43%). **CONCLUSION:** The improvement in force steadiness for older adults during the NMES-evoked contractions indicates that the age-associated decline in force steadiness is attributable to changes in the neural drive to muscle, rather than the mechanical properties of muscle. In contrast, the decline in force steadiness for young adults during concurrent TENS suggests that heightened sensory feedback compromised the neural drive to muscle during the steady contraction.

Effects Of Resistance Training On Maximal Motor Unit Firing Rates In Young And Older Males

Phuong L. Ha[1], Garrett M. Hester[1], Ryan J. Colquhoun[2], Mitchel A. Magrini[2], Zachary K. Pope[2], Alejandra Barrera-Curiel[2], Carlos A. Estrada[2], Jason M. DeFreitas[2]. [1]Kennesaw State University, Kennesaw, GA. [2]Oklahoma State University, Stillwater, OK.
(No relevant relationships reported)

It is unknown if resistance training (RT) has differential effects on maximum firing rates (MAX_{FR}) of motor units (MUs) across the recruitment threshold (REC_T), and whether or not age has an influence. **PURPOSE:** To examine the effects of short-term RT on MAX_{FR} of MUs in young and older males. **METHODS:** Thirteen young and seventeen older males were randomly assigned to either a training (young group [YTG]: n = 8, age = 21 ± 1.6 yrs; old group [OTG]: n = 10, age = 64.1 ± 7.4 yrs) or control (young group [YCG]: n = 5, age = 22 ± 3.1 yrs; old group [OCG]: n = 7, age = 64 ± 9.3 yrs) group. RT involved knee extensions for 4 sets of 10 repetitions for 2 weeks. Before (PRE) and after (POST) RT subjects performed 2 maximum isometric ramp contractions (MVCs) of the knee extensors while 4 surface electromyography (sEMG) signals were recorded from the vastus lateralis. The raw sEMG signals were then decomposed into their constituent MU action potential trains. REC_T, defined as the relative force level (%MVC) when the MU began firing, and MAX_{FR} were calculated for each MU. The highest 500 ms average for torque was considered peak torque (PT). Linear regression was used on the pooled and individual data for the groups separately, to examine the relationship between REC_T and MAX_{FR}. Two-way (group [young vs. old] × time [PRE vs. POST]) repeated measures analyses of variance were used to compare individual slope coefficients (SLP_c) and PT across time. **RESULTS:** A total of 1,403 (PRE = 713; POST = 690) MUs were detected. SLP_c (p = 0.136) and PT (p = 0.781) remained unaltered in the control groups at POST. No significant group × time interactions were observed for SLP_c (p = 0.678) or PT (p = 0.100), but a main effect for time was demonstrated for SLP_c (-44.1%; p = 0.001) and PT (+12.5%; p = 0.001). **CONCLUSION:** These findings, in addition to a qualitative, visual inspection of the pooled regression lines (figure below), indicate RT induced a slightly more negative relationship between REC_T and MAX_{FR} and this effect was not influenced by age.

Dynamic Balance Changes in Older Adults Following 12-Weeks of a Self-Managed Exercise Program

Michele Nofal, Saad Alhammad, Lisa MK Chin, Jeffrey E. Herrick, Clinton J. Wutzke. *George Mason University, Fairfax, VA.* (Sponsor: Randall E. Keyser, FACSM)
(No relevant relationships reported)

INTRODUCTION: Static and dynamic balance declines with age. A training program including aerobic (AT), resistance (RT) or balance training (BT) may improve dynamic and static balance in older adults. **PURPOSE:** To determine the influence of a 12-week self-managed exercise program combining AT, RT, and BT on static and dynamic balance measures in unimpaired older adults. **METHODS:** 17 participants attended three educational seminars on AT, RT, and BT prior to beginning exercise, consulting with their physician, and selecting exercises including AT, RT, or BT. Based on activities chosen, participants were organized into three groups; G1 (AT only): n=8, age:73.0±2.4yrs, BMI: 26.1±3.5kg/m2; G2 (AT+RT): n=5 age:68.2±3.1yrs, BMI: 25.5±6.0kg/m²; and G3 (AT+RT+BT): n=4 age:70.0±1.4yrs, BMI: 27.8±6.8kg/m². Exercises were based on National Institute of Aging guidelines. Assessments were conducted prior to the start (PRE) and completion (POST) of the program. An ANOVA was used to analyze dynamic (Timed Up and Go, TUG; Four Square Step Test, 4S) and static (Sway area: 95% confidence ellipse during 30 seconds of standing balance with eyes open, SA) measures of balance between groups. T-tests were used to analyze within-group differences and Cohen's d was used to analyze effect size within groups. **RESULTS:** No differences were found between groups in the TUG, 4S, or SA following the program at POST. T-tests showed improved TUG scores (all participants p=0.0019, G1: p=0.0049, G2 p= 0.413, G3: p=0.0242) and 4S times (all participants p=0.0365, G1 p=0.0224, G2 p=.522, G3 p=0.0172) from PRE to POST. Cohen's d values for the TUG (all participants=0.832, G1=.917, G2=.145, G3=1.75) and the 4S (all participants=0.383, G1=.517, G2=-.037, G3=.505) suggest a large effect for the TUG for all participants, G1, and G3. A small effect was found for all participants for the 4S and a medium effect was found for G1 and G3. **CONCLUSION:** The exercise mode did not influence dynamic or static balance between groups of older adults after a 12-week self-managed exercise program. However, measures of dynamic balance improved in the TUG and 4S for all participants as well as some individual groups. Additional investigation is necessary to identify community-based exercises that appropriately challenge and improve static balance in older adults.

D-61   Free Communication/Poster - Biomechanics of Resistance Training

An Analysis of Squat Mechanics Between Individuals With High and Low Strength Levels

Kevin H. Choe[1], Pablo B. Costa[2], Jared W. Coburn, FACSM[2], Derek N. Pamukoff[2]. *[1]University of Nevada, Las Vegas, Las Vegas, NV. [2]California State University, Fullerton, Fullerton, CA.*
(No relevant relationships reported)

Individuals with weak hip musculature may have compensatory hip and knee motion during common strengthening exercises, such as the back squat (BS), that elevate frontal plane joint loading.
PURPOSE: The purpose of this study was to compare frontal plane squat mechanic.0s between strong and weak individuals during the BS. **METHODS:** Twenty-eight individuals (17 males and 11 females, 23.42±3.34 yrs., 1.72±0.09 m, 73.20±11.41 kg) who consistently performed the BS were recruited for this study, and were

categorized into strong (n=14, 23.00±0.08yrs, 1.69±0.09m, 71.97±11.80kg) and weak (n=14, 23.86±3.86yrs, 1.76±0.08m, 74.43±11.32kg) groups using a median split of BS 1-repetition-maximum (1RM) normalized to body mass. This study required two visits, with the first being 1RM testing and the second consisting of a 3-dimensional assessment of squatting mechanics. During the second visit, participants performed 2 sets of 3 repetitions of the BS at 70% and 85% 1RM in a random order. The average of the second repetitions of each set was used for analysis. Dependent variables included the peak knee abduction angle and external moment, and peak hip adduction angle and external moment. 2 (group) x 2 (load) mixed model ANOVA was used to compare peak external knee abduction moments and angles, and peak external hip adduction moments and angles at 70% and 85% 1RM. **RESULTS**: Group x load interactions were not significant for peak knee abduction angles ($F_{1,26}$=1.05, p=0.31) and moments ($F_{1,26}$=0.61, p=0.44), or for peak hip adduction angles ($F_{1,26}$=0.87, p=0.61) and moments ($F_{1,26}$=0.11, p=0.79). There were also no main effects of load or group on any dependent variable. **CONCLUSIONS:** Results suggest that strong and weak individuals have similar frontal plane hip and knee mechanics during the BS at 70% and 85% 1RM. However, these loads were relatively similar, and loads greater than 85% 1RM are frequently used in exercise programs. Differences may also become evident during repetitions closer to failure. Future research should examine if compensatory frontal plane actions are found with greater resistance. Furthermore, all participants were trained regardless of group, and training status may influence the magnitude of frontal plane hip and knee motion during the BS.

1823   Board #84   May 31 3:30 PM - 5:00 PM

Improving Posterior Chain Engagement and Forward Trunk Lean During The Front Squat

Scott Wilson, William Goodman, Christopher Casillas, Linnea Zavala, James Becker. *Montana State University, Bozeman, MT.*
(No relevant relationships reported)

Front squats are a commonly used squat variation as they place less load on the lumbar spine. However, when done incorrectly, front squats may have inefficient posterior-chain activation and reduced trunk stability, thus negating any potential benefits. Various techniques have been proposed to mitigate such consequences but, to date, few have been quantified. **PURPOSE:** This study examined the effects of an intervention designed to increase posterior chain engagement on kinematics and muscle activity during the front squat. **METHODS:** 7 physically active adults (4 male, 3 female; ages 25 +/- 4 years) performed front squats under two conditions: baseline and after instruction in a specific front squat technique emphasizing foot alignment and using EMG biofeedback to help engage the glutes. All squats were performed at 70% of a tested 1 rep max. Whole-body kinematics were recorded with a 12-camera motion capture system while ground reaction forces were measured using two force plates. Peak hip extensor moments, pelvic tilt, and forward torso lean were calculated on each repetition. Activity of the erector spinae (ES) and gluteus maximus (GM) muscles was analyzed by calculating average root mean square (RMS) amplitude across the squat. Differences from pre to post intervention were evaluated using paired *t*-tests and effect sizes. **RESULTS:** Peak pelvic tilt, forward trunk lean, and hip extensor moments were all not statistically different after the intervention and all showed small effect sizes (Table 1). While mean ES activity decreased after the intervention the effect size was small (Table 1). In contrast, while mean GM activity was not significantly different post-intervention, there was a moderate effect size (Table 1). **CONCLUSION:** The intervention technique changed activation of some posterior muscle groups, but not kinematics or kinetics. Whether this was due to the intervention itself or participants requiring more training time requires further investigation.

Table 1. Means (± standard deviations) pre and post intervention.

	Pre	Post	p	d
Peak pelvic tilt (°)	30.4 ± 10.5	28.7 ± 14.2	.341	0.134
Forward trunk lean (°)	28.9 ± 5.6	29.9 ± 6.9	.521	0.157
Peak hip extensor moment (Nm)	89.6 ± 66.9	85.8 ± 68.3	.313	0.057
Mean erector spinae RMS (mV)	6.0 ± 3.2	5.5 ± 3.0	.034	0.148
Mean gluteus maximus RMS (mV)	1.1 ± 0.7	1.5 ± 1.0	.069	0.472

1824   Board #85   May 31 3:30 PM - 5:00 PM

Effects of Squat Depth and Stance Width on Lower Extremity Frontal Plane Kinetics

Lauren R. Williams[1], Tyler W. Standifird[1], W. Matt Denning[2], Brad Gardiner[3]. *[1]Utah Valley University, Orem, UT. [2]Brigham Young University Idaho, Rexburg, ID. [3]Weber State University, Ogden, UT.*
(No relevant relationships reported)

The squat is an exercise commonly used to improve lower-extremity (LE) strength and performance. Repeated frontal plane movement in the LE could have detrimental effects by contributing to certain joint pathologies. Therefore, investigating squat

technique on LE kinetics is warranted. Purpose: This study compared hip and knee frontal plane kinetics during body-weight squats with varying depths and stance widths. Methods: 11 healthy, college-aged participants (6 female, 5 male, height = 1.68 ± 0.08 m, mass = 67.4 ± 10.7 kg) performed 5 body squats at 100%, 150% and 200% of shoulder width for each of the following knee flexion angles: 55º, 90º and 125º. Trials were randomized and data were collected using Vicon Nexus and AMTI force plates. Frontal plane kinetics were processed using Visual 3D. Results: At the hip, adduction moments showed significant increases as the width (100% = 0.301 ± 0.02, 150% = 0.539 ± 0.04 and 200% = 0.736 ± 0.04; $p < 0.001$) and depth (55º = 0.306 ± 0.03 Nm/kg, 90º= 0.545 ± 0.04 Nm/kg and 125º = 0.725 ± 0.05 Nm/kg, $p < 0.001$) increased. At the knee, adduction moments significantly increased with wider stances (100% = 0.116 ± 0.02 Nm/kg, 150% = 0.178 ± 0.01 Nm/kg and 200% = 0.221 ± 0.01 Nm/kg; $p < 0.001$) while greater knee abduction moments were observed as depth of the squat increased (55º = 0.006 ± 0.02 Nm/kg, 90º = 0.147 ± 0.04 Nm/kg and 125º = 0.465 ± 0.05 Nm/kg; $p < 0.001$). Conclusion: Deep squats and larger stance widths may place greater demand on the hip and knee joints as evidenced by increased frontal plane moments. These data may benefit rehabilitation and strength training programs. For example, clinicians using squats as a rehabilitative exercise might decrease stance width when aiming to avoid LE frontal plane joint loading. Further, athletes who repeatedly stress the frontal plane stabilizing structures of the LE during dynamic movements may benefit from deeper and wider squats in training that would prepare these structures for their sport specific movements. Further research is needed to investigate other means of altering joint loading in the LE during exercise.

1825   Board #86   May 31 3:30 PM - 5:00 PM

Influence of Attentional Focus in a Weighted Barbell Back Squat Among Experienced Performers

Blake Loxtercamp[1], Marcus Moore[1], Scott Austen[2], Greg DeNunzio[2], Lesley M. Scibora[1]. *[1]University of St. Thomas, St. Paul, MN. [2]Northwestern Health Sciences University, Bloomington, MN.*
(No relevant relationships reported)

Previous research suggests that adopting an external attentional focus (i.e. an object) rather than an internal focus (i.e. a body part) improves motor skill performance such as jump height, and increases peak force during isokinetic elbow flexion. However, little is known about the impact of attentional focus during a barbell back squat (BBS). PURPOSE: To determine the influence of attentional focus on ground reaction force (GRF), peak power (PP), and peak moment (PM) in the sagittal, frontal, and transverse planes at the knee, hip, and ankle joints in weight-lifters performing a BBS. METHODS: Male weight-lifters (age 23.1 ± 2.4; >3 years strength training experience) performed 8 BBS repetitions at 50% of their 1RM. Repetitions were performed under 3 conditions: Control (CON) followed by counterbalanced internal (INT; putting pressure on the heels and lateral aspect of the feet) and external (EXT; pushing the ground away from the body) focus conditions. PP (W) and PM (Nm) were measured using the software Motion Monitor; GRF (N) was measured using Bertec force plates. Participants also completed an attentional focus adherence questionnaire. RESULTS: For inversion PP at the ankle (i.e., negative power in the frontal plane), the absolute value for EXT (-59.5 W ±6.6; 0.021, 0.016) was significantly greater than CON (-42.3 W ±4.1) and INT (-42.2 W ±4.8). For valgus PP at the knee (i.e. negative power in the frontal plane), the absolute values for EXT (-231.8 W ±18.8; 0.016) and INT (-227.3 W ±23; 0.033) were significantly greater than CON (-187.4 W ±15.9). For abduction ankle PM (i.e. positive moment in the transverse plane), the EXT (39.4 Nm ±4.6; 0.016) was significantly greater than INT (30.7 Nm ±3.7). With an EXT focus, participants focused on pushing the ground away in significantly more repetitions (6.3 ±0.72; 0.03) than the INT focus (5.2 ±1.9). Focus conditions elicited no significant differences in the other variables. CONCLUSION: Results indicate attentional focus has little influence on hip, knee, and ankle joint kinetics during a BBS among experienced weightlifters. Instructing experienced weightlifters to shift their attentional focus may have little effect on BBS performance. Future studies should investigate the impact of attentional focus on novice weightlifters performing lower body multi-joint movements.

1826   Board #87   May 31 3:30 PM - 5:00 PM

Load-dependent Relative Muscular Effort of the Knee Extensor Muscles During Back and Front Squats

John Krzyszkowski, Kristof Kipp, Sandra Dahling, Jordi Heeneman. *Marquette University, Milwaukee, WI.* (Sponsor: Paula Papanek, FACSM)
(No relevant relationships reported)

Introduction: The back squat (BS) and the front squat (FS) are mainstay exercises of strength training programs. However, not much is known about joint-specific kinematic and kinetic changes during the execution these two exercises as the external load is varied. In addition, the Relative Muscular Effort (RME), which quantifies a muscle groups operating level with respect to its maximum capacity, of the knee extensor muscle group during both exercises is not well characterized.

PURPOSE: To investigate load-dependent RME of the knee extensor muscles during the BS and FS.
METHODS: Seven collegiate athletes (4 male, 3 female) participate in this study. Each athlete completed motion analysis and isometric muscle strength testing. During motion analysis testing each athlete performed, in counterbalanced order, both the BS and FS at loads of 40, 60, and 80% of their FS one-repetition maximum (1-RM). Kinematic and kinetic data were captured from markers placed on anatomical landmarks (Plug-in Gait marker set) and from two force plates underneath the athletes' feet. These data were used to calculate the net joint moments (NJM) during each exercise and at each load. During the isometric strength testing sessions each athlete performed maximal voluntary isometric contractions (MVIC) at 30, 60, and 90 degrees of knee flexion. A moment-angle curve was fitted to the MVIC data and used to calculate the theoretical peak NJM during the squats, which was then compared against the actual NJM during the execution of the BS and FS to calculate the RME. A 2x3 ANOVA ([Exercise: Front, Back] x [Load: 40, 60, 80]) was used to determine the effects of exercise and load on RME.
RESULTS: : The interaction ($p = 0.025$) and load main effect were significant ($p = 0.004$). Post-hoc testing, however, indicated that only the exercise-pooled RME differed across loads (40% RME: 51.6±0.05, 60% RME: 61.3±0.06, 80% RME: 69.3±0.06). Specifically, the RME differed significantly between 40% and 60% ($p = 0.049$), 40% and 80% ($p = 0.015$), and 60% and 80% ($p = 0.008$).
CONCLUSIONS: : RME did not differ between BS and FS at any load, but increased linearly from 40% through to 80% of FS 1-RM. These results suggest that at the same absolute load both exercises impose similar demands upon the knee extensor muscle groups, and that greater loads increase that demand.

Development and Validation of Efficient Assessment Tool to Quantify Strength Training Technical Expertise

Erich Petushek[1], Sarah B. Clarke[2], Sandor Dorgo[3], William Ebben[4], Gregory D. Myer, FACSM[5], Tron Krosshaug[6]. *[1]Michigan State University, East Lansing, MI. [2]Northern Michigan University, Marquette, MI. [3]University of Texas at El Paso, El Paso, TX. [4]Lakeland University, Plymouth, WI. [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH. [6]Norwegian School of Sports Sciences, Oslo, Norway.* (Sponsor: Gregory D. Myer, FACSM)
(No relevant relationships reported)

The ability to assess, prescribe, and modify exercises based on biomechanical characteristics of the movement is an essential skill that personal trainers, strength and conditioning coaches, physical therapists or other fitness/exercise practitioners must possess. Currently no tool exists that assesses this overall perceptual-cognitive skill.
PURPOSE: To gain item level feedback and begin to evaluate an efficient instrument to accurately and reliably assess strength training technique expertise. METHODS: Fifteen exercise science students (Mean age: 22.6 +/- 2.4 SD; 27% with B.S.) and 15 experienced academics in the strength training field (Mean age: 42.2 +/- 10.7 SD; 67% with Ph.D.) completed a 26-item test with various questions eliciting knowledge of strength training technique skill. Additional questions relative to perceived importance, confidence, and education preparations of various skill applications (e.g., modifying exercises, optimizing muscle activation, selecting exercises, and identifying poor technique) were also characterized. Item level metrics such as discrimination and difficulty were calculated. RESULTS: Overall, academics performed better than students with a medium to large effect size ($d = 0.78$, $p = .041$). Four items displayed poor discrimination (item-total correlation <0.1) and two items were relatively easy (overall percent answered correctly >85%). Qualitative item level feedback was helpful to further modify/refine wording of questions. Almost all individuals (93%) indicated they wanted to learn more about techniques to assess strength training exercises. CONCLUSIONS: Initial evidence indicates this tool demonstrates sufficient difficulty and discriminability to characterize strength training technique expertise. In addition, individuals perceive this evaluative skill of strength training technical performance as very important for practical application and desire further training/education to improve this skill (even in high level academic individuals). Larger sample - factor analytic, reliability, and predictive/discriminant validity evidence should be gathered to further assess and refine this assessment tool.

Dynamic Resistance Training Promotes Better Neuromuscular Benefits And Reduces Oxidative Stress In Healthy Wistar Rats

Michel Souza[1], Rodrigo Neves[2], Thiago Rosa[2], Alexsander Oliveira[2], Gustavo Gomes[2], Rafael Costa[2], Bernardo Brixi[2], Luiz Souza[2], Rafael Olher[2], Lysleine Deus[2], Milton Moraes[2]. [1]Universidade Católica de Brasília, São Paulo, Brazil. [2]Universidade Católica de Brasília, Brasília, Brazil.
(No relevant relationships reported)

PURPOSE: Resistance training (RT) is used as a non-pharmacological tool in the prevention and treatment of various diseases. However, few studies have evaluated the different neuromuscular adaptations promoted by dynamic (DRT) and isometric (IRT), and their impact on redox status.This study aimed to compare the different adaptations on muscle strength and oxidative stress in healthy Wistar male rats.
METHODS: Fifteen male Wistar rats at 12 weeks of age were randomized into 3 groups: control group (CTL; n = 5), DRT (n = 5) and IRT (n = 5). All animals were adapted for 2 weeks on the vertical ladder. After the animals were submitted to dynamic strength muscle (DSM) (test performed every 15 days) and maximum isometric resistance (MIR) (pre and post-training) tests. Both DRT and IRT were performed 5 times a week on non-consecutive days for 12 weeks, with a duration of ~ 22 min per session, consisting of 1 set of 8 uninterrupted climbs for 1 min, with a 30% overload of DSM. The animals of the IRT group remained in isometry for 1 minute. The level of significance was set at $P<0.05$.
RESULTS: The DRT group presented a greater gain of the DSM (390±86 and 686±66 g, pre and post-training, $P<0.05$) compared to the groups CTL (339±65 and 427±39 g, pre and post-training, $P<0.05$) and IRT (369±31 and 393±41 g, pre and post-training, $P<0.05$). The DRT (6.9±3.4 and 24.7±5.3 min, pre and post-training) and IRT (9.6±4.6 and 39.1±15.9 min, pre and post-training) groups showed the same gain in MIR ($P>0.05$). The DRT group presented reduction of lipid peroxidation (17±4 and 9±3 μM, pre and post-training, $P<0.05$) (TBARS), with increased bioavailability of nitric oxide (NO) (122±28 and 177±14 μM, pre and post-training, $P<0.05$) and total antioxidant capacity (627±32 and 715±45 μM, pre and post-training, $P<0.05$) (TAC). These redox status indicators did not change between CTL; TBARS (15±5 and 17±7 μM, pre and post-training), NO (118±15 and 125±32 μM, pre and post-training) and TAC (636±29 and 660±10 μM, pre and post-training) and IRT; TBARS (16±3 and 15±3 μM, pre and post-training), NO (126±18 and 133±14 μM, pre and post-training) and TAC (631±8 and 647±20 μM, pre and post-training) groups ($P>0.05$).
CONCLUSIONS: These results suggest that DRT promotes better neuromuscular benefits with improved oxidative stress in healthy Wistar male rats.

Mechanomyographic Amplitude Is Sensitive To Neuromuscular Adaptations Following High- Versus Low-load Resistance Training

Patirck M. Tomko[1], Amelia Miramonti[2], Ethan C. Hill[2], Cory M. Smith[2], Kristen C. Cochrane-Snyman[3], Ryan J. Colquhoun[1], Terry J. Housh[2], Joel T. Cramer[2], Nathaniel D.M. Jenkins[1]. [1]Oklahoma State University, Stillwater, OK. [2]University of Nebraska-Lincoln, Lincoln, NE. [3]Fresno State University, Fresno, CA.
(No relevant relationships reported)

PURPOSE: To examine the changes in mechanomyographic (MMG) amplitude following 3 and 6 weeks of 80% vs. 30% one repetition maximum (1RM) resistance training in the leg extensors. **METHODS**: Twenty-six healthy men (23.1 ± 4.7 years; height = 180.6 ± 6.0 cm; weight = 80.0 ± 14.1 kg) participated in this randomized, repeated measures, between-group design. Participants were assigned to either an 80% 1RM (n = 13) or a 30% 1RM (n = 13) group and completed leg extension training to failure 3 times per week for 6 weeks. MMG amplitude was recorded and averaged from the three superficial quadriceps femoris muscles (MMG_{QAMP}) during randomly ordered, isometric step-muscle actions at the absolute torques associated with 10 - 100% of each subject's baseline maximal voluntary isometric strength (MVIC) at baseline, 3, and 6 weeks of training, and expressed relative to the baseline MVIC. **RESULTS**: There were no significant interactions for time × torque × group (p = 0.08; $\eta 2p$ = 0.06) or torque × group (p = 0.14; $\eta 2p$ = 0.06), but there were for time × group (p = 0.02; $\eta 2p$ = 0.15) and time × torque (p < 0.001; $\eta 2p$ = 0.12). We further evaluated the time × group interaction by collapsing across torque and using ANCOVAs with baseline MMG_{QAMP} as the covariate to examine between group differences at week 3 and 6, and one-way ANOVAs to examine the change in MMG_{QAMP} across time within groups. The adjusted mean for MMG_{QAMP} during the submaximal isometric step muscle actions was lower in the 80% than 30% 1RM group at week 3 (mean ± SE; 67.8 ± 4.5% vs. 83.2 ± 4.7%) and 6 (65.9 ± 4.5% vs. 80.5 ± 4.6%). In the 80% group, MMG_{QAMP} decreased from baseline to week 3 (77.7 ± 4.3% to 66.8 ± 4.5%; p < 0.01), and from baseline to week 6 (77.7 ± 4.3% to 65.2 ± 3.8%; p < 0.05), but did not change from week 3 to 6 (p = 0.93). There were no changes in MMG_{QAMP} for the

30% 1RM group (p = 0.69; $\eta 2p$ = 0.03). **CONCLUSION**: We observed a decrease in MMG_{QAMP} during submaximal isometric contractions performed at the same absolute torques following 3 and 6 weeks of 80% 1RM, but not 30% 1RM resistance training. These decreases are similar to the reductions in voluntary activation that we observed previously at submaximal torques following 3 and 6 weeks of high-, but not low-load training. Therefore, we suggest that MMG amplitude is sensitive to training-induced changes in motor unit activation during high- versus low-load training.

Prediction of Ground Reaction Forces of Flexible Barbells using their Bar End Displacement

Mehmood Mallick, Sunyeop Lee, Randolph E. Hutchison, Anthony Caterisano, FACSM. Furman University, Greenville, SC. (Sponsor: Anthony Caterisano, FACSM)
(No relevant relationships reported)

PURPOSE: The Flexible Barbell (FB) has been used in various strength and conditioning programs at levels from high school athletics to professional programs such as the National Football League. Yet, fundamental characteristics of the various models of the barbell are unknown. The purpose of this study was to investigate if flexible bar end displacement could predict peak ground reaction forces (GRFs) to aid in training applications.
METHODS: Six models of flexible barbells at nine different loading conditions were lifted by a machine set atop a force platform with barbell motion recorded by an eight-camera 3-D motion capture system. Typical exercises such as the bench press and squat were simulated lifting the barbell a total displacement of 30.5 cm up and 30.5 cm down per repetition at a range of lifting velocities from 0.15 m/s to 1.55 m/s. Linear regression models were run to predict measured GRFs from FB bar end displacements.
RESULTS: Significant linear regression models predicted peak GRFs for all models of the FB and the associated loading conditions based upon maximal bar end displacements (Table 1).
CONCLUSIONS: Although these results will require follow-up confirmation studies with human subjects, coaches in training programs can use bar end displacement to predict peak external loading from lifting the FB. These predictions are useful among a large range of physiologically relevant lifting velocities typically seen in athletic training programs.

Comparison of Peak Ground Reaction Forces at Natural Frequencies of a Flexible Barbell

Randolph E. Hutchison, Sunyeop Lee, Anthony Caterisano, FACSM. Furman University, Greenville, SC. (Sponsor: Anthony Caterisano, FACSM)
(No relevant relationships reported)

PURPOSE: The Flexible Barbell (FB) has been used in various strength and conditioning programs at levels from high school athletics to professional programs such as the National Football League. Yet, fundamental characteristics of the various models of the barbell are unknown. The purpose of this study was to compare peak ground reaction force (GRF) response at natural frequencies (NF) of various models of the FB at typical loading conditions.
METHODS: Six models of FBs and a steel Olympic barbell (SB) at nine different loading conditions were lifted by a machine set atop a force platform with barbell motion recorded by an eight-camera 3-D motion capture system. Typical exercises such as the bench press and squat were simulated lifting the barbell a total displacement of 30.5 cm up and 30.5 cm down per repetition at a range of lifting velocities from 0.15 m/s to 1.55 m/s. Two NFs were identified at the lifting velocity in which both the previous and following lifting velocities showed a decrease in bar end displacement. Independent-samples t-tests were used to compare the FB to a similarly loaded and lifted SB at the FB's NFs. Effect sizes were calculated using Cohen's d.

RESULTS: All models and loading conditions of the FB had significantly higher peak GRFs than the SB at all NFs (Table 1).
CONCLUSIONS: Although these results will require follow-up confirmation studies with human subjects, coaches in training programs can use bar end displacement to predict peak external loading from lifting the FB. These predictions are useful among a large range of physiologically relevant lifting velocities typically seen in athletic training programs.

Relationship between Mechanical & Neuromuscular indices of Fatigue during Resistance Exercise

Andrew Renggli, Jarod Vance, Randal Claytor. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
(No relevant relationships reported)

Methods for monitoring resistance exercise (RE) loads have been popularized through new technologies. However, little is known about the use of these technologies to explore the relationship between mechanical & neuromuscular indices of muscle fatigue during RE. Purpose: (1) To examine the relationship between changes in external mechanical variables such as Work (W), Power (P) & Velocity (V) & EMG of the quadriceps muscles during 1 set of 1-leg knee extension (RE) to failure. (2) To determine if external mechanical variables can be used as a proxy to predict EMG-based acute muscle fatigue during RE. Methods: 28 males familiar with resistance training volunteered. Body composition (air plethysmography) & 1-RM for a 1-leg knee extension RE was completed. After at least 96 hours, subjects performed as many reps (5.4+/-1.1) as possible at 90% 1-RM until failure. EMG was collected from the vastus medialis (VM), vastus lateralis (VL), and rectus femoris (RF) of the exercise leg & VM of the non-exercise leg. Total Power (TP), Mean frequency (MF) & Area (A) spectral/amplitude data were used for EMG analysis. Mechanical data was collected via an ultrasound sensor & custom-built software to measure weight-stack movement (time & distance). 1 X 4(Reps) ANOVA & 3(Muscle) X 5(Reps) MANOVA with Repeated Measures, and a-priori contrasts were used to make specific pairwise comparisons. Results: V & P for Reps1&2 (V=23.6+/-15.5 cm/s; P=182.5+/-125.4 J/s) was significantly greater than Reps3-5 (V=14.3+/-9.4 cm/s; P=107.3+/-77.8 J/s); p<0.05. W was not statistically different across Reps1-5. EMG for VM, VL & RF exhibited similar patterns of activation (no between muscle differences or interactions). TP, M & A during Reps1&2 (TP=118758+/-18066mV2/Hz; MF=254.0+/-20.7 Hz; A=571.2+/-84.5 uV/s) were significantly less than Rep3-5 (TP=229874+/-66374 mV2/Hz; MF=318.8+/-21.2 Hz; A=994.0+/-155.5 uV/s); p<0.05). Conclusion: Quadriceps EMG responses representative of local neuromuscular fatigue begins to occur after Rep2 during 90% of 1-RM RE. Similarly, V & P during the concentric phase of the muscles' action significantly decrease after Rep2, without a decrease in W. These data suggest that measures of V & P can be used as proxy measures of local neuromuscular fatigue during localized high-intensity knee extension RE.

Relationship Between Mechanical Work and Metabolic Cost of Multiple Sets of Resistance Exercise to Failure

Eric W. Slattery, Andrew Renggli, Jarod Vance, Randal Claytor. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
(No relevant relationships reported)

Resistance Exercise (RE), due to its short high intensity nature, primarily uses glycolysis; producing more CO_2 than utilizing O_2. The relationship between Mechanical Work, O_2, CO_2, and acute muscular fatigue during RE is not well understood. **PURPOSE**: To investigate the relationship between volume of O_2 (VO_2), volume of CO_2 (VCO_2), and total mechanical work (TMW) in response to multiple sets of high intensity (90% 1-RM) 1-Leg Leg Extension (LE) RE completed to failure. **METHODS**: 25 males, Age=20.3±1.1yrs, BMI=24.2±2.1, BodyFat%=13.7±6.1, volunteered: Day1 included body composition (air-plethysmography) and 1-RM assessment of dominant 1-leg LE; Day2: (≥96 hours later) subjects' completed multiple sets of 90%1-RM LE Each set was completed to failure; 15-20 seconds later another set to failure was completed. This sequence (sets to failure) continued until a set was composed of < 1 repetition; subjects' then completed 10 minutes of sitting rest (Post-RE R). Metabolic measures were recorded on a breath-by-breath basis. VO_2 and VCO_2 were calculated as the sum totals, in ml/min, for the total RE time period (all reps & sets) & Post-RE R. TMW was measured with an ultrasound sensor (distance & time of weight stack movement) and custom-built software. Correlations, Linear Regression, and Min-Max Accuracy were used to assess the relationship between TMW, VO_2, and VCO_2. **RESULTS**: Averages and standard deviations for comparison variables of interest: TMW=3491.1±2127.9Nm, VO_2=13210.9±2858.5ml/min, VCO_2=15407.4±4136.1ml/min, and failure-set=3.1±1.2. Insignificant correlations were found between TMW and VO_2 (r=0.28) & TMW and VCO_2 (r=0.21). Linear Regressions suggested TMW had little explanatory power for VO_2(p=0.18, AdjR^2 = 0.04), and VCO_2(p=0.31, AdjR^2 = 0.01). Min-Max Accuracy measures, comparing in-sample predictions (TMW data plugged into Linear Regression Models) to observed values, were 84.5% for VO_2, and 79.1% for VCO_2. **CONCLUSIONS**: Weak Correlations and low AdjR^2 values suggest very little relationship between TMW and metabolic measures during and following RE. Min-Max Accuracy measures suggest TMW does not predict VO_2 & VCO_2 well. These results are not unexpected as the work of RE is primarily governed by anaerobic processes and O_2 is not the primary energy source for this type and intensity of activity.

Influence Of Anthropometric Factors On Balance In Masters Olympic Weightlifters

Mara A. Mercado, Kayleigh R. Erickson, Robert J. Burke, Bryan L. Riemann. *Armstrong State University, Savannah, GA.*
(No relevant relationships reported)

Whether participating in Olympic Weightlifting prompts balance adaptations to reduce age-related decrements is unknown. Previous research has examined the relationship between anthropometric factors and balance performance in the general population. It is likely that adults participating in Olympic Weightlifting possess different anthropometric characteristics. Thus, prior to comparing balance abilities of Olympic Weightlifters to other groups, the relationship between various anthropometric factors and balance needs to be established. **PURPOSE**: To determine if age and sex related balance differences exist in Masters Olympic Weightlifters and to examine the relationship between balance performance and anthropometrics, body composition, and strength. **METHODS**: 26 men (35-65yrs) and 22 women (35-61yrs) competitors from the Masters Olympic Weightlifting Championship volunteered to undergo 30s balance testing trials on firm (FI) and foam (FO) surfaces with eyes open (EO) and eyes closed (EC) while average medial-lateral center of pressure velocity was recorded. Body weight, height and body mass index were measured while lean mass (LM), and percent body fat were determined using dual energy X-ray absorptiometry. Strength was defined as the meet clean and jerk to body mass ratio. **RESULTS**: There were no significant (p>.05) relationships between age and balance performance (r: -.068 to .265). Except for LM and FI EO and EC performance in the women, there were no significant (p>.05) relationships between anthropometrics (r: -.277 to .267), body composition (r: -.304 to .271) and strength (r: -.341 to .016) with balance performance. No sex differences (p>.05) were identified. Complex post hoc comparison of a significant surface by vision interaction (p<.001) demonstrated the EO-EC difference for the FO surface as significantly greater than the FI (p<.001, d=3.4). **CONCLUSIONS**: In contrast to the general population, except for LM and FI EO and EC performance for the women, balance performance in Masters Olympic Weightlifters was not related to anthropometrics or body composition. The lack of age-related differences suggests the need for further study comparing this group to age-matched individuals participating in other modes of physical activity.

Support Moment Distribution While Squatting With Different Depths and Percentages One Rep Max

William Goodman[1], Scott Wilson[1], Linnea Zavala[1], Victoria Flores[2], Joshua Cotter[2], James Becker[1]. [1]*Montana State University, Bozeman, MT.* [2]*California State University, Long Beach, Long Beach, CA.*

(No relevant relationships reported)

Squatting to different depths or with different loads changes the demands on the neuromuscular system, thus potentially altering training effects. Previous studies have used EMG to assess joint contributions with various depths or loads. Another method for assessing this is to examine how each joint contributes to the total support moment (M_s) during the squat. **PURPOSE:** Examine how hip, knee, and ankle contributions to M_s change with increasing squat loads and depths. **METHODS:** 19 females (age: 25.1 ± 5.8 year; squatting experience: 3.8 ± 2.6 years) participated in this study. Participants performed squats at above parallel (AP), parallel (P), and below parallel (BP) depths with 0%, 50%, and 85% of a measured 1 rep max. Kinematics were recorded using a 12-camera motion capture system while ground reaction forces were measured with two force plates. Joint moments at the ankle, knee, and hip were summed to calculate M_s. Differences between depths and loads in peak M_s and the percent each joint contributed to peak M_s were evaluated using a 3x3 repeated measures ANOVA. **RESULTS:** Peak M_s increased as load increased (0%: 2.2 ± 0.3 Nm/kg, 50%: 3.1 ± 0.2 Nm/kg, 85%: 3.8 ± 0.1 Nm/kg, $p<.001$), but not as depth increased ($p=.149$). There was a significant depth*load interaction for hip contributions to M_s ($p=.013$), with hip contributions increasing with heavier loads for AP and P depths, but not BP (Figure 1A). There was also a depth*load interaction for knee contributions to M_s ($p=.046$). However the opposite pattern was displayed. As load increased, knee contributions to M_s decreased for the AP and P depths, but not BP (Figure 1B). Ankle contributions to M_s did not change with depth ($p=.483$) or load ($p=.581$). **CONCLUSION:** Total demand on lower extremity joints increases with increasing load but not depth in the back squat. At AP and P depths, increasing load involves the hip musculature more and the knee musculature less. At deep depths changing load does not impact how much each joint contributes to M_s.
Figure 1. Percent contributions to total support moment at different depths and loads for the hip (A) and knee (B).

Reliability and Validity of a Wireless Inertial Sensor for Assessing Vertical Jump Biomechanics

Joseph J. DeVita, Ian J. Kremenic, Karl F. Orishimo, Malachy P. McHugh, FACSM. *Nicholas Institute of Sports Medicine and Athletic Trauma, Lenox Hill Hospital, New York, NY.* (Sponsor: Malachy P McHugh, FACSM)

(No relevant relationships reported)

Title: Reliability and Validity of a Wireless Inertial Sensor for Assessing Vertical Jump Biomechanics
Authors: Joseph J DeVita, Malachy P McHugh FACSM, Karl F Orishimo, Ian J Kremenic
Purpose: Compare vertical jump metrics measured using force plates (FP) versus a wireless inertial sensor (IS).

Methods: 9 men (age 35 ± 14 yr, height 178 ± 8 cm, mass 84 ± 9 kg) performed 3 vertical countermovement jumps with arms akimbo (CMJ) and with arm thrust (CMJAT) while standing on force plates (BTS 6000D, BTS Bioengineering, Brooklyn, NY) and wearing a wireless inertial sensor (BTS G-Sensor 2, Brooklyn, NY) placed on the lumbar spine. CMJ and CMJAT biomechanical metrics were compared between FP and IS using paired t-tests, with reliability assessed using Pearson correlation coefficients. The following metrics were assessed: flight height, jump height (flight height + difference between standing height and takeoff height), low force (unweighting during initiation of countermovement), countermovement distance dropped, force at low point (end of countermovement), rate of force development, eccentric power, peak propulsive force, peak and takeoff velocity, maximum power, and peak landing force. Results: For CMJ there was good agreement between FP and IS for most parameters (Table 1); all metrics were significantly correlated between the FP and IS, but the IS significantly underestimated flight height, low force and force at low point. For CMJAT there was poor agreement for most jump parameters.

Table 1	CMJ			CMJAT		
Performance Metrics	FP	IS	r-Value	FP	IS	r-Value
Flight Height (cm)	30.9	29.6*	0.987	37.1	34.6*	0.989
Jump Height (cm)	40.4	38.0	0.916	48.2	46.4	0.885
Countermovement Metrics						
Low Force (N)	408	375*	0.986	423	351*	0.750
Countermovement (cm)	33.5	36.5	0.778	33.8	29.9	0.205#
Force at Low point (N)	1648	1517*	0.908	1574	1562	0.418#
Rate of Force Development (N/s)	3303	3056	0.879	3000	3956	0.275#
Eccentric Power (W)	-1019	-962	0.691	-1039	-1125	0.405#
Propulsive Metrics						
Peak Propulsive Force (N)	1766	1726	0.778	2721	2467	0.750
Peak Velocity (m/s)	2.54	2.61	0.836	2.78	2.92	0.713
Takeoff Velocity (m/s)	2.41	2.50	0.814	2.65	2.81	0.743
Maximum Power (W)	3687	3895	0.851	4350	5613*	0.850
Landing Metrics						
Peak Landing Force (N)	3690	1969*	0.626#	3489	2245*	0.332#

*sig. dif. (bias/fixed error) P<0.05; #nonsig. correlation P>0.05
Conclusions: This wireless inertial sensor was effective for quantifying the countermovement and propulsive phases of a CMJ, but was not effective for quantifying landing force. The sensor was not effective for quantifying CMJAT parameters.

1837 Board #98 May 31 3:30 PM - 5:00 PM

Validity of a Commercially Available Inertial Measurement Unit for Vertical Jump Height Measurement

Gregory A. Crisafulli, Jeffrey B. Taylor, Anh-Dung Nguyen, Kevin R. Ford, FACSM. *High Point University, High Point, NC.* (Sponsor: Kevin R. Ford, FACSM)

(No relevant relationships reported)

3D motion capture (3D) systems are the gold standard for assessing displacement during movements such as a drop vertical jump (DVJ) and a countermovement jump (CMJ). However, it is not feasible to use 3D in the field during game or practice situations. **PURPOSE:** To examine validity of vertical jump height measured by inertial measurement units (IMU). **METHODS:** Eleven male (15.4 ± 0.9yrs, 178.0 ± 6.5cm, 80.5 ± 13.04kg) high school football players participated. A small IMU placed in an elastic belt was worn around the waist of each subject during 3 CMJ and DVJ trials. Maximum vertical jump height was recorded as the vertical displacement of the pelvis using standard 3D techniques. A 2X2 repeated measures ANOVA (p<0.05) was used to determine differences in vertical displacement between measurement methods and movement type. 95% limits of agreement (LOA) and Bland Altman plots were utilized to determine the level of agreement between IMU and 3D during each task. **RESULTS:** A significant interaction between measurement and movement was found in vertical displacement (p<0.05). During the CMJ, the displacement measurement was not different (3D: 46.9 ± 5.4cm, IMU: 45.9 ± 3.8cm p=0.36). However, during the DVJ, the IMU measurement was statistically underestimated (45.0 ± 3.7cm p=0.001) compared to 3D (48.7 ± 5.7cm). Bland Altman plots and 95% LOA (Figure) illustrate a systematic error between the IMU and 3D during the DVJ where jump height was underestimated by the IMU. Interestingly, during both tasks, agreement between measurement methods seem to increase at higher jump heights. **CONCLUSIONS:** IMU technology is advancing with potential utility for on-field and in-game use. However, the algorithms which calculate vertical jump height may need to be adapted for varying types of complex movements.

Countermovement Jump / Drop Vertical Jump

submaximal running, the runners were paced by a cyclist maintaining a constant speed using a speedometer. Interclass correlations were run between Power Meter 1 and Power Meter 2 on all surfaces including treadmill, track, and grass.
RESULTS: Running power values were reliable between the two power meters on trials 1 and 2 for the three different surfaces (Power: R=0.998).
CONCLUSIONS: The results support that the Stryd running power meter can reliably measure power of submaximal running on three different surfaces including treadmill, grass, and track.

Differences In Wearable Running Power On Three Different Surfaces During Submaximal Running

Mason Coppi, Lee Shearer, Nicholas Hayden, Jake Ogden, Frank Lara, Scott Murr, Eric Sobolewski, Randolph Hutchison. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)

(No relevant relationships reported)

Running pace is one of the primary measures of running intensity, however, variations in grade and surface limit quantifying intensity solely based on pace. With the advent of wearable running power meters, runners can assess the external work stimulus inclusive of pace, grade, and surface.
PURPOSE: To assess differences in running power (RP) on different surfaces, a Stryd running power meter was evaluated based on submaximal running on three different surfaces.
METHODS: Eight collegiate cross country runners (male n=4, age=21.25±0.50 yrs, weight=63.45±9.73 kg, height=178.5±10.82 cm; female n=4, age=20±1.41 yrs, weight=56.45±4.95 kg, height=169.5±7.97 cm) participated in two trials of submaximal running at 85% of lactate threshold (LT) on each of three different surfaces: treadmill, grass, and track. All subjects completed a VO2max and LT running test. For this investigation, sub-maximal running speed/pace was determined from the maximal effort / LT test. During subsequent submaximal running trials, ventilatory and metabolic measures and heart rate (HR) were collected with a portable breath by breath analyzer (COSMED K4B2) and HR monitor (Polar). For the track and grass submaximal running, the runners were paced by a cyclist maintaining a constant speed using a speedometer. ANOVAs were run between trials on all surfaces including treadmill, track and grass.
RESULTS: The running power for the treadmill surface was significantly lower than both the grass and track (Mean±SE: RPtreadmill = 237±12.7 W*, RPgrass = 244±13.4 W, RPtrack = 242±13.0 W). There were no significant differences between grass and track surfaces (*p<0.05).
CONCLUSIONS: This investigation found that running power (Stryd) is less when running on a treadmill compared to running on grass and a track which may indicate a different training stimulus when training on a treadmill versus other surfaces.

Reliability Of A Running Power Meter Between Trials Of Submaximal Running On Three Different Surfaces

Frank Lara, Lee Shearer, Mason Coppi, Nicholas Hayden, Jake Ogden, Scott Murr, Randolph Hutchison, Eric Sobolewski. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)

(No relevant relationships reported)

Running pace is one of the primary measures of running intensity, however, variations in grade and surface limit quantifying intensity solely based on pace. With the advent of wearable running power meters, runners can assess the external work stimulus inclusive of pace, grade, and surface. **Purpose**: To assess reliability, a running power meter was evaluated based on two trials of submaximal running on three different surfaces.
METHODS: Eight collegiate cross country runners (male n=4, age=21.25±0.50 yrs, weight=63.45±9.73 kg, height=178.5±10.82 cm; female n=4, age=20±1.41 yrs, weight=56.45±4.95 kg, height=169.5±7.97 cm) participated in two trials of submaximal running at 85% of lactate threshold (LT) on each of three different surfaces: treadmill, grass, and track. All subjects completed a a VO2max and LT running test. For this investigation, sub-maximal running speed/pace was determined from the maximal effort / LT test. During subsequent submaximal running trials, ventilatory and metabolic measures and heart rate (HR) were collected with a portable breath by breath analyzer (COSMED K4B2) and HR monitor (Polar). For the track and grass submaximal running, the runners were paced by a cyclist maintaining a constant speed using a speedometer. Intraclass correlations were run between trials 1 and 2 on all surfaces including treadmill, track and grass.
RESULTS: VO$_2$, HR, and running power were all reliable between trials 1 and 2 on the 3 different surfaces (VO$_2$: r$_{treadmill}$ = 0.980, r$_{grass}$ = 0.876, r$_{track}$ = 0.977; HR: r$_{treadmill}$ = 0.938, r$_{grass}$ = 0.978, r$_{track}$ = 0.981; Power$_1$: r$_{treadmill}$ = 0.995, r$_{grass}$ = 0.999, r$_{track}$ = 1.00; Power$_2$: r$_{treadmill}$= 1.00, r$_{grass}$ = 1.00, r$_{track}$ = 1.00)
CONCLUSIONS: The results support that the Stryd running power meter can reliably measure power of submaximal running on three different surfaces including treadmill, grass, and track.

Comparisons of Ankle and Knee Kinetics during Demi-Plié Ballet Movements

Morris Levy[1], Darren Dutto[2], LilaAnn White[1]. [1]*University of Minnesota, Duluth, MN.* [2]*Eastern Oregon University, La Grande, OR.*

(No relevant relationships reported)

The Demi-Plié (DP) and Demi-Plié Relevé (DP-R) movements are foundational to performance in Ballet. The DP and DP-R have similar downward phases with the main difference consisting of an upward phase in the DP-R when the dancer goes up on her/his toes, while extending ankle and knees.PURPOSE: The purpose of this study was to compare ankle and knee motion (kinetics) during the downward phase of the Demi-Plié and Demi-Plié Relevé, with a hypothesis that peak moments would increase during the DP-R. METHODS: Ten college ballet students (mass = 70 ± 14 kg) performed three sets of eight Demi-Plié and Demi-Plié Relevé movements. Full body kinematics were collected using a 12-camera Vicon motion capture system (Oxford, UK). Two Force plates (AMTI) were used to isolate the Ground Reaction Forces (GRF) of each foot. For each individual, average peak ankle/foot and knee moments in the sagittal and frontal planes were determined for each leg, using the average of values determined for each cycle of movement. Beginning of each movement was identified as initiation of knee flexion during the downward phase. Peak moments were compared between the two movements using t-tests. RESULTS: Ankle extension moments were greater in the DP-R (Left: DP = 0.60 ± 0.11, DP-R: 0.76 ± 0.13 Nm/

kg, p<0.05). In the frontal plane, knee abduction moments were smaller for the DP-R (Left: DP = 0.31 ± 0.10, DP-R = 0.23 ± 0.12 Nm/kg, p=0.11), while ankle eversion moments tended to be larger (Left: DP = 0.19 ± 0.12, DP-R= 0.28 ± 0.12 Nm/kg, p=0.10). Knee extension moments were not different (Left: DP=0.66 ± 0.30, DP-R= 0.69 ± 0.31 Nm/kg, p=0.73) between the two movements, although there was an additional 4° knee flexion during DP-R. CONCLUSION: During the DP-R, ankle moments are greater in the sagittal and frontal planes. While the movement during the downward phase is similar, the DP-R has the intervening upward phase consisting of ankle extension. This intervening upward motion of the DP-R appears to alter ankle control during the downward phase requiring greater sagittal and frontal plane moments. However, knee varus stress was reduced.

Technical Note: Measuring Muscle Activity During Plyometric Exercise In Shallow Water

Cordero Duvon Roche, Leland Barker, John A. Mercer, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John A Mercer, FACSM)

(No relevant relationships reported)

Plyometric exercise in water is used by a variety of people. Recently, a water proof system to measure muscle activity has become available but the procedures for analyzing muscle activity during water plyometrics are not established. **PURPOSE:** The aim of this study was to describe the procedures for collecting and analyzing muscle activity data during plyometrics in the water and on land. **METHODS:** A single subject (male, 29 yr, 170 cm, 81.8 kg) completed all conditions. The subject completed two plyometric exercises (countermovement jump (CMJ), drop jump (DJ)) during the two environmental conditions (on land, water). Electromyography (EMG) signals were recorded using a water proof EMG system (Cometa Miniwave Infinity, 2000 Hz). Each sensor measured EMG as well as accelerations along 3 orthogonal axes. EMG was recorded from four muscles (rectus femoris (RF), bicep femoris (BF), gastrocnemius (GA) and tibialis anterior (TA)) during CMJ and DJ while on land and in water. The subject then performed three trials of CMJ then three trials of DJ (from 30.5 cm platform) on land. The subject stood still for at least 1-sec between each trial. After completion on land the subject preformed the same conditions in the same order in the water. Depth of water was set to about navel high. EMG data were processed by removing zero offset and full wave rectifying with percent difference (%diff) calculated between on land and in water for each movement. The start and end of each movement was identified using acceleration in the z direction (a_z). Start of movement was first a_z 5% greater than baseline corresponding with burst of EMG and end of movement (standing still after landing from jump) was a_z 5% less than baseline after landing. EMG data were then averaged between start and end times. %Diff data were averaged across trials. **RESULTS:** The CMJ movement duration was similar on land (2.1±0.08 s) and in water (2.4±0.20 s) but different during DJ on land (1.9±0.13 s) vs. in water (3.0±0.86 s). During CMJ, %diff for RF (-0.6%) and TA (6.5%) was similar but BF (55.9%) and GA (70.9%) were more active during water. During DJ, BF (55.9%), GA (70.9%), and TA (34.4%) were more active but RF (-9.5%) less active during water vs. on land. **CONCLUSION:** Using sensors that incorporated EMG and accelerometers allowed for analysis of muscle activity during plyometrics.

Kinematic Comparison of Dolphin Kicking Performed in a Prone and Supine Body Position

Mickey B. Scharbrough, Taylor L. Adams, Peter E. Robinson, Kali T. Rose, Scott P. McLean. *Southwestern University, Georgetown, TX.* (Sponsor: John Bartholomew, FACSM)

(No relevant relationships reported)

Despite an increasing emphasis on underwater dolphin kicking in competitive swimming, little objective research exists to explain its preference over flutter kicking. PURPOSE: To examine kinematic characteristics of flutter and dolphin kicking performed in prone and supine body positions. METHODS: Ten collegiate swimmers (1.77±0.07 m, 72.4±7.6 kg, 19.8±1.0 yrs) experienced with dolphin and flutter kicking completed eight 10 m maximal effort underwater kicking trials. Body position and kicking style were randomly varied between trials such that half of all trials were performed using each kicking style and each body position. A calibrated underwater camera was used to record each trial at 60 Hz. Six body landmarks were digitized for three complete kicking cycles to determine linear and angular kinematic measurements. Whole body speed was defined as horizontal hip velocity. Kicking amplitude and frequency were determined using vertical toe movements. The Strouhal number, a dimensionless index related to the efficiency of underwater undulatory movement, was computed using the kicking amplitude, frequency and velocity. Kinematic data were filtered using a fourth order Butterworth low-pass digital filter with cutoff frequencies individually determined for each coordinate. Linear velocities were computed using the first central difference method. Kinematic measures were compared between kicking style and body positions using a 2x2 (kick x position) repeated measures ANOVA. RESULTS: Dolphin kicking velocity (1.22±0.18 m/s)

---

was faster (p<0.001, η^2=0.88) than flutter kicking velocity (0.99±0.12 m/s). Dolphin kicking amplitude (0.58±0.10 m) was larger (p<0.001, η^2=0.93) than flutter kicking amplitude (0.48±0.08 m). Dolphin kicking frequency (1.85±0.34 Hz) was lower (p=0.002, η^2=0.68) than flutter kicking frequency (2.33±0.33 Hz). Dolphin kicking (0.88±0.12) was more efficient as indicated by a lower Strouhal number (p=0.001, η^2=0.71) than flutter kicking (1.11±0.21). Body position had no effect on any measure of kicking performance (p>0.05). CONCLUSION: For these participants, dolphin kicking was a faster, more efficient form of underwater kicking. However, body position had little effect on the ability of these participants to perform the respective kicking style.

Higher Vertical Stiffness Is Related To Greater Fifth Metatarsal Bone Mineral Density In Football Players

Thomas J. Hockenjos, Kevin R. Ford, FACSM, Justin P. Waxman, Anh-Dung Nguyen, Audrey E. Westbrook, Michelle A. Aube, Jeffrey B. Taylor. *High Point University, High Point, NC.* (Sponsor: Kevin Ford, FACSM)

(No relevant relationships reported)

Lower-extremity stiffness is suggested to contribute to lower-extremity injury risk. Specifically, lower stiffness is believed to lead to excessive joint motion and contribute to soft tissue injuries. Alternately, higher stiffness is thought to enhance overall joint stability, reduce ligament loading, and potentially increase bone loading. Though beneficial in the short-term, long-term bone loading and the reduced ability to attenuate lower extremity forces may also increase injury risk. Thus, it may be important to elucidate the relationship between stiffness and bone mineral density (BMD). **PURPOSE**: To identify differences in BMD between athletes with relatively higher and lower levels of vertical stiffness (K_{Vert}). **METHODS**: BMD of the whole body (BMD_{WB}), dominant limb (BMD_{DL}) and second and fifth metatarsals (BMD_{Met2} and BMD_{Met5}, respectively) of the dominant leg, was assessed in 41 male American football players (age: 16.1±1.4 yrs, height: 176.5±6.8 cm, mass: 80.6±18.3 kg) via dual-energy x-ray absorptiometry. Additionally, vertical stiffness (K_{Vert}) of the dominant leg was assessed via a repetitive single-leg vertical hopping task at a set hopping frequency of 2.2 Hz. Participants were divided into tertiles based on their body mass normalized K_{Vert} values. Differences in BMD-related variables between the low- and high-stiffness groups were evaluated using independent t-tests. **RESULTS**: Athletes in the high-stiffness group displayed significantly greater K_{Vert} than the low-stiffness group (0.28±0.01 vs. 0.20±0.02 kN·m⁻¹·kg⁻¹, $p<0.001$); however, there were no between-group differences identified in terms of age, height, or mass ($p>0.05$). Athletes in the high-stiffness group were found to possess significantly greater BMD_{Met5} compared to the low-stiffness group (0.44±0.11 vs. 0.34±0.11 g/cm², p=0.029). Similar between-group differences in BMD_{WB}, BMD_{DL}, and BMD_{Met2} were not observed ($p>0.05$). **CONCLUSIONS**: Athletes with relatively high K_{Vert} also had greater BMD_{Met5}, indicating that relatively higher stiffness may impose stress on the bone that results in favorable adaptation (increased BMD). Continued work investigating the relationship between K_{Vert}, BMD, and training load may elucidate the risk of bony injury in these athletes is warranted.

The Influence Of Load On Preferred Countermovement Depth During Jump Squats

Leland Barker, John Mercer, FACSM. *UNLV, Las Vegas, NV.* (Sponsor: John Mercer, PhD, FACSM, FACSM)

(No relevant relationships reported)

ABSTRACT
The jump squat exercise is used in training to provide increased stress to the countermovement jump. However, it is not clear how load influences preferred countermovement depth during the jump squat.
PURPOSE
Compare preferred countermovement depth (PREF) to full and quarter depths (FULL, QTR) during the jump squat across a range of loads.
METHODS
On day one, participants (Male, n=12; 25.2 ± 3.9 yrs, 1.77 ± 0.7 m, 88.3 ± 15.7 kg) performed a 3 repetition maximum (3 RM) back squat, which was used to estimate the 1 RM back squat (1 RM = 3 RM/0.9). On the second collection 2-10 days later, jump squats were performed with barbell loads of 0%, 15%, 30%, 45%, 60%, and a return to 0% of 1 RM. Three trials at each load were performed with instructions being to jump as high as possible. Order between conditions was counterbalanced. Vertical ground reaction force (vGRF) was measured from a dual force platform setup (fs=1000 Hz). Verbal cues were given for each depth. Acceleration was calculated from vGRF (∑F=m*a), velocity was integrated from acceleration, and position was integrated from velocity. Countermovement depth was calculated as the minimum position during the jump squat. Jump height was calculated as: (takeoff velocity)²/(2*9.81). 3 (technique)

---

x 5 (load) repeated measures ANOVAs were performed on depth and jump height, followed by planned comparisons (1x5 and 1x3 ANOVAs) if an interaction was present (α=0.05). A paired-samples t-test was used to compare first and last 0% loads to assess possible fatigue and/or potentiation.
RESULTS
Neither depth nor jump height were influenced by an interaction (p>0.05). Countermovement depth was influenced by technique (p<0.05). Countermovement depth was significantly different among PREF (-0.33 m ± 0.09 m), FULL (-0.44 m ± 0.08), and QTR (-0.24 m ± 0.06) regardless of load (p<0.05). Jump height was not influenced by technique (p>0.05), but there was a main effect for load (p<0.05) with jump height decreasing with load regardless of technique. Jump height was not different between the first and last 0% 1RM jump squat trials (p>0.05).
CONCLUSION
Countermovement depth was different among PREF, FULL, and QTR across loads, but jump height was not influenced by PREF, FULL, or QTR. These results demonstrate that verbal cues can elicit three distinct countermovement depths during jump squats.

The Relationship Between 2D and 3D Biomechanics Data in a Single Leg Hurdle Task

Gaelen Athanaze, Chelsey Roe, Samantha Price, Hayley Reed, Jessica Schilling, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: Brian Noehren, FACSM)
(No relevant relationships reported)

Three-dimensional (3D) motion analysis has been regarded as the gold standard for measuring landing mechanics. However, motion analysis is limited in clinical settings due to the time and expertise requirements. The amount of knee flexion during a single leg landing task is commonly assessed and has been found to be related to a number of injuries. However, to date there have been few studies investigating the relationship between a simple two dimensional (2D) measure to 3D measurements. Establishing this relationship would be important to provide better tools for clinicians to use.
Purpose: To determine if there is there is a relationship between 2 and 3 dimensional knee flexion angle during a single leg hurdle task.
Methods: 20 Healthy Subjects (11 M, Age 22.4± 3.14, BMI 22.96 ± 3.06). Subjects performed instrumented single leg jumps over a series of 30.5 cm hurdles. The landing over the final hurdle was recorded with both a video camera and motion capture equipment. 2D knee flexion angles were measured using National Institute of Health image J program at the point of initial contact and peak knee flexion. An angle was determined by bisecting the knee along the mid shaft of the femur and tibia for the 2D motion. Peak knee flexion was determined in both the 2D video and 3D motion capture data with the association between the two assessed with a Pearson product moment correlation coefficient.
Results: Mean values for knee flexion in 3D were 24.8±9.0° at initial contact and 59.8±9.2° at peak knee flexion. Mean values for the 2D data were 28.0±6.8° at initial contact and 66.0±8.9° at peak knee flexion. There was a significant correlation at initial contact (r=0.717, p=.001) as well as for peak knee flexion angle (r=0.617, p=.006) between the 2D method and 3D motion capture.
Conclusion: At both initial contact and peak knee flexion, there was a strong relationship between the 2D and 3D angle values. Both measurements trended similarly but were different in magnitude. This suggests a simple 2D technique may be applicable in the clinical setting providing similar precision but different accuracy to the 3D motion capture data.

Effects And Interactions Of Ncaa Di Basketball Participation On Measures Of Reactive Strength

Nile Banks[1], Dennis Dolny[2], Eadric Bressel[2], Talin Louder[1]. [1]*The University of South Dakota, Vermillion, SD.* [2]*Utah State University, Logan, UT.*
(No relevant relationships reported)

Measures of reactive strength attempt to model the neuromuscular regulation of muscle tissue stress and strain. The specificity of neuromuscular training is important for maximizing the effectiveness of neuromuscular regulation of stress and strain within muscle and tendon tissue. Additionally, failure to regulate stress and strain within the muscle may lead to stresses placed on supporting structures of the body, including ligaments and bones. It is important to understand how sport participation effects neuromuscular reactivity and to develop strategies that maximize neuromuscular reactivity through specific training foci.
PURPOSE: The purpose of this study was to evaluate the effects and interactions of sport participation on the Coefficient of Reactivity (CoR), Reactive Strength Index (RSI), and Reactive Strength Kinetic (RSK).
METHODS: Fifty-nine young adults from the general community and 21 NCAA Division I basketball players performed five repetitive countermovement jumps (RCM) and a single depth jump from heights of 0.51 m, 0.66 m, and 0.81 m. The CoR, RSI, and the RSK were computed using tri-axial force platform data and two-dimensional

videography. A Multivariate General Linear Model Analysis of Variance (GLM ANOVA) was performed on RCM data and another on depth jump data. Condition, sport participation, sex, and age were included as factors in each model.
RESULTS: The CoR, RSI, and RSK were 30%, 22%, and 28% greater in males performing depth jumps versus females (*p*<0.05). The RSI and RSK were 23%, and 21% greater in males performing RCM jumping versus females (*p*<0.05). Main effects for sport participation were observed for the CoR, RSI, and RSK in depth jumping and for the RSI and RSK in RCM jumping (*p*<0.05). Sex by sport participation interactions were observed for the RSI and RSK, but not for the CoR.
CONCLUSION: All three measures of reactive strength were sensitive to sex. Sex by sport interactions on the RSI and RSK suggest that involvement in NCAA Division I basketball may lead to a divergence in lower extremity neuromuscular reactivity between male and female athletes (males>females). This result makes sense from the perspective that female athletes tend to sustain higher incidence of lower extremity injuries when participating in sport.

Identifying the Effects of Sex on Reactive Strength Scores using Receiver Operating Characteristic (ROC) Curves

Lara Boman, Jordan Preuss, Jake Rosburg, Nile Banks, Talin Louder. *The University of South Dakota, Vermillion, SD.*
(No relevant relationships reported)

Receiver operating characteristic curves are used as a technique to evaluate the sensitivity and specificity of a continuous variable to discrete, categorical variables. It is known that post-pubescent females tend to diverge from males in neuromuscular performance. Measures of reactive strength attempt to model lower extremity neuromuscular reactivity in agile movement tasks. It is likely that constructing ROC curves would reveal that reactive strength scores are sensitive and specific to the effects of sex on neuromuscular reactivity.
PURPOSE: The purpose of this study was to construct ROC curves to evaluate the sensitivity and specificity of the Reactive Strength Kinetic (RSK), Reactive Strength Index (RSI), and the Coefficient of Reactivity (CoR) to the effects of sex on neuromuscular reactivity.
METHODS: Fifty-nine young adults from the general community and 21 NCAA Division I basketball players performed depth jumps from heights of 0.51 m, 0.66 m, and 0.81 m. The RSK, RSI, and CoR were computed using tri-axial force platform data and two-dimensional videography. Multiple paired *t*-tests, Cohen's *d* effect sizes, and ROC curve analysis were used evaluate sex differences and the extent that reactive strength scores are sensitive and specific to sex (α=0.05).
RESULTS: RSK, RSI, and CoR scores were greater in males versus females across all depth jump conditions (*p* < 0.000 - 0.002). ROC areas under the curve were larger for CoR (0.78 - 0.87) versus RSI (0.73 - 0.77) and RSK (0.69 - 0.77) across all three depth jump heights. Average sensitivity of all measures was largest in the 0.81 m condition (0.80 versus 0.73 (0.66 m) and 0.76 (0.51 m)).
CONCLUSION: Results suggest that all measures evaluated in this study were sensitive to differences in neuromuscular reactivity across sexes. ROC analyses suggested that the CoR may be the most sensitive measure of sex effects on lower extremity neuromuscular reactivity in depth jumping. Additional research using higher depth heights may confirm this. Additionally, the CoR is a field-test that may be easy to implement by strength and conditioning and clinical professionals.

Evaluating A Kinetic-based Assessment Of Reactive Strength

Talin Louder[1], Nile Banks[1], Eadric Bressel[2], Dennis Dolny[2]. [1]*The University of South Dakota, Vermillion, SD.* [2]*Utah State University, Logan, UT.*
(No relevant relationships reported)

The Reactive Strength Index (RSI) is the most commonly used reactive strength assessment and its assumed validity among researchers and practitioners is strong. The RSI is a spatiotemporal ratio that used to model a characteristic of strength. In addition, the RSI is computed using theoretical assumptions that are likely variable and inaccurate. There is a need to address the theoretical validity of the RSI, and consider adopting a kinetic-based assessment of reactive strength
PURPOSE: The purpose of this study was to evaluate the validity of a new kinetic-based assessment of reactive strength, the Reactive Strength Kinetic.
METHODS: Eighty young adults (22.9±2.2years, 76.1±14.9kg, 175.9±12.0cm) completed one maximal effort depth jump from three incremental drop heights (0.51m, 0.66m, and 0.81m) and a single trial of five repetitive countermovement jumps (RCM). Using two-dimensional videography and tri-axial force platform dynamometry, the Coefficient of Reactivity (CoR), RSI, RSK, and RSKa (a=kinematic-adjusted) were computed for all jumping trials. Linear regressions were performed to assess the statistical association between the CoR, RSI, RSK, and RSKa.

RESULTS: Linear regressions detected the strongest association in the RSK v. RSI (R^2=0.599,p<0.001) and RSKa v. RSI (R^2=0.636,p<0.001) comparisons. Additionally, a linear regression performed on drop height v. measured impact velocity revealed marginal statistical association (R^2=0.346,p<0.001).

CONCLUSION: The proportion of explained variance in the comparisons of RSK v. RSI and RSKa v. RSI suggest that the RSI, RSK, and RSKa all attempt to model the construct of reactive strength. The CoR, RSI, and RSK all assume that drop height in depth jumping and flight time in RCM jumping perfectly predict impact velocity. Results suggest that using theoretical assumptions to compute reactive strength scores is invalid. The RSKa is kinetic-based and kinematic-adjusted to eliminate theoretical assumptions known to introduce measurement error in the RSI, CoR, and RSK.

Previous Injury History and Landing Error Scoring System and Single-Leg Squat Scores in Collegiate Athletes

Peter Lisman, Daniel C. MacLea, Jennifer Gannon, Bethany Hansberger, Nathan Wilder. *Towson University, Towson, MD.*

(No relevant relationships reported)

The Landing Error Scoring System (LESS) and Single Leg Squat (SLS) are two clinical assessments that can be used to identify faulty lower extremity biomechanics for screening injury risk in athletic populations. To date, few studies have examined the effect of prior injury on these tests or the relationship between LESS and SLS scores. **PURPOSE:** Determine if prior history of lower extremity injury affected LESS and SLS scores and examine the association between LESS and SLS performance. **METHODS:** Thirty-eight collegiate female athletes (n=26 field hockey, n=12 basketball; 19.4 ±1.4y; 167.5± 9.4cm; 67.2±11.3kg) underwent LESS and SLS testing. Participants completed 3 jump landing tasks followed by 3 consecutive SLSs on each leg. A Microsoft Kinect sensor using Athletic Movement Assessment software (PhysiMax®) was used to automatically score the LESS and SLS. The LESS consisted of 22 items while the SLS was comprised of 14 items; both were adjusted to omit the overall impression item. The highest scores possible for the LESS and SLS were 22 and 10, respectively. The lowest score of the 2 sides for the SLS was used for analyses. An injury history survey was completed to identify previous history of injury. Independent *t*-tests were used to compare mean LESS and SLS scores between participants with and without a history of injury. A Pearson correlation coefficient was used to examine the association between LESS and SLS total scores while chi-square statistics were used evaluate relationships between scores for medial knee displacement (MKD R/L side errors) across tests. **RESULTS:** No differences were found between participants with and without a history of injury in LESS (5.3±1.9 vs. 6.0±1.7; p=0.375) or SLS (4.6±0.9 vs. 4.3±1.3; p=0.403) total scores. No correlation was found between LESS and SLS total scores (r=0.127; p=0.453). Although not statistically significant, players displaying an error for MKD during a right-legged SLS were 3 times more likely to also display this error (right MKD) on the LESS (χ^2=1.97; p=0.160, OR=3.3, 95%CI=0.59-18.31). **CONCLUSION:** Prior injury history did not affect LESS or SLS scores. More research is necessary to determine potential associations between scores on similar items across tests and their clinical implications for injury risk screening and corrective exercise programming.

Fatigability of Plantar Flexor Muscles After Remote Ischemic Preconditioning

Hugo M. Pereira[1], Bruno M. Silva[2], André F. Kohn[1]. *[1]University of São Paulo, São Paulo, Brazil. [2]Federal University of São Paulo, São Paulo, Brazil.*

(No relevant relationships reported)

Exposure to brief periods of circulatory occlusion and reperfusion before an exercise (i.e. ischemic preconditioning - IPC) has been suggested to decrease exercise-induced fatigability, but placebo effects are yet to be fully determined. It is also not known if IPC can alter perceived pain and effort during isometric contractions performed with the lower extremity muscles. **PURPOSE:** To determine if IPC can decrease fatigability, perceived effort and pain of the lower extremity muscles during isometric contractions. **METHODS:** 12 individuals (27± 4 years) were submitted to cycles of ischemia and reperfusion by inflating a cuff to the non-dominant leg and arm in 3 separate and randomized sessions: A) IPC that consisted of 3 cycles of ischemia and reperfusion of 5 minutes each; B) SHAM session where cuffs were inflated for only 1 minute (not sufficient to induce ischemia), but reperfusion and total times of intervention were similar to those of the IPC session; C) Control session with no cuffs involved. Placebo induction was performed by saying that both IPC and SHAM would improve performance compared to control. Nocebo avoidance was accomplished by telling individuals that IPC would be harmless despite circulatory occlusion sensations. In each session, isometric contraction of the plantar flexor muscle was performed at 20% of maximal voluntary contraction (MVC), with the dominant leg, until task failure. Pain and ratings of perceived exertion were assessed during contractions with a Visual Analogue Scale (0-10). **RESULTS:** Time to task failure was greater in the

---

IPC compared with SHAM and control sessions (25.1 ± 4 vs. 19.2 ± 2 vs. 20.3 ± 3 min respectively, session effect: P = 0.04). MVC at task failure was 60 ± 2 % lower than baseline (time effect: P < 0.001) for all test sessions (session × time: P = 0.31). At 25 % of time to task failure, exercise-induced pain was lower in IPC compared with SHAM and control sessions (1.3 ± 1 vs. 1.9 ± 1 vs. 2.6 ± 2 respectively, P = 0.03). Ratings of perceived exertion were similar between test sessions (session effect and session × time: P > 0.05). **CONCLUSIONS**: Compared with the control session, IPC increased time to task failure and decreased exercise-induced pain during fatiguing contraction of the plantar flexor muscles. Placebo effects induced in the SHAM session had minimal effects in these variables.

Laboratory Assessment of Pristine and Used Soft-Shell Headgear for Girls' High School Lacrosse

Patricia Kelshaw[1], Trenton E. Gould[2], Mark Jesunathadas[2], Nelson Cortes[1], Amanda Caswell[1], Elizabeth Edwards[2], Shane Caswell[1]. *[1]George Mason University, Manassas, VA. [2]University of Southern Mississippi, Hattiesburg, MS.*

(No relevant relationships reported)

Increased participation in high school girls' lacrosse has coincided with higher rates of game related head and facial injury. In response, rules allowing for the use of headgear following American Society for Testing and Materials (ASTM) performance standards has been adopted. However, due to the novelty of this equipment it remains unknown how lacrosse headgear responds to blunt impacts after repeated use. **PURPOSE:** To compare the resultant peak linear acceleration (RPLA) between used and pristine girls' lacrosse headgear during blunt impacts. **METHODS**: 10 pristine and 10 used Cascade LX Women's Lacrosse Headgear were tested. Pristine headgear were tested in their original condition and were not worn or exposed to external elements or impacts prior to testing. Used headgear were worn for an entire competitive season (15 games, 51 practices). A Cadex Monorail Impactor impacted all headgear fitted to a EN 960 size J headform following ASTM standards (F1446-15b, F2220-15, and F3137-15) in the front, side, rear, rear and front boss, crown and one random locations. The resultant tri-axial acceleration of the EN 960 J headform was measured with Cadex Software. A factorial ANOVA was employed to compare RPLA among headgear conditions (pristine and used) and impact locations. **RESULTS**: A significant main effect for position was observed (p<0.001). With the exception of random location with side location, all other pairwise comparisons denoted statistically significant differences among them for RPLA (front = 50.6 ± 3.5, side = 37.1 ± 1.8, rear = 23.4 ± 2.1, rear boss = 56.5 ± 4.3, front boss = 63.1 ± 4.9, crown = 58.7 ± 3.5, random = 38.5 ± 5.2 RPLA). There was no significant difference between headgear conditions for RPLA. **CONCLUSIONS**: All headgear regardless of condition, met the ASTM performance standard. No differences existed in RPLA between pristine and used headgear. No differences existed among the pristine and used headgear. This indicates that the headgear is capable of being used beyond a single season. Our findings are comparable to those that investigate the RPLA of verified head impacts in high school girls' lacrosse games. Further field research is necessary to evaluate if headgear improves the safety of girls' lacrosse, including changes in behavior subsequent to the additional safety standard.

Do Compression Socks Influence Muscle Activity of the Lower Extremities?

Andrew Craig-Jones. *UNLV, Las Vegas, NV.* (Sponsor: John A. Mercer, FACSM)

(No relevant relationships reported)

Compression clothing is commonly worn by athletes and anecdotally believed to elicit beneficial responses both physiologically and biomechanically during a performance. PURPOSE To determine if compression socks influence muscle activity of the lower extremities while running. A secondary purpose was to assess whether compression socks had an effect on heart rate (HR) or rating of perceived exertion (RPE) during running. METHODS Recreational runners (n=5; 1.65 ± 0.07m; 67.48 ± 8.9kg; 21.8 ± 3.25yr) completed three running conditions: wearing graduated compression socks (CS), regular socks (RS), and placebo socks (PS). Each run was 10 minutes at a self-selected pace with speed controlled between conditions. CS were knee-high socks that had graduated compression moving proximally up the leg. Sock size used was based on shoe size as per manufacture instructions. RS were determined by the type of sock each subject was wearing on the day of testing. PS were regular soccer socks in which we fitted all subjects with L/XL to minimize any compression and instructed each subject they were a different brand of compression socks. Subjects were blind to conditions. HR was recorded during the last 30s of all trials telemetrically (Polar, Lake Success, NY). Muscle activity of the lower extremity was measured through electromyography (EMG; Delsys, Natick, MA). RPE was recorded at 3 minute intervals. EMG data were processed by removing any zero offset, rectifying, and averaging over 30 seconds of minutes 4, 7, and 10 of each trial. Dependent variables (EMG, HR, RPE) were each compared between conditions using repeated measure

---

ANOVAs (α=0.05). RESULTS HR and RPE were not significantly different between conditions (p>.05). Muscle activity for the Rectus Femoris (RF), Biceps Femoris (BF), and Gastrocnemius (GA) were not significantly different between conditions (p>.05). Muscle activity for the Tibialis Anterior (TA) was significantly different (p=0.042) during CS condition (47.8±2.2μv) compared to RS condition (63.0±2.0μv). This accounts for ~24% reduction in muscle activity while wearing compression socks. CONCLUSION Compression socks significantly decrease muscle activity of the TA during running but had no effect on the RF, BF, or GA.

Effects of Lumbar Spine Position on Hamstring Flexibility During Passive Straight Leg Raise

Kevin E. Finn, FACSM, Andrew Cannon, Erica Campbell. *Merrimack College, North Andover, MA.*
(No relevant relationships reported)

The straight leg raise test and its variations are ubiquitous in clinical sports medicine practice to assess hamstring flexibility. According to the available literature, testing techniques such as the straight leg raise test may not provide an accurate measurement of hamstring flexibility due to the many confounding variables including lumbar spine motion, lumbar spine positioning and femoro-acetabular motion. **PURPOSE.** The current study contrasted the difference in the measurement of supine, passive straight leg raise with lumbar spine blocked in slight extension to replicate a neutral lumbar spine and normal contra-directional lumbo-pelvic rhythm and a non constrained lumbar spine during a passive straight leg raise via goniometric measurements of hamstring flexibility. **METHODS.** Utilizing 25 collegiate male and female cross country runners, goniometric measurements of the passive straight leg raise with and without a blocked lumbar spine were taken on both the right and left leg. **RESULTS.** A correlation between the average straight leg raise with and without at blocked lumbar spine was found to have a moderate to high correlation (r= 0.693, p value < .001). A dependent t-test revealed that that there was a significant difference between straight leg raise measurements with and without a blocked lumbar spine; M (SLR) =66.3, M (Blocked SLR) = 39.54, SD= 9.4418, t (24) =-14.71, p<.001. **CONCLUSION.** Maintaining neutral lumbar spine position, replicating normal contra-directional lumbo-pelvic rhythm during a passive straight leg raise significantly decreased goniometric measurements of hamstring flexibility. The results of this study indicate that consideration must be given to lumbar spine position and normal, functional, contra-directional lumbo-pelvic rhythm during the measurement of hamstring flexibility. Changes in testing procedures need to be made in the clinical setting to ensure that athletes are being correctly identified as demonstrating normal hamstring flexibility before being cleared to return to activity after hamstring injury.

Impact Control in High-Intensity Interval Training Can Be Improved by Creatine Supplementation

Ana P. S. Azevedo[1], Fernanda M. Acquesta[1], Antonio H. Lancha Jr.[1], Romulo Bertuzzi[1], Jacques R. Poortmans[2], Hamilton Roschel[1], Alberto C. Amadio[1], Julio C. Serrão[1]. [1]*School of Physical Education and Sport - University of São Paulo, São Paulo, Brazil. [2]Faculté des Sciences de la Motricité - Université Libre de Bruxelles, Brussels, Belgium.*
(No relevant relationships reported)

High-intensity interval training (HIIT) is an exercise mode designed to repeatedly stress the body with intense stimulus. Intense running can increase impact forces and alter muscle activation intensity. As skeletal muscles have an important role in shock attenuation, the depletion of muscle phosphorylcreatine (PCr) stores and the diminished energy sources could lead to exhaustion and impairments in the protective functions of muscle during running. We hypothesize creatine supplementation could avoid peripheral fatigue during intense exercise and reduce impairments on shock attenuation. **PURPOSE:** This study investigated the effects of creatine supplementation on biomechanical parameters related to shock attenuation during a session of HIIT. **METHODS:** A single-blind, placebo-controlled, crossover design was adopted to test 8 elite soccer players (males; 16.3± 0.5 years; 70.7 ± 4.16 kg; 1.78± 0.06 m) during HITT sessions under two conditions: after placebo supplementation (Pl) and after creatine supplementation (Cr). HITT test sessions consisted of an intermittent test (5 bouts of running) with constant load applied until exhaustion was reached. The vertical component of Ground Reaction Force (VGRF) and Electromyography (EMG) data were recorded by Gaitway and Lynx-EMG Systems, respectively. Heart rate (HR), Rated Perceived Exertion (RPE – Borg's Scale) and lactate concentration were also obtained. **RESULTS:** Creatine supplementation did not affect HR, RPE and lactate concentration. Decreased values (p<0.05) of magnitude of first peak (Fy1) of VGRF and impulse of first 50 ms (Imp50) were observed for Cr (about 16.2 – 24.2% and 34.3% of decrease, respectively), whereas higher values (p<0.05) of time to reach first

peak (tFy1) were detected for Cr as compared to Pl (28.9 % of increase). Significant modifications (p<0.05) in muscle activation were also observed. Changes occurred in intermediary bouts, mainly in bout 2. **CONCLUSION:** Creatine supplementation has potential to influence biomechanical parameters related to impact control during a single session of HIIT based on running.
Results indicate possible improvements in shock attenuation under creatine supplementation.

Predictors of Meet Performance in Masters Weightlifters

Jeremy Ford, Bryan L. Riemann, Robert G. LeFavi. *Armstrong State University, Savannah, GA.*
(No relevant relationships reported)

The snatch is a high-speed lift that is performed by many weightlifters ranging from recreational to Olympic athletes across a wide spectrum of ages. Despite the regular use of the snatch by athletes, limited research exists on the components of the movement that produce the greatest success. Research on competitive weightlifters is even more limited, particularly those individuals competing at the Masters level. **Purpose:** To determine the extent to which several second pull components relate to snatch performance, and the relation between age, sex, and success in a high-level Masters competition. **Methods:** 42 competitors, 23 women (35 to 64yrs) and 19 men (36 to 76yrs), from the 2017 National Masters Championship completed four snatch lifts using 85% of their most recent 1RM. Simultaneously, three-dimensional barbell kinematics were collected and used to compute several characteristics describing the second pull, including peak (relative to body weight) and time (relative to full snatch time) to peak vertical force and power, and second pull time. Additionally, the barbell distance to displacement trajectory ratio across the entire snatch was computed as an indicator of mechanical efficiency. Backward multiple regression analysis was conducted to determine the factors that could predict each lifter's championship meet performance, defined as their final snatch to body mass ratio. **RESULTS:** The final set of variables which were significant predictors (P<.001, R^2_{adj}=.84) of meet performance included second pull time (β=-.175, P=.013), peak vertical second pull force (β=.503, P<.001), sex (β=.326, P=.001), and age (β=-.412, P<.001). **CONCLUSION:** When comparing sex and age, men and younger competitors lifted more weight relative to their body mass while performing the snatch. Even when shorter second pull times were accounted for in the model, peak vertical force remained the most potent predictor for meet performance. Therefore, for optimal competitive success, Masters weightlifters should consider training that maximizes their capacity to exert high-speed force against the bar in the second pull. Such training might focus on vertical explosion utilizing shrug and triple-extension techniques while minimizing curvature in their second pull trajectory.

1857　　Board #118　　　　　May 31 3:30 PM - 5:00 PM

Stand And Deliver: Muscle Activity And Mechanical Energetics Of The Lower Limb During Cycling

Ross D. Wilkinson, Glen A. Lichtwark, Andrew G. Cresswell. *The University of Queensland, St Lucia, Queensland, Australia.*
(No relevant relationships reported)

Cyclists tend to spontaneously switch from a seated to standing (non-seated) position when they need to produce high pedal torque and power (i.e. during steep climbs, accelerations and sprinting). Existing evidence shows that adopting a non-seated position can result in better economy at high power outputs and an increased level of peak power, yet the mechanisms underpinning these performance advantages remain unclear. **PURPOSE:** To compare lower limb muscle activity, joint moments and joint mechanical energetics between seated and non-seated cycling at varying cadences. **METHODS:** Sixteen, male participants rode on an instrumented ergometer at 50% of peak power (above the reported threshold for sit to stand transition) under different position (seated: S and non-seated: NS), and cadence (70 rpm and 120 rpm) conditions, whilst we recorded electromyography from lower limb muscles, full body motion capture and crank radial and tangential forces. A scaled full-body OpenSim model was used to calculate joint kinematics, moments and mechanical energetics. Statistical comparisons were made using a repeated measures, two-way ANOVA (position x cadence). **RESULTS:** There was a main effect of position on the distribution of total work across the joints in comparing seated to non-seated conditions. This was demonstrated by a decrease in knee work (S=1.74±0.01 vs. NS=1.38±0.01 W.kg⁻¹, p<0.05) and an increase in hip (S=2.33±0.52 vs. NS=2.57±0.53 W.kg⁻¹, p<0.05) and ankle work (S=0.85±0.15 vs. NS=0.97±0.17 W.kg⁻¹, p<0.05) in the non-seated relative to the seated position. At 70rpm, the mean knee joint moment was reduced and ankle power increased in the non-seated condition. In contrast, at 120 rpm knee power was reduced in the non-seated position, while there was only a moderate increase in ankle power (S=0.75±0.24 vs. NS=0.85±0.29 W.kg⁻¹, p<0.05). **CONCLUSION:** These

results provide evidence for the theory that the non-seated position can decrease the mechanical requirements of the knee when cycling at high power output, but the benefits may be cadence dependent.

Relationship Between Neurocognitive Testing and Saccadic Eye Movements in Symptom Free Division I Athletes

Sydni V. Wilhoite[1], Brian J. Szekely[1], Peter Chrysosferidis[1], Kristen L. Neitz[1], Douglas W. Powell[2], Barry A. Munkasy[1], Nicholas G. Murray[1]. [1]Georgia Southern University, Statesboro, GA. [2]University of Memphis, Memphis, TN.
(No relevant relationships reported)

Saccadic eye movements are produced from several frontal and parietal cortical regions of the brain that also aid in the execution of cognitive functions. However, no known research has examined the relationship between a sport-like antisaccade task and standard neurocognitive exams. **Purpose:** To evaluate the relationship between the Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT) cognitive domains and a sport-like antisaccade task (SLT) of Division I athletes on symptom free-day of post-sport like concussion. **Methods:** 10 concussed individuals (8 males; 2 females; age: 20 ± 2 years) were assessed on the ImPACT test and the SLT on a symptom free day post-sport related concussion. A monocular eye tracker (240Hz, Argus Science) synced with the Vicon Motion Capture System (Vicon Motion Ltd., Version 1.85, Oxford, England) was employed to track raw ocular coordinates and further analyzed to obtain resultant distance (RD), mean horizontal velocity (MHV), and prosaccade errors (PE) during the athlete's participation in the SLT. ImPACT variables included verbal and visual memory composite, visual motor speed, reaction time composite (RT), and impulse control. All eye variables were run through a custom MatLab code (MATLAB 2017, Mathworks, Inc., Matick, MA). Spearman rho correlations were used to assess the relationship between ImPACT variables and ocular metrics. **Results:** Significant negative moderate relationships ($r = -0.70$, $p = 0.02$) between MHV (5.78 ± 1.28 pixels/second) and reaction time composite score (0.57 ± 0.07) were observed. Similarly, there was a significant negative moderate relationship ($r = -0.65$, $p = 0.03$) between RD (2.73 ± 1.03 pixels) and Impulse control composite score (6.4 ± 3.75). No other significant relationships were noted. **Conclusion:** These significant relationships suggest that as eye velocities increase, RT decreases which is possibly due to a decrease in accuracy on overall cognitive efficiency. As impulse control decreases, the eye movement resultant distances are minimal. This may be due to more cognitive errors that lead to an inability to properly control antisaccadic eye movements. Due to the relationships exhibited between the ImPACT and SLT, it can be suggested that antisaccade eye movements contain a neurocognitive component.

The Influence of Directional Compression Tights onMuscle Activity and Performance in Recreational Alpine Skiers

Cory J. Snyder, James Becker, John G. Seifert. Montana State University, Bozeman, MT.
(No relevant relationships reported)

INTRODUCTION Recent studies reported reduced muscle activity in competitive alpine skiers using directional compression (DC). It is not known whether the effects of DC are limited to competitive skiers, or if similar changes would be observed in recreational skiers. The purpose of this study was to examine changes in hip and leg muscle EMG patterns in recreational alpine skiers when skiing with and without a lower body DC garment. **METHODS** 11 intermediate and expert skiers volunteered for this study. Subjects skied 2 days, 2 weeks apart, with DC and non-compressive (TNC) base layer in a randomized order. EMG of the gluteus medius (GMED), rectus femoris (RF), and adductor longus (ADL) were recorded using surface EMG during measurement runs. Two measurement runs with standardized turns were taken on each visit. Subjects free skied for 1.75 hrs between measurement runs. This sequence of ski runs was replicated on the second testing day. Standardized turns were normalized to 100% turn duration and averaged together for each trial in each condition. A 2x2 ANOVA with repeated measures was used to compare turn time, edge angle, RMS, and MF within trials. Paired t-tests were used to compare percent change (%Δ) RMS, MF and self-paced skiing between trials. **RESULTS** Subjects skied more runs (8.0 ± 1.5 vs. 5.6 ± 1.8; p<0.05) and vertical (1969 ± 489 m vs. 1382 ± 304 m; p<0.05) during free skiing with DC than TNC. No differences were observed between trials for turn duration or edge angle. Although no statistical differences in %Δ RMS or MF were found, there was a trend towards smaller magnitude %Δ MF with DC (Table 1). **CONCLUSIONS** Although there were no differences in muscle activity between trials in either condition, subjects improved their self-paced skiing performance in the DC condition. There was also a trend towards smaller %Δ MF the DC condition. Further research should investigate the biomechanical influence of DC on skiing performance.

Table 1 % Δ RMS & MF	DC-RMS	TNC - RMS	DC-MF	TNC-MF
GMED	55.0 ± 126.7	-17.0±75.3	11.9±37.0	8.9±36.5
RF	12.9±88.6	-36.6±48.0	-1.3±16.9	-6.8±23.6
ADL	12.7±65.2	-2.9±55.45	-2.5±22.0	10.3±36.1

Narrowing The Gap In Movement Ability from the Perspective of the Female Athlete

Mike Decker[1], Casey Myers[1], Kevin Shelburne[1], Matt Shaw[1], Julie Graves[2], Eric McCarty[2], Michelle Wolcott[2]. [1]University of Denver, Denver, CO. [2]University of Colorado, Boulder, CO.
(No relevant relationships reported)

PURPOSE: The purpose of this study was to assess movement ability from the female athlete's perspective before and after a novel field-based training program. **METHODS**: Twenty-five, elite female soccer athletes (13.3 ± 0.6 y; 161.9 ± 5.3 cm; 50.9 ± 4.9 kg) participated in a 7-week, training program performed with a wearable neuromuscular device. Movement ability was measured with a computer-adaptive test version of the Movement Ability Measure (MAM-CAT) at the start (pre) and end (post) of the training program. The MAM-CAT has 18 items, three for each of the six movement dimension of strength, flexibility, speed, accuracy, endurance and adaptability. Each item contains six statements representing six increasing movement ability levels addressing how they currently move and how they would prefer to move during activities of daily life and sports participation. The MAM-CAT software computes standardized current and preferred movement ability scores on a scale from 0 (cannot move) to 6 (moves competitively). Changes in summed current movement ability and current-preferred differentials (movement gap) were compared pre and post training with paired t-tests (p=.05). A self-assessment transition item of pre versus post movement ability with five Likert response options ("much better", "slightly better", "about the same", "slightly worse", and "much worse") was used to determine the minimal important difference (MID) by the mean change method between "slightly better" and "about the same" subgroups. **RESULTS**: Twenty-one athletes completed pre and post MAM-CAT testing. At the end of the training program, 62% of the athletes reported "slightly better" movement ability and 33% reported "about the same." The MID for narrowing the movement gap was calculated to be 1.1. Group mean current movement ability scores increased 7% (pre, 29.2 ± 4.2; post, 31.8 ± 2.8; t=2.926, p=.008). The current-preferred differentials decreased on average by 25% (pre, -6.0 ± 3.6; post, -4.5 ± 3.0; t=2.267, p=.035) and exceeded the MID metric. **CONCLUSIONS**: The novel field-based training program enhanced movement ability from the female athlete's point of view. Future studies are recommended to use the MAM-CAT as a tool to modify individual or group training programs by emphasizing the movement dimension with the largest current-preferred gap.

Biomechanical And Physiological Differences Between Two Rowing Ergometers

Silvano Zanuso[1], Giuseppe Fedele[2], Jonathan Folland, FACSM[3], Matthew Black[4], Simonetta Senni[2], Horsham Esser Ethan[2], Paolo Benvenuti[5], Francesco Cuzzolin[6]. [1]University of Coventry, Coventry, Italy. [2]Technogym Scientific Dept, Cesena, Italy. [3]Loughborough University, Loughborough, United Kingdom. [4]University of Exeter, Exeter, United Kingdom. [5]University of Verona, Verona, Italy. [6]University of Padova, Padova, Italy.
(No relevant relationships reported)

PURPOSE: To compare the biomechanical (force, handle velocity) and physiological (oxygen consumption, EMG) responses to rowing at equivalent power outputs on two rowing ergometers, Skillrow (TechnoGym, Italy) and Concept II (Model D, Concept II, UK). The hypothesis was that at the same power output peak force will be lower, and handle velocity more consistent, for the SkillRow than Concept II. **METHODS**: Seven young, competitive on-water male rowers (age 24 + 3 y; BW 89.5 + 6.8 kg) volunteered to participate in this study. Participants performed a discontinuous submaximal incremental rowing protocol of two 5 min periods (one on each ergometer) at each power output (150, 180 and 210W; drag factor 130), in a counterbalanced order between participants. Handle displacement and velocity was measured with a calibrated linear draw wire displacement transducer and force with a calibrated high resolution strain gauge and force with a calibrated linear draw wire displacement transducer. These recordings were used to derive stroke kinematics (stroke rate, stroke length, drive phase duration, peak velocity) and kinetics measures during the drive phase of the stroke (peak force, average force, impulse) as well as plots of force, displacement and velocity over time during the rowing stroke. Surface EMG was recorded continuously from the bicep femoris long head, vastus lateralis,

rectus abdominis, erector spinae longissimus, and biceps brachii long head using a wireless EMG system (Trigno, Delsys, USA). Breath-by-breath pulmonary gas exchange data were measured continuously throughout (Vyntus, Carefusion, USA). **RESULTS:** There were no differences between the two ergometers in energy cost or neuromuscular activation (peak EMG amplitude) of 5 muscles. However, mean handle force and impulse during the drive phase were greater on the Skillrow than Concept II (P=0.002), also with a tendancy for higher peak force (P=0.087). Skillrow involved a lower peak handle velocity (P=0.006) and longer drive phase (P=0.003) than Concept II. **CONCLUSIONS:**The two ergometers were similar in terms of energy cost and neuromuscular activation. In term of biomechanical parameters rowing with the Skillrow required a higher average force and impulse, a lower peak velocity and a longer drive phase.

Differences in Ground Reaction Forces When Collegiate Quarterbacks Throw Using Different Drop Patterns

Cailyn Schroeder, Samantha Bessert, John Seifert, James Becker. *Montana State University, Bozeman, MT.*

(No relevant relationships reported)

While there is limited research examining the kinematics of the quarterback passing throw, to date there have not been any studies reporting on ground reaction forces (GRF) during this type of throwing motion. Additionally, there have been no studies reporting how foot positions or drop patterns used by quarterbacks might change GRF parameters. This information would useful to both coaches and sports medicine professionals as it provides both performance and injury related insights. **PURPOSE:** Compare GRF parameters between three commonly used quarterback drop patterns: a one step (1S), a three step (3S), and a three plus one step (3P1) when performed with the rearfoot angled 90° relative to the throwing direction and 45° relative to the throwing direction. **METHODS:** Three NCAA Division I quarterbacks participated in this study. Participants performed three throws using each type of drop and each foot position. Two force plates were used to record GRF data at 1000 Hz. Trials were considered valid if both the front (FF) and rear (RF) feet landed on their respective force plates, with the RF foot in the appropriate orientation. For both the RF and FF, peak horizontal and vertical forces, and horizontal and vertical impulses were calculated. Differences between foot positions and drop patterns were evaluated using a 2x3 repeated measures ANOVA. **RESULTS:** There were no differences in any force metrics for the FF. For the RF, peak horizontal GRFs showed a main effect of drop ($F_{2,4}$=43.9, p=.002), with peak forces being lower in the 3P1 (210.7 ± 13.5 N) than the 3S (476.7 ± 50.5 N) or 1S(378.7 ± 2.6 N) conditions. Peak vertical forces in the RF also showed a main effect of drop ($F_{2,4}$=20.3, p=.008), with peak forces being lower in the 3P1 (1201.7 ± 39.8 N) than the 3S (1359.9 ± 105.8 N). Lastly, there was a main effect of drop for RF horizontal impulse ($F_{2,4}$=55.7, p=.001), with impulses being lower in the 3P1 (58.2 ± 9.12 Ns) than the 3S(150.7 ± 4.5 Ns) or 1S (150.8 ± 5.1 Ns) conditions. **CONCLUSION:** A 3P1 drop pattern makes use of horizontal momentum, thus requiring the athlete to generate less force and smaller impulses with the RF during the throw. As such, coaches should emphasize pushing with the RF when using a 1S or 3S drop pattern. Changing foot positions does not appear to influence force parameters.

Hip Joint Torques During the Golf Swing of Young and Senior Healthy Females

Judy Foxworth, Chris Wendt, Audrey L. Millar, FACSM. *Winston-Salem State University, Winston-Salem, NC.* (Sponsor: Audrey Lynn Millar, FACSM)

(No relevant relationships reported)

Hip joint torques during the golf swing of young and senior healthy females Female participation in golf has increased throughout the past few decades and now comprises approximately 20% of all golf participants. However, little is known regarding the biomechanics of the golf swing for women, and even less is known about hip torques. **PURPOSE:** To describe and compare the hip torques associated with the golf swing of healthy young and senior female golfers. **METHODS:** 21 right-handed, female golfers, aged from 18-70 years old volunteered. Age groups were divided into young (18 – 39) and senior (40 – 70). Subjects completed 10 swings with a standardized driver. A high speed motion capture system and force plates were used to collect kinematic and kinetic data. . 3-D hip torques for trail and lead legs were calculated using inverse dynamic analyses. 2-way mixed model ANOVAs (group by leg) were calculated, with club head velocity as a covariate. **RESULTS:** There were no differences between the groups for BMI (24.6 ± 3.5), handicap (22 ± 7), or club head velocity (30.1 ± 4.2 m/s). The trail hip extensor torque was the largest torque produced by both groups. A main effect for leg was found for hip internal rotator torque (p=.024) with the largest torques produced by the trail leg. There was an interaction between the legs by groups for hip abductor torque (p=.043); the young group had larger torques for the lead leg, while the senior group had no difference between legs. Club head

velocity was significantly (p<.05) correlated with hip internal rotator torques of both the lead and trail leg (r=.7 and .56, respectively), however, when separated by group, these correlations were only significant for the young group (r-.8; p=.001).

Peak Hip Torque	Young (n=12)	Senior (n=10)
Trail - Extensor	10.13 ± 1.95	8.7 ± 1.28
Lead - Extensor	4.70 ± 1.76	3.32 ± 1.14
Trail - Adductor	3.23 ± 1.96	2.42 ± 1.03
Lead- Adductor	.68 ± .87	.7 ± .81
Trail -IR	2.17 ± .68	1.97 ± .50*
Lead-IR	1.90 ± 1.17	1.86 ± .84*
Trail - Flexor	4.70 ± 1.34	4.33 ± 1.10
Lead - Flexor	6.38 ± 1.96	5.85 ± .98
Trail - ER	2.76 ±.52	2.77 ± .7
Lead - ER	2.52 ± .94	2.21 ± .74
Trail - Abductor	4.61 ± 1.21	4.78 ± 1.23
Lead - Abductor	6.39 ± 1.68**	5.02 ± 1.34

Units in N*m/(BW*BH); * = between legs; ** = leg by group
CONCLUSIONS: Overall, hip torques in the trail leg were larger, which suggests their important contribution to the golf swing. These findings are similar to previous literature for healthy male golfers.

Effects of Metronome Training on Timing of the Golf Putt and Neural Connectivity in Professional Golf Players

Jin Hyun Kim[1], Joung Kyue Han[2], Doug Hyun Han[3]. *[1]Kent state Univ, Kent, OH. [2]Chung ang Univ, Seoul, Korea, Republic of. [3]Chung ang Univ, seoul, Korea, Republic of.* (Sponsor: J. Derek Kingsley FACSM, FACSM)

(No relevant relationships reported)

During putting in golf, the direction of movement and force of the club head should be consistent among each swing. In order to maintain consistency in swing timing, the cerebellum provides temporal information, motor timing, control of rhythm, and timing of movements. We utilized a brain training neurotechnology that combines the concept of a musical metronome with a computer-based program that facilitates the improvement of an individual's rhythm and timing. **PURPOSE:** To determine if metronome training(MT) activates neural networks involved in the putt swing and decreases variation in the swing speed. **METHODS:** Twenty professional female golfers (KLPGA) were randomly assigned to either MT training group (n=10, 35-40 min per session, twice a week for 6 weeks) or a control group (n=10). The putting performance and brain activity were analyzed using kinematic software and resting state functional MRI. Consistency was measured as the standard deviation of the mean swing speed (SSD) during three sections of the swing: backswing(AD-BS), backswing-impact (BS-IMP), impact-finish (IMP-FIS) **RESULTS:** The MT group improved consistency in the time between the back swing and ball impact in a 2 meter putt compared to the control group (pre: .09±.07 vs .04±.02, post: .05±.03 vs .05±.02, F=5.27, p=0.03). In addition, the MT group showed greater consistency (measured as a lower SSD) in the duration of the full swing of the 5 meter putt compared to the control group (pre: .21±.09 vs .16±.07, post: .14±.09 vs .11±.06, F=5.59, p=0.02) and in swing time in the 5AD-BS section of the 5 m putt compared to the control group (pre: .07±.04 vs .05±.02, post: .04±.03 vs .04±.02, F=9.24, p<0.01). After the training period, the MT group showed increased functional connectivity from the superior cerebellar vermis to the right medial frontal gyrus, left superior temporal gyrus, right middle occipital gyrus, right middle temporal gyrus, right cingulate gyrus, and right supramarginal gyrus (uncorrected p<0.001, voxels>40). **CONCLUSION:** MT training in professional female golf players may improve the consistency and reduce variability in putt timing. In addition, MT training may increase brain connectivity from the cerebellum to the frontal cortex which plays an important role in the timing process. Reducing Lower Back Injury in Golf: Cross-sectional Assessment of Novel Swing Technique

Reeves Weedon[1], Erich Petushek[2], Katja Osterwald[3], Sarah B. Clarke[4], J. Bryan Dixon[5], Chris Richter[3]. *[1]RW Golf ltd, Epping, United Kingdom. [2]Michigan State University, East Lansing, MI. [3]Sports Surgery Clinic, Dublin, Ireland. [4]Northern Michigan University, Marquette, MI. [5]Advanced Center for Orthopedics and Plastic Surgery, Marquette, MI.*

Reported Relationships: R. Weedon: *Intellectual Property; Author and*

Abstracts were prepared by the authors and printed as submitted.

conceptor of The Lower Body Golf Swing.

Lower back pain (LBP) in golf has been associated with repeated swing performance and high-speed spinal loads/rotations. While different swing techniques exist, no studies have examined the "traditional" or modern swing with the lower body swing. The lower body swing, a novel technique, is believed to reduce the risk of LBP, as it does not require extensive lateral axis tilt of the upper body as rotations are achieved through increased motion at the knees and hips. **PURPOSE:** To analyze, the modern and lower body swing with respect to the risk of developing LBP. **METHODS:** Nine athletes performed the modern swing (Age 48.0+/-13.6 yrs, Height 176.8+/4.4 cm, Mass 82.1+/5.3 kg) and seven lower body swing (Age 53.9+/12.1 yrs, Height 182.9+/6.1 cm, Mass 92.5+/14.8 kg), all free from LBP. Whole-body kinematics were recorded using a motion analysis system and a continuous t-test (point by point) was performed to identify differences in examined kinematic measures associated with LBP (high crunch factor and thorax to pelvis abduction velocity and acceleration, flexion velocity, thorax rotational velocity and acceleration). Cohen's d was calculated to determine the magnitude of effects. **RESULTS:** Significant differences with strong effects ($p < .05$; $d > .80$) were observed for: thorax to pelvis abduction acceleration (lower$=358+/334°/s^2$, modern$=1024+/464°/s^2$), thorax to pelvis abduction velocity (lower$=53+/25°/s$, modern $107+/24°/s$), thorax to pelvis flexion velocity (lower$=-38+/60°/s$, modern $-113+/42°/s$), thorax rotation velocity (lower$=428+/63°/s$, modern $550+/68°/s$) and thorax rotation acceleration (lower$=2432+/535°/s^2$, modern$=3681±712°/s^2$). **CONCLUSION:** The lower body swing displayed favorable kinematics in comparison to the modern swing in relation to LBP risk in healthy golfers. Future work should include larger sample sizes and prospective or intervention-based approaches to explore injury prevention efficacy of this novel swing technique.

Trunk Flexibility, Balance, Muscle Endurance, And Contralateral Lean In Collegiate Baseball Pitchers

Kaitlin M. Ford, Karen Myrick, Juan Garbalosa, Rich Feinn. *Quinnipiac University, Hamden, CT.*
(No relevant relationships reported)

Excessive contralateral trunk lean at maximal shoulder external rotation has been linked with increased pitching velocity and increased joint forces. Pitchers with a less efficient transmission of the generated force from the lower limbs to the upper extremities consistent with less forward trunk flexion, less upper torso rotation, and greater upper torso contralateral flexion at maximal shoulder external rotation demonstrated excessive contralateral lean; however the physical characteristics contributing towards excessive contralateral trunk lean during the pitching kinetic chain have not been well described in collegiate level pitchers. **PURPOSE**: To examine the relationship between trunk muscle fatigue, trunk flexibility, and balance in relation to maximum contralateral lean at maximal shoulder external rotation in collegiate baseball pitchers during fastball pitches. **METHODS**: Anthropometric measurements, isometric holds in trunk flexion, extension, lateral planks, flexibility, and STAR Excursion Balance Test assessments were performed on 10 Division I Collegiate baseball pitchers ages 18-21 (mean 19.6, SD=1.04) with an average of 7.36 years of pitching experience (SD=3.23). Pitching kinematic analysis of fastball pitches was performed using 3-dimensional motion analysis techniques. **RESULTS**: Pearson correlations were performed to assess the association between functional assessments with trunk contralateral lean. The average degree of contralateral lean was 2.33 (SD=3.66). The average pitch speed was 80.3 (SD=5.40). No statistically significant correlations were found between any of the assessments and degree of contralateral lean. However, there was a moderate negative correlation between contralateral trunk lean and pitch speed ($r = -.494$, $p=.146$). **CONCLUSION**: The negative correlation between contralateral trunk lean and fastball pitch velocity and trunk assessments and contralateral trunk lean mean be a result of the small sample size (10 subjects) as previous studies of approximately 100 subjects have shown a positive correlation of contralateral trunk tilt of 10 degrees from neutral with an increase of only 0.5-1mph in pitch velocity.

Sparta Testing and Vertical Jump Co-Predict Fastball Speed in Collegiate Pitchers

William P. Lydon, J. Mark VanNess, John Mayberry, Joey Rossi, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
(No relevant relationships reported)

In competitive baseball, the most common pitch is the fastball; its velocity associates with strikeout rate and fielding-independent pitching values. The most effective predictors of pitch velocity are currently debated. Coaches and trainers are increasingly relying on advanced systems of assessment, such as Sparta Performance Science (SPS); fewer are relying on simple assessments, such as the vertical jump (VJ). Data supporting the added value of complex assessments are limited. **PURPOSE:** To test the effect of VJ and SPS performances on fastball velocity among collegiate pitchers.

METHODS: We enrolled 30 pitchers at a Division 1 athletics program in Northern California. Every pitcher on the team's roster between 2014 and 2017 was tested. During collection, heights and body weights were documented; an SPS force plate measured Load, Explode, and Drive data; and VJ height was recorded as the best of 3 performances. Fastball velocity was quantified as the mean mph of the fastest 3 in-game pitches at the time of testing. Multiple linear regression tested the effect of VJ and SPS data on pitch speed, controlling for appropriate confounders. **RESULTS:** Players were evenly distributed throughout year in school. Average VJ was $19.8 ± 2.5$ inches, fastball velocity was $87.4 ± 4.0$ mph, SPS Load was $54.2 ± 8.6$, Explode was $51.5 ± 8.4$, and Drive was $54.2 ± 8.8$. Multiple linear regression, holding the players' height and grade constant, found each additional inch of VJ predicted a 0.5 mph increase in pitch velocity ($p<0.001$; 95% CI: 0.21-0.70). The collection of predictors explained 56% of the variance in speed ($p<0.001$). In this model, each additional unit of Load predicted a 0.2 mph decrease in speed ($p<0.001$) while each additional unit of Explode predicted a 0.2 mph increase ($p<0.001$). The most powerful predictor was year in school: for each additional year, fastball velocity increased by 2.1 mph ($p<0.001$). SPS Drive was not a significant predictor ($p=0.491$). **CONCLUSION:** In the age of sophisticated analytics equipment, the VJ remains a compelling predictor of fastball velocity, but it predicts in tandem with the SPS technology. The information gathered from a comprehensive athletic evaluation can help coaches evaluate the athleticism of their athletes and inform decisions regarding individualized conditioning programs.

Influence of Therapeutic Horseback Riding on Motor Proficiency in Youth with Sensory Processing Dysfunction

Brandon R. Rigby[1], Ronald Davis[1], Melissa Bittner[2], Robin Harwell[3], Eileen Leek[3], Geoben Johnson[1], David Nichols, FACSM[1]. *[1]Texas Woman's University, Denton, TX. [2]California State University Long Beach, Long Beach, CA. [3]ManeGait Therapeutic Horsemanship, McKinney, TX.* (Sponsor: David Nichols, FACSM)
(No relevant relationships reported)

Individuals with sensory-integration delays may have some deficit in motor planning, or difficulty interacting with and influencing their surroundings. The demonstration of age-appropriate motor skills is therefore a primary outcome measure in this population. Therapeutic horseback riding may provide the necessary physical adaptations to improve motor skill proficiency. **Purpose**: To characterize motor skill proficiency following 8 weeks of therapeutic horseback riding with sensory integration therapy in children with sensory processing dysfunction. **Methods**: Twenty-seven children, ages 5 to 18 years, were recruited. All participants completed the same 32-week protocol that was separated into 4, 8-week blocks: a) a control period (no riding); b) a riding only period; c) a washout period (no riding); d) riding with additional sensory integration therapy (combination). Before and after each period, motor skills were assessed using the *Bruininks-Oseretsky Test for Motor Proficiency (2ⁿᵈ edition)*. A one-way repeated-measures ANOVA was used to determine any differences between testing periods. A significance level of 0.05 was used. **Results**: All subtest scores were statistically similar ($p > 0.05$), with the exception of manual dexterity, which was different between pre-control and post-washout ($p = 0.018$), post-control and post-washout ($p = 0.024$), and pre-control and post-combination ($p = 0.037$). Overall scores were different between pre-control and post-combination ($p = 0.003$) and post-control and post-combination ($p = 0.009$). **Conclusion:** Therapeutic riding may have a latent effect of improving overall motor skills in children with sensory processing dysfunction. Table 1: Average and overall scores on the *BOT-2* subtests at different time points

Subtest	Max	Pre-control	Post-control	Post-riding	Post-washout	Post-combination
Fine motor precision	14	6.0±4.9[a]	6.0±4.7[a]	6.1±4.9[a]	6.2±4.5[a]	6.4±5.2[a]
Fine motor integration	10	4.4±3.2[a]	4.2±3.0[a]	4.4±2.9[a]	5.0±3.3[a]	4.8±3.1[a]
Manual dexterity	9	2.2±2.1[a]	2.6±2.0[ab]	2.9±2.0[ac]	3.3±2.4[c]	3.2±2.4[bc]
Bilateral coordination	7	3.4±3.0[a]	3.7±2.7[a]	4.0±3.2[a]	4.0±3.0[a]	4.7±2.9[a]
Balance	8	4.0±3.1[a]	3.9±2.9[a]	3.4±2.8[a]	4.1±2.7[a]	4.3±2.7[a]
Running speed and agility	10	4.0±3.6[a]	4.0±3.4[a]	3.9±3.3[a]	4.0±3.4[a]	4.8±3.2[a]
Upper-limb coordination	12	4.7±4.4[a]	3.9±3.8[a]	5.2±4.2[a]	4.7±4.1[a]	6.0±4.1[a]
Strength	18	3.6±3.3[a]	4.4±3.3[a]	5.1±3.6[a]	4.7±3.3[a]	5.2±3.0[a]

(No relevant relationships reported)

Adherence and Continued Participation in a Wellness Class for Individuals with Disabilities

Megan Ware, Kathleen DeMarrais, Kevin K. McCully FACSM. University of Georgia, Athens GA 30602

Adherence and continued participation are areas of concern in wellness interventions and programming. For individuals with disabilities, this can be an even larger challenge because of barriers like transportation and decrease in overall health. However, the factors that could increase participation and adherence in this population group remains unclear. Adherence and continued participation were explored in a wellness class at the University of Georgia for people in the surrounding community with disabilities. This class is driven by students under the supervision of a graduate student and a faculty member. **PURPOSE:** To understand what factors impact participant adherence and participation in the unique environment of the wellness class. **METHODS:** Eight wellness class participants, with a wide range of physical and mild intellectual disabilities who had been in the class for 6-36 months, were chosen for in-depth qualitative interviews. Interview responses across participants were coded and analyzed for overarching themes. **RESULTS:** 71 codes were obtained from the interview data, with 7 categories from these codes. The primary theme identified was that adherence in the class was related to personal interaction with the student trainers. The personal interaction could be divided into subthemes of social accountability, motivation, supporting classroom environment, and student interaction. The overwhelming majority of these codes were positive, indicating satisfaction with the wellness class on the part of participants. Duration in the class did not influence the subthemes, other than longer durations were associated with a greater appreciation of the role of the participants educating the students. **CONCLUSION:** The primary factor that influences adherence and continued participation was related to personal interaction with the student trainers. These results suggest that encouraging positive social interactions related to social accountability and a positive environment can play a powerful role in maintaining exercise adherence in people with physical and intellectual disabilities.

Static Standing Balance Before And After A Maximal Treadmill Test In Adults With Intellectual Disabilities

Míriam Guerra-Balic[1], Casimiro Javierre[2], Guillermo Oviedo[1]. [1]*University Ramon Llull, Barcelona, Spain.* [2]*University of Barcelona, Barcelona, Spain.* (Sponsor: Bo Fernhall, PhD, FACSM, FACSM)

(No relevant relationships reported)

Introduction: Static standing balance (SSB) is essential for upright posture and for most functional activities. It has been shown that fatigue worsens SSB in general population. Adults with intellectual disability (ID) may have delayed responses to postural perturbations, especially with concurrence of fatigue. Little is known about SSB in individuals with ID. **Purpose:** To study the effects on SSB before and after a maximal treadmill test (MTT) in adults with ID. **Methods:** 92 adults (49 men) with mild to severe ID including Down syndrome (age: 43.6 ±12.0 y; weight: 72.45±15.0 kg; height: 159.8±11.1 cm) were recruited from an occupational day center. Participants performed a MTT until exhaustion. Immediately before and after the MTT, the center of pressure (COP) radial area, total travel distance (TTD), mean medium-lateral (MLD) and mean anterior-posterior (APD) displacements, and mean velocity sway (MVS) of the COP were measured with a pressure platform for 52sec at 100Hz, with open and closed eyes. Paired t-tests were applied to analyze differences between tests (p<.05). **Results:** After a MTT, a significant increase in APD with OE (3.7 vs 4.4mm; p = 0.020) was observed. Also, a significant improvement in the X axe position of the COP (MCOP X) with CE (9.9 vs 7.1mm; p = 0.039) was observed. The other variables showed no significant changes. **Conclusions:** Regular exercise may improve balance in persons with ID, but if fatigue appears, their postural motor system may be impaired. More research is needed, as balance is important to prevent falls.

Descriptive values of the studies parameters of the COP				
Variables	Pre-Treadmill test		Post-Treadmill test	
	OE	CE	OE	CE
TTD (mm)	225.0 (25.4)	264.1 (34.2)	236.5 (14.5)	242.1 (19.1)
COP radial area (mm²)	608.4 (1419)	520.1 (156.5)	495.0 (79.3)	546.7 (130.0)
MVS (mm/s)	3.9 (0.4)	4.6 (0.6)	4.1 (0.3)	4.2 (0.3)
MLD (mm)	4.2 (0.6)	3.9 (0.6)	3.9 (0.3)	3.7 (0.3)
APD (mm)	3.7 (0.4)	3.6 (0.3)	4.4 (0.4)*	3.5 (0.3)
MCOP X (mm)	8.7 (1.8)	9.9 (1.8)	7.4 (1.8)	7.1 (1.7)**
MCOP Y (mm)	-9.4 (1.6)	-10.9 (1.5)	-11.8 (1.5)	-11.5 (1.5)

Note: values are means (Standard Mean Error)
Abbreviations: OE: Open Eyes; CE: Closed Eyes, COP area: Center of Pressure area; TTD: total travel distance; MLD: mean medium-lateral displacement; APD: anterior-posterior displacements; MVS: mean velocity sway length; MCOPX: mean COP-X position; MCOPY: mean COP-Y position
* Significant difference (p < 0.05) between APD with OE
** Significant difference (p < 0.05) between MCOP X with CE

A Multilevel Patient Engagement Model for Recruiting Hard-to-Reach Populations into Exercise Training Studies

Emily S. Goodner[1], Whitney Neal[2], Tracy Tracy[3], Tapan Mehta[1], Mohanraj Thirumalai[1], William H. Neumeier[1], Hui-Ju Young[1], James H. Rimmer[1]. [1]*University of Alabama at Birmingham, Birmingham, AL.* [2]*Lakeshore Foundation, Birmingham, AL.* [3]*Tanner Foundation for Neurological Diseases, Birmingham, AL.*

(No relevant relationships reported)

Many of the current studies today involving exercise science research never reach their target sample sizes. This is particularly true for studies that include people with disabilities, as this population typically faces issues such as lack of transportation, exercise not individualized to their functional level, or intervention not targeting primary symptoms of their disabilities. Strategies for enhancing participant recruitment are needed to guide future exercise training studies in the disability population. PURPOSE: The purpose of this qualitative study is to describe a multilevel, patient-centered model for recruiting people with multiple sclerosis (MS) for a cluster-randomized controlled study named Tele-Exercise and Multiple Sclerosis (TEAMS), which involves a 12-week complementary and alternative medicine intervention consisting of neurorehabilitative exercise, yoga and Pilates. METHODS: A multilevel model that consists of three elements: 1) stakeholder engagement throughout the entire research process, 2) clearly defined research team effort shaping the study design based on stakeholder feedback, and 3) external support systems. The three elements of this model work together to disseminate research evidence that can be easily translated and

---

Abstracts were prepared by the authors and printed as submitted.

replicated in real world settings. RESULTS: The TEAMS study, which aims to enroll 820 individuals with MS across Alabama, Mississippi, and Tennessee over 24 months, has already garnered a list of 300 interested participants since active recruitment began for 8 of the 38 clinic sites in September 2017. Anticipated results include successfully reaching recruitment goals and participants demonstrating adherence to the study. CONCLUSION: Although this study was focused on MS, this multilevel recruitment model, starting with stakeholders at the center of the model in helping to design the study, is generalizable to other underserved, difficult-to-reach study populations. Exercise Physiologists can use this model as a framework for increasing their enrollment into various types of training studies.

The work of this abstract was supported by the Patient-Centered Outcomes Research Institute (PCORI), Award # MS-1511-33653.

Changes in Physical Activity during a Pilot Weight Loss Program Before and After Knee Replacement

Christine A. Pellegrini[1], Rowland W. Chang[2], Dorothy D. Dunlop[2], David E. Conroy[3], Jungwha Lee[2], Kenzie A. Cameron[2]. *[1]University of South Carolina, Columbia, SC. [2]Northwestern University, Chicago, IL. [3]The Pennsylvania State University, University Park, PA.*

(No relevant relationships reported)

PURPOSE: Although knee replacement (KR) surgery typically results in pain reductions and functional improvement, most patients do not increase their physical activity. This study examined changes in objectively measured physical activity in KR patients who were participating in a weight loss program that started either before or after surgery.

METHODS: Consented patients scheduled for KR were randomized to a 14 session pilot weight loss program starting ≤6 weeks before surgery (PACE) or 12 weeks post-op (Delayed PACE). Participants were encouraged to increase activity, set weekly activity goals, and self-monitor using paper, website, app, or Fitbit. Coaching sessions took place weekly or biweekly based on patient preference. Activity (moderate-to-vigorous activity [MVPA] bouts of ≥10 min of ≥2020 cpm and daily steps) was assessed using Actigraph GT3X monitors. PROMIS was used to assess pain intensity and function. Assessments were completed at baseline (pre-op), 12, and 26 weeks after surgery. Intent-to-treat was used with the last observation carried forward. Repeated measures ANOVAs examined changes in activity across time and group. **RESULTS**: Thirteen participants (mean±SD 63.5±7.9 years, 69% female, 69% White, BMI 35.7±5.1 kg/m2) provided physical activity data at baseline. Physical activity data was obtained for 77% of the sample at 12 and 26 weeks. Pain intensity decreased (P≤0.001) and function improved (P≤0.001) significantly, but no significant changes were observed in physical activity (Table 1). **CONCLUSIONS**: On average, KR patients participating in a weight loss program did not increase physical activity (weekly bouted MVPA and daily steps) after surgery. The lack of changes in activity, even in the presence of an intensive behavioral intervention and improvements in pain and function, highlight the challenges of altering behavior in this population. Future studies are needed to explore methods to increase activity after knee replacement.

Physical Activity Pre- and Post-Surgery in PACE (n=6) & Delayed PACE (n=7)			
	Baseline	12 Weeks	26 Weeks
Bouted MVPA, min/week			
PACE	81.2±141.8	3.5±5.4	33.3±76.4
Delayed PACE	37.6±85.7	62.1±135.8	78.1±108.0
Steps/day			
PACE	5715.7±3098.0	4255.6±1687.8	4991.8±2910.2
Delayed PACE	6062.4±2817.6	4943.6±1653.2	6324.4±2201.3

Use of Video Modeling to Teach Weight Lifting Techniques to Adults with Down Syndrome

Kathy Carter[1], Alexandra Roberts[2], Robert Pennington[1], Elizabeth Ledford[1]. *[1]University of Louisville, Louisville, KY. [2]Australian Institute of Sport, Canberra, Australia.*

(No relevant relationships reported)

As adults with Down syndrome (DS) age strength decreases resulting in difficulty performing activities of daily living. Research suggests that progressive resistance training for adults with DS may lead to improvements in their functional ability. PRT requires minimal equipment, which may be important for individuals with DS, as they may have limited disposable income for gym memberships, and reduced access to transportation to and from training facilities. Video modeling (VM) involves the demonstration of a target behavior through the video recording of that behavior. PURPOSE: The purpose of this study was to determine whether the use of video modeling is appropriate for teaching adults with DS to perform weight lifting

techniques. METHODS: Three adult males with Down syndrome, ages 24 to 34 years, participated in this study. A single subject multiple probe design across behaviors (i.e. lifts) was used to evaluate the effectiveness of VM. A certified U.S. weight lifting coach completed a task analysis for split squat (SS), punch-out squat (POS), and overhead press (OP). For baseline measures participants watched a demonstration of each lift and were then recorded performing the lift. Once baseline measures became stable, participants viewed a video of a model using correct lifting technique three times. They were then video recorded performing the lift. No verbal prompts or corrections were given. Participants performances were scored by taking the number of steps performed correctly, dividing that number by the total number of steps in the task, then multiplied by 100. RESULTS: Participants were least successful with the SS averaging 16% correct at baseline and 36% correct after viewing the videos. POS went from 50% correct to 87%; OP started at 42% and increased to 80% correct movement. Our video-modeling intervention, alone was not sufficient to produce an effective outcome across all lifts,

but did help participants acquire more components of each lift. CONCLUSION: This study suggests that VM might serve as a useful component of a larger intervention; one that includes VM, rehearsal with feedback, and programmed reinforcement contingencies. It is our hope that future research with provide a path forward in this critical area.

Changes of Physical Activity Patterns among Down Syndrome Youth In a Weight-loss Randomized Control Trial

Qun Le, Philimon Gona, Richard Fleming. *UMASS Boston, Boston, MA.*

(No relevant relationships reported)

Children with intellectual and development disabilities (IDD) engage in lower levels of moderate to vigorous intensity physical activity (MVPA) than do typically developing children. In addition, research suggests that light intensity physical activity (LPA) might have health benefits independent of those recognized for MVPA in people in general. To our knowledge, there is no recommendation for LPA, and the recommendation for all people with disabilities is to simply encourage them to do "as much physical activity (PA) as they can". **PURPOSE:** The purpose of this study was to analyze the baseline PA patterns of adolescents and young adults with Down syndrome (DS) who participated in a 12-month weight loss intervention, and to assess whether the intervention would change PA patterns. **METHODS:** A total of 21 adolescents and young adults with DS aged 13 to 26 years were enrolled and randomized to either a 6-month nutrition and activity education intervention (NAE) or a nutrition and activity education+ behavioral intervention (NAE+BI), with a 6-month follow-up. Accelerometers were used to assess the PA levels of participants at baseline, 10-weeks, 6-months, and 12-months. **RESULTS:** Results indicated that at baseline participants spent a high proportion of their time in SB (68.2%), and lower proportions in LPA (28.5%) and MVPA (3.2%). At the same time, a strong negative linear correlation was found between SB and LPA (r= -0.938, p<0.001); and a weak negative linear correlation was found between SB and MVPA (r= -0.468, p=0.038). Linear trend analysis showed that SB decreased more in the NAE+BI group than in NAE at 6-months, and the trajectory of LPA increased more steeply at 10-week, 6-month, and 12-month in NAE+BI than in NAE. **CONCLUSIONS:** LPA was found to have a stronger inverse association to SB than did MVPA to SB. We conclude that decreasing SB and promoting healthy outcomes may be achieved more effectively by increasing LPA, as compared to increasing MVPA, among this population. The implications could be used to fill in the gap of PA guidelines to include promoting LPA among adolescents and young adults with IDD, a step that could bring health benefits.

Influence of Pain and Mood on Physical Activity after Knee Replacement

Sara M. Rothberger, Courtney M. Monroe, Christine A. Pellegrini. *University of South Carolina, Columbia, SC.*

(No relevant relationships reported)

Many patients undergoing knee replacement do not increase physical activity levels after surgery.

PURPOSE: The proposed study aimed to use ecological momentary assessment (EMA) and accelerometry to examine the time-varying associations between mood, pain, and physical activity following knee replacement to determine if mood is influencing activity.

METHODS: : Over one week, knee replacements patients ≤12 months of surgery rated their mood (1 negative to 9 positive) and pain (1 none to 9 extreme) after 6 random prompts during waking hours. Physical activity was assessed during the same week using an Actigraph GT3X worn on the waist. Only valid days of ≥10 hours/day were included. Average steps/day and the time spent in sedentary (<100 cpm)

and moderate-vigorous physical activity (≥ 2020 cpm) were calculated across all participants. Pearson or Spearman correlations were used to examine the relationship between pain, mood, the time from surgery, and physical activity counts. **RESULTS**: Fourteen participants (mean±SD 64.7±6.4yrs, 57% female, 79% white, 70.3±75.9 days after surgery) completed the study. One participant had less than four accelerometer valid wear days and was excluded from analyses. Participants spent 74.1±10.4% of the day in sedentary behavior, took 3352.1±1861.9 steps/day, and engaged in 36.8±53.5 min/week of MVPA. Over one week, participants provided 35.5±6.5 responses, 73% were in response to random prompts, with the remaining responses being self-initiated. Pain ranged from 1-4 (m±SD 2.9±1.2) and mood ranged from 1-9 (m±SD 6.9±1.5). A higher number of days since surgery was associated with less pain (r=-0.28, p<0.001) and better mood (r=0.58, p<0.001); however, neither pain nor mood influenced current or subsequent physical activity. The time since surgery was associated with subsequent physical activity 30 minutes later (r=0.17, p=0.002), but not current or activity 60 minutes later. **CONCLUSIONS**: Knee replacement patients who had surgery within the last 12 months spend the majority of the day engaged in sedentary behavior. Participants who were further out from surgery experienced less pain and better mood; however pain and mood did not influence current or subsequent physical activity. Future studies are needed to explore alternative factors that may be influencing activity after surgery.

Noncompliance Patterns In Accelerometer-based Research For Children And Adolescents With A Developmental Disability

Jooyeon Jin[1], Byungmo Ku[2]. [1]*University of Seoul, Seoul, Korea, Republic of.* [2]*Oreon State University, Corvallis, OR.* (Sponsor: Stamatis Agiovlasitis, FACSM)
(No relevant relationships reported)

An accelerometer is widely used to objectively assess physical activity (PA) levels in field-based research. Accelerometer-wearing compliance has been one of critical issues for a successful data collection because it directly affects the quality of accelerometer data. However, the noncompliance patterns are unknown in children and adolescents with a developmental disability (DD). **PURPOSE**: To assess the noncompliance patterns of children and adolescents with DD in accelerometer-based research. **METHODS**: Forty-eight children and adolescents with DD who could independently walk were recruited from 6 schools in the U.S. (30 from 4 schools) and Korea (18 from 2 schools). Participants were asked to wear a GT3X+ accelerometer (Actigraph, Pensacola, FL) from the time they wake up until going to bed for the next six consecutive days, except for water activities. Data inclusion criteria were >10 hours wear time from 8am to 10pm a day, and 20 consecutive minutes of zero counts as was considered non-wear time (Belton et al., 2013). Time of day was broken into four segments: (a) morning (8am-noon), (b) afternoon (noon-5pm), (c) evening (5pm-8pm), and (d) night (8pm-10pm). **RESULTS**: Seventeen participants met the inclusion criteria on all 6 days, followed by 25 participants on 5 days and 28 participants on 4 days. For further analysis, 3 weekdays/1 weekend day criteria (n=27) was added. A Wilcoxon Signed-ranks test indicated weekend non-wear time (Mdn = 167.50) was significantly higher than weekdays (Mdn = 98.75), Z=-2.28, p =.02. Mean non-wear time in each time segment over 6 days was 49.88, 23.91, 42.74, and 140.07 minutes in order. A repeated measures ANOVA with a Greenhose-Geisser correction showed a significant difference of non-wear time between four time segments, F(1.41, 36.72)=17.56, p < .001, and post-hoc analysis using Bonferroni correction found a significant difference between night non-wear time and all other time segments (morning p< .01; afternoon, evening p<.001). One-way ANOVA and independent t-test revealed no difference of mean non-wear time between schools and between two countries. **CONCLUSIONS**: Future research efforts may be necessary to develop accelerometer wearing compliance strategies, particularly to improve wearing time on a weekend and a night period, for children and adolescents with DD.

Feasibility of Underwater Treadmill Training to Improve Mobility: A Case Study of a Transtibial Amputee

Shannon L. Mathis[1], Ryan T. Conners[1], Adan Vazquez[2], David E. Walls[2]. [1]*The University of Alabama in Huntsville, Huntsville, AL.* [2]*Fourroux Prosthetics, Huntsville, AL.*
(No relevant relationships reported)

Underwater treadmill training (UTT) has been shown to be successful in improving health related fitness in inactive populations with reduced mobility. Walking on a treadmill submerged in a self-contained tank of water allows for precise control of walking speed, water depth, and water temperature while unloading one's body weight. **PURPOSE** The purpose of this study was to determine the feasibility and efficacy of an 8-week (3d·wk^{-1}) UTT program in a unilateral, transtibial amputee with limited ambulation potential. The hypothesis was that the participant's post-UTT and three month scores relative to pre-UTT scores would improve in mobility (Amputee Mobility Predictor [AMP]), walking speed (10-M Walk Test), balance (single leg

stance and Romberg test), and fall risk (Timed-Up-And-Go [TUG]). **METHODS** The patient was a 72 year-old male who underwent transtibial amputation for the development of an infection coupled with Charcot neuroarthropathy. He has used a prosthetic device two years. He walks with a cane in the community and uses a wheelchair while at home. Mobility is defined by the Medicare Functional Class K-Level system with stages ranging from K-0 to K-4 and is determined by the score of the AMP. Prior to UTT, a prosthetist administered the AMP and classified the patient as a K-2 with a total score of 32. The patient had a secondary prosthetic limb which was fitted by the prosthetist for use in the underwater treadmill. **RESULTS** After UTT, the patient was classified as a K-3 with a total score of 37. Time to complete the 10 M Test was 12.8 s before, 11.4 s after, and 11.1 s at 3-months. TUG test times pre, post, and 3 months post-UTT were 15.6 s, 13.5 s, and 13.3 s, respectively. The patient was unable to balance for 30 s with eyes closed before UTT and was able to complete this task after UTT and 3-months post-UTT. He was unable to perform a single leg balance test without assistance for 30 s on either limb at any time-point. Total underwater treadmill walking time increased from 26 min to 48 min and walking speed increased from 1.1 mph to 1.6 mph. **CONCLUSION:** Following UTT, the patient achieved a higher K-level. Patients classified as a K-3 or higher are eligible for health care coverage for higher level componentry for the prosthetic device. His walking speed improved and fall risk decreased following UTT with only minor improvements in balance.

Qualitative Assessment Of The Implementation Of A 12-week Game-based At-home Intervention For Young Children

Paloma Pallante, Daniela A. Rubin, FACSM, Kasen M. Bras, Kathleen S. Wilson. *California State University Fullerton, Fullerton, CA.* (Sponsor: Daniela A Rubin, FACSM)
(No relevant relationships reported)

PURPOSE: A 12-week game-based physical activity (PA) curriculum was developed for children ages 4-7 with and without Prader-Willi Syndrome (PWS), a rare genetic neurodevelopmental disorder leading to medical, motor, and behavioral challenges. This study evaluated preliminary findings on intervention completion and adherence and parent reflections on their participation**.
METHODS**: Parents (N=25) of children with (n=6) or without PWS (n=19) and their children were enrolled. At baseline parents received the curriculum training and the equipment and materials. During the 12-week intervention, parents reported the number of days/week they used the curriculum (two day minimum required) on-line or using paper logs (n=19). In the post visit, parents participated in a semi-structured interview reflecting on their experiences with the curriculum implementation and any changes perceived in their child. Each interview was transcribed and analyzed for common themes using hierarchical content analysis (preliminary analyses n= 15). **RESULTS**: 19 families completed the baseline and post visits (76% retention), with 52.6% of participants adhering to completing twice a week sessions (PWS=80%, without PWS=42.9%). The challenges of implementation included: time management (e.g., challenges with scheduling), lack of motivation by the parent and the child (e.g., unmotivated, sick). Facilitators of implementation included: incorporating the program into their lives (e.g., making it a routine and scheduling it), making a commitment, fostering their child's motivation (e.g., children actively making choices, tailoring to their child's interests), social support and the equipment and curriculum (e.g., easy to use and child-friendly). Parent perceived outcomes included: improvement in child's motor skills, confidence, and motivation, improvement in parents' ability to teach motor skills as well as enjoyment and quality time with their child. **CONCLUSIONS**: Implementation of an at home PA intervention with young children is challenging. Parent strategies such as scheduling, building a routine and engaging their child may help overcome difficulties. Nonetheless, parents perceived the PA routine implementation led to building motor skills and self-confidence in their children.

A Survey Of Parents Of Children With Mild Developmental Disabilities: Perspectives On Digital Health

Courtney M. Monroe[1], Allison Brazendale[2], Keith Brazendale[1], Marie Knoll[1], Catherine Ivey[3], Michael W. Beets[1]. [1]*University of South Carolina, Columbia, SC.* [2]*Autism Academy of South Carolina, Columbia, SC.* [3]*Wofford College, Spartanburg, SC.* (Sponsor: Sara Wilcox, FACSM)
(No relevant relationships reported)

Youth with developmental disabilities have an equal if not higher prevalence of obesity than their typically developing peers, but little is known about parents' views on this issue in the context of digital health.

PURPOSE: The aim of this study was to assess concerns about obesity-related topics, as well as interest in and delivery medium preferences for digital programs focused on these areas, among parents of children with mild developmental disabilities. **METHODS:** A survey of digital health perspectives was administered to parents of children who attended a special summer camp (i.e., campers) focused in part on health behaviors. Parents (N=28) responded to items about themselves and their camper(s) (N=28 campers; there were 31 total parent responses for select survey items about campers [3/28 parent responders had 2 campers, reflecting 6 campers and 6 responses; 6/28 parent responders comprised 3 pairs of parents, and each pair had 1 camper, reflecting 3 campers and 6 responses; 19/28 parent responders had 1 camper, reflecting 19 campers and 19 responses]). Data on health-related concerns and associated interest in digital programs targeting these concerns, as well as preferred program delivery medium and technology use were analyzed using descriptive statistics. **RESULTS:** Most parents (M_{BMI} = 27.2 $\pm$ 4.4 kg/m^2, 82% female, 93% White) expressed concern about weight control (75%) and related topics (e.g., stress: 79%, diet: 75%, physical activity: 61%). Parent responses also highlighted concern about anxiety and depression (74%), diet (71%), and stress (71%) for their children (M_{age} = 10.6 $\pm$ 3.3 yr, 68% male). Interest in a tailored, digital-delivered program targeting assessed topics was also high (ranging from 54% for sleep to 75% for anxiety and depression). Email and YouTube were the top electronic platforms used by parents (100%) and children (87%), respectively, and 42% of children had a tablet. Email was the top cited preferred digital health-delivery platform for parents and children. **CONCLUSION:** These findings suggest most parents of children with developmental disabilities have concerns about obesity-related topics and are interested in receiving digital programs targeting these areas, with opportunities to leverage various mediums. Future studies should verify these findings in larger samples.

The Efficacy of Dynamic Cycling in an Individual with ALS: A Pilot Study

Bryan Dowdell, Kristin Noll, Angela Ridgel. *Kent State University, Kent, OH.* (Sponsor: Ellen L Glickman, Ph.D., FACSM)

(No relevant relationships reported)

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease that is characterized by muscular atrophy which leads to increased fatigue, loss of balance, and spasticity. Currently, there is no cure for ALS and limited medical treatments are available. Weak muscles make it challenging for these individuals to exercise although physical activity is important to prevent deconditioning. However, dynamic cycling, which utilizes a motor to assist rapid movement of the legs, may be an effective mode of exercise for individuals with muscle weakness and has yet to be investigated in this population. **PURPOSE:** The purpose of this case study was to determine the efficacy of two weeks (6 sessions) of dynamic cycling at a high cadence on gait function and daily activity function in an individual with ALS. **METHODS:** One male individual with ALS (67 years old) completed an amyotrophic lateral sclerosis functional rating scale revised (ALSFRS-R) assessment and a 6-minute walk test (6MWT) on a treadmill before and after the two week intervention. After the baseline visit, the six subsequent visits consisted of the dynamic cycling intervention and 6MWT. The dynamic cycling sessions consisted of repeated bouts of cycling at 75-85 revolutions per minute for 5 minutes with 5 minutes of rest for a duration of 30 minutes. **RESULTS:** The 6MWT showed progressive improvement from baseline to after the last cycling session. The subject walked 306 m, 338 m, 370 m, 354 m, 354 m, 386 m, and 386 m respectively (a 21% improvement). The subject's ALSFRS-R score slightly improved from 41 to 42. **CONCLUSION:** The dynamic cycling paradigm proved to be effective in improving mobility and gait in our subject. The individual was able to successfully complete the intervention despite muscle weakness. The promising results of dynamic cycling in our subject warrants the need for further studies within the ALS population.

Cardiovascular Fitness and Body Composition in Spinal Cord Injured after a 36-session Exoskeleton Program

William H. Scott, Paula Geigle, Peter Gorman. *University of Maryland, Baltimore, MD.*

(No relevant relationships reported)

Background: Spinal cord injury (SCI) disrupts motor recruitment patterns at or below the injury site resulting in diminution or loss of ambulatory function. Individuals with SCI exhibit reduced daily physical activity levels and an increased sedentary lifestyle. Cardiovascular risk factors are prevalent post-injury with increased adiposity, elevated triglyceride concentrations, insulin insensitivity, and reduced cardiovascular fitness. Technologic advancements have emerged to provide individuals with SCI an opportunity to ambulate in the community and increase daily activity level using exoskeletal robotic assist devices. **Purpose:** To examine cardiovascular fitness (as measured by peak VO$_2$) and body composition (as measured by DXA) in non-ambulatory individuals with SCI before and after a 36-sesssion exoskeleton walking program. **Methods:** Four males with a spinal cord injury greater than six months prior all requiring wheelchair use for community mobility, agreed to participate in a randomized six-month study (with a three month 36 session exoskeleton intervention phase) designed to examine multiple outcome measures. As part of the collected dataset, pre and post exoskeletal intervention assessments were determined for peak VO$_2$ (arm ergometry) and body composition (DXA). **Results:** Participants experienced the following changes after the 36-session exoskeleton intervention: **Participant 1**, peak VO$_2$ (20.73 to 20.89 ml·kg^{-1}·min^{-1}), body mass (64.5 to 68.1 kg), %body fat (13.3 to 17.6%); **Participant 2**, peak VO$_2$ (15.60 to 16.63 ml·kg^{-1}·min^{-1}), body mass (79.6 to 80.6 kg), % body fat (31.1 to 32.7%); **Participant 3**, peak VO$_2$ (26.11 to 27.19 ml·kg^{-1}·min^{-1}), body mass (60.5 to 61.9 kg), %body fat (5.2 to 5.7%); **Participant 4**, peak VO$_2$ (23.06 to 20.70 ml·kg^{-1}·min^{-1}), body mass (57.2 to 56.3 kg), %body fat (6.5 to 4.7%). **Conclusion**: In this preliminary group of four non-ambulatory chronic SCI individuals, a 36 session exoskeleton walking intervention failed to consistently improve cardiovascular fitness, body mass, and body composition (percent fat). Exoskeletal ambulation may not provide an adequate cardiometabolic stimulus to alter standard measures of cardiovascular health in this population.

Getfit: An Interdisciplinary Approach To Exercise And Nutrition For Individuals With Autism Spectrum Disorder

M. Alysia Mastrangelo, FACSM[1], Mary Kientz[1], Joan Perks[1], Rachel Gavigan[1], Carissa Clayton[1], Edward C. Chaloupka, FACSM[2]. *[1]Stockton University, Galloway, NJ. [2]Rowan University, Glassboro, NJ.*

(No relevant relationships reported)

PURPOSE: GetFIT for All is an interdisciplinary exercise and nutrition program designed for individuals with a diagnosis of Autism Spectrum Disorder (ASD) and other developmental disabilities. The purpose of the GetFIT program is to improve participants' health and wellness, quality of life and socialization. OT, PT, Nursing, and Health Science students collaborate to educate and enhance the healthy habits of participants. Together these disciplines create a client-centered nutrition and fitness program. Get FIT for All addressed behaviors associated with ASD: restrictive eating habits, poor nutritional intake, and gross motor skill deficits that may lead to an unhealthy lifestyle and lack of participation and exercise. Adolescents diagnosed with ASD were two times more likely to be obese than adolescents without developmental disabilities. Young adults diagnosed with ASD were found to have a higher incidence of developing type 2 diabetes when compared to those without ASD. METHODS: Participants included 8 individuals with ASD who completed the pre-test; age range 16-42 with a mean age of 24 y.o. One participant dropped out, 2 others did not come to the final data collection session. Pre and post data were collected the first and last day of a 12 week session. The Sensory Profile 2 was used to identify sensory issues so that modifications could be made to the program. Social skills were measured using the Social Responsiveness Scale, 2nd ed. Data collected included anthropometric measures, vital signs, cardiovascular endurance, strength, flexibility, a nutritional screen, and a QOL measure. Summary of RESULTS: Percent change was used to assess data due to the sample size. Positive changes in health indicators including strength (plank +85%) (push-ups +35%), cardiovascular endurance (step test +49%), and balance (Stork +26%, right and +64%, left). Results indicated decreased waist (-8%) and hip (-5%) circumference and Timed up and Go (-13%). CONCLUSION: These results indicated improvement in overall fitness measures for participants with ASD involved in a 12 week client-centered fitness and nutrition education program. In addition, participants expressed their enjoyment in attending GetFIT and the social interaction with university students. Funded by a Doug Flutie Jr. Foundation Grant

Accuracy Of Parent And Child Self-Reported Physical Activity In Children With Special Needs: A Pilot Study

Michele L. Polfuss, Ph.D. R.N.[1], Bethany M. Forseth, M.S.[1], Dale A. Schoeller, Ph.D.[2], Paula E. Papanek, PhD FACSM, FACSM[3]. *[1]University of Wisconsin - Milwaukee, Milwaukee, WI. [2]University of Wisconsin, Madison, WI. [3]Marquette University, Milwaukee, WI.* (Sponsor: Paula Papanek, FACSM)

(No relevant relationships reported)

Physical activity (PA) is an essential component of health that necessitates accurate measurement. Parents of children with special needs (SN) have an increased involvement in their child's daily life; therefore, it would seem plausible that they could provide an accurate assessment of their child's PA. The accuracy of self-report measures in children with SN has not been established. **PURPOSE:** Determined the accuracy of self-reported PA as compared to doubly labeled water (DLW) for children with SN. Furthermore, we assessed if child's age or diagnosis was related to the accuracy.

METHODS: This prospective cross-sectional study, included 36 child/parent dyads stratified by child's age (4-7; 8-12; and 13-18 years), diagnosis and ambulatory status (spina bifida-ambulatory n= 9; spina bifida-wheelchair n= 9; Down syndrome n= 9, and control n= 9). PA energy expenditure by weight (kcal·kg^{-1}·day^{-1}) was calculated from total energy expenditure, measured via DLW, by subtracting an estimated resting metabolic rate and thermic effect of food and then dividing by the child's weight. Self-reported PA (MET·min^{-1} day^{-1}) was measured by an activity journal completed by parents and children ≥13 years for four weekdays and two weekend days. T-tests compared MET·min·day^{-1} reported between the parents and children. Pearson correlations assessed relationships between journals and DLW.
RESULTS: No significant differences between activity levels reported by parents and children (25.05 vs. 27.32 MET·hrs·day^{-1}; $p = 0.29$). Parent and child self-reported activity levels were moderately correlated to DLW (r=0.63, $p<0.001$; r=0.74, $p<0.05$, respectively). When examined by age, parent reported activity and DLW were significantly related all age groups. No significant relationship between self-reported activity levels and DLW based on diagnosis.
CONCLUSION: With their increased involvement, parents of children with SN were able to report activity levels of their child similar to the child's self-reported activity. Both parent and child reporting had moderate relationships to the criterion. Self-report methods while cost-effective, have been minimally tested in children with SN. Therefore, further examination in larger samples is recommended along with utilizing objective measures of PA.

Guardian Perception Of Self-esteem And Mastery In A Special Needs Population

Kelly D. Barns, Jason D. Wagganer, Anthony J. Faber, Thomas J. Pujol, FACSM. *Southeast Missouri State University, Cape Girardeau, MO.* (Sponsor: Thomas Pujol, FACSM)
(No relevant relationships reported)

Self-esteem and mastery are psychological factors that may be affected by learning a new physical skill. The primary objective of iCan Bike (ICB) is to instruct individuals with special needs and/or disabilities on how to ride a two-wheeled bicycle. Very few studies have assessed the effects of learning a new physical skill on self-esteem and mastery in special needs and/or disabled populations. **PURPOSE:** To assess guardian perceived self-esteem and mastery scores, of the ICB participant, as measured by the Rosenberg Self-Esteem Scale (RSES) and Pearlin Mastery Scale (PMS). **METHODS:** The RSES (10 items; 5 positive and 5 negatively worded items) and PMS (7 items) questionnaires were completed by the guardian of the participant in the ICB camp. A one-way repeated measures Analysis of Variance, with a Bonferroni *post-hoc* test, was conducted to compare questionnaire results across pre-, post-, and 30 days post-camp. All data was analyzed using SPSS (v24.0) with significance set at $p<0.05$.
RESULTS: A total of 141 questionnaires were completed on an ICB participant sample consisting of 63.8% (n=90) males and 36.2% (n=51) females. A total of 63.1% (male=65.6%; female=58.8%) of participants learned to independently ride a bicycle. A significant increase in mastery was observed [F(2,280)=23.699, ($p<0.001$)], with significant increases observed pre- (23.03±4.64) to post-camp (25.44±4.60) ($p<0.01$), and post- to 30-days post-camp (26.61±5.24) ($p<0.001$). No significant RSES effect was observed. **CONCLUSIONS:** A significant increase in mastery may be related to the daily observable progress associated with watching the participant learn to ride a bicycle. The success rate of this study (63.1%) was lower than the ICB advertised rate of 80%, which may be a primary reason for the lack of change in self-esteem scores. More research needs to be completed on the psychological effects that learning to ride a bicycle has on self-esteem and/or mastery in the special needs population.

Replacing Sedentary Time with Light Physical Activity Reduces Mobility Limitation in Older Adults: NHANES 2003-2006

Nicholas L. Lerma, Chi C. Cho, Hotaka Maeda, Ann M. Swartz, FACSM, Scott J. Strath, FACSM. *University of Wisconsin - Milwaukee, Milwaukee, WI.* (Sponsor: Scott Strath, FACSM)
(No relevant relationships reported)

PURPOSE: Increased time spent in sedentary behavior (SB) and reductions in total physical activity (PA) are linked to functional limitations in aging populations. The purpose of this study is to examine the relationship of replacing SB time with light-intensity PA (LPA) and/or moderate-vigorous-intensity PA (MVPA) on physical function in a nationally representative sample of older adults.
METHODS: A cross-sectional analysis using isotemporal substitution models with multinomial regression was performed in older adult participants from the 2003-2006 National Health and Nutrition Examination Survey. A hip-worn accelerometer with counts per minute (cts/min) cut-points for SB (<100 cts/min), LPA (100-1951 cts/min), and MVPA (≥1952 cts/min) were used to estimate the odds of reporting 0, 1, or 2+ self-reported functional limitations when replacing SB with LPA and/or MVPA. Covariates included age, sex, race/ethnicity, body mass index, smoking, education, income, and marital status.
RESULTS: The analysis included a sample of 1971 older adults (60-85 years) averaging 583 ± 166 min·d-1 (mean ± SD) in SB, 287 ± 102 min·d-1 in LPA, and 11 ± 15 min·d-1 in MVPA. Within the sample 39.8% reported no limitation, 16.7% with one limitation, and 43.5% with 2+ limitations. The odds of having one functional limitation was significantly reduced when replacing 60 min of SB with 60 min MVPA (odds ratio 0.303, 95% CI 0.116-0.791), but not with 60 min of LPA (0.926, 0.832-1.031). However, replacing 60 min of SB with a combination of 55 min of LPA and as little as 5 min of MVPA significantly reduced the odds of having one limitation (0.844, 0.746-0.955). The odds of having 2+ limitations was significantly reduced when replacing 60 min of SB with LPA (0.736, 0.679-0.798) or MVPA (0.074, 0.018-0.293). Lastly, the odds of transitioning from one to 2+ limitations was significantly reduced when replacing 60 min of SB with LPA (0.794, 0.716-0.881) or MVPA (0.245, 0.070-0.858).
CONCLUSION: While the functional benefits of MVPA are well-established, altering the daily balance between LPA and SB is shown to be protective against developing functional limitations. Further, replacing SB with LPA and complimentary doses of MVPA may be a more practical approach to effectively prevent or reduce functional limitations among older adults.

[9]University of Massachusetts Amherst, Amherst, MA.*
(No relevant relationships reported)

PURPOSE: To examine the associations between participation in Physical Education (PE) classes and objective measures of physical activity (PA) and sedentary behavior (SB) in children from 12 countries at different levels of human and socioeconomic development. **METHODS:** This multinational, cross-sectional study included 5874 children aged 9-11 years from sites in Australia, Brazil, Canada, China, Colombia, Finland, India, Kenya, Portugal, South Africa, the United Kingdom, and the United States. PA and SB were measured over 7 consecutive days using a waist-worn accelerometer. Participation in PE classes was determined by questionnaire. Multilevel modeling analyses were used to account for the hierarchical nature of the data.
RESULTS: PE classes were not attended by 6.6% of the total sample, and in low- and middle-income countries this prevalence was higher than in high-income countries (8.4% vs. 4.7%, respectively, p<0.01). After adjusting for age, sex, parental education, and BMI z-score, results showed that children from low- and middle-income countries who participated in PE classes at least once a week were more likely to meet the moderate-to-vigorous physical activity (MVPA) recommendations (male - OR: 1.80; 95%CI: 1.17-2.77; female - OR: 2.17; 95%CI: 1.44-3.27), to spend more time at different PA intensities, and to have shorter SB time (male - OR: 1.61; 95%CI: 1.01-2.60; female - OR: 2.20; 95%CI: 1.38-3.50) than those who did not attend PE classes. In high-income countries, boys that participated in PE classes were more likely to meet the recommendations for PA (OR: 2.20; 95%CI: 1.29-3.76) and to have shorter SB time (OR: 2.42; 95%CI: 1.22-4.81). For girls in high-income countries, attending PE classes increased the likelihood of spending more time in MVPA, especially if they attended three or more classes per week (OR: 2.42; 95%CI: 1.22-4.80).
CONCLUSION: Attending PE classes is associated with a higher level of PA and lower level of SB in children from countries at various levels of human and socioeconomic development. PE classes should be compulsory in all countries as an important contributor to healthy movement behaviors of children.

Difference In Physical Activity Between Children Without Siblings And With Siblings

Chelsea L. Smith[1], Emily Guseman[2], Laura Hubbs-Tait[3], Jennifer Graef[1], Sandra Arnold[1], Allen Knehans[1], Susan B. Sisson, FACSM[1]. [1]*University of Oklahoma Health Sciences Center, Oklahoma City, OK.* [2]*Ohio University, Athens, OH.* [3]*Oklahoma State University, Stillwater, OK.* (Sponsor: Susan B. Sisson, FACSM)

(No relevant relationships reported)

Children without siblings, singletons, have higher rates of obesity than children with siblings, non-singletons. Physical activity, such as increased moderate-to-vigorous physical activity (MVPA) and decreased sedentary behavior, can curb excess weight gain early in life. **PURPOSE**: The purpose of this study is to examine the differences in physical activity and sedentary behavior between singleton and non-singleton children. **METHODS**: Mothers of singleton children ages 5.0-7.9 years old and mothers of non-singleton children ages 5.0-7.9 years old with a sibling between the ages of 2.0-4.9 years old in their primary household were recruited. Height, weight, and waist circumference (WC) of child were objectively measured. Mothers reported demographic characteristics of the child and self, and completed a questionnaire on their physical activity. Children wore an accelerometer at the ankle for at least 5 full days while parents recorded daily activities and time spent in away from home care (such as child care or kindergarten). Body mass index (BMI) was calculated, and BMI and WC percentiles were calculated for age and sex. MVPA and sedentary behavior per hour were calculated using accelerometer cut points and total wear time. **RESULTS**:43 mother-child dyads (10 singletons and 33 non-singletons) participated. On average mothers were 34.7 years old, employed full time (69%), married (77%), and the child's biological mothers (97%); while children were 5.81 years old and predominantly white (62%). Singletons had a higher BMI percentile (80.1±21.3) and waist circumference percentile (77.6±21.7) compared to non-singletons (55.7±29.0, *p*=0.02; 53.4±21.3, *p*<0.01). In individual models, singletons did not differ in time away from home care (*p*=0.60) or in their mother's average MET minutes per week compared to non-singleton children (*p*=0.90). After adjusting for child BMI percentile and month of wear, singletons spent 2.96 less minutes per hour in MVPA (*p*<0.01) and 5.18 more minutes per hour in sedentary behavior compared to non-singletons (*p*=0.01). **CONCLUSIONS**: In this sample, singletons had a higher BMI percentile and were less active compared to non-singletons. Investigation into differences in singleton/non-singleton families, including family health behaviors, may support understanding of the mechanism.

Parent Physical Activity Practices and Associations with Physical Activity and Sedentary Time in Preschool-Age Children

Emily C. Huber[1], Jessica R. Meendering[2]. [1]*Loras College, Dubuque, IA.* [2]*South Dakota State University, Brookings, SD.* (Sponsor: Matt Vukovich, FACSM)

(No relevant relationships reported)

Preschool-age children have the potential to be influenced by parent physical activity (PA) practices more than older children as preschool-age children are more reliant on parents for PA opportunities. Previous research with this focus has relied predominantly on various subjective assessments of child activity which often results in an overestimation of PA and an underestimation of sedentary time (ST). **PURPOSE**: The purpose of this study was to explore associations among parenting PA practices and child PA and ST by utilizing objective measures of activity and the full range of PA intensities in a cross-sectional sample of preschool-age children. **METHODS**: Child PA was assessed for 7 days via accelerometer (ActiGraph GT3X+) using age-appropriate cut-points. Parent PA practices were assessed via parent completion of the Activity Support Scale for Multiple Groups (ACTS-MG). A total of 169 parent (34.5 ± 8.1 yrs.; 30 males, 134 females, 5 unreported)/child (3.6 ± 0.7 yrs.; 80 boys, 89 girls) dyads had compliant PA and survey data and were used for analyses. Multiple multilevel mixed-effects linear regression analyses were utilized to identify parent PA practices that were significantly associated with PA intensities, including total PA (TPA). ACTS-MG individual item analyses were also completed by rescaling ACTS-MG item responses. Statistical significance was set at p≤0.05. **RESULTS:** Vigorous PA (VPA) (p=0.02) and moderate-to-vigorous PA (MVPA) (p=0.04) in boys was positively associated with the parent PA practice of using community resources and negatively associated with parents that reported "I take my child to places where he can be active (p=0.01; p=0.05, respectively). VPA in boys was positively associated with parents that reported "I enroll my child in community-based programs (such as Girls and Boys Club, YMCA) where he can be active" (p=0.05). VPA in girls was positively associated with parents that reported "I limit how long my child plays video games" (p=0.03). **CONCLUSION**: Parent utilization of community resources and restricting sedentary activity, especially video game use, have been found to be

significantly associated with preschool-age child activity. However, there is a need to help parents understand other strategies to promote PA and discourage ST in young children.

The Relationship Between Screen Time and Sleep Duration in Children

Joseph Carlson[1], Nara A. Paulsen[2], Breanne Carlson[1], Erich J. Petushek[1], Karin A. Pfeiffer, FACSM[1]. [1]*Michigan State University, East Lansing, MI.* [2]*Northern Michigan University, Marquette, MI.*

(No relevant relationships reported)

Excess screen time (ST), low sleep duration (SLD), and physical inactivity, are risk factors for childhood obesity. Also, excess ST has been associated with poorer sleep quality and shorter SLD. The American Sleep Foundation recommends 9-11 hours of sleep per night for school aged children. **PURPOSE**: To determine the relationship between ST and SLD among children who participated in a school based nutrition and physical activity intervention.
METHODS: Cross sectional analysis of 5th grade public school students (N =742, mean age 10.5 years, range 9-13 years). Participants self-reported their ST, SLD, and wake time.
RESULTS: A Pearson correlation coefficient indicated a small but significant negative correlation between ST and SLD (r = -0.13, p < 0.01). A one-way ANOVA comparison between three groups categorized into "low", "medium", and "high" ST levels showed a significant difference in SLD between groups (F 2,739) = 6.82, p < 0.001). Post hoc comparisons using the Tukey HSD test indicated the mean SLD for the low ST group (M =10.17, SD =1.20) was significantly higher compared to the SLD in the high ST group (M = 9.77, SD =1.29), but the Cohen's effect size value (d = 0.34) indicated a small difference in magnitude.
CONCLUSIONS: The results suggest an inverse relationship between ST and SLD. The children categorized with low ST had significantly higher SLD versus children with high ST, though the mean hours of sleep for all groups met current recommendations. Intervention studies in youth should consider incorporating strategies to decrease ST in youth not only increase physical activity, but also to improve SLP duration. Lipoprotein Subclasses And Their Associations With Physical Activity, Cardiorespiratory Fitness And Adiposity In Norwegian Schoolchildren

Paul R. Jones[1], Olav M. Kvalheim[2], Geir K. Resaland[3], Sigmund A. Anderssen[1], Ulf Ekelund, FACSM[1]. [1]*Norwegian School of Sport Sciences, Oslo, Norway.* [2]*University of Bergen, Bergen, Norway.* [3]*Western Norway University of Applied Sciences, Sogndal, Norway.* (Sponsor: Professor Ulf Ekelund, FACSM)

(No relevant relationships reported)

Physical activity (PA), cardiorespiratory fitness (CRF) and adiposity are associated with certain lipoproteins. Research in adults has shown that these associations are not consistent across lipoprotein subclasses.
Purpose: To examine cross-sectional associations in children between objectively measured PA and sedentary time (SED), CRF and adiposity with a number of biomarkers of lipoprotein metabolism.
Methods: We included 1056 healthy fifth-grade (mean age 10.2 yrs) Norwegian children (47.3% females). Total PA (tPA), PA intensity (light (LPA); moderate (MPA); vigorous (VPA)), and SED were assessed using triaxial accelerometry. We used the Andersen test to measure CRF, and waist circumference to measure abdominal adiposity. We quantified 31 measurements of lipoprotein metabolism including concentrations of 15 subclasses and particle size of three major classes (VLDL, LDL, HDL) using nuclear magnetic resonance spectroscopy. We used multiple linear regression models adjusted for age, sex, pubertal development and socioeconomic status (standard model). Additional tPA, PA intensity and CRF models were adjusted for adiposity, and additional adiposity models were adjusted for moderate-vigorous PA (MVPA) and CRF separately. We applied a false discovery rate (FDR) correction to *p*-values of each regression model.
Results: Adiposity was associated with all 31 biomarkers in the standard and PA-adjusted models, and 30 biomarkers having adjusted for CRF. CRF was associated with 29 of the biomarker measures in the standard model and 22 having adjusted for adiposity. Total PA, VPA, MPA, LPA and SED were associated with 13, 21, 14, 0 and 9 of the 31 biomarker measures, respectively in the standard model. After adjusting for adiposity, there were 8, 7, 7, 0, and 4 biomarker associations, respectively. All FDR-corrected *p*-values < 0.05.
Conclusion: CRF is associated with the majority of markers of lipoprotein metabolism independent of adiposity. Physical activity, especially of higher intensity, is associated

with some of these biomarkers independent of adiposity, whereas LPA and sedentary time appear associated with a small number of biomarkers. This suggests that improving CRF and increasing physical activity of at least moderate intensity may favourably affect lipoprotein metabolism in healthy children.

Physical Activity does not Modify the Relationship between Asthma and Obesity in African American Youth

Matthew Nagy, Kellye McGlumphy, Erika Shaver, Rebecca Hasson, FACSM. *University of Michigan, Ann Arbor, MI.*
(No relevant relationships reported)

Asthma is an important health issue in adolescents, particularly among African Americans (AA). Previous research has identified obesity as a risk factor for childhood asthma, however, less research has examined whether asthma predicts obesity. It is plausible that the presence of asthma symptoms may contribute to inactivity and subsequent obesity risk in AA youth.
PURPOSE: The purpose of this study was to assess the cross-sectional relationships between the presence of asthma symptoms, weight status, moderate-vigorous physical activity (MVPA) and sedentary time (SED) among AA adolescents.
METHODS: A community-based sample of 163 AA youth (55% female, 31% obese, ages 11-18 years), recruited from southeast Michigan were included in this analysis. Asthma symptoms were evaluated and given a single score from 0 (no symptoms ever) to 11 (all symptoms often) using the International Study of Asthma and Allergies in Children's Phase Three questionnaire. MVPA and SED were measured via accelerometry. Weight status was assessed via body mass index (BMI) where weight and height were measured via an electronic scale and stadiometer, respectively.
RESULTS: Of the 163 adolescents included in the analysis, 68 reported no symptoms of asthma (54% female, 22% obese). T-tests revealed those with no symptoms of asthma engaged in less MVPA (no symptom: 12.5±0.1min; $\geq$ one symptom: 13.6±0.1min, p<0.001) and more SED (no symptom: 758.3±1.2min; $\geq$ one symptom: 753.8±1.0min, p=0.004) compared to adolescents with one or more symptoms of asthma. After accounting for the confounding effects of sex, parental education, and pubertal development; asthma symptom score was positively associated with BMI (β=0.6±0.2, p=0.004). When MVPA and SED were included in the model, the relationship between asthma symptom score and BMI remained significant (β=0.5±0.2, p=0.007).
CONCLUSION: A higher presence of asthma symptoms predicted increased weight status in AA adolescents. Physical activity participation and sedentary time did not modify this relationship, suggesting that other factors contribute to the increased obesity risk in children exhibiting asthma symptoms. Longitudinal studies are needed to better understand the relationship between asthma and obesity in AA adolescents.

Cardiovascular Fitness, Body Composition, And ADHD Diagnosis Among Youth In NHANES1-2004

Lundon C. Burton. *University of Illinois at Chicago, CHICAGO, IL.* (Sponsor: Dr. Eduardo Bustamante, FACSM)
(No relevant relationships reported)

Abstract
Purpose: The study investigated the relationship between cardiovascular fitness, body composition, and ADHD diagnosis. Obesity and ADHD are highly comorbid—ADHD children are twice as likely to become obese adults than typically developing peers. However, the role of physical fitness in this relationship remains unexplored.
Methods: Youth age 12-19 years old (N=4,790) participating in the National Health and Nutrition Examinations Survey (NHANES) 2001-2004 were included. Parents reported demographics and whether their child had ever been diagnosed with ADHD. Children underwent examinations of body fat percentage via bioelectrical impedance and estimated VO2 max via a submaximal treadmill test. *Chi-square* analyses and *t*-tests assessed differences between ADHD and typically developing (TD) youth on fitness and composition. Significant differences variables entered a logistic regression analysis with ADHD diagnosis as the dependent variable and estimated VO2 max, percent body fat, age, race/ethnicity, gender, and household income as predictors.
Results: Males were 3 times more likely to be diagnosed with ADHD than females (12% vs. 4%) (β=1.109, Exp(B)=3.03, p < .001). Non-Hispanic Whites were more likely to have been diagnosed with ADHD (13%) compared to Mexican Americans (4%) and Non-Hispanic Blacks (7%); they were also more likely to have seen a mental health professional in the last year (13%), compared to Blacks (8%) and Mexican Americans (6%). Children diagnosed with ADHD evidenced significantly higher VO2 max than typically developing peers (45.3 ml/kg/min vs. 42.0 ml/kg/min; t= -5.00, p<.001) and lower % body fat (26% vs. 29%; t=4.83, p<.001). In regression analyses age, gender, and estimated VO2 Max were related to ADHD, while body fat %, race/ethnicity, and household income were not. For each 1ml/kg/min increase in VO2 max odds of ADHD diagnosis increased by 2% (β=.017, Exp(B)=1.02, *p*< .01).
Conclusion: The associations between ADHD, physical fitness and percent body fat

were in the opposite direction of hypotheses and previous literature. This may be a function of ADHD diagnosis as the outcome, rather than symptoms. Unfortunately low-income and racial/ethnic minority children are less likely to be diagnosed and more likely to be obese and unfit. Future studies should directly assess ADHD.

Youth Participation in Competitive Sports Associates with Midlife Lean Body Mass and Physical Activity

Eija Laakkonen[1], Janne Kulmala[2], Tuija Tammelin[2], Harto Hakonen[2], Mirja Hirvensalo[1], Urho Kujala[1], Vuokko Kovanen[1], Sarianna Sipilä[1], Urho Kujala[1]. *[1]University of Jyväskylä, Jyväskylä, Finland. [2]LIKES Research Center for Physical Activity and Health, Jyväskylä, Finland.*
(No relevant relationships reported)

Benefits of life-long physical activity (PA) are widely recognized. Fewer studies have investigated how being young competing athlete reflects to later life body composition and PA. **PURPOSE:** To investigate the impact of participation in competitive sports in youth on the body composition and subjectively and objectively measured PA at middle-age. **METHODS:** The study participants are 47-to-55-year old Finnish women (n=985) attending to the Estrogenic Regulation of Muscle Apoptosis study (ERMA). Their participation in competitive sports at the age of 13-to-16 was assessed with retrospective self-report. Midlife lean body mass (LBM), skeletal muscle mass (SMM) and fat mass (FM) were measured with bioimpedance (Inbody 720) after overnight fast (n=866). Midlife PA included *7-scaled self-estimate* that was reclassified to form sedentary, light, moderate and vigorous PA categories (n=985), *a detailed assessment of leisure-time PA* volume, duration and intensity (a modified Kuopio Ischemic Heart Disease Risk Factor Study Questionnaire, n=982) enabling calculation of mean daily metabolic equivalent (MET-h/day) index as a proxy of the previous 12 months PA and *objectively measured total PA* over seven-days by hip-worn accelerometer (Actigraph GT3X+ or wGT3X+, n=734). Statistical differences were tested using chi-squared test, independent samples t-test or Mann-Whitney U test. **RESULTS:** Participants were assigned into youth athlete (n=136) or non-athlete (n=849) groups based on their participation in competitive sports at the age of 13-to-16. Youth athlete group had 1.5 kg higher LBM (p=0.002) and 1.0 kg higher SMM (p=0.001) at middle-age, but no statistically significant difference in FM. Youth athletes reported more vigorous PA (32.4% vs. 20.3%, p=0.007) and higher leisure-time MET index (4.3 vs. 3.4 h/day, p<0.001) than non-athletes. No difference was observed in accelerometer-measured sedentary time, light PA, moderate-to-vigorous PA or total PA (counts) between groups. **CONCLUSION:** Participation in sport competitions as a teenager has long lasting health benefits that associates with healthier body composition and higher leisure-time PA later in life. However, the discrepancy between self-reports and objective measures needs further studies to delineate the benefits of different components of PA.

Differences and Agreements in Physical Activity of Older Adolescents and Young Adults

Piroska Boros, Kathleen F. Janz, FACSM, Elena M. Letuchy, Steve M. Levy. *University of Iowa, Iowa City, IA.* (Sponsor: Kathleen Janz, FACSM)
(No relevant relationships reported)

PURPOSE: To examine the differences in physical activity (PA) from older adolescence to young adulthood and the likelihood of meeting the aerobic component of the 2008 Physical Activity Guidelines (PAG) at both times.
METHODS: This study analyzed the Iowa Bone Development Study participants' moderate- and vigorous PA (MVPA) and vigorous PA (VPA) measured with accelerometers at ages 17 and 21 (N = 303). Questionnaire estimated living status (LS, with parents vs not), and student status (SS, enrolled in college/tech/junior college vs not) at age 21. Spearman correlation compared PA of age 17 and 21. Fisher's exact test identified the odds of meeting PAG at both ages. Wilcoxon test examined the effects of LS and SS on PA at age 21. Alpha was set at 0.05.
RESULTS: MVPA at age 17 was associated with MVPA at age 21 (males r = 0.31, females r = 0.22). VPA at age 17 was associated with VPA at age 21 (males r = 0.29, females r = 0.18). Table 1 shows participants' PA characteristics. Ninety-five percent of males and seventy-one percent of females who met PAG at age 17 also met corresponding PAG at age 21. Living with parents at age 21 decreased MVPA minutes in males by 17.7 and in females by 5.92; and VPA minutes in males by 2.48 and in females by 1.85 compared to living elsewhere. Being a student at age 21 increased MVPA minutes in males by 10.52 and in females by 11.46; and VPA minutes in males by 2.56 and in females by 3 compared to not being a student.
CONCLUSION: PA association between ages 17 and 21 were low but statistically significant.
Most participants who met PAG at age 17 also met PAG at age 21. The weak association between older adolescent and young adult PA suggests that PA is not an intractable behavior and that intervening during this transition time may successfully increase young adult PA.

Abstracts were prepared by the authors and printed as submitted.

Associations of Short Bout Sedentary Behavior and Physical Activity with Adiposity and Fitness in Children

Melissa A. Jones[1], Paula Skidmore[2], Lee Stoner[3], Harriet Harrex[2], Pouya Saeedi[2], Katherine Black[2], Bethany Barone Gibbs[1]. [1]*University of Pittsburgh, Pittsburgh, PA.* [2]*University of Otago, Dunedin, New Zealand.* [3]*University of North Carolina, Chapel Hill, NC.*

(No relevant relationships reported)

PURPOSE: Total duration of sedentary behavior (SB) is not consistently associated with adiposity and fitness in children. In adults, SB accumulated in long bouts has been positively associated with adiposity while short bouts are inversely related. We studied the effect of displacing long bout SB with short bout SB and physical activity in children.
METHODS: This cross-sectional study included 450 children aged 9-11 from New Zealand. Objective SB and activity were measured via wrist-worn accelerometer for ≥ 3 days. Activity was classified as long (≥10 min) and short (<10 min) bout SB, light, and moderate-to-vigorous physical activity (MVPA). Estimated cardiorespiratory fitness (mL/kg·min) was assessed using the 20 metre shuttle run test. Adiposity measures were World Health Organization BMI z-score (zBMI), waist circumference (WC) and Fat Mass Index (FMI). Isotemporal substitution estimated the effect of displacing long bout SB with short bout SB, light and MVPA (per SD) on adiposity and fitness in adjusted linear mixed models.
RESULTS: Children accumulated the following mean (SD) in min/day: 32 (17) long bout SB, 302 (42) short bout SB, 235 (27) light activity, and 131 (29) MVPA. Overall and in boys only, substituting long bout SB with short bout SB and physical activity was not associated with adiposity. Among girls, substituting with short bout SB (std. coef. = -0.84, p=0.038) and MVPA (std. coef. = -0.78, p=0.017) were inversely associated with FMI. Overall and by sex, substituting with MVPA was associated with higher fitness (std. coef.=2.08 mL/kg·min, p≤ 0.001). Substituting with short bout SB was associated with higher fitness in girls (std. coef. = 1.44 mL/kg·min, p=0.036). (Table 1)
CONCLUSIONS: As compared to long bouts, short bout SB (<10 min) was not adversely associated with outcomes and, in some cases, was related to more favorable f adiposity and fitness. SB pattern (long vs. short bout) may be important for clarifying health risks related to SB in children.

Table 1. Associations between Sedentary Behavior (SB), Light, and Moderate-to-Vigorous Intensity Physical Activity (MVPA), Adiposity, and Fitness among Children aged 9-11

Associations Between School Transport And Obesity By Gender, Grade, Physical Activity, Ethnicity, And Economic Disadvantage

Allen M. Hallett[1], Nalini Ranjit[1], Harold W. Kohl, III, FACSM[1], Kelley Pettee Gabriel, FACSM[1], Natalie P. Archer[2], Deanna M. Hoelscher[1]. [1]*University of Texas Health Science Center-Houston (UTHealth) School of Public Health in Austin, Austin, TX.* [2]*Texas Department of State Health Services, Austin, TX.* (Sponsor: Harold W. (Bill) Kohl, III, FACSM)

(No relevant relationships reported)

PURPOSE: To examine the prevalence of school transport modes and obesity by gender, grade, physical activity, race/ethnicity, and economic disadvantage in a representative sample of Texas school children.

METHODS: Cross-sectional data on reported sociodemographic characteristics, school transport mode, and physical activity behavior were collected from the Texas School Physical Activity and Nutrition (SPAN) Survey, 2015-2016. Measured height and weight were used to calculate BMI and classify 4th, 8th, and 11th grade students by obesity status. The sampling frame had 14,976 students from 452 schools to provide weighted state-level estimates by grade. Descriptive statistics and associations were conducted between school transport modes and obesity. Interaction terms were included to test if school transport mode-obesity associations differed by gender, grade, physical activity, race/ethnicity, or economic disadvantage.
RESULTS: Participants were predominately Hispanic (69.8%), normal weight (55.8%), used passive school transport modes (90.9%), and did not meet physical activity guidelines (82.4%). Active and passive school transport modes were not significantly associated with obesity (all *p*s>0.05). Gender, race/ethnicity, physical activity, and economic disadvantage were significantly associated with obesity (all *p*s<0.05). Bike to school by race/ethnicity and walk to school by grade were significantly associated with obesity (all *p*s<0.05). Hispanic/AA students who biked to school were significantly more likely to have obesity compared to White/Other students who did not bike to school (OR=5.48, *p*<0.05, 95% CI: 1.25, 24.00). Students in 8th grade who walked to school were significantly less likely to have obesity than 4th/11th grade students who did not walk to school (OR=0.42, p<0.05, 95% CI: 0.19, 0.91).
CONCLUSIONS: These findings suggest that associations between active school transport modes and obesity differ by sociodemographic characteristics, including race/ethnicity and grade. Population-based approaches to childhood obesity prevention may benefit from understanding disparities in opportunities for school transport modes. Supported by the Texas DSHS with funds from the Title V MCH Block Grant to Texas, the CDC HHS Block Grant, and the Michael & Susan Dell Foundation.

Freestyle Swimming Performance From Childhood To Adolescence Of Japanese Top-Class Swimmers.

Minoru Kunii[1], Susumu S. Sawada, FACSM[2], Naofumi Yamamoto[3], Yuko Gando[2], Hisashi Naito[4]. [1]*Central Sports Co., Tokyo, Japan.* [2]*National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan.* [3]*Ehime University, Matsuyama, Japan.* [4]*Juntendo University, Tokyo, Japan.*

(No relevant relationships reported)

Various studies, including genetic studies, to find elite athletes have been carried out. Childhood records may be a good index for finding elite athletes. However, limited data are available on this topic. **PURPOSE:** The purpose of this study was to evaluate the relationship of freestyle swimming performance between childhood and adolescence of Japanese top-class swimmers. **METHODS:** Subjects were male and female swimmers who participated in official competition accredited by the Japan Swimming Federation held from April 2007 to April 2017. The records of 100 m freestyle short-course performances of 22 year olds during 2016 to 2017 (latest TIME), and 12 to 21 year olds during 2006 to 2016 were analyzed. We evaluated the relationship between the latest TIME and the record of each age using Pearson's correlation coefficient. Also, we compared the average value of the records of the 2 groups, divided into the upper group and the lower group using the median of the fastest records of each individual by independent t-test for each age group. **RESULTS:** The table shows the matrix of correlation coefficient of male swimmers. In males, the correlation between the latest TIME and each age record for 10 years gradually became stronger from 16 years old, but there was not a clear tendency from the previous record. In females, a clear tendency was not observed. The difference between the records of the upper group and the lower group was statistically significant (P <0.05) before the record at 17 years old in males and 16 years old in females. **CONCLUSION:** These results suggest that there isn't a strong relationship between early childhood performance and latest TIME of Japanese top-class swimmers.

Dose Response of Cardiorespiratory Fitness Interventions in Adolescents: A Systematic Review

Zezhao Chen, Jingyuan Zhu, Weimo Zhu, FACSM. *University of Illinois at Urbana Campaign, Urbana, IL.*

(No relevant relationships reported)

PURPOSE: The decline of cardiovascular fitness (CRF) in adolescents has become a major concern. Efforts have been to improve adolescents' CRF through exercise interventions, but the dose response of the interventions has not been summarized. This study was to determine the exercise dose response needed for increasing CRF in adolescents (12-19 yr. old).
METHODS: Google scholar, Web of Science, PsycINFO, Scopus, SPORTDiscus, and Cochrane databases were searched. In addition, the listed studies' methodological quality was assessed. The standardized mean differences and 95 % confidence intervals (95 % CIs) were calculated as the effect size measures (ES).

RESULTS: The search yielded 50 studies, a total of 15 studies were included in the review. Most of the included studies employed a randomized control trial study design (12/15, 67%). Samples sizes ranged from 20 to 60. Intervention length ranged from 6-60 weeks. The major indicator of CRF was VO_{2max}, measured by laps (20-m shuttle run) or minutes (1-mile run). Aerobic exercise was utilized in most of the interventions (73%), followed by resistance training (20%), and a combination of aerobic and resistance training (6.7%). Interventions with intensity of "> 60% maximal heart rate (HRmax)" were found statistically significant for improving CRF (ES =0.87, 95% CI 0.23 to 1.11, p=0.04). Frequency of "3 times weekly" was found to be statistically significant for improving CRF (ES =1.07, 95% CI 0.37 to 1.77, p=0.003). Duration of an intervention that was "10-15 weeks" yielded statistically significance in improving CRF (ES =1.02, 95% CI 0.27 to 1.27, p=0.002). The effects of CRF interventions were moderate to significant (ES = 0.59, 95 % CI 0.55-0.88), with high heterogeneity (I^2 = 94 %). There was no sex difference (p=0.07) in terms of the interventions.
CONCLUSIONS: Exercise interventions achieving at least 60% of HRmax, meeting 3 times weekly for 10-15 weeks seem to have a positive effect on CRF among adolescents, but there is a high heterogeneity among those studies.

Dose-response Effects Of Exercises In Children With Asthma: A Review

Peibei Li, Zezhao Chen, Weimo Zhu, FACSM. *University of Illinois at Urbana-Champaign, Champaign, IL.*
(No relevant relationships reported)

PURPOSE: Exercise is shown to improve pulmonary function of asthmatic children, reduce asthma-related symptoms, and reduce physician office visits. Exercise can also improve physical fitness and quality of life for both children and their parents. This systematic review provides a summary of the dose-response effects of various exercise interventions for children with asthma, specifically pulmonary function, asthma-related symptoms and quality of life.
METHODS: A systematic search in several databases was performed. Fourteen randomized controlled studies of exercise interventions for children with asthma (aged 7-14 yrs.) were identified and compared. The effect size (ES) and 95 % confidence intervals (CIs) were computed and summarized.
RESULTS: Fourteen studies were included in this review. Most of the studies performed a randomized controlled study design (93%), with 19 to 61 participants. Length of interventions ranged from 4 to 15 weeks. Aerobic exercises like swimming and Tai-Chi, were employed in 12 of 14 studies (86%). Anaerobic training was employed in 1 of 14 studies (7.1%). Exercise interventions with moderate to vigorous intensity, 50%~75% VO_{2max}, were shown to most effectively improve cardiovascular fitness as well as pulmonary function for asthma control. Interventions with a duration from 8 to 12 weeks with a frequency of 2 to 4 times a week showed statistically significant improvements in pulmonary function. Pulmonary function was indicated by forced expiratory volume (ES=0.77, 95% CI, 0.56 to 0.99, p=0.002), peak expiratory flow rate (ES=0.50, 95% CI 0.25 to 0.97, p=0.007) and maximal inspiratory/expiratory pressure (ES=0.80, 95% CI 0.36 to 1.21, p=0.008). Most of the studies demonstrated reduced symptoms and physician visits, along with increase in self- reported quality of life.
CONCLUSIONS: Exercise interventions are safe and beneficial to asthmatic children. Effective interventions are suggested to have a duration of three months, with 3 training sessions per week consisting of 40-50 min of aerobic exercise. Moderate to vigorous intensity is recommended with resting period during each session.

Exercise Interventions for Children with Autism: A Review

Samuel Streeter, Zezhao Chen, Weimo Zhu, FACSM. *University of Illinois at Urbana-Champaign, Champaign-Urbana, IL.*
(No relevant relationships reported)

Samuel Streeter, Zezhao Chen, and Weimo Zhu
University of Illinois at Urbana- Champaign

PURPOSE: Autism is a spectrum of closely-related disorders with a collective core of symptoms. Research has been conducted to determine what the best exercise intervention for autism would be. However, the dose response of an exercise intervention for autism is unknown. The purpose of this study was to determine the dose response of exercise interventions for children (aged <12 yr. old), with autism spectrum disorder (ASD). **Method:** A systematic review of research, published from 1985 to 2017, was conducted using a number of criteria, including application of an exercise intervention for individuals diagnosed with ASD and utilization of an experimental/quasi experimental, correlational, single–subject, or qualitative research design. The standardized mean differences and 95 % confidence intervals (95 % CIs) were calculated as the effect size measures (ES). **Results:** 25 articles were identified using Google Scholar, Web of Science, and Ovid MEDLINE, but only 10 met the criterion for the review. 4 of the 10 were randomized control trials, 3 were repeated measure trials, 2 were multiple-baseline studies, and 1 was a pilot study. Eight (80%) included aerobic types of exercises. Nine (90%) employed moderate intensity (64%-76% %HRmax). The intervention length and duration that had the largest ES would be 20-45 minutes at 3-4 days per week for 10-12 weeks. Seven (70%) included results that showed improvement in "social and behavioral issues" and "motor skill development" from pre-to post trial. One (10%) showed an effect size that was statistically significant (ES=0.8, 95 % CI =-0.17- 2.04, p<0.00). **Conclusion:** The exercise interventions with moderate intensity, 20-45 minutes, 3-4 days per week, and lasting 10-12 weeks seemed helpful for children with autism.

Differences in CVD Risk Factor Status and Micronutrient Intakes by Physical Activity Level in Youth

Jeanette M. Ricci, Joseph J. Carlson, Erich Petushek, Karin A. Pfeiffer, FACSM. *Michigan State University, East Lansing, MI.*
(No relevant relationships reported)

Physical inactivity is an independent CVD risk factor. In 5th graders few reports show associations between moderate to vigorous physical activity (MVPA) and multiple CVD risk factors, or between MVPA and micronutrient intakes that contribute to cardiovascular health. **PURPOSE:** To determine if high PA youth have a better CVD risk factor status and higher intakes of micronutrients linked to cardiovascular health, compared to low PA youth. **METHODS:** In a cross-sectional analysis of data from 5th grade students (N=947, 11 ± 0.5 y; 58.2% females; 58.4% white), trained research assistants collected height, weight, percent body fat (%BF) via bioelectrical impedance, resting blood pressure (SBP,DBP), and non-fasting blood samples by finger prick for total cholesterol (TC), low density lipoprotein (LDL), high-density lipoprotein cholesterol (HDL-C) and TC:HDL levels. Micronutrient intakes were derived from the Block Kids Food Frequency Questionnaire. MVPA groups were determined by median split (High PA≥5days, Low PA<5days). One-way ANCOVAs were used to determine if CVD risk factors and micronutrients differed between High- and Low PA- groups, when controlling for age and gender. **RESULTS:** High PA youth had lower %BF (23.1 vs. 25.3, F(1,926)=14.98, p<0.05) and higher HDL-C (49.7 vs. 46.5, F(1,667)=9.12, p<0.05) compared to Low PA, with no differences in TC, TC:HDL, or BP measures. Micro-nutrient intakes were assessed per 1000 kcals. High PA youth reported higher intakes of K+ (1.38 g vs. 1.29 g, F(1,890)=19.98, p<0.05), Mg+ (136 mg vs. 128 mg, F(1,890)=26.27, p<0.05), vitamin A (353 mcg vs. 332 mcg, F(1,890)=5.04, p<0.05), vitamin C (79 mg vs. 67 mg, F(1,890)=12.37, p<0.05), vitamin E (3.6 mg vs. 3.3 mg, F(1,890)=6.64, p<0.05) and lower Na+ (1.48 g vs. 1.52 g, F(1,890)=4.19, p<0.05) compared to Low PA, with no differences in calcium or vitamin D. **CONCLUSIONS:** The better CVD risk factor status in High PA compared to Low PA youth parallels previous cross-sectional findings. The higher intakes of cardioprotective micronutrients in High PA youth may have contributed to better CVD risk status.

Research on Relationship between Chinese Female Students' Height and Geographical Meteorological Indexes

zhiping zhen[1], hanran li[2], liangyi hu[1], chao luo[1]. [1]*Beijing normal university, beijing, China.* [2]*China University of Mining and Technology (Beijing, beijing, China.*
(No relevant relationships reported)

PURPOSE: This study explores the trend and relationship of Chinese 7-17 year old female students'height and major geographical meteorological indicators in the six Chinese major geographical regions from 1979 to 2014.Then, uses the map visualization method to show the visualization characteristics of the students' Height change trend.
METHODS: Using the principal component analysis method and the spatial interpolation technique in the geographic information system,the spatial structure of the Chinese students' physique has been reflected. Based on the mathematical statistics method and the regional comparison method, the height data of urban girls aged 7-17 years in China from 1979 to 2014 were divided and the height maps were mapped. The horizontal and vertical comparative analysis about meteorological indexes and the height was carried out according to the geographical division.

Abstracts were prepared by the authors and printed as submitted.

RESULTS: (1) regional characteristics: the overall trend of urban girls aged 7-17 in China showed an upward trend, from east to west, from coastal to inland gradient decreasing trend. 5 provinces in North , 4 provinces in northeast, 6 coastal provinces in southeast and Xinjiang Uygur Autonomous Region, higher than the central and northwest provinces.(2) characteristics of the times: With the increase of he year, the differences between provinces and cities gradually reduced . Untile 2014, short students in all provinces had been eliminated. This feture is most significant change in Inner Mongolia from 1991-2000.(3)There was a significant positive correlation between the temperature and the height of the urban girls in China. The temperature was positively correlated with the height of the female. The precipitation had a negative correlation with the height of the urban girls.
CONCLUSIONS:Air pressure and sunshine make a positive influence of girl's height, while a negative influence on temperature. The general trend of Chinese Female Students' height presented a trend of declining from east to west and decreasing from coastal to inland. GIS strong data management analysis and display function is the good way to explore the quality of students physical fitness database. It will serve and apply to student physique promotion and intervention.

Thirty Years Secular Trend Of Rest Heart Rate In An Epidemiological Transtition Society

Wesley Dornelas[1], Victor KR Matsudo[1], João P. Junior[1], Timoteo L. Araujo[2]. [1]*CELAFISCS, São Caetano do Sul, Brazil.* [2]*CELAFISCS - FMU, São Caetano do Sul, Brazil.*
(No relevant relationships reported)

PURPOSE: to analyze the rest heart rate secular trend among schoolchildren from Ilhabela, a city in a marked epidemiologial shift. Methods: the study is part of the Mixed-Longitudinal Project on Growth and Development from Ilhabela, organized by CELAFISCS since 1978. Sample consisted of 197 boys, aged 12 to 14 years-old, divided into 4 decades: 1978 (n=41), 1988 (n=43), 1998 (n=61), and 2008 (n=52). Measures included body weight and height, and rest heart rate (RHR) measured right before a bycicle ergometer test. Statistic analysis included an ANOVA one way to determine eventual differences among RHR from diferent decades. A post hoc Scheffé test was used to localize these differences. A level of p<,01 was taken as significant. Results: Mean RHR was 81.3 bpm in the 1978 decade, of 85.2 bpm in 1988 decade, of 89.4 bpm in 1998 decade, and of 91.7 bpm in the 2008 decade, confirming a positive secular trend with a significant increase of RHR between 1998 and 2008 in comparison to 1978 velues. It represented an increase of 9.1% and 11.3%, respectively, when compared 1998 and 2008 values to 1978 ones. It was also noted a increase of 11.4 kg in body weight, and an increase of BMI from 17.1 to 18.1, suggesting an important change in level of physical activity and/or diet. Conclusion: This positive secular trend in RHR values between 1978 and 1998 and 2008 represents a signal of cardio-vascular health deterioration in that community under marked epidemiological shift, as consequence of a decline in active life standards.

1904   Board #165   May 31 2:00 PM - 3:30 PM

Knowledge of the Adult and Youth 2008 Physical Activity Guidelines for Americans

Eric T. Hyde, John D. Omura, Kathleen B. Watson, Janet E. Fulton, FACSM, Susan A. Carlson. *Centers for Disease Control and Prevention, Atlanta, GA.*
(No relevant relationships reported)

PURPOSE: The *2008 Physical Activity Guidelines for Americans* recommends adults engage in at least 150 minutes/week of moderate-intensity aerobic equivalent physical activity to achieve substantial health benefits. Youth should engage in 60 minutes of physical activity daily to receive overall health benefits. This study estimated the proportion of U.S. adults knowledgeable of the adult aerobic guideline and the proportion of parents knowledgeable of the youth aerobic guideline. **METHODS**: Data from a nationwide sample of U.S. adults who completed the 2017 *Summer ConsumerStyles* survey were analyzed. Participants were asked to identify the government recommended amount of physical activity needed for adults and youth to gain health benefits. Knowledge was defined as a response of "150 minutes spread out over a week" for the adult guideline, and "60 minutes, 7 days a week" for the youth guideline. Prevalence of knowledge of the adult guideline was estimated among all respondents (n=3,910), and of the youth guideline among respondents with school aged children (n=1,288). Differences by demographic characteristics, body mass index (BMI) categories, and physical activity levels were tested using adjusted chi-square tests. **RESULTS**: Overall, 2.4% (95% confidence interval (CI): 1.9, 3.1) of adults were knowledgeable of the adult guideline and 22.9% (95% CI: 20.5, 25.7) of parents were knowledgeable of the youth guideline. Knowledge of the adult guideline differed significantly by sex, education, income, physical activity level, and BMI category, while knowledge of the youth guideline differed by parental education and physical activity level. For example, knowledge of the adult and youth guideline was lowest among those with a high school degree or less compared to those with a college degree or higher (adult: 1.9% (95% CI: 1.2, 3.0) versus 4.0% (95% CI: 2.9, 5.3); youth: 16.1%

(95% CI: 12.3, 20.8) versus 24.9% (95% CI: 21.1, 29.2)). **CONCLUSIONS**: Despite the release of the *2008 Physical Activity Guidelines for Americans* nearly a decade ago, most U.S. adults and parents lack knowledge of the adult and youth aerobic physical activity guidelines. Effective communication strategies may help raise awareness of current and future editions of national guidelines for physical activity.

Member Movement Rates Of Fitness Facilities In England

Nadja Willinger[1], Elizabeth Horton[1], Lou Atkinson[2], Tim Williams[3], Alfonso Jimenez[1], Steven Mann[3]. [1]*Coventry University, Coventry, United Kingdom.* [2]*Aston University, Birmingham, United Kingdom.* [3]*ukactive Research Institute, London, United Kingdom.* (Sponsor: Gary Liguori, FACSM)
(No relevant relationships reported)

PURPOSE: Low retention rates of fitness centre customers have previously been reported in the UK. To understand the scale of this problem, data were collected from fitness centres across England with respect to acquisition and attrition rates, or 'rate of movement'. **METHODS**: Data were obtained from 481 fitness facilities throughout England during 2016 (private 22%; public 73%; university <1%; council operated 4%) , resulting in a representative sample of the UK fitness sector. Movement rates, which are defined as the net gain or loss of members from the beginning to the end of each month, are the main outcome measure, and are analysed using Friedman's Two-Way ANOVA, Wilcoxon Signed tests, and linear regression, with significance set at p=0.05. **RESULTS**: An average annual movement rate of 0.12±0.01% was reported across all centres. A comparison of the data provided for each quartile resulted in significant differences between all quartiles (p<0.001). The highest movement rate was observed during the first quartile of the year (2.29±0.04%), with a continuous decrease until quartile four (-1.38±0.02%). The rate reversed in quartile three from a net gain towards a loss of members. Regression analysis demonstrated a significant correlation between calendar month and movement rate (R=-0.816, p<0.001), where calendar month explained over 60% of the variation (adjusted R^2=0.632). On average, movement rates decreased by 0.4% each month (B=-0.404, 95% CI (-0.606 to -0.202)).
CONCLUSIONS: Fitness centres in the UK only report a net increase of members during the first six months of the year, with a constant decrease in rates for each quartile. This indicates the need for interventions aiming to increase retention rates of members of fitness facilities. More information is needed to correlate attrition rates with member characteristics to identify high risk customers and develop suitable interventions.

1906   Board #167   May 31 2:00 PM - 3:30 PM

Improving the Operationalization of Neighborhood Built Environment Exposures in Physical Activity Research: Houston TRAIN Study

Deborah Salvo[1], Casey P. Durand[2], Abiodun Oluyomi[3], Kelley Pettee Gabriel, FACSM[1], Alexandra van den Berg[1], Adriana Pérez[1], Harold W. Kohl III, FACSM[1]. [1]*The University of Texas Health Science Center at Houston - School of Public Health (Austin), Austin, TX.* [2]*The University of Texas Health Science Center at Houston - School of Public Health (Houston), Houston, TX.* [3]*Baylor College of Medicine, Houston, TX.*
(No relevant relationships reported)

Although evidence links the built environment (BE) to physical activity, findings remain inconsistent. Baseline Houston TRAIN study data were used to examine how geographic scale affects the relation between neighborhood BE measures (NBEMs) and physical activity.
PURPOSE: Determine if model fit and statistical significance of the associations between NBEMs and physical activity vary by participant-centric buffer sizes and identify an optimal geographic scale for operationalizing NBEMs.
METHODS: Using Geographic Information Systems, participant addresses were geocoded and a series of street-network, participant-centric buffers were built, with radii 250m-2500m (250m increments). NBEMs studied were park access and transit stop access (counts/buffer). Physical activity was measured with wGT3X-BT Actigraph monitors, and weekly minutes of moderate to vigorous physical activity (MVPA) were estimated using Freedson cut-points. Linear regressions were run estimating the association between NBEMs and MVPA per buffer size. Optimal geographic scale was determined based on model fit (R^2) and statistical significance. Models were adjusted for sex, age, education, marital status and race/ethnicity.
RESULTS: Data were available for 337 adults. For park access, significant (p<0.05) associations were observed at buffer sizes 2250m and 2500m. The 2500m scale had the best fit (R^2=0.15). Each additional park in the 2500m buffer was associated with 1.0 additional minutes of weekly MVPA. The interquartile range for number of parks within 2500m was 13. For transit access, significant associations with MVPA were observed at all scales. The highest R^2 (0.16) was at 2000m. Each additional transit

stop within 2000m was associated with 1.1 additional minutes of weekly MVPA. Those living in the highest quartile of transit access had 79 more transit stops within 2000m than those in the lowest quartile.
CONCLUSIONS: Larger scales (≥2000m, i.e. ≥24 min walk) than those commonly used in physical activity research (400-1000m) may be better suited for studying the relation of the BE with physical activity. Despite low effect sizes per unit increase, the geospatial variability of park and transit access is large, and could account for substantial differences in physical activity across Houston.

Objectively Measured Physical Activity and Self-Reported Screen Time Behaviors in Omani Children: A Cross-Sectional Study

Youngdeok Kim[1], Marc Lochbaum[1], Azhaar Al-Abri[2], Majeed Al-Jabri[2], Hafsa AlSabti[2], Sabah Almuqbali[2], Suad Alfori[2]. *[1]Texas Tech University, Lubbock, TX. [2]Ministry of Education, Muscat, Oman.*
(No relevant relationships reported)

World health organization recommends that children engage in at least 60 minutes of moderate- and vigorous-intensity PA (MVPA) per day, with at least 30 minutes of MVPA being achieved afterschool hours. Worldwide, the evidence shows that the prevalence of meeting PA recommendation in children is low. But the majority are from the Western and Asian countries and there is little data available from a country in the Middle-East that have different ethnic and cultural backgrounds. **PURPOSE**: This study examined the levels and patterns of objectively measured MVPA during afterschool hours in Omani children and to relate them with the self-reported PA and screen time behaviors. **METHODS**: 4th-grade children attending public elementary schools in Oman during October 2017 participated in the cross-sectional survey. A stratified, two-stage cluster sampling method resulted in a total of 324 children (boys=144; mean age=9.16 yrs old) completing all measures. Children were asked to wear the Polar Active watch across the three consecutive school days and to complete a questionnaire on PA and screen time behaviors. 30-sec epoch, metabolic equivalent (MET) data obtained from the device were used to estimate time spent in sedentary (<2) and MVPA (≥4) during 7-hour of afterschool period. **RESULTS**: On average, boys were less sedentary (251.3 mins/d) and more active, with greater MVPA (35.9 mins/day) and vigorous-intensity PA (VPA; 11.5 mins/d) than girls (251.3 mins/d, 26.0 mins/d, and 7.3 mins/d, for sedentary, MVPA, and VPA, respectively). Boys (69.9%) were more likely meeting 30-min MVPA guideline than girls (30.9%; Odds Ratio = 0.3). Most children reported one or less hours of watching TV (76.6%) and using computer/video games (85.5%) during school days, with girls being more likely to report No-TV watching (20.0%) or using computers (62.8%) than boys (13.2% and 41.67%, respectively). Girls are less likely participating in at least one sport team outside of school (45.0%) than boys (62.5%); yet PA and screen time behaviors were not associated with a likelihood of meeting 30-min MVPA guideline. **CONCLUSIONS**: The results showed that objectively measured PA levels of Omani children during afterschool hours are similar with those from the western countries. However, gender-disparities shown in the results should receive further attention.

Prevalence And Characteristics Of Us State-level Physical Activity And Public Health Planning

Harold W. Kohl, III, FACSM[1], Ashleigh M. Johnson[2], Brooke C. Towner[3], Erin E. Dooley[2], Kurt Heischmidt[4], Eloise Elliott[3]. *[1]University of Texas, Austin, TX. [2]University of Texas School of Public Health, Austin, TX. [3]West Virginia University, Morgantown, WV. [4]University of South Carolina, Columbia, SC.*
(No relevant relationships reported)

PURPOSE. The prevalence and attributable risk of disease due to physical inactivity requires it be made a public health priority. Public health planning allows for prioritization and resource allocation, particularly at the state and local level. The extent to which state planning efforts for physical activity exist in the US is unknown. **METHODS**. We developed and conducted a standardized internet search audit of each of 50 US states and the District of Columbia to determine the prevalence and characteristics of health planning documents that include physical activity. Data regarding prevalence and characteristics and degree of alignment with existing physical activity guidelines were abstracted for analyses.
RESULTS. Overall, physical activity was part of 215 health planning documents in 50 states. These documents ranged from those addressing various chronic diseases in adults, physical education in children and/or adolescents, or specifically stand-alone physical activity physical activity plans (n=2). Only 9.8% of documents specifically mentioned older adults as a priority population. For children and adolescents, 28.5% of documents aligned correctly with current aerobic physical activity guidelines, 6.6% with current muscle strengthening guidelines and 5.3% with current bone-strengthening guidelines. For adults, 28.5% of health planning documents aligned

with current aerobic activity guidelines and 11.6% aligned with muscle strengthening guidelines. Only 22 (11%) of state planning documents aligned entirely with the US National Physical Activity Plan sector-based approach to physical activity promotion.
CONCLUSION. Efforts to improve state-level physical activity planning in the US are needed.

Global Physical Inactivity

David Q. Thomas, FACSM, Lea J. Anderson, Monica N. Tyler, Rachel M. Sherman, Jennifer Spring. *Illinois State University, Normal, IL.*
(No relevant relationships reported)

The World Health Organization (WHO) labelled physical inactivity the fourth leading risk factor for global mortality. The rate of physical inactivity is increasing globally. Participating regularly in physical activity reduces risk for many non-communicable diseases. **PURPOSE:** To investigate the extent of physical inactivity, causative factors, and common obstacles. **METHODS:** A descriptive analysis of data generated by the WHO, governmental, and non-governmental organizations was conducted to discern the extent of physical inactivity, causative factors, and common obstacles. Percentages were calculated and analyzed to provide global, regional, and individual country profiles of physical inactivity. **RESULTS:** Data are not available from all countries equally. Wide variability exists between countries as to the prevalence of, and obstacles causing physical inactivity. Almost one-third of adults are physically inactive globally (15.0% in Southeast Asia to 43% in the Region of the Americas and the Eastern Mediterranean Region). The prevalence was lowest in South-East Asia (15%) and Africa (21%). Women were less active then men with differences of 10% and greater in some areas and greatest in the Eastern Mediterranean Region and Region of the Americas. Physical inactivity was highest in countries with technological advancement. **CONCLUSIONS:** Physical inactivity is a global issue affected by regional factors. It is also a universal problem world-wide and a leading cause of non-communicable diseases. Common factors: age, health, sex, socio-economic status, and urbanization are associated with the level of physical activity/inactivity. Cultural and religious factors limit opportunities for women in many places. Countries with high levels of physical activity rely on human powered transportation and physical labor. Leisure-time physical activity is low in all countries and does not make up for the lost activity associated with access to technology.

Differences in Park Plans and Policies Across US Municipalities

Erin L. Peterson. *CDC, Atlanta, GA.* (Sponsor: David R. Brown, FACSM)
(No relevant relationships reported)

Purpose: Park use has been positively associated with physical activity, and people are more likely to use parks they perceive to be safe and attractive. Park planning documents and municipality policy or budget provisions that address park safety and maintenance can play an important role in promoting park use. This study examines differences in the presence of park plans, policies, or budget provisions by municipality characteristics and examines the association between presence of park plans and municipal policy or budget provisions to provide safe and well-maintained parks.
Methods: Data from a survey of local officials from the 2014 National Survey of Community-Based Policy and Environmental Supports for Healthy Eating and Active Living (CBS HEAL) were analyzed for a nationally representative sample of US municipalities (n=2005, response rate: 45%). Data were merged with Census data to determine municipality characteristics, and ESRI Street Map Premium's HERE GIS database to determine number of local parks in respondent municipalities. Prevalence of a parks and recreation plan, and policies or budget provisions (related to lighting, patrols by police or security, maintenance of green space and equipment) were analyzed using survey weights to create national estimates.
Results: Overall, 68% of US municipalities had a parks and recreation plan. A higher prevalence of plans was observed among municipalities that had more parks (>2 compared with 0 or 1), had a larger population size, were classified as urban, were located in the West, and had a higher median municipal education level. Prevalence of specific policies or budget provisions in parks or outdoor recreation areas was 78% for lighting, 85% for patrols by
police and security, and 87% for maintenance of green space and equipment. The presence of each policy or budget provision had a positive association with presence of a parks and recreation plan (p < 0.05) and population size (p < 0.05), controlling for other municipality characteristics.
Conclusions: About 7 out of every 10 US municipalities have a parks and recreation plan. Addressing differences across municipalities in plan prevalence can be an important step toward improving access to safe and well-maintained parks.

1911   Board #172   May 31 2:00 PM - 3:30 PM

Lower Energy Availability Is Associated With Low Resting Enrgy Expenditure In Japanese Female Athletes.

Kuniko Moto[1], Rie Ishizawa[1], Machiko Otaka[1], Suguru Torii[1], Akira Namba[2], Motoko Taguchi[1]. [1]*Waseda University, Saitama, Japan.* [2]*Saitama Medical University, Saitama, Japan.*
(No relevant relationships reported)

Adequate energy availability (EA) is important for the health of female athletes. EA is calculated by subtracting exercise energy expenditure from total energy intake, and normalizing by fat-free mass (FFM). The international consensus statement indicates that reproductive function, energy metabolism, endocrine function, and bone health are affected by the threshold of EA, which falls below 30 kcal/kg FFM/day. However, several previous studies have reported that low EA is not associated with menstrual function or metabolism. Further, these data have been based on active women of Caucasian, European, or European-American descent. There are no published scientific studies regarding EA in Asian athletes. **PURPOSE:** To investigate the relationship between EA and resting energy expenditure (REE) in Japanese female athletes. **METHODS:** Fifteen collegiate athletes participated in this study. Menstrual status was based on self-reported menstrual history and confirmed by the ovulation test kit. Energy intake was determined by 3-day weighed food records. Exercising energy expenditure was assessed by the HR-VO$_2$ method. REE was measured by indirect calorimetry using the Douglas bag technique during the early follicular phase. Body composition was measured by dual-energy X-ray absorptiometry (DXA). **RESULTS:** Subjects with lower EA (<25 kcal/kg FFM/day) had lower REE/FFM than those with normal EA (23.2±3.1 vs. 27.0±2.4 kcal/kg FFM/day, $p<0.05$), and had lower triiodothyronine (T$_3$) levels (80±8 vs. 101±9 ng/dl, $p<0.01$). In addition, energy intake level was significantly lower (1615±317 kcal/day vs. 2102±364 kcal/day, $p<0.05$) in subjects with lower EA. However, the levels of estradiol, insulin-like growth factor 1, luteal hormone, follicle stimulating hormone, and progesterone were not significantly different between the two groups. **CONCLUSIONS:** In Japanese female athletes, energy metabolism was suppressed in subjects with lower EA, which was under 25 kcal/kg FFM/day, and was associated with lower REE due to lower T$_3$ levels. Thus, lower EA may influence energy metabolism in Japanese female athletes.

Predicting Energy expenditure in Males And Females During High-intensity Functional Training

Jesse A. Stein[1], Yuri Fieto, FACSM[2], Katie M. Heinrich[1]. [1]*Kansas State University, Manhattan, KS.* [2]*Kennesaw State University, Kennesaw, GA.*
(No relevant relationships reported)

PURPOSE: Researchers report improved body composition after high-intensity functional training (HIFT), which may result from high energy expenditure (EE) during training sessions. Incorporating predictive models for EE during HIFT may benefit practitioners, yet no investigation has attempted to predict EE during HIFT; which is likely different between sexes. Our study aimed to compare EE between sexes and predict EE using anthropometric, physical fitness and performance characteristics during a HIFT session. **METHODS:** Participants with ≥ 4 weeks of HIFT were recruited (n = 98; age = 31.3 ± 7.2 years; 41% female). Height (HT) and weight (WT) were determined using a stadiometer and electronic physicians scale, respectively. Level of experience (LVL) was assessed via self-reported time on a popular HIFT workout. Dual Energy X-Ray Absorptiometry (DEXA) was used to determine percent body fat (%BF). Participants completed a graded exercise test to determine peak oxygen consumption (VO$_{2peak}$). Participants returned after one week to perform a HIFT session while wearing a portable calorimetry system to determine EE. Participants completed as many rounds as possible of a 250-meter row, 20 kettlebell swings, and 15 thrusters in 15 minutes. Independent-samples t-test was used to compare EE between females and males, and multiple linear regression with stepwise selection was used to predict EE for females and males based on age, HT, WT, LVL, VO$_{2peak}$, and %BF. **RESULTS:** Mean EE was significantly different between females (48.9±18.2 kcals/min) and males (71.2±20.0 kcals/min; p < .001). For females, greater LVL (β = 9.92) and WT (β = 0.94), and lower %BF (β = -1.03) predicted 67% of the variance in EE, $f(3, 40) = 24.9$, p < .001. For males, greater LVL (β = 15.50) and height (β = 0.96), and lower %BF (β = -0.69) predicted 70% of the variance in EE, $f(3, 58) = 43.3$, p < .001. **CONCLUSIONS:** During a HIFT session, males exhibit higher EE than females, and anthropometric and experience measures predicted EE. It is promising for

practitioners that greater experience along with decreased %BF are related to increased EE. However, since HIFT utilizes different exercises in each session, EE likely varies. Future research could assess EE across a variety of HIFT sessions and continue to translate findings to practical applications for practitioners.

Effect Of Training Periods On Energy Deficiency And Physical Activity Level In Male Runners

Erina Muramatsu[1], Mizuho Adachi[2], Keisuke Teramoto[3], Shoji Igawa[4]. [1]*Suzuka National College of Technology, Mie, Japan.* [2]*Nippon Sport Science University, Tokyo, Japan.* [3]*Aichi University of Education, Aichi, Japan.* [4]*Nippon Sport Science University, Yokohama, Japan.*
(No relevant relationships reported)

PURPOSE: Relative energy deficiency affects the health and performance of both female and male athletes. It is important to understand the total energy expenditure (TEE) and physical activity level (PAL) required by each sport to prevent energy deficiency. The purpose of this study was to examine energy deficiency and PAL in Japanese male runners, with a particular focus on the different training periods and characteristics of the sports**.** **METHODS:** The subjects were 4 Japanese male sprint runners (SP group: age, 19.9±0.8 yr; height, 174.4±2.7 cm; body weight, 64.5±2.7 kg; body mass index (BMI), 21.2±0.3 kg/m^2) and 5 Japanese male endurance runners (EN group: age 19.8±0.9 yr; height, 172.2±6.3 cm; body weight, 59.1±4.9 kg; BMI, 19.9±0.8 kg/m^2). The evaluation index for energy deficiency was energy balance (EB), which was calculated by subtracting the TEE from energy intake (EI) during normal training (NT) and tapering training (TT) periods. TEE was determined using the double-labeled water method. The PAL was defined as TEE divided by resting energy expenditure (REE), which was measured using a gas analyzer. Physical activity energy expenditure (PAEE) was determined by subtracting REE and diet-induced thermogenesis from TEE. EI was determined through self-reported dietary records. **RESULTS:** The PAL and PAEE values in the SP group during the NT period were significantly higher than those during the TT period (p<0.05 for both parameters), which was due to decreased training volume during the tapering period. Meanwhile, no significant differences between the NT and TT periods were observed in the EN group. Furthermore, the EI in the SP and EN groups did not change during the NT and TT periods, and the EI for all athletes was found to be insufficient, as a negative EB was observed in both groups. **CONCLUSIONS:** Our results identified severe energy deficiency in Japanese runners because the EB in both groups was negative. In particular, the PAL in the SP group changed during the training seasons, whereas the EI did not change. EI cannot be adjusted according to PAL, which may be the cause of energy deficiency. Therefore, EI for athletes can be managed by adjusting the PAL based on the type of sport and training period.

Water Induced Thermogenesis

Robert M. Otto, FACSM, John Petrizzo, Melhaney Reichelt, Jessica Machaby, Glen Reid, Lauren Yanni, Abigail LeBlanc, Daniel Hagan, John Wygand, FACSM. *Adelphi University, Garden City, NY.*
(No relevant relationships reported)

The ingestion of water is purported to enhance resting metabolic rate (RMR) and because of the absence of calories in water, it may be considered part of a weight loss intervention. This premise is not without controversy. Boschmann, et al. report a 30% increase in RMR following the ingestion of 500 mL of 22ºC water at 40 min post ingestion, while Brown, et al. report no difference following ingestion of 480 mL of either distilled water or saline. **PURPOSE:** The purpose of this study was to determine the thermogenic effect of consuming two temperatures (4º [C] and 37º [H] C) and two volumes of distilled water (7 and 21 mL H$_2$O/kg body mass) on metabolism. **METHODS:** 10 subjects (age 22.3 ± 1.3 yr, ht. 1.74 ± 15.2 m., body mass 75.1 ± 18.5 kg, 4σ) reported to the lab in a euhydrated state and refrained from ingestion of food and beverage (other than water) for 10 hrs and abstained from water for 2 hours prior to each trial. Subjects rested for 30 minutes on an examination table, in a quiet, dimly lit, 23° C lab. RMR was obtained by open circuit spirometry for ten minutes at the conclusion of the 30 minutes of rest (PRE), as well as four additional 10 min samples at 20 minute intervals following water ingestion (T1, T2, T3 & T4). Immediately following the PRE RMR, subjects ingested C7, C21, H7 or H21 with the volume calculated from individual bm at a mean of 526 and 1577 mL for 7 and 21 trials, respectively. Subjects served as their own control in the randomized assignment of trials. **RESULTS:** Statistical analysis by factorial ANOVA revealed NSD (p>.05) among trials for energy cost. The greatest deviation from baseline RMR was a NSD of 4.4%, 6%, -4.2%, and 4.3% for C7, C21, H7, and H21, respectively.

VO$_2$ mL/min	PRE	T1	T2	T3	T4
C7	252 ± 46	263 ± 47	248 ± 50	260 ± 52	249 ± 50
C21	266 ± 67	262 ± 55	272 ± 66	282 ± 66	272 ± 62
H7	260 ± 58	257 ± 66	257 ± 74	249 ± 69	258 ± 62
H21	258 ± 67	269 ± 67	264 ± 67	264 ± 66	267 ± 58

CONCLUSION: Despite the ingestion of water in the range of common temperatures and volumes that are suggested to alter metabolic rate, none of these four conditions elicited a significant change in RMR. Although water ingestion can maintain euhydration, water does not enhance caloric expenditure in a significant manner.

Lessons Learned From Tennis Coaches' Limited Disordered Weight Control Behaviors And Disordered Eating Knowledge

Brian P. Reagan[1], Matt M. Beekley, FACSM[2], Kirby Jones[1]. [1]*University of Indianapolis, Indianapolis, IN.* [2]*Depauw University, Greencastle, IN.* (Sponsor: Matthew D. Beekley, FACSM, FACSM)

(No relevant relationships reported)

Irrational fears of food and weight gain are the foundation for Disordered Weight Control Behaviors, (DWCB), methods of weight control deemed unhealthy (e.g. severe Caloric restriction). Those extreme behaviors serve as clinical diagnostic criteria for Eating Disorders (ED). Adolescence is the time when DWCB and ED are likely to originate, especially in athletes. DWCB is linked to nutrition misinformation. The most frequently athlete cited source of nutrition information is equally misinformed coaches. **PURPOSE:** To assess high school tennis coaches' knowledge in 5 domains: (1) Macronutrients/Energy, (2), ED Etiology (3) Symptoms (4) Scope of Practice, and (5) ED Treatment. **METHODS:** The Nutrition & Eating Disorders in Tennis Survey (NETS) was created through modification of Turk et al.'s survey as no survey specific to all of the domains existed. An expert panel confirmed the Face and Construct Validity of the NETS before it was piloted. A link to Qualtrics survey and informed consent form was emailed to Indiana High School coaches. The criterion for "Adequate Knowledge" (AK) was set at 80%. Mean knowledge scores were calculated for each question and the 5 domains. A three - way ANOVA tested for any significant differences (p < 0.05) between means of total knowledge scores and demographic variables. **RESULTS:** Seventy-nine coaches (male = 61, female = 18) ages 24 to 71 (43.97, ± 11.97) completed every question, which corresponds to a 23% rate of return, 90% statistical power according to Insel, G.D. The most cited source of nutrition knowledge was "experience as an athlete" (48.1% or 38 of 79) and the least was a Registered Dietitian (1.3% or 1 of 79). Data analysis revealed that the coaches lacked knowledge: the mean total score was 17.65 correct out of 25 or 70.6% (± 10.9%), falling below the established AK criterion. The lowest mean scores were 57.0% (± 22.4%), 60.0% (± 21.7%), 63.6% (± 22.9%), for domains 1, 3, and 5, respectively. There was no significant differences between knowledge scores and education. **CONCLUSION:** The low knowledge scores suggest that the coached athletes are at a higher risk of DWCB. Likewise, they are likely to be misinformed about the importance of correct energy intake. The common notion that experience as an athlete or taking a nutrition course makes one a qualified nutrition educator, must be questioned.

Macronutrient Intake and Resting Metabolic Rate in Middle and Long Distance Recreational Female Runners

Joanne DiFrancisco-Donoghue[1], Mina Divan[1], Ashley DeLuca[1], Courtney Baranek[1], William G. Werner[2], Hallie Zwibel[1]. [1]*New York Institute of Technology College of Osteopathic Medicine, Old Westbury, NY.* [2]*New York Institute of Technology, Old Westbury, NY.*

(No relevant relationships reported)

Energy deficit due to caloric restriction and increased expenditure has been shown to decrease resting metabolic rate (RMR). However, it is unclear how much of this deficit creates the reduced RMR. **PURPOSE:** To examine macronutrient intake on resting metabolic rate and body composition in recreational female middle distance runners compared with long distance female runners. **METHODS:** Twenty-one female runners were recruited; 12 middle distance (age 23.6±1.19) and 9 long distance (age 24.4±1.3), who completed a 3- day dietary food recall on non-consecutive days. Subjects were grouped by weekly mileage; middle distance averaged 9.5±6.1 miles weekly and long distance runners averaged 30.5±7.4 miles weekly. Subjects completed a morning fasting 15- minute indirect calorimetry resting metabolic rate (RMR) and a body composition assessment using dual-energy

---

X-ray absorptiometry. Kilocalorie and macronutrient intake were assessed utilizing an online application. Subjects were also given the BSQ-16A self-report questionnaire of body shape preoccupation typical of eating disorders.
RESULTS: There was a significant difference in body fat % between the middle distance and long distance runners (31±4.3 vs 25.1±3.73, p=0.004) and in lean body mass % (63.8±4.2 vs 71.2±3.8). There were no significant differences in body mass index (21.4±2.0 vs 23.6 ±3.3, p=0.11). RMR was approaching a significance difference between groups with the long distance runners having a lower RMR and the middle distance runners demonstrating a higher RMR (1242.4 kcal±190.4 vs 1462.8 kcal± 281.2, p=0.06). Energy intake was similar between both long distance runners and middle distance runners, with both groups only eating minimally above their RMR (284.5±120.7 kcal above RMR vs 121±281.2 kcal above RMR). Results from the BSQ-16A revealed neither group suffered from body shape concern.
CONCLUSIONS: Both middle distance runners and long distance runners demonstrated caloric restriction. Despite having significantly more lean body mass, long distance recreational runners had a lower RMR. This may have been due to the greater energy deficit and increased energy expenditure found in the long distance runners.

1917   Board #178   May 31 2:00 PM - 3:30 PM

Current Energy Availability Is Not Associated With The Menstrual Status Among Japanese Female Athletes

Eri TAKAI, Rie ISHIZAWA, Mika GOSHOZONO, Machiko OTAKA, Suguru TORII, Motoko TAGUCHI. *Waseda University, Tokorozawa, Saitama, Japan.*

(No relevant relationships reported)

PURPOSE: Energy availability (EA) is defined as dietary total energy intake (TEI) minus exercise energy expenditure (EEE) normalized to fat-free mass (FFM). It is well known that chronic reduction in EA, below 30 kcal/kg FFM/day, is associated with impairments of a variety of body function such as menstrual disorder, endocrine dysfunction and decreased bone mineral density (BMD). Little is known regarding EA and the physiological parameters of Japanese female athletes classified according to menstrual status. Therefore, this study aimed to determine the current EA status, hormonal status and BMD in Japanese female athletes.
METHODS: Eighteen female collegiate athletes were classified into two groups; the eumenorrheic group (EU, 22±1 years, n = 7) and the menstrual disorder group (MD, 20±1 years, n = 11). The ovulation status was checked before the experimental period using an ovulation test kit, and the date were collected during the early follicular phase in EU group. TEI was assessed using 7-days dietary records, EEE was measured via HR-VO$_2$ methods, and hormonal status was measured from a fasting blood sample. Body composition and BMD were measured by dual energy X-ray absorptiometry. The eating attitude test (EAT-26) was used to assess susceptibility to eating disorders.
RESULTS: EA was not significantly different between EU and MD groups (32.2±9.6 kcal/kg FFM/day vs 32.6±8.1 kcal/kg FFM/day). Further, no significant differences were observed in terms of body composition, BMD, and EAT-26 score between the two groups. However, triiodothyronine (T$_3$; 84±14 ng/dL vs 114±21 ng/dL, p<0.01) and progesterone (P$_4$; 0.2±0.1 ng/mL vs 0.4±0.1 ng/mL, p<0.05) were significantly lower in MD group than those in EU group.
CONCLUSIONS: The results of the present study suggested that the menstrual status is not associated with current EA, but may be related to chronic energy deficiency among Japanese female athletes.

Effect Of Low Energy Availability During Three Consecutive Days Of Endurance Training On Muscle Glycogen Contents And Serum Hepcidin Levels In Male Long Distance Runners.

Aya Ishibashi[1], Chihiro Kojima[2], Akiko Kamei[1], Kaito Iwayama[1], Yoko Tanabe[1], Goto Kazushige[2], Hideyuki Takahashi[1]. [1]*Japan Institute of Sports Sciences, Tokyo, Japan.* [2]*Ritsumeikan University, Shiga, Japan.*

(No relevant relationships reported)

PURPOSE: Hepcidin is a crucial mediator of iron homeostasis and may be associated with iron deficiency in response to exercise training. Exercise-induced interleukin-6 (IL-6) elevation stimulates hepcidin synthesis after exercise. Low energy availability induced by insufficient dietary energy intake during strenuous endurance training period in athletes, and it may elicit depletion of muscle glycogen contents. Moreover, lowered muscle glycogen content augments exercise-induced IL-6 elevation probably leading to increase in hepcidin levels. We investigated that effect of low energy availability during three consecutive days of endurance training on muscle glycogen contents and hepcidin levels.
METHODS: Seven male long distance runners participated in the present study (mean ± standard error, age : 19.8 ± 0.4 yrs ; height : 1.75 ± 0.02 m ; body mass: 61.4 ± 2.0 kg). The present study was a repeated-measures crossover design. All subjects completed two exercise trials consisting of low energy availability (LEA) trial or neutral energy

---

Abstracts were prepared by the authors and printed as submitted.

availability (NEA) trial. Energy availability was manipulated to set as 20 kcal / kg FFM / day for LEA trial and 45 kcal / kg FFM / day for NEA trial, respectively. The subjects completed three consecutive days of endurance training (75 min of treadmill running at 70 % of VO_{2max}) during days 1-3. Venous blood samples were collected in early morning on days1-4 and 3 h after exercise completion on day 3. Serum hepcidin, ferritin, iron, myoglobin and plasma IL-6 levels were evaluated. Muscle glycogen contents were evaluated in early morning on days 1-4 by ^{13}C-MRS.
RESULTS: Average energy intake was 2,081 ± 61 kcal / day in LEA trial and 3,967 ± 90 kcal / day in NEA trial ($p < 0.001$). Muscle glycogen content were decreased in LEA trial during days 2-4 ($p < 0.05$, vs. day1) whereas no significant change was observed in NEA trial. Area under the curve of serum hepcidin levels during days 1-4 was significantly higher in LEA trial (40.2 ± 11.8 ng/mL in LEA trial) than in the NEA trial (17.0 ± 7.0 ng/mL, $p = 0.04$).
CONCLUSIONS: Three consecutive days of endurance training under LEA decreased muscle glycogen content and increased serum hepcidin levels in male long distance runners.

Development Of A Validated Energy Expenditure Prediction Equation In Asian Adults

Xi Jin, Paul Dinneen Loprinzi, Martha Ann Bass, Ling Xin, Teresa Carr Carithers, Mark Loftin, FACSM. *The University of Mississippi, University, MS.*
(No relevant relationships reported)

Knowledge of energy expenditure (EE) is an important factor for weight management and helps fitness professionals more appropriately design exercise programs for obesity reduction in the obesity prevalence of Asian.
PURPOSE: The aim of this study was to develop a regression equation to predict EE during walking or running corrected for one mile in normal weight and overweight Asian adults and to cross-validate the equation. **METHODS**: Eighty-five subjects, including normal weight walkers (NWW) (fat percentage≤25 for males, ≤30 for females), overweight walkers (OW) (fat percentage>25 for males, >30 for females) and runners (R), participated to test EE through indirect calorimetry. Analysis of variance was used to test overall significance with post hoc Scheffe test employed to compare energy expenditure in three groups (NWW, OW, and R). Multiple regression analysis was employed for EE prediction and differences between the measured and predicted EE in the cross-validation group was compared by a dependent t-test. Also, regression coefficients generated from cross-validation group were compared to the original equation's coefficients using the Chow statistical test. **RESULTS**: There was not significantly different absolute EE among three groups (p>0.05). When EE was expressed relative to body weight, R group (1.7±0.03 kcal·mile^{-1}kgBW^{-1}) was found to expend significantly more energy than the other two groups (NWW: 1.5±0.04 kcal·mile^{-1}kgBW^{-1}; OW: 1.4±0.03 kcal·mile^{-1}kgBW^{-1}, p<0.05). However, when EE was expressed relative to fat free mass, there was significant difference between NWW (2.0±0.05 kcal·mile^{-1}kgFFM^{-1}) and R groups (2.3±0.05 kcal·mile^{-1}kgFFM^{-1}, p<0.05). Predicting EE (kcal) during walking or running corrected for one mile yielded the following equation: EE=0.933body weight–4.127Gender (M=1, F=2)+47.256 (standard error of estimate, SEE=12.1 kcal·mile^{-1}). The dependent t-test revealed no significant difference between measured EE (101.4±4.3 kcal) and predicted EE (100.0±2.8) (p>0.05). Also, the coefficients for body weight and gender between the original equation and the predicted equation in the cross-validation group were not significantly different (p>0.05). **CONCLUSION**: These results provide a validated equation for predicting EE in Asian adults during walking or running.

The Effects of Wearing Cold Garments on Energy Expenditure

John P. Porcari, FACSM, Samuel Hartinger, Scott Doberstein, Kimberly Radtke, Abigail Ryskey, Carl Foster, FACSM. *University of Wisconsin - La Crosse, La Crosse, WI.*
(No relevant relationships reported)

Stimulation of brown adipose tissue (BAT) by cold exposure purportedly upregulates energy expenditure and has been suggested as a method to reduce adiposity. BAT in humans is located primarily in the upper torso. Manufacturers have developed garments that contain ice packs and are designed to be worn over these areas. Two such products are the Cool Fat Burner and the Cool Gut Buster. The Cool Fat Burner places ice packs against the shoulders and neck, while the Cool Gut Buster targets BAT around the abdomen. **Purpose:** This study was designed to determine changes in energy expenditure and heart rate when wearing the Cool Fat Burner and the Cool Gut Buster. Twenty subjects (12 males; 8 females) sat quietly for a total of 90 minutes while heart rate and VO_2 were recorded. Data collection was separated into three 30-minute phases: rest, low-intensity, and high-intensity. Subjects sat quietly during the rest phase, wore both the Cool Fat Burner and the Cool Gut Buster during the low-intensity phase, and wore both garments and drank cold water during the high-intensity phase. **Results:** Average VO_2 increased significantly across all three phases

(rest: 295.6 ± 69.1 ml/min; low intensity: 333.0 ± 83.2 ml/min; high intensity: 372.8 ± 87.5 ml/min). Average heart rate decreased significantly across all three phases (rest: 67 ± 8.2 bpm; low intensity: 65 ± 7.1 bpm; high intensity: 59 ± 6.8 bpm). When VO_2 was converted to caloric expenditure, it was found that 11.2 additional kcals were burned in the 30-min low-intensity phase compared to rest, and that 23.1 additional kcals were burned during the 30-min high-intensity phase compared to resting values. **Conclusion:** Wearing cold garments resulted in a significant increase in energy expenditure. However, the magnitude of the increase may not be practically useful as a weight loss tool.

Test of Two Distinct Protocols in Indirect Calorimetry

Andressa F. de Abreu, Anderson Santana, Domingos R. Pandelo Jr. *Centro de Alta Paerformance, Santos, Brazil.*
(No relevant relationships reported)

Andressa F de Abreu; Anderson Santana; Domingos R Pandeló Jr.. High Performance Center (CAP). Federal University of São Paulo/UNIFESP
Indirect calorimetry is an interesting tool for establishing diets. Through this test we can calculate the resting metabolic rate and the percentage of carbohydrate and fat oxidation in the energy metabolism.
Purpose: Although it is an important exam, in clinical practice, it is observed that there is no standardization in relation to the protocols used to perform the exam. Some are done with the patient in the sitting position while others are done with the patient in the lying position. The objective of this research was to verify the existence, or not of differences, in practical terms, in relation to such protocols.
Methods: To perform the tests, 10 volunteers, all male, and physically active were selected. The mean height of the volunteers was 1.75m (SD 12.18 cm) and the mean weight was 74.78 kg (SD of 11.32 kg). A properly calibrated gas analyzer was used, as recommended by the manufacturer. Gas collection was established with a 30-minute duration and was performed on the same day. Each volunteer did a sit-down and lay-down. The interval between one evaluation and another was recorded within 15 minutes. To verify the existence or not of differences between the groups (sitting) and (lying down) the Hedges g was used as a measure of effect size. The purpose of such a measure was to assess practical significance.
Results: As can be seen in Table 1, there was no difference in the resting metabolic rate, and even in the case of oxidation of energetic substrates (fat and carbohydrate), the difference was not significant, considering the mean, since the effect size (hedges g) was 0.012.
Conclusions: For clinical purposes, the use of the sitting or lying position does not present differences in terms of resting metabolic rate, as well as energetic substrate oxidation.

Table 1: RMR and Oxidation of FAT and CHO

	RMR (sitting and lying)	% Fat Sitting	Lying	% CHO Sitting	Lying
1	1885,0	48,82	41,03	51,18	58,97
2	1777,3	16,83	15,38	83,17	84,62
3	1279,8	73,25	71,28	26,75	71,25
4	1332,8	5,09	12,81	94,91	87,19
5	1502,6	21,47	20,40	78,53	79,60
6	1526,0	43,22	46,31	56,78	53,69
7	1958,8	24,63	28,59	75,37	71,41
8	1958,7	34,78	36,80	65,22	63,20
9	1516,6	74,83	72,00	25,17	28,00

Extending Traceable Validation To Metabolic Carts

Jon Moon[1], Eric Ruud, 55436[1], Erica Wohlers-Kariesch[1], Christopher Bock[2]. *[1]MEI Research, Ltd, Edina, MN. [2]Translational Research Institute for Metabolism and Diabetes, Florida Hospital and the Sanford Burnham Medical Research Institute, Orlando, FL.*
(No relevant relationships reported)

PURPOSE: Metabolic carts (MC) measure O_2 consumed (VO_2) and CO_2 produced (VCO_2) to estimate energy expended. There is little information on the absolute accuracy of MC. We adapted NIST traceable gas infusions used widely for "Room" calorimeter (RC) systems to MC.

METHODS: Blended CO_2 and N_2 simulated VO_2 by displacing O_2, and added CO_2 represented VCO_2. Traceability to NIST was maintained by calibrating the infusion system to a primary standard. Three MC were tested (Max II, AEI Technologies, Pittsburgh, PA; and two TrueOne 2400, Parvo Medics, Sandy, UT). MC were prepared and flow set as recommended by the manufacturer. High and low infusions (Low: VO_2 = 230, VCO_2 = 170 ml/min, EE = 1.1 kCal/min, RQ = 0.74; High: VO_2 = 330, VCO_2 = 287, EE = 1.6, RQ= 0.87) were made for 10 min followed by a null test. Gases were delivered into tubing connected to the MC mixing chamber. VO_2 and VCO_2 calculated by MC were averaged for 7 min. Average errors were differences between simulated and measured VO_2 and VCO_2.

RESULTS: Infusions were made without leaks despite differences in MC design. 57 infusions were run on the TrueOne 2400. High infusion error was 2.6% (Range: 1.7 to 3.9%) for VO_2 and 1.8% (Range: -0.3 to 2.3%) for VCO_2. Low infusion error was 6.5% (Range: 4.3 to 8.6%) for VO_2 and 1.7% (Range: -1.7 to 2.9%) for VCO_2. 104 infusions were run on the Max II: High infusion error was 7.4% (Range: 0.5 to 13.4%) for VO_2 and -3.2% (Range: -8.9 to 3.0%) for VCO_2. Low infusion was 8.9% (Range: -6.2 to 17.8%) for VO_2 and -3.2% (Range: -15.4 to 5.7%) for VCO_2. Variations were seen in baseline O_2 and CO_2 readings taken at the beginning of the test then every 5 min: O_2 (20.85 - 20.94 vol%); CO_2 (0.037 - 0.12 vol%).

CONCLUSIONS: Gas infusions are an independently traceable standard providing calibration and validation for most RC across a wide range of VO_2 and VCO_2. Traceability also establishes a standard between labs independent of model and manufacturer. Extending the same techniques to MC provides essential assurance to users, allows data to be analyzed between locations, and enables manufacturers to improve performance. More testing will determine best practices for MC, and possibly reduce the effects of environmental changes on MC.

Comparison of Predicted and Measured Resting Metabolic Rate Methods Among CrossFit-Trained Athletes.

Aylisis Rodriguez, Isabel Fabacher, Kathryn Brown, Alyssa J. Holmes, Trisha A. VanDusseldorp, Gerald T. Mangine, Tiffany A. Esmat, Yuri Feito, FACSM. *Kennesaw State University, Kennesaw, GA.*
(No relevant relationships reported)

The use of prediction equations and machinery estimation for the assessment of resting metabolic rate (RMR) has grown in popularity. While RMR is crucial when assessing dietary intakes, the accuracy may be dependent on the distinct characteristics of the individual. **PURPOSE**: To compare RMR assessed by indirect calorimetry with estimates obtained from three predictive equations for a group of advanced CrossFit-trained athletes. **METHODS**: RMR was estimated for six-experienced CrossFit-trained athletes [3 men (27.5 ± 6.5 yrs.; 87.5 ± 5.9 kg; 179.2 ± 2.2 cm), and 3 women (27.7 ± 1.5 yrs.; 67.8 ± 3.3 kg; 168.1 ± 5.3 cm)] using the ParvoMedics 2400 metabolic system (PV) following established protocols. Additionally, RMR was calculated using the Harris-Benedict (HB), Mifflin-St. Jeor (ME) and Nelson (NE) prediction equations. All data is presented as mean ± standard deviation (M ± SD). **RESULTS:** Repeated measures analysis of variance revealed significant differences among the four models (F(3) = 7.1, $p = 0.003$, $\eta^2 = 0.59$), where a greater (p = 0.01) predicted RMR was observed in ME (1646 ± 241 Kcals) was lower compared to HB (1733 ± 271 Kcals, p = 0.01) and ME & NE (1839 ± 322, p = 0.04). No differences were observed between the equations and PV. Moderate intra-class correlations were found PV and HB (ICC = 0.63, 95%CI = -0.10 - 0.94), ME (ICC = 0.52, 95% CI = -0.14 - 0.91), and NE (ICC = 0.73, 95%CI = 0.07 - 0.96). **CONCLUSION:** These results suggest that even though significant differences exist between each of the predictive equations, individually, each equation has good agreement with the values measured by indirect colorimetry.

Priming Whole-room Calorimeters With Co2 To Improve Performance And Reduce Test Time

Michael Busa[1], Eric Rudd[2], Erica Wohlers-Kariesch[2], Jon Moon[2]. *[1]University of Massachusetts Amherst, Amherst, MA. [2]MEI Research, Ltd., Enida, MN.* (Sponsor: Patty Freedson, FACSM)
(No relevant relationships reported)

PURPOSE: Studies using whole-room calorimetry to quantify resting and/or long-term metabolic rate often exclude initial data from analysis. Controlled gas infusions to simulate metabolic rate also show higher error in these initial measurements. This study examined if infusing CO_2 into the chamber prior to measurement reduced the time before measurements are within error specifications. We hypothesized that priming the chamber to 0.2% CO_2 will significantly reduce the time to get valid measurements of VO_2 and VCO_2.

METHODS: We used a precision gas blender to infuse pure gases (N_2 and CO_2) into a 32,500 L metabolic chamber (MEI Research Ltd, Edina, MN). Five different infusion profiles constructed to mimic VO_2 and VCO_2 associated with 1.1 METS in 50, 70, 90, 110, and 130 kg individuals with an RQ of 0.74, with and without infusing CO_2 to

bring the chamber to 0.2% CO_2 prior to infusion. Ambient inflow rate to the chamber was held constant at 45 L•min^{-1}. Additionally, an 88 kg male individual completed a resting metabolic rate study and the time it took to for the chamber to reach 0.2% CO_2, i.e. enter the validated range, was found experimentally. A pairwise t-test was used to compare the time before both VO_2 and VCO_2 to exhibit error of less than 4% in CO_2 primed vs. ambient (~0.04% CO_2) conditions, α=0.05. For the human data, the time it took for the chamber to reach 0.2% CO_2 is reported. No statistical comparison was made for the human data.

RESULTS: Priming the chamber to 0.2% CO_2 significantly (p=0.02) reduced the time it took for the chamber to be brought into the calibrated range. Specifically, when the chamber was primed to 0.2% CO_2 it took 101, 91, 62, 75, and 31 min before the infusion data came within the chamber specification compared to greater than 120 min in every condition when the chamber was not primed. It took 190 min before the chamber reached the 0.2% CO_2 when the participant entered a chamber with ambient CO_2 levels.

CONCLUSIONS: Priming a metabolic chamber to a CO_2 level that brings the chamber into its validated range could significantly reduce the time after a participant enters a whole-room calorimeter before valid data is observed. This could improve experimental efficiency and reduce participant burden by 80 min on average.

D-68   Free Communication/Poster - Energy Balance and Weight Management

The Effects Of Aerobic, Concurrent, And Resistance Exercise On Compensatory Eating Behaviors

Mark P. Takacs, Shawn Munford, Chad A. Witmer, Emily J. Sauers. *East Stroudsburg University, East Stroudsburg, PA.*
(No relevant relationships reported)

Obesity is a worldwide epidemic and can be defined as a disorder of positive energy balance, which occurs when the amount of energy consumed is greater than the amount of energy expended. **Purpose:** To observe the differences in compensatory eating behaviors between four groups (aerobic training, concurrent training, resistance training, and a non-exercise control) in recreationally active, resistance trained, college-aged subjects. **Methods:** Ten recreationally active college-aged (21.7 ± 1.3yrs) males and females participated in this study. A 5-week, randomized, crossover design with one full week between each session. Preliminary assessments consisted of a PAR-Q, informed consent, body composition, rep-set best, and VO_{2max}. Aerobic exercise (AE) consisted of 30-minutes of cycling at 70% HR$_{max}$. Resistance exercise (RE) consisted of seven, full-body circuit of three sets of 12 repetitions at 70% set-rep best. Concurrent exercise (CE) consisted of four resistance exercises at the same intensity with 15-minutes of cycling at 70% HR$_{max}$. The control (CON) consisted of 30-minutes of sitting. Food logs via MyFitnessPal were required for the 24-hour period following each session. SPSS 24.0 was used for data analysis using one-way and two-way ANOVAS and deltas. Level of significance was set at $p \leq 0.05$. **Results:** There were no significant difference in total caloric (CON: 2,145 ± 807.9kcal, AE: 2,040 ± 657.2kcal, CE: 1,973 ± 764.8kcal, RE: 2,354 ± 1,077.0kcal, p = 0.743), carbohydrate (CON: 219 ± 66.4g, AE: 244 ± 87.3g, CE: 204 ± 55.4g, RE: 237 ± 94.9g, p = 0.657), fat (CON: 57 ± 21.9g, AE: 58 ± 24.0g, CE: 59 ± 31.3g, RE: 63 ± 23.8g, p = 0.964), or protein intake (CON: 97 ± 48.6g, AE: 101 ± 48.0g, CE: 89 ± 53.4g, RE: 99 ± 46.4g, p = 0.942), HR (CON: 77 ± 10.3bpm, AE: 151 ± 21.9bpm, CE: 153 ± 16.2bpm, RE: 136 ± 15.8bpm, p = 0.122), or RPE (CON: 6 ± 0.0, AE: 11 ± 2.1, CE: 12 ± 1.9, RE: 10 ± 2.7, p = 0.147) between the four sessions. **Conclusion:** These findings demonstrate that the exercise-induced caloric deficit was not compensated via an increase in caloric and/or macronutrient intake, therefore, resulting in a negative energy balance. Further, the aforementioned findings provide evidence that exercise is a viable mechanism to create an energy deficit, which can ideally lead to successful weight loss.

Leptin And Ghrelin Concentrations Differ At Fasting, Post-prandial, And Post-exercise In Active And Inactive Females

Dina Acosta, Mindy Patterson, Jenna Lin, Jonathan Craig, Alexis Ortiz, FACSM. *Texas Woman's University, Houston, TX.*
(No relevant relationships reported)

Leptin and ghrelin are counterregulatory hormones that control food intake and energy expenditure to maintain energy balance. **PURPOSE:** To determine changes in leptin and ghrelin between collegiate female runners (n=12; age 22.2±3.3 years) and inactive females (n=14; age 25.3±1.9 years) across time.

Abstracts were prepared by the authors and printed as submitted.

METHODS: Using a cross-sectional design, blood was collected at three different time points: fasting, immediately following plain bagel consumption (T1), and immediately following a 30-minute steady-state submaximal VO_2 treadmill test (T2) in both groups. Leptin and ghrelin were measured using enzyme-linked immunosorbant assay. Fat mass (FM) was determined by dual-energy X-ray absorptiometry. Repeated measures ANCOVA (time x group) compared differences in leptin and ghrelin across time.
RESULTS: Body mass index differed between runners (19. ±1.4 kg/m²) and inactive females (22.6±2.8 kg/m²; p = .004). FM also differed between groups (runners: 10.76 kg; inactive: 18.32 kg, p ≤ .001). Baseline fasting leptin was lower in runners (3.3±1.5 ng/mL) than the inactive females (11.1±6.7 ng/mL; p = .003). Therefore, FM and baseline leptin levels were used as covariates. The time by group interaction was significant (p = .035; F = 4.598) with no differences between groups. In both groups, fasting leptin (7.4±4.08 ng/mL; p) was higher at baseline (fasting) than T1 (6.2±3.5 ng/mL; p ≤ .001) and T2 (6.1±3.2 ng/mL; p ≤ .001). Ghrelin also differed across time (p ≤ .001) with no interaction between groups. In both groups combined, fasting ghrelin (744.2±303.6 pg/mL) did not differ from baseline to T1 (708.9±243.8 pg/mL). However, following the treadmill test (T2) ghrelin (452.4±111.6 pg/mL; p ≤ .001) was lower than fasting and following bagel consumption.
CONCLUSION: Fasting leptin was lower in collegiate runners than inactive females due to lower levels of FM. Leptin concentrations decreased across time in both groups following food intake and exercise. Ghrelin was highest at fasting and immediately following food intake, and decreased only after exercise. Leptin and ghrelin concentrations change in a similar manner between female runners and inactive females.

The Effect Of Resistance Training On Morphology Of Rat Skeletal Muscle During Food Restriction

Kohei Sase, Satoru Ato, Yuma Katamoto, Satoshi Fujita.
Ritsumeikan University, Kusatsu, Shiga, Japan.
(No relevant relationships reported)

PURPOSE: Skeletal muscle is critical for muscle strength and exercise performance. Severe food restriction observed among athletes for rapid weight loss (i.e. fasting or skipping meals) activates autophagy-lysosomal pathway and protein breakdown and that causes muscle atrophy. It is well known that resistance exercise stimulates protein synthesis and muscle hypertrophy. Resistance exercise also attenuates skeletal muscle protein breakdown via the autophagy-lysosomal pathway, hence it may prevent the food restriction-induced muscle atrophy. To investigate the effect of resistance training (RT) on skeletal muscle mass and muscle fiber cross sectional area during muscle atrophy-inducing food restriction in rats. **METHODS:** Eleven weeks old male Sprague-Dawley rats were divided into four groups: normal fed group (C), normal fed and resistance training group (TR), 7 days of 70% food restriction group (FR) and 7days of 70% food restriction and resistance training group (FR-TR). In training group (TR and FR-TR), rats were subjected to 6 exercise sessions and then were killed 72 hours after final exercise session. Resistance exercise was conducted by percutaneous electrical stimulation in right gastrocnemius muscle three times per week. Hematoxylin-eosin staining was used to measure the gastrocnemius muscle fiber cross-sectional area (CSA).**RESULTS:** Body weight, gastrocnemius muscle wet weight, liver wet weight, epididymal fat weight and fiber CSA were significantly reduced by 70 percent with food restriction (p<0.05). Although no significant difference in fiber CSA among normal fed groups (C and TR), FR-RTgroup tended to show a reduced fiber CSA compared with FR group (p<0.09).**CONCLUSIONS:**This study suggests that resistance training during atrophy-inducing food restriction did not attenuate muscle atrophy in rat skeletal muscle.

Post-exercise Whole Body Cryotherapy Treatment Increases Energy Intake Among Well-trained Athletes

Chihiro Kojima[1], Nobukazu Kasai[1], Chika Kondo[1], Yasushi Suzuki[2], Kumiko Ebi[1], Kazushige Goto[1]. [1]*Ritsumeikan University, Shiga, Japan.* [2]*Saraya Co., Ltd., Osaka, Japan.*
(Sponsor: Robert R Kraemer, FACSM)
(No relevant relationships reported)

PURPOSE: Exercise-induced loss of energy intake during post-exercise period may delay recovery and impair exercise performance among athletes. However, the efficient procedures which can attenuate post-exercise reductions of appetite and energy intake have not been investigated. Previous studies demonstrated that cold environment was likely to promote appetite and energy intake. The aim of the present study was to investigate the effect of whole body cryotherapy (WBC) after exercise on appetite regulations.
METHODS: Thirteen male athletes (20.5 ± 0.2 years, 174.8 ± 5.2 cm, 66.6 ± 1.4 kg) were recruited in the present study. They conducted two trials on different days; consisting of WBC trial and CON trial. Subjects performed repeated sprint exercise initially in both trials. In WBC trial, WBC treatment for 3 min (about -140℃) was

applied from 10 min after completing the exercise. In CON trial, subjects kept resting for identical periods of WBC trial after exercise. At 30 min following exercise, ad-libitum buffet meal test was conducted to evaluate energy intake and macronutrient intake ratio. Blood samples were obtained to measure plasma acylated ghrelin, PYY3-36, serum leptin and other metabolic hormonal concentrations before and after exercise. Subjective feeling parameters, respiratory gas samples and skin temperature were also measured after exercise.
RESULTS: Skin temperature was decreased rapidly after WBC (pre: 31.6 ± 0.2 ℃, immediately after WBC: 7.1 ± 4.1 ℃), and the temperature remained significantly lower until the onset of buffet meal test (P < 0.001). Although plasma ghrelin, PYY3-36 and serum leptin concentrations were significantly changed after exercise (P < 0.05), no significant differences between trials were observed at any points for these hormones. During post-exercise period, minute ventilation and heart rate were significantly lower in WBC trial than those in CON trial (P < 0.05). Energy intake during buffet meal test was significantly higher in WBC trial (1371 ± 139 kcal) than that in CON trial (1106 ± 130 kcal, P = 0.007).
CONCLUSIONS: Cold exposure using WBC following strenuous exercise increased energy intake in male athletes.

MCT1 Gene Function on Percentage Fat Responses in Overweight and Obese Humans

Rocío Cupeiro[1], Barbara Szendrei[1], Teresa Amigo[2], Pedro J. Benito[1], Domingo González-Lamuño[2]. [1]*Universidad Politécnica de Madrid, Madrid, Spain.* [2]*University of Cantabria/ IDIVAL, Santander, Spain.*
(No relevant relationships reported)

Transgenic mouse for the Monocarboxylate Transporter 1 (MCT1) gene (*SLC16A1*) with one invalidated allele presented resistance to diet-induced obesity. In humans a single-nucleotide polymorphism (SNP), T1470A (rs1049434), for this gene has been related with an impaired lactate transport in T male carriers. Therefore, this SNP could have an influence in body composition changes, simulating the results seen in transgenic mice.**PURPOSE:** To investigate the influence of the T1470A SNP of the MCT1 gene on percentage fat (%fat) changes after a 6-month weight loss program in obese and overweight healthy people.
METHODS: 91 women (39.1±8.3 years, 80.7±10.5 kg) and 84 men (39.6±8.2 years, 96± 10.7 kg) followed a 24-week weight loss intervention including a controlled training program (supervised exercise group, S: 3 times/week, 38-60 min/session; strength, endurance and combined training; N=134) or exercise recommendations (non-supervised exercise group, NS; N=39). All groups had caloric restriction of 25-30% of their energy expenditure. Genotyping was done using PCR and direct sequencing or Real Time PCR. Three-way (genotype x exercise group x sex) ANCOVA was conducted for compare the final values of %fat, adjusting by the initial values. Effects sizes (ES) and their 90% confidence intervals (CI) were calculated to show the magnitude of the effect (standardized differences in means: Cohen's units) of carrying the A allele.
RESULTS: A genotype x exercise group x sex interaction was observed (p=0.017). TT women had less final %fat in the whole group (p=0.025, 1.94%) as well as within the NS group (p=0.002, 4.49%) than A carriers. The ES associated indicate that the A allele has a moderate (ES=1.15, CI=1.88, 0.42) and very likely positive effect only in women within the NS group. For men the A carriers ended with less %fat than TT subjects (p=0.037, 1.87%), with small and possibly negative ES in the S group (ES=-0.25, CI=-0.02, 0.52) and small and likely negative in NS (ES=-0.46, CI=0.01, 0.91).
CONCLUSIONS: The T1470A SNP might have an influence on %fat changes after a weight loss program. The effect seems to be different depending on sex and type of exercise intervention. Further studies are necessary to confirm this association and to clarify the underlying mechanisms.

Effects Of Exhaustive Exercise On PHB1 Expression And Mitochondrial Function In Rats

Hong Feng[1], Ze Li[1], Wen Fang[2], Zhaoming Liu[1], LiLi Ji, FACSM[3]. [1]*Tianjin Unversity of Sport, Tianjin, China.* [2]*Tsinghua Unversity, Beijing, China.* [3]*University of Minnesota, Minneapolis, MN.* (Sponsor: Li Li Ji, FACSM)
(No relevant relationships reported)

F0F1-ATP synthase is the key enzyme of mitochondrial oxydative phosphorylation, which largely determines the exercise endurance. PHB1 participates in mitochondrial oxidative phosphorylation. The content of PHB1 predicts that of F0F1-ATP synthase in many biological conditions.
PURPOSE: To observe the changes of PHB1 content in mitochondria and its relationship with mitochondrial function and energy metabolism in response to an acute bout of exhaustive exercise. **METHODS:** Male Sprague-Dawley rats were subjected to an acute bout of exhaustive exercise on treadmill at 20 m/min, at which

0% grade. Mitochondria of heart, brain and gastrocnemius were isolated to detect the changes of RCR and ROS. The content of PHB1 protein in mitochondria was detected by Western blot. ATP content in the organs and F0F1-ATP synthase activity were measured by spectrophotometer. **RESULTS**: 1. Compared with resting control group, ATP content decreased in the brain(-76%, $p<0.05$), heart(-77%, $p<0.01$) and skeletal muscle (-55%, $p<0.05$) after exercise. 2. F0F1-ATP synthase activity declined significantly in the brain(-26%, $p<0.05$), heart(-58%, $p<0.01$) and skeletal muscle(-55%, $p<0.01$) after exercise. 3. Mitochondrial respiratory control ratio (RCR) was reduced in the brain(-52%, $p<0.05$), heart(-43%, $p<0.05$) and muscle (-39%, $p<0.05$) in response to exercise. 4. ROS generation in mitochondria of brain(-64%, $p<0.01$), heart(-42%, $p<0.05$) and muscle (-44%, $p<0.05$) decreased significantly after exhaustive exercise. 5. Exercise decreased PHB1 content in the mitochondria of muscle(-30%, $p<0.01$) and brain(-37%, $p<0.05$) but had no effect on PHB1 in the heart. 6. ATP content was positively correlated with PHB1 level in the brain(r=0.836, $p<0.05$), heart (r=0.909, $p<0.05$) and muscle(r=0.913, $p<0.05$) after exercise, whereas F0F1-ATP synthase activity was positively correlated with PHB1 in the brain(r=0.896, $p<0.05$), heart (r=0.909, $p<0.05$) and muscle(r=0.955, $p<0.05$). 7. ROS generation was positively correlated with muscle PHB1 level (r=0.874, $p<0.05$) but there was no such correlation in the heart or brain. **CONCLUSIONS**: An acute bout of exhaustive exercise reduced the expression of PHB1 in the mitochondria of organs examined and decreased mitochondrial bioenergetics.

Effects Of A Ketogenic Or A Whey Protein Supplement On Metabolism, Appetite And Energy Intake

Isabel L. Smith, Elizabeth K. Bailey, Theresa Ramos, Takudzwa A. Madzima. *Elon University, Elon, NC.* (Sponsor: Paul C. Miller, FACSM)
(No relevant relationships reported)

The satiating effects of protein and its role in energy expenditure have been compared to carbohydrates and fats. Less data exists on the effects of a high fat ketogenic supplement consumed as part of a breakfast smoothie on metabolism, ratings of appetite and energy intake when compared to a protein based breakfast smoothie. **PURPOSE:** To determine the effects of whey protein (WP) vs. a ketogenic supplement (KS), added to a breakfast smoothie on energy expenditure (EE), appetite and energy intake. **METHODS:** Fifteen women (age, 3011 yrs; body fat 29.3±5.7%) participated in this randomized, double blind, crossover study. After a 12-hr fast, resting oxygen consumption (VO_2) and respiratory quotient (RQ) were assessed via indirect calorimetry. Ratings of appetite (hunger (H), fullness (F), desire to eat (DE) and prospective food consumption (PC)) were assessed via visual analog scales (VAS). After consuming the isocaloric (450 kcals) test meal containing either 54g WP (40% kcals protein) or 52g KS (40% kcals fat), VAS on appetite were administered every 30 min for the 3-hr post-prandial period. The thermic effect of the meal (VO_2) and RQ were assessed at 45, 105 and 165 min after meal completion. An ad libitum lunch meal was provided to assess subsequent energy intake. Repeated measures ANOVA were used to analyze data. **RESULTS:** There was a significant group by time effect for VO_2 ($p<0.001$) and RQ ($p=0.001$). WP elicited a greater VO_2 compared to KS at 45, 105 and 165 min (WP: 4.05±0.59, 3.86±0.53, 3.57±0.55 vs. KS: 3.66±0.59, 3.43±0.60, 3.26±0.45 ml/kg/min). RQ was significantly lower after WP compared to KS at all three time points (WP: 0.79±0.03, 0.79±0.04, 0.77±0.03 vs. KS: 0.84±0.04, 0.80±0.06, 0.77±0.08). Significant group by time interactions were observed for H ($p=0.022$), F ($p<0.001$) and DE ($p=0.02$) but not PC ($p=0.107$). Perceived H and DE were significantly lower, and perceived F was greater in the WP condition compared to KS. Energy intake (WP: 578±282 vs. KS: 625±220 kcals) did not differ between conditions ($p=0.197$). **CONCLUSION:** WP appeared to have a marked improvement in increasing both fat oxidation and energy expenditure during the post-prandial period. As such, WP would seem to be more advantageous than KS in promoting overall fullness, however it did not elicit lower subsequent energy intake at an ad libitum lunch meal.

1932   Board #193   May 31 2:00 PM - 3:30 PM

Changes In 6-Minute Walk Performance Is Associated With Weight Loss Following A 6-Month Weight Loss Program

Katherine A. Collins[1], Sara J. Kovacs[2], Shawn D. Raybuck[1], Audrey M. Collins[1], Marissa L. Marcin[1], Alexander L. Carne-Clark[1], Alyssa M. Harris[1], Gary D. Foster[3], Alexis Wojtanowski[3], John M. Jakicic, FACSM[1], Renee J. Rogers[1]. *[1]University of Pittsburgh, Pittsburgh, PA. [2]Temple University, Philidelpha, PA. [3]Weight Watchers International, Inc, New York, NY.* (Sponsor: John M. Jakicic, FACSM)
(No relevant relationships reported)

There is evidence of a relationship between obesity and decrements in mobility and function, making these important targets for weight loss interventions. Within commercial weight loss programs, there is limited data to quantify changes in functional outcomes such as walking performance and whether weight loss contributes to improvements in this important health outcome.
PURPOSE: To examine change in body weight and walking performance in participants enrolled in a commercial weight loss program, and to examine the association between weight loss and walking performance.
METHODS: Participants (N=140; 93.3% of enrolled participants, age: 46.9±12.6 years; body mass index: 32.6±4.5 kg/m²) who enrolled and provided complete data following a 6-month commercial weight loss program (Weight Watchers). The intervention was delivered by trained Weight Watchers staff and outcomes were evaluated by independent research staff who were not engaged in the delivery of the weight loss intervention. The intervention included weekly group sessions, instruction on behavioral strategies for weight control, and the use of a mobile app to self-monitor weight loss behaviors. Assessment of body weight and walking distance and gait speed using the 6-minute walk test occurred at baseline and 6 months.
RESULTS: Weight decreased from 88.0±16.2 at baseline to 81.0±15.6 kg at 6 months (weight loss = 7.0±5.6 kg) ($p<0.001$). Walking distance increased from 526.6±15.7 meters at baseline to 553.4±63.9 meters at 6 months ($p<0.001$). Gait speed during the 6-minute walk test increased from 1.46±0.17 meters per second to 1.54±0.18 meters per second from baseline to 6 months ($p<0.001$). Weight loss was significantly associated with improved walking distance (r=0.312, $p<0.001$) and gait speed (r=0.312, $p<0.001$) during the 6-minute walk test.
CONCLUSION: These findings indicate that this commercial weight loss program resulted in significant weight loss, and the magnitude of weight loss was associated with improved walking distance and gait speed. Thus, this type of commercial weight loss program appears to be effective for individuals seeking weight loss, which may also result in additional function benefits in adults with obesity.

Dietary Fat and Carbohydrate Intake and Physical Activity Independently Predict Android Fat in College Women

I. M. Castillo-Hernández[1], M. Vishwanathan[1], C.D. Beck[2], M.V. Fedewa[2], B.M. Das[3], W.J. McConnell[1], E.D. Hathaway[4], S.D. Higgins[5], M.D. Schmidt[1], E.M. Evans, FACSM[1]. *[1]University of Georgia, Athens, GA. [2]University of Alabama, Tuscaloosa, AL. [3]East Carolina University, Greenville, NC. [4]University of Tennessee Chattanooga, Chattanooga, TN. [5]Elon University, Elon, NC.* (Sponsor: Ellen M. Evans, FACSM)
(No relevant relationships reported)

PURPOSE: It is well established that abdominal or android obesity is a risk factor for numerous metabolic diseases. Dietary intake, expressed as both energy intake and quality of the diet, and physical activity (PA) are known to influence risk for android obesity. Specifically, the role that relative macronutrient intake (% energy intake) plays in risk for android obesity is of interest. Although college students are relatively healthy, their dietary and PA habits can predispose them to an increased risk for abdominal obesity. These health behaviors are of special interest given the transition to college and the establishment of health behaviors at this time of life. The aim of this study was to examine the contributions of energy intake, relative macronutrient intake (i.e., % of energy intake), and moderate-vigorous PA (MVPA) relative to android fat (%AFat) in female college students. **METHODS**: Female college students (n = 336; 18.7 ± 1.2 yo; BMI = 24.4 ± 4.7 kg/m²; %AFat = 38.6 ± 11.7%) were assessed for dietary intake using 3-day dietary records. Outcomes of interest included daily energy intake (KCAL), and relative daily energy intake of carbohydrate (%CARB), fat (%FAT) and protein (%PRO). MVPA was measured using accelerometry (NL-1000; 4 valid, 10-h days of wear). %AFat was determined via DXA using standard software designations (iDXA, Lunar, GE). A multiple linear regression model was utilized to predict %AFat from the dietary and MVPA variables. **RESULTS**: Daily MVPA (β = -0.25, $p < 0.001$), %CARB (β = 0.57, $p < 0.001$), %FAT (β = 0.64, $p < 0.001$) significantly predicted %AFat**,** explaining 92.1% of the variance ($p < 0.001$). Neither KCAL (β = -0.07, $p = 0.21$) nor %PRO were significant predictors of %AFat (β = 0.05, $p = 0.41$). **CONCLUSIONS**: Our results suggest that carbohydrate and fat content of the diet along with MVPA independently contribute to the risk for abdominal obesity whereas total caloric intake and protein content of the diet is less important in college-aged women.

Weight Gain and Changes in Cardiovascular and Metabolic Risk Factors Throughout the First Year of College

Krystle K. Sanders[1], Nuo Thao[1], Yi-Hung Liao[2], Jeffrey R. Bernard[1]. [1]California State University- Stanislaus, Turlock, CA. [2]National Taipei University of Nursing and Health Sciences, Taipei, Taiwan.
(No relevant relationships reported)

PURPOSE: It is well documented that the first year of college is associated with many physical changes. Of these, it is common for students to gain weight, which is often times referred to as the "Freshman 15." Although most "Freshman 15" studies report weigh gain, it is typically much less than 15 lbs. Despite some weight gain it is not well know if these changes in body weight are also associated with changes in both cardiovascular and metabolic risk factors. Thus, the purpose of this study was to evaluate morphological and physiological changes in students throughout their first year of college. METHODS: Twenty-seven Freshman college students (female n = 15, males n = 12) were recruited for this repeated measures design study. Throughout the 10 month study participants logged their eating and exercise habits and were tested on four separate occasions (each approximately 2.5 months apart). Each testing session consisted of body composition screening, oxygen consumption test (VO2max), fasting blood analysis, and an oral glucose tolerance test (OGTT). Repeated measure ANOVA was used on all data sets. All values were expressed as the mean + SE and p < .05 set for statistical significance.RESULTS: There was no difference in exercise (118 + 101 min/wk) over the 10 months, but there was a non-significant decrease (2.5 + 2.2 ml/kg/min) in VO2max by the end of the study. Compared to the start of their Freshman year, weekly caloric intake was significantly increased each testing session thereafter (1,268 + 677, 1,702 + 972, and 1,091 + 608 kcals respectively). At the conclusion of the study there was a significant increase in body weight (2.5 + 2.1 kg) which translated to an increase in percent body fat (1.5 + 2.4%) but not muscle mass (0.2 + 2.1%). In addition, the blood glucose and plasma insulin response to an oral glucose challenge did not change throughout the study, nor did fasting triglycerides, total cholesterol, and high density lipoprotein (HDL cholesterol). CONCLUSION: Although participants gained weight throughout their first year of college it was less than that predicted by the "Freshman 15". This added body weight was also not associated with increased risk of cardiovascular or metabolic diseases. Further research is needed to evaluate weigh gain and the development of risk factors in college students.

Weight Loss, Physical Activity, And Conception In Obese Infertile Women

Anna M. Gorczyca, Richard Washburn, FACSM, Felicia L. Steger, Courtney Marsh, Joseph E. Donnelly, FACSM. University of Kansas Medical Center, Kansas City, KS.
(No relevant relationships reported)

PURPOSE: To compare weight loss and physical activity in obese infertile women who did or did not become pregnant following completion of a weight loss program. METHODS: Obese infertile women, referred by a reproductive endocrinologist, completed the University of Kansas Weight Management Program (KWMP). This program included reduced energy intake (portion controlled entrees, low calorie shakes), increased moderate-to- vigorous physical activity (MVPA) targeting 300 min•wk. and lifestyle strategies were provided. Participants were asked to monitor weekly MVPA (self-report) and pedometer step counts. Height and weight were assessed by trained staff in the clinic. The cumulative average of MVPA and steps over the last 3-wks. of participation were used in the analysis. Pregnancy outcomes were obtained from a review of medical records. The Kruskal-Wallis nonparametric test was used to compare differences in percent weight loss, physical activity (MVPA min•wk.[-1], steps•wk.[-1]), and time in the KWMP between women who did, or did not become pregnant.
RESULTS: Obese infertile women (n = 14, BMI=40.0 $\pm$ 5.9 kg•m[2], age = 33.4$\pm$ 4.5 yrs.) completed an average of 17 wks. of the KWMP. Eight of 14 women (57%) became pregnant. Weight loss was greater in women who became (-15.4 $\pm$ 7.7 %) compared with those who did not become pregnant (-10.9 $\pm$ 11.3 %); however, the differences were not statistically significant (p= 0.17). Physical activity assessed by pedometer was significantly higher in women who became pregnant (64,774 $\pm$ 13,798 steps•wk.[-1]) compare with those who did not (51,207 $\pm$ 5,060 steps•wk.[-1], p =0.02). Self-reported MVPA was not significantly higher in women who became pregnant (212 $\pm$ 89 min•wk.[-1]) compared with those who did not (175 $\pm$ 106 min•wk.[-1], p = 0.37. Women who became pregnant participated in the KWMP 11 wks. longer than those who did not (p = 0.016).
CONCLUSION: Length of treatment and reported step counts were associated with increased pregnancy rates. Additional investigation with larger samples is warranted to evaluate the magnitude of weight loss and the potential independent contributions of weight loss and physical activity to improve conception.

The affect of exercise on hypothalamic kiss-1 and GPR54 in the puberty development of male rats

Author Block: Rui Xu[1], Yi Yan[1], Minhao Xie[2].
1. Beijing Sport University, Beijing, China
2. Sports Medicine Institute, General Administration of Sport of China, Beijing, China

Abstract:
Kisspeptin ,in addition to reflects its ability to inhibit cancer metastasis, which have been implicated in the regulation of GnRH secretion with its receptor GPR54, play an essential role in normal reproduction and pubertal development. PURPOSE: To explore the moderate-intensity treadmill training (MIT) in modulating the hypothalamic expression of kiss-1 and its G protein coupled receptor -GPR54 mRNA relative expression in the different time of puberty.
Methods: 3 weeks male Sprague-Dawley rats (weight:62.03±3.13) were randomly assigned to two experimental groups (n=36): control group (n=18) and the MIT group (n=18). MIT group did the 60%-70%V(·)O2max treadmill training (5 days/week,1 hour/day). All the rats were used to detect the hypothalamic expressions of kiss-1 and GPR54 mRNA, animals in the both groups were sacrificed , which on the week of 5 weeks, 6 weeks, and 8 weeks.
Result: Compared with C group, every weeks of the rats' MIT group had lower hypothalamic expression of kiss-1 mRNA and GPR54 mRNA. Especially the kiss-1 mRNA, After moderate-intensity treadmill training, compare with the control groups , the 5 weeks(0.22±0.09 vs 2.28±0.49, p<0.01), 6 weeks(1.09±0.13 vs 1.73±0.18,p<0.01), 8 weeks(0.69±0.21 vs 2.82±0.79) kiss-1 mRNA had significant reduced. All the MIT groups' hypothalamic expression of GPR54 mRNA had lower than C groups, especially at the age of 6 weeks(0.58±0.1 vs 0.79±0.23,p<0.05).
Conclusions:MIT could reduce the hypothalamic expression of kiss-1 and its receptor GPR54mRNA in the puberty development of male rats, and kiss-1mRNA are more affected.

Patient Experience on Weight Management Advice Prior to Pregnancy from Physicians andDietitians

Taniya S. Nagpal[1], Praja Vaikuntharajan[1], Barbra de Vrijer[2], Harry Prapavessis[1], Debbie Penava[2], Michelle F. Mottola, FACSM[1]. [1]University of Western Ontario, London, ON, Canada. [2]London Health Science Centre, London, ON, Canada. (Sponsor: Dr. Michelle F. Mottola, FACSM)
(No relevant relationships reported)

PURPOSE: More women are entering pregnancy with a pre-pregnancy body mass index (BMI) $\geq$30 kg/m[2], increasing the risk of pregnancy complications. Many women, however, will seek support from healthcare professionals pre-conceptually to try to lose weight. Using a mixed-methods approach, we determined if women seek support from physicians and/or dietitians for weight related issues and whether they found this experience helpful. METHODS: Data were reviewed from a Weight and Health History Questionnaire (n=206) completed by pregnant women with BMI of $\geq$30 kg/m[2] on intake for obstetrical care. This questionnaire included information regarding the type of health provider (physician or dietitian) accessed for weight loss advice pre-pregnancy and whether that experience was helpful (with explanation). A thematic analysis was conducted to determine the underlying reasons for these experiences. RESULTS: Of 206 women, 147 saw a physician (n=80) or dietitian (n=67). The number of women that found their experience helpful was significantly greater with a dietitian (51/67) than with a physician (34/80; p<0.05). Women who rated their experience with a physician as helpful noted referral to a dietitian or exercise professional (n=25) and receiving nutritional information (n=6) as important factors. The top helpful experiences with dietitians included new information being provided (n=21) and realistic goal setting (n=16). CONCLUSION: Women receiving weight loss support from physicians pre-pregnancy found their experience helpful when the physician offered support from dietitians and exercise professionals and when the physician provided nutritional information. Initiatives and resources like 'Exercise is Medicine', www.eatrightontario.ca or the Society of Obstetricians & Gynecologists of Canada's 'Nutrition is hard' can help bridge the gap between physicians and allied health care professionals and educate physicians on addressing lifestyle behavior, especially for obese women seeking weight management advice before pregnancy. Funding sources: CIHR and CHRI

The Relationship Of Cognitive Scores With Muscle Power, Strength, And 6-minute Walk In Breast Cancer Survivors

Rachael Hunt, Ashley Artese, Jeong-Su Kim, Lynn Panton, FACSM. *Florida State University, Tallahassee, FL.* (Sponsor: Lynn Panton, PhD, FACSM)

(No relevant relationships reported)

The relationship between cognition and aerobic fitness is well studied in breast cancer survivors (BCS); however, there is a lack of research evaluating the relationships between cognition and anaerobic fitness. **PURPOSE:** This study examined the relationship between cognition, muscle power, strength, and the 6-min walk (6MW) in BCS. **METHODS:** Forty-four BCS (60±8 yrs; BMI: 29.9±6.5 kg/m^2) completed Trail-Making Test A and B [TMTA (processing speed), TMTB (executive function)], Digit Span Forward (attention) and Backward (working memory), and Controlled Oral Word Association Test [COWAT (executive function)] to assess cognitive domains. Lower body isokinetic (ISK) power and strength were assessed by the Biodex™. Endurance was assessed by the 6MW. Pearson product-moment correlations were used to evaluate relationships between cognition and anaerobic fitness. Significance was accepted at p≤0.05. **RESULTS:** Faster TMTA and TMTB scores were correlated with greater ISK average power for extension at 60 degrees/sec (TMTA: r=-0.40; TMTB: r=-0.31) and 180 degrees/sec (TMTA: r=-0.45; TMTB: r=-0.30) while TMTA was correlated with greater ISK average power for extension at 120 degrees/sec (r=-0.34). A subcategory of the COWAT was correlated with greater 6MW distance (r=0.31) and greater ISK average power for extension at 180 degrees/sec (r=0.30). **CONCLUSION:** Higher cognitive functioning, specifically processing speed and executive function domains, may be correlated to greater average power. These findings warrant more research on the benefits of power and strength training on cognition in BCS.

Perceptions on Exercise is Associated with Self-Reported Physical Activity in Hematopoietic Stem Cell Transplant Patients

Melanie Potiaumpai, Tamia Medina, Stacy E. Cutrono, Denise Pereira, William F. Pirl, Krishna V. Komanduri, Joseph F. Signorile. *University of Miami, Miami, FL.* (Sponsor: Kevin Allen Jacobs, FACSM)

(No relevant relationships reported)

Hematopoietic stem cell transplant (HSCT) treatment, used to treat an array of hematological cancers, significantly impacts patients' physical, psychological, and psychosocial stress before, during, and after treatment. HSCT is associated with severe symptomology, including nausea, pain, and fatigue, which may discourage movement and significantly increase sedentary behavior. Patients are advised of the benefits of increased physical activity during HSCT, including attenuation of the severity of their symptoms. However, there is a paucity of research on patients' perceptions of the benefits of exercise and how that translates to their participation in physical activity. **Purpose:** To evaluate the relationship between perceived benefits and barriers of exercise and self-reported physical activity levels in patients undergoing HSCT. **Methods:** Twenty-three subjects (13M, 10F; 58.1 ± 8.4 years), enrolled in an in-patient physical activity intervention, were administered the Exercise Barriers and Benefits Survey (EBBS), and the International Physical Activity Questionnaire- Short Form (IPAQ) prior to their admission for HSCT. The benefits and barriers scale were scored separately. Higher scores on the Benefits Scale indicate a more positive perception of exercise while a higher score on the Barriers Scale indicates greater perception of barriers to exercise. Time spent walking (WALK) and time spent sitting (SIT), recounted in minutes, were reported on the IPAQ for the seven days prior to admission. A Pearson correlation coefficient was computed to assess: the relationship between the EBBS Benefits scale, WALK, and SIT, and the relationship between the EBBS Barriers scale, WALK, and SIT. **Results:** Results of the Pearson correlation indicated that there was a significant positive correlation between the benefits score and patient-reported WALK (r(21)= .44, p= .04). There was also a significant negative correlation between the benefits score and patient-reported SIT (r(21)= -.49, p= .02). There was no significant correlation between the Barriers scale and WALK (r(21)= .23, p=.30) or SIT (r(21)= -.18, p=.42). **Conclusion:** These preliminary results indicate that HSCT patients who report higher benefits to exercise are more likely to spend more time walking and less time sitting.

Structured Exercise in the Cancer Patient Improves Insomnia and Fatigue, but Not Depression

Chandee L. Pressnall[1], Cynthia Villalobos[1], Justin C. Brown[2], Paul D. Vosti[3], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]Harvard University, Cambridge, MA. [3]St. Joseph's Medical Center, Stockton, CA.* (Sponsor: Kathryn H. Schmitz, FACSM)

(No relevant relationships reported)

There are over 12 million cancer survivors in the United States. Nearly all of them have experienced physical, emotional, and psychological symptoms including fatigue, insomnia, and depression. This can contribute to the erosion of overall quality of life. While exercise is commonly prescribed to mitigate these symptoms, the optimal dose and characteristics of its prescription require further investigation. **PURPOSE:** To evaluate the effect of structured exercise on fatigue, insomnia, and depression in cancer survivors. **METHODS:** We enrolled 157 cancer survivors in a 10-week exercise intervention that included aerobic, resistance, and flexibility training. At baseline, patients completed the Fatigue Symptom Index, Athens Insomnia Instrument, and Zung-Self Rating Depression Scale to assess fatigue, insomnia, and depression respectively. Upon conclusion of the program, follow-up data were collected. Paired-samples t tests were conducted on patients who completed the intervention. Logistic regression tested the effect of fatigue, insomnia, and depression on odds of completion. Linear regression evaluated predictors of fatigue, insomnia, and depression. **RESULTS:** Among patients who completed the intervention (n=58), fatigue decreased (p<0.001); insomnia (p=0.673) and depression (p=0.675) were unchanged. Fatigue (p=0.432), insomnia (p=0.759), and depression (p=0.932) did not predict program completion. Patients who were more fatigued at baseline experienced greater reductions in fatigue at follow-up, assessed by score (r= -0.677; p<0.001) and category (r=-0.685; p<0.001). Patients with worse insomnia at baseline reported greater improvements at follow-up (r=-0.761; p=0.079); elevated depression did not facilitate greater improvement (p=0.228). **CONCLUSIONS:** Fatigue, insomnia, and depression are often indissoluble from the daily experience of a cancer survivor. A biweekly exercise intervention improved fatigue and insomnia after 10 weeks, with greater improvements among the more severely affected; however, we did not find significant alleviation of depression symptoms. These findings suggest exercise is a safe, effective strategy to relieve some symptoms associated with cancer. Further research is required to address potential bias owing to the high rate of attrition in our study.

Perceived Exertion Responses While Wearing Tight- and Loose-Fitting Powered Air-Purifying Respirators

Edward J. Sinkule, FACSM[1], Jeffrey B. Powell[1], Tyler D. Quinn[2]. *[1]Centers for Disease Control & Prevention/NIOSH, Pittsburgh, PA. [2]University of Pittsburgh, Pittsburgh, PA.*

(No relevant relationships reported)

PURPOSE: This study compared ratings of perceived exertion (RPE) among participants performing the same energy expenditures while wearing NIOSH-approved powered air-purifying respirators (PAPRs) from different manufacturers: one tight-fitting (PAPR-T) and three different models of loose-fitting PAPRs (small hood (PAPR-S), medium hood (PAPR-M), and large hood (PAPR-L)). **METHODS:** The study consisted of six trials: Initial exercise evaluation to determine treadmill speed and elevation to achieve three absolute energy expenditures, labeled LOW (VO$_2$ 1.0 L/min, STPD), MODERATE (VO$_2$ 2.0 L/min, STPD), and HIGH (VO$_2$ 3.0 L/min or maximum, STPD); a baseline evaluation wearing no respirator; and four PAPR evaluations randomly assigned between two visits. Eleven men and 11 women provided informed consent approved by the NIOSH IRB (#12-NPPTL-01). Baseline and PAPR evaluations consisted of four minutes each during standing rest and the three energy expenditures. All PAPRs used HEPA filters. RPE using the 6-20 Borg scale were obtained during the last 15 seconds of each energy expenditure. **RESULTS:** RPE results for the men and women were not statistically different. Table 1 provides the average RPE for men and women by experimental trial:

Table 1. Average RPE for each study trial by energy expenditure (n=22).

Abstracts were prepared by the authors and printed as submitted.

MODERATE	11.5	11.0	11.7	11.9*	12.3*	12.5*
HIGH	15.3	14.4	15.9*	15.9*	16.5*	16.5*

* $P < 0.01$ compared to Baseline

CONCLUSIONS: RPE while using PAPRs were greater compared to the same energy expenditures while not using a PAPR at baseline. Compared to baseline, RPE using a tight-fitting PAPR were lower compared to loose-fitting PAPRs. The lower RPE for baseline results compared to the exercise evaluation may be attributed to a learning effect where outliers were observed from the exercise evaluation. Trends in the RPE difference between loose-fitting PAPRs at the same energy expenditure appear to be related to hood size or dead space.

Moderate-vigorous Intensity Run Vs. Walk On Hemodynamics, Metabolism And Perception Of Effort

Patrick M. Davitt, Troy Hartman, Steven Estremera, Phil Barone, Jillian Grassano, Gregory Muy, Olivia Akers-Goodwin, Andrew Marrero, Astrid Mel. *Mercy College, Dobbs Ferry, NY.* (Sponsor: M. Allison Williams, FACSM)

(No relevant relationships reported)

The ability to use an alternative (i.e., walking) to running would provide great benefit to those who are uncomfortable running or can't run, in order to meet minimum activity recommendations**. PURPOSE**: We compared two exercise modalities (Run, Walk) matched for VO2, on HR, RPE, and a visual analog scale (VAS). **METHODS**: Active, college-aged males (n=7; weight = 72.5 $\pm$ 3.9 kg; Bf% = 17.9 $\pm$ 1.2; VO_{2max} = 51.5 $\pm$ 1.36 mL/kg/min) participated in a crossover-designed study, and studied on each of 2 occasions: Walk (W) and Run (R). Subjects completed a body composition and VO_2max test. (R) = 60-min on a treadmill at 0%grade and speed equal to 65% VO_{2max} (694.4 $\pm$ 26.1 kcal). (W) = 60-min at 3.3mph and a steep incline equal to 65% VO_{2max} (677.9 $\pm$ 20.9 kcal). Pulmonary gas exchange (VO2, RER, respiratory rate (RR)) was assessed within the first 10 min of exercise, with HR and RPE recorded every 15 min. A VAS was used to assess overall perceived effort (0-100mm). RM ANOVAs were used for statistical analysis. Values were calculated as mean $\pm$ SE. **RESULTS:** There was no significant difference in VO2 (Run, 33.2 $\pm$ 1.1; Walk, 32.7 $\pm$ 1.1 mL/kg/min; Con, p=0.59), RPE (Run, 11.1 $\pm$ 0.8; Walk, 11.7 $\pm$ 0.8, p=0.28), VAS (Run, 51.2 $\pm$ 5; Walk, 48 $\pm$ 5mm, p=0.54), or %VO_{2max} (Run, 64.6 $\pm$ 1.2; Walk, 63.5 $\pm$ 1.2%, p=0.56) between the groups. There was a significant difference in HR (Run, 167.0 $\pm$ 4.9; Walk, 157.3 $\pm$ 4.9 BPM), RR (Run, 35.1 $\pm$ 2.3; Walk, 30.5 $\pm$ 2.3 BPM), and RER (Run, 0.86 $\pm$ 0.02; Walk, 0.9 $\pm$ 0.02) between the groups. There was no significant difference in the amount of sleep (R, 6.6; W, 6.8hr) between the two groups (p=0.68). 5 out of 7 subjects complained about their legs "burning" or "hurting" during the W trial. **CONCLUSION**: Walking and Running, even when matched for intensity, via VO_2, led to the R having a significantly higher HR and breathing rate for 60-min in active males, but a significantly lower RER. Despite the subjects complaining of their legs being sore (W), RPE did not reflect a difference in perception, nor did the VAS post-exercise. These results indicate that a walk can be recommended for a moderate-vigorous intensity, and elicit a similar metabolic and hemodynamic response, without causing a significant increase in perceived effort. This promotes the use of "steep" walking as energetically beneficial for those not able or desiring to run at higher intensities.

Music With and Without Lyrics Improves Motivation, Affect, And Arousal During Moderate-intensity Cycling

Daniel Marshall, Scott B. Martin, FACSM, Ryan L. Olson. *University of North Texas, Denton, TX.* (Sponsor: Scott Martin, FACSM)

(No relevant relationships reported)

Music is used to distract, energize, and entertain during exercise by producing positive psychological and physiological responses. Previous investigations suggest that listening to music during exercise enhances performance, increases motivation, improves affect, and optimizes arousal. Researchers have identified several elements of music that may moderate the music-performance relationship, including lyrics. However, few studies to date have examined the influence of motivational lyrics on psychological and physiological responses during exercise. **PURPOSE:** The primary purpose of this study was to investigate the effects of lyrics in music on motivation, affect, arousal, and perceived exertion during moderate intensity cycling. **METHODS:** Thirty (Mage = 21.0 $\pm$ 2.9 years old) college-aged individuals performed three, 8-min acute bouts of moderate-intensity exercise on a cycle ergometer during music with lyrics (ML), music without lyrics (MNL), and no music control (MC) conditions. Measures of motivation, affect, arousal, and perceived exertion were taken before and after a 6-min warm-up, every 2-min during the exercise bout, and following a 2-min

cool-down. **RESULTS:** For ML and MNL conditions, participants reported higher motivation (ML: 5.11 $\pm$ 0.35; MNL: 5.14 $\pm$ 0.36), affect (ML: 2.51 $\pm$ 0.23; MNL: 2.47 $\pm$ 0.23), and arousal (ML: 3.32 $\pm$ 0.19; MNL: 3.23 $\pm$ 0.18) during exercise relative to the MC (motivation: 4.10 $\pm$ 0.43; affect: 1.94 $\pm$ 0.27; arousal: 2.84 $\pm$ 0.23) condition. As expected, RPE increased throughout the exercise period, $F(6,24) = 42.24$, $p < .001$, with no between condition differences observed. Additionally, there were no differences in primary outcome variables between the ML and MNL conditions ($ps > .05$). **CONCLUSION:** The results suggest that music, regardless of whether lyrics are included, can enhance psychological responses during exercise. The current findings may help address common exercise barriers and inform exercise practitioners on music selection to improve exercise adherence.

1944 Board #205 May 31 3:30 PM - 5:00 PM

Does Body-weight Circuit Training Have The Ability To Induce Hypoalgesia?

Panagiotis Koutakis[1], Kelsey Uno[2], Emily Pritchett[2], Timothy Michael[2], Nicholas Hanson[2], Michael Miller[2]. *[1]Baylor University, Waco, TX. [2]Western Michigan University, Kalamazoo, MI.*

(No relevant relationships reported)

PURPOSE: Exercise-induced hypoalgesia (EIH) is a phenomenon that often occurs following exercise. It is believed to be related to the endogenous opioids that are released during physical exercise that affect pain perception. Many of the studies investigating EIH have used either aerobic, isometric or resistance training protocols. It is not currently known if circuit training, using bodyweight exercises, can lead to EIH. Therefore, the purpose of this study was to determine if EIH can be elicited through bodyweight exercise circuit training. **METHODS**: Thirty (11 men, 19 women; age 22.8±3.3 years, height 169.71±10.44 cm, mass 75.74±21.56 kg) healthy recreationally active individuals volunteered for this study. Subjects were asked to come to the laboratory, in a randomly assigned order, for two visits: once for a control condition and once for a circuit training condition. In the control condition, subjects were asked to simply rest quietly for 20 minutes. In the experimental condition, they were guided through a series of bodyweight exercises such as squats, lunges, push-ups and chair dips. Pre/post, and at various points during recovery, pain pressure threshold (PPT) was assessed with a strain algometer. Four sites were tested: upper trapezius, index finger, patellar tendon and the dorsal foot. A repeated-measures 2 (condition) by 7 (time: pre/post, and 10, 15, 20, 25 and 30 min post) ANOVA was performed for each site. **RESULTS**: There was only a significant main effect of condition seen in the upper trapezius (p<.05). A significant increase was seen in PPT for the index finger immediately after exercise (2.87±0.15 kg/cm^2 at pre and 3.24±0.19 post; (mean±SD)) and the dorsal foot (2.63±0.14 pre and 2.94±0.15 post). While the index finger PPT returned to baseline quickly, the patellar tendon PPT reached significance at the 10 min post exercise point, and remained elevated. **CONCLUSIONS**: Three out of the four sites showed increased PPT following exercise, suggesting that EIH can be elicited through circuit training implementing bodyweight exercises. Further research is needed but there is a possibility for certain populations such as the elderly or individuals with chronic pain that could benefit from EIH, especially those that cannot perform traditional training methods.

Concurrent Validity Of The Children's Omni Scale Of Perceived Exertion In A Field Setting

Timothy J. Michael, FACSM, Erin Berner, Carol Weideman, Nicholas Hanson, Sangwoo Lee, Michael Miller. *Western Michigan University, Kalamazoo, MI.*

(No relevant relationships reported)

The children's OMNI RPE Scale was developed because of a need and want to measure perceptions of physical exertion in children and adolescents. The term OMNI is from the word omnibus, referring to its wide encompassing properties. The OMNI RPE Scale contains pictorial, numerical and verbal descriptors positioned along an inclined line. Previous research with children and the OMNI RPE Scale was validated in controlled lab settings using exercise equipment. **PURPOSE:** The purpose of this study was to determine if the Children's OMNI RPE Scale is valid in a field setting (at school during recess and Physical Education Class (PE)). **METHODS:** 93 healthy children (male (n=44) and female (n=49)) age 8.5±1.4 years volunteered as subjects. Subjects were recruited from a local public elementary school with parental consent. All subjects demonstrated sufficient ability to read out loud and understand each verbal descriptor on the OMNI RPE Scale. The instruments that were used during this study consisted of a Polar Heart Rate Monitor and a copy of the Children's OMNI-walk/run Scale. A definition of perceived exertion specifically written for children and a standard set of instructions regarding the use of the OMNI-walk/run Scale to rate perceptions of exertion were explained to the subjects immediately before the testing. Data was collected during 30-minute testing sessions, one week apart, during recess and PE class. Heart rate was recorded every 5-minutes for a thirty-minute period, along with perceived exertion. **RESULTS:** Repeated measure ANOVA procedure identified

that Heart Rate and RPE each had a significant (p<0.01) change over time during both recess and PE. Recess: HR±SE (157.9±2.8; 170.1±2.2; 173.8±2.2; 173.9±2.4; 179.7±2.1; 185.6±2.2). RPE±SE (4.3±0.2; 5.2±0.2; 5.8±0.2; 6.3±0.2; 6.8±0.2; 7.4±0.2). PE: HR±SE (148.8±2.4: 153.9±1.8; 160.3±1.7; 164.9±1.9; 167.3±1.9; 168.3±1.9). RPE±SE (3.6±0.2; 4.2±0.2; 4.9±0.2; 5.2±0.2; 5.3±0.2; 5.6±0.2). Pearson correlational analysis indicates a significant relation between Heart Rate and RPE during recess (r=.38l; p<0.001) and PE (r=.552; p<0.001). **CONCLUSION:** Data from the present study suggests that the Children's OMNI RPE Scale is a valid indicator of children's physical effort during structured and unstructured physical activity.

The Effect of Movement Speed on Mental Workload During a Simple Visually Guided Task
E. Daniel Syrett, Matthew E. Holman, Tanu Bhargava, Benjamin J. Darter. *Virginia Commonwealth University, Richmond, VA.*
(No relevant relationships reported)

Mental workload (MW) is a subjective measure of the cognitive effort required to complete a task. Factors such as task speed and the use of feedback can affect the perceived MW and ability to correctly perform an activity. **PURPOSE**: 1) Determine the effect of task speed on perceived MW during a wrist movement pattern guided by visual feedback (VF); and 2) Determine if MW is different for those who correctly perform the task (Performer: *P*) compared to those who do not (Non-performer: *NP*). **METHODS**: Twelve healthy young subjects were recruited and asked to flex and extend their wrist to match two different speeds of a target sine wave: 0.7 Hz (*FAST*) or 1.0 Hz (*SLOW*). VF of wrist movement and the target pattern were provided concurrently on a screen. Five 20-second trials with two-minute rest intervals were completed at each speed. During rest periods the Raw NASA-TLX (RTLX), a tool used to assess perceived workload, was administered. RTLX categories representing purely MW include: mental demand (MD), temporal demand (TD), and frustration (FR). Cross-correlation analysis of task performance was computed for each subject's 5th trial at both speed conditions in order to categorize individuals as either *P* (r ≥ 0.8) or *NP* (r < 0.8). 2x2 mixed model ANOVAs compared the change in perceived MD, TD, and FR from trial one to five between speed conditions (*FAST* vs. *SLOW*) and the two groups (*P* vs. *NP*). Post hoc Tukey HSD tests were used to compare differences. Positive changes in MD, TD, and FR denote improvements in MW. **RESULTS**: Significant speed x group interactions were observed for MD (p=0.008) and TD (p=0.005). No significant interaction or main effects were found for FR (p=0.204). Post hoc tests revealed significant differences in changes in MW between *FAST* and *SLOW* speeds among P (MD *FAST*: 31.4, *SLOW*: 11.4, p=0.027; TD *FAST*: 30.0, *SLOW*: -0.71, p=0.022) and between *P* and *NP* during the *FAST* speed (MD *P*: 31.4, *NP*: -2.0, p=0.044; TD *P*: 30.0, *NP*: -8.0, p=0.031). **CONCLUSIONS**: *P* and *NP* showed similar changes in MW from trial one to five during the *SLOW* speed, whereas only *P* experienced improved MW during the *FAST* speed. These results suggest MW is affected by movement speed in accordance with subject performance.

Compression Sleeve Does Not Speed DOMS Recovery When Compared to Placebo Garment
Molly R. Winke, Celeste Harris. *Hanover College, Hanover, IN.* (Sponsor: Bryant Stamford, FACSM)
(No relevant relationships reported)

Wearing compression garments during recovery from delayed onset muscle soreness (DOMS) is known to attenuate decreased range of motion (ROM) and muscular performance and lessen muscle swelling and pain perception. However, whether a placebo effect is present when wearing compressive clothing, and to what extent recovery may be influenced by this effect, is poorly understood. **PURPOSE:** To determine the effects of a placebo sleeve (PLA) compared to a compression sleeve (CS) during a 5-day recovery period from DOMS of the elbow flexors. **METHODS:** Eight untrained female college students participated in this crossover design study. Upper and lower arm circumference was measured to determine muscle swelling; pain during elbow flexion and elbow extension was measured using a 0 - 100mm visual analog scale to determine muscle soreness; flexion and extension ROM were measured to determine joint mobility; elbow flexion torque production 60° and 180° per second was measured to determine muscular performance. A brief questionnaire measured perceived effectiveness of the garments. The muscle-damage protocol consisted of 4 sets of 25 repetitions of isokinetic concentric elbow flexion followed by eccentric elbow extension. Immediately following the protocol, subjects wore either the PLA (cooling sleeve) or the CS continually for five days. Swelling, ROM, pain, and torque production were measured pre- and post-exercise, and daily during the recovery period. Subjects rested for 7 days before completing another muscle-damage protocol and the remaining treatment. Repeated measures ANOVA was used to determine differences between treatments. **RESULTS:** There were no significant differences between trials in any measured variables indicating that recovery from DOMS was similar in both treatments (*p* > 0.05). Thus, the "true" compressive garment was no more effective at reducing pain, swelling, ROM losses, or strength losses that

accompany DOMS. Subjects preferred PLA or rated the sleeves equally 62% of the time. **CONCLUSION:** These findings suggest that PLA was just as effective as CS at alleviating the symptoms of DOMS in untrained subjects. Subjects indicated a preference for PLA despite the higher compression provided by the CS (15-20mmHg CS vs 5 mmHg PLA).

Relationship Between Perceived and Actual Hydration Levels in Recreationally Active College Students
Seth M. Sievers, Jason D. Wagganer, Jeremy T. Barnes, Thomas J. Pujol, FACSM. *Southeast Missouri State University, Cape GIrardeau, MO.* (Sponsor: Dr. Thomas J. Pujol, FACSM)
(No relevant relationships reported)

Maintaining adequate hydration status is important to safely maintaining a physically active lifestyle. Most individuals are unable to accurately predict internal (i.e., perceived) hydration status. Urine Specific Gravity (USG) is a criterion measure (i.e., actual) of hydration status, and can be used to accurately and objectively gauge the hydration status of an individual. PURPOSE: To examine the relationship between perceived and actual hydration status in recreationally active college students. METHODS: A total of 58 participants (20 Male, 38 Female, Age=22.8+4.2yr, Ht=1.72+.22m, Wt=73.40+14.25kg) were assessed for various hydration-related indicators. Perceived hydration was assessed via a survey upon arrival at the laboratory. Participants provided a mid-stream urine sample in a sterile, clear container. Self-perceived hydration was assessed using the urine color (UC) eight-point scale. Actual hydration status was assessed utilizing using a pen refractometer (Atago model 3749, Bellevue, WA) and UC. A Pearson Product Moment Correlation was used to analyze relationships between perceived and actual hydration values using Statistical Package for the Social Sciences (v24.0). RESULTS: A weak but significant correlation was shown between perceived hydration status and USG (r= 0.284; p<0.05). Perceived hydration status and UC had a strong correlation (r= 0.776; p<0.01). CONCLUSIONS: The relationship between USG, urine color, and perceived hydration indicate a strong sense of internal hydration status in participants. The findings of this study are supported by past research on competitive athletes, suggesting that a high level of physical activity (and the associated high hydration demands) correlates with a strong sense of hydration status. Future research should assess the relationship between activity level and perceived compared to actual hydration status.

Setting, Age, & Intensity Influence Psychological and Physiological Processes in Young Female Endurance Runners
Elizabeth Queathem, Kayla Morrissey. *Grinnell College, Grinnell, IA.*
(No relevant relationships reported)

Exercise has tremendously beneficial effects on human psychological and physical health, yet many people still choose not to exercise. PURPOSE: Our study investigated how girls' responses to exercise intensity and exercise environment as they age through adolescence. METHODS: We recruited female runners of different ages (middle school, high school, college) to perform running sessions on a treadmill and in an outdoor environment. Each participant ran at three different intensities, 6 minutes per intensity, for both the treadmill and outdoor environment. Data were collected on what the runners thought about while running (Thoughts During Running Inventory), how they felt (Feeling Scale), how their bodies physiologically responded to the running (blood lactate, heart rate), and how fast they ran (speed). RESULTS: Participants ran faster and harder, indicated by speed (ANOVA, p < 0.0001), blood lactate levels (ANOVA, p = 0.008), and heart rate (ANOVA, p = 0.004), in the outdoor environments, and younger participants were more likely to feel worse after exercise (ANOVA, p < 0.0001). CONCLUSIONS: We extended the work of Reich and Queathem (in review) to females, demonstrating that despite their very different hormonal milieu as they age through adolescence, female endurance runners respond to environment and exercise intensity in much the same way as male endurance runners of similar ages. Our study suggests that outdoor running may confer greater health benefits than treadmill running because exercisers push themselves harder in outdoor conditions. In addition, we surmise that either girls acquire more positive affective response to exercise as they mature, or only those girls who respond positively to exercise continue to run competitively as they age.

Affective States of Active and Inactive Individuals While Sitting

Tia M. Dupont[1], Luke M. Krynski[1], Sean Thomez[1], Mark E. Hartman[2], Laura D. Ellingson[2], Robert W. Pettitt, FACSM[3], Cherie D. Pettitt[3]. [1]Minnesota State University, Mankato, Mankato, MN. [2]Iowa State University, Ames, IA. [3]Rocky Mountain University of Health Professions, Provo, UT. (Sponsor: Robert W. Pettitt, FACSM)

(No relevant relationships reported)

Arousal levels are affected by activity levels such that increased sedentary behavior is associated with lower levels of vigor and higher levels of fatigue. Individuals who meet minimum physical activity guidelines have higher levels of vigor and vitality regardless of prolonged sedentary behaviors; however, the assessment of feeling states during prolonged sitting have not been explored. PURPOSE: To determine if there is a difference in affective states of fit vs unfit individuals and if fitness influences affective states during prolonged periods of sitting. METHODS: A total of 9 females and 5 males (age = 19.9±1.9 y; body mass index 23.2±2.7 kg·m^2) underwent submaximal exercise testing to determine maximum oxygen uptake (VO$_{2max}$) and to include a heterogeneous group relative to fitness (range: 30.7 to 55.9 ml·kg^{-1}·min^{-1}). Affective states were assessed hourly using the Activation Deactivation Adjective Check List (ADACL) which subscales of energy, tired, tension, and calmness. Each group completed two separate 4-h sitting bouts whereas one bout was continuous and the other was interrupted by 13 min·h^{-1} of standing. RESULTS: In both conditions, a decline in energy levels occurred from baseline (~2.0±1.0) to 2 h (~1.4±0.8) (main effect for time, p<0.05), whereby the metrics of tiredness, tension, or calmness were neither altered by time nor by allowing subjects to interrupt sitting (p > 0.05). With no standing permitted, significant inverse correlations were observed between energy and VO$_{2max}$ the second (tau = -0.56, p = 0.009) and third hour of sitting (tau = -0.49, p = 0.028). With fitter participants, decline in energy occurred over time regardless of the interruption. CONCLUSION: Fit compared to less fit individuals experience greater declines in energy levels as a result of prolonged sitting. Standing 13 min·h^{-1} is insufficient to attenuate the declines in energy levels associated with bout of sitting 2 h and beyond.

1951   Board #212   May 31 3:30 PM - 5:00 PM

Exercise Performance and Perception of Breathlessness after Caffeine Ingestion in Trained Cyclists

Erica M. Larson, Jayvaughn T. Oliver, Jonathon L. Stickford, Kimberly S. Fasczewski, R. Andrew Shanely. *Appalachian State University, Boone, NC.* (Sponsor: David C. Nieman, FACSM)

(No relevant relationships reported)

Caffeine (CAF) is commonly ingested as an ergogenic aid among cyclists, in part, due to its effect on pain perception. CAF also may improve exercise performance by altering the perceptions related to ventilatory work and dyspnea. **PURPOSE:** The purpose of this study was to compare exercise performance and the rating of perceived breathlessness (RPB; Likert Scale) after ingestion of a moderate dose of CAF or placebo (PLA) in trained cyclists. **METHODS:** Six male cyclists completed pulmonary function testing and a peak aerobic capacity test (age: 31.8±10.4 y; VO$_{2max}$: 61.2±6.1 ml·kg^{-1}·min^{-1}). During the second visit, cyclists completed a fixed-work familiarization time trial (TT) equivalent to a distance of 20km. Subsequently, and on separate days, subjects completed in a randomized, counterbalanced order, TTs with ingestion of a placebo (TT$_{PLA}$) or caffeine (TT$_{CAF}$; 5 mg·kg^{-1}) 60 min prior. Elapsed time, power output, perceptual responses, and ventilatory parameters were measured every 2 km during each TT. **RESULTS:** Subjects displayed normal pulmonary function during baseline testing. Elapsed time did not significantly differ between TT$_{CAF}$ and TT$_{PLA}$ trials (33.4±4.3 vs. 34.3±4.23 min, p=0.095). Ventilation and mouth pressure did not differ at 50% (133±31.8 vs. 123±22.0 L·min^{-1}, p=0.190; -107±26.5 vs -100±18.4 cmH$_2$O·min^{-1}, p=0.237) and 100% (175±42.3 vs. 176±48.8 L·min^{-1} p=0.901; -149±45.5 vs -133±78.3 cmH$_2$O·min^{-1}, p=0.506) of TT$_{CAF}$ compared with TT$_{PLA}$. RPB did not differ at 50% (4.5±2.1 vs. 3.2±2.5, p=0.017) and did not differ at 100% (7.3±2.4 vs. 6.6±2.2, p=0.250) of TT$_{CAF}$ compared with TT$_{PLA}$. Rating of perceived exertion (RPE) did not differ at 50% (13.1±2.9 vs. 12.1±2.4, p=0.266) and 100% (17.5±1.8 vs. 17.8±1.8, p=0.380) of TT$_{CAF}$ compared with TT$_{PLA}$. **CONCLUSIONS:** Exercise performance, ventilation, and RPB did not differ in trained cyclists during 20km time trials after ingestion of CAF or PLA. Supported by the Office of Student Research and Graduate Student Association Senate at Appalachian State University.

1952   Board #213   May 31 3:30 PM - 5:00 PM

Attitude toward and Perceived Discomfort from Neuromuscular Electrical Stimulation

Jennifer A. Jasso, Lindsay E. Kipp, Joni A. Mettler. *Texas State University, San Marcos, TX.* (Sponsor: Tinker Murray, PhD, FACSM)

(No relevant relationships reported)

Neuromuscular electrical stimulation (NMES) is commonly used to improve muscle function in physical rehabilitation settings. However, reasons for limited use as an alternative to voluntary exercise may be due to lack of familiarity and perceived discomfort during treatment. **PURPOSE:** The purpose of this study was to determine attitude toward NMES exercise and perceived pain and muscle soreness experienced from NMES exercise with increasing stimulation intensity. **METHODS:** Thirty healthy adults (age: 23.6 ± 0.5 years) who had not experienced electrical stimulation within the last year completed the study. Repetitive, intermittent stimulation of 10 seconds on and 15 seconds off was applied to the quadriceps muscles for 60 minutes with the stimulation frequency set at 60 Hz. Stimulation intensity was increased every 5 min throughout the course of the intervention to achieve a target torque of 15% maximal voluntary contraction as measured by an isokinetic dynamometer. During the NMES application, participants rated the pain they experienced using a standard pain scale (0-10 scale: 0 = no pain; 10 = most pain possible) at minute 0, 15, 30, 45, and 55 of the treatment. Participants were also asked to rate muscle soreness felt 48 hours after exercise (0-10 scale: 0 = no soreness; 10 = greatest soreness possible). A survey on attitude toward NMES exercise (e.g., useful, pleasant, beneficial) was administered pre and post NMES on a 1-7 scale (e.g., 1 = useless; 7 = useful). Repeated measures analysis of variance (ANOVA) was used to test statistical differences between scores over time. Data are reported as mean ± SE. **RESULTS:** Attitude toward NMES exercise was high and did not change pre-post exercise (pre: 6.2 ± 0.1, post: 6.1 ± 0.2, $p = 0.21$). Reported pain during NMES was low and was not different across time points (0 min: 2.1 ± 0.4, 15 min: 2.7 ± 0.4, 30 min: 2.6 ± 0.4, 45 min: 2.9 ± 0.4, 55 min: 2.5 ± 0.4, $p = 0.126$). Muscle soreness remained elevated 48-hours post-NMES (3.5 ± 0.593, $p < 0.001$). **CONCLUSION:** Pain reported during NMES was low and did not increase as stimulation intensity increased. Attitudes toward NMES sessions were relatively high and were unchanged after exercise, indicating that any pain and soreness experienced did not change participants' attitude regarding the benefits of NMES exercise.

1953   Board #214   May 31 3:30 PM - 5:00 PM

Exercise Effects On Depressive and Anxiety Symptoms, Fatigue And Pain in Rheumatoid Arthritis: A Meta-Analysis

Sean G. McKenna[1], Matthew P. Herring[1], Alan Donnelly[1], Laura Comber[1], Alexander Fraser[2], Norelee M. Kennedy[1]. [1]University of Limerick, Limerick, Ireland. [2]University Hospitals Limerick, Limerick, Ireland.

(No relevant relationships reported)

Elevated anxiety and depressive symptoms, persistent fatigue, and pain are prevalent co-morbidities in Rheumatoid Arthritis (RA). Though the available evidence supports exercise effects on these outcomes, no quantitative synthesis of evidence from randomized controlled trials (RCTs) of exercise effects on these critically important symptoms in RA has been conducted. **PURPOSE:** To estimate the overall population effect of exercise on depressive and anxiety symptoms, fatigue, and pain derived from available RCTs. **METHODS:** Twelve articles published before September 2017 were located using Google Scholar, PsycINFO, PubMed, and Web of Science. Trials involved 1,031 participants and included both randomization to exercise and non-exercise control and validated measures of depression, anxiety, fatigue, and/or pain assessed at baseline and post-intervention. Hedges'*d* effect sizes (95%CI) were computed and random effects models were used for all analyses. **RESULTS:** Participants were aged 49±9 years and 83%±14% female. Exercise training consisted on average of 3±1 weekly sessions, 60±17 minutes per session, and 11±5 weeks in duration. Mean reported adherence was 87%±11%. For depression, 18 of 20 effects (90%) were >0. The mean effect size Δ was 0.20 (0.10-0.31; $p<0.001$). No significant heterogeneity was observed (Q$_{19}$=26.72; $p>0.10$), and consistency was low across effects (I^2=32.63%). For anxiety, seven of seven effects (100%) were >0. The mean effect size Δ was 0.50 (0.27-0.74; $p<0.001$). No significant heterogeneity was observed (Q$_6$=2.46; $p>0.87$), and consistency was low across effects (I^2=0%). For pain, seven of 16 effects (44%) were >0. The mean effect size Δ was 0.04 (-0.14-0.21; $p>0.69$). The effect was heterogeneous (Q$_{15}$=32.82; $p≤0.005$), and consistency was moderate across effects (I^2=57.34%). For fatigue, six of 11 effects (54.5%) were >0. The mean effect size Δ was -0.01 (-0.20-0.19; $p>0.93$). The effect was heterogeneous (Q$_{10}$=19.08; $p<0.04$), and consistency was moderate across effects (I^2=52.83%). **CONCLUSION:** Exercise resulted in significant small-to-moderate reductions in depressive and anxiety symptoms. However, pain and fatigue were not significantly changed. Further investigation of sources of variability in the effects of exercise on pain and fatigue among adults with RA is warranted.

The Cortisol Awakening Response is Associated With Activity Level on the Preceding Day

Travis Anderson, Suzanne Vrshek-Schallhorn, James A. Janssen, Maria Ditcheva, Gail M. Corneau, Laurie Wideman, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Laurie Wideman, FACSM)
(No relevant relationships reported)

The cortisol awakening response (CAR) describes the initial rise in cortisol following waking, and has been suggested to be a potential biomarker for monitoring exercise training stress. However, it is currently unknown if CAR is sensitive enough to track changes in daily physical activity (PA). **PURPOSE:** Therefore, the purpose of this study was to assess the impact of daily PA on CAR and associated derived measures. **METHODS:** Male (n = 24) and female (n = 71) college-aged students (19.0±1.8y, 72.1±19.5kg) wore wrist-worn accelerometers (ActiGraph) for four consecutive days (24 hour protocol). Actigraph data were analyzed using six custom activity bands as totals (Bands) and percentage of total time (Bands$_\%$), since moderate-vigorous PA was minimal in this sample. Salivary samples were collected each morning, immediately after waking (C_0) and 30 mins later (C_{30}) and were analyzed in duplicate for cortisol (ng.ml^{-1}) using DELFIA. CAR and CAR$_\%$ were calculated as the difference between C_{30} and C_0 and the percentage increase from C_0, respectively. Only subjects with two complete days of data were included in the current analysis. Differences between PA and CAR variables between days were assessed via paired-sample t-tests. Multivariate multiple linear regression with univariate follow-up tests fit CAR variables by PA. Models were computed for each day individually, as well as ratio (Q) values between days (Day2/Day1). **RESULTS:** No differences were observed between days for CAR or derived measures, or activity bands (all p>0.05). Day 1 showed a significant model for CAR by Bands$_\%$ ($R^2 = .13$, p = 0.04), while the Day 2 CAR$_\%$ by Band model was significant ($R^2 = 0.15$, p = 0.02). Ratio models further elucidated these relations, with a significant model for Q•CAR$_\%$ by Q•Band$_\%$ ($R^2 = 0.15$, p = 0.02). **CONCLUSION:** These results suggest that CAR and its derived measures are relatively stable across days. Also, CAR does appear to be sensitive to the degree of PA or sedentary behaviors during the preceding day in college-aged persons, such that change in CAR is partially accounted for by changes in PA. Therefore, PA should be considered in future CAR research and interventions that specifically manipulate PA (i.e., exercise interventions) are needed to confirm the usefulness of CAR for tracking changes in exercise training stress.

Effect Of Acute High-Intensity Interval Exercise Vs. Continuous Moderate-Intensity Exercise On The BDNF, Lactate, And Cortisol Responses In Obese Individuals

Alexandra Rodriguez, Michael Whitehurst, FACSM, Brandon Fico, Katelyn Dodge, Peter Ferrandi, Gabriel Peña, Avraham Adelman, Chun-Jung Huang, FACSM. *Florida Atlantic University, Boca Raton, FL.*
(No relevant relationships reported)

PURPOSE: Obesity may attenuate the expression of brain-derived neurotrophic factor (BDNF), thereby increasing the risk of cognitive dysfunction. High-intensity interval exercise (HIIE) has been shown to be as or more effective than continuous moderate exercise (CME) in promoting the expression of BDNF in normal weight individuals. Therefore, the purpose of this study was to compare the effect of acute HIIE and CME on BDNF expression in obese individuals. **METHODS**: Twelve male subjects (6 obese and 6 normal-weight) participated in a randomized and caloric equated experiment: HIIE (30 minutes, 4 intervals of 4 minutes at 80% - 90% of VO$_{2max}$ with 3 minutes rest between intervals) and CME (38 minutes at 50% - 60% VO$_{2max}$). Blood samples were collected for measurements of serum BDNF, blood lactate, and plasma cortisol prior to and following exercise. **RESULTS**: The BDNF response to acute HIIE was greater than CME in obese subjects when compared to normal-weight subjects. Similarly, although acute HIIE induced greater lactate and cortisol levels than CME, obese subjects produced less lactate, but no difference in cortisol than normal-weight subjects. **CONCLUSIONS**: Acute HIIE may be an effective protocol to upregulate BDNF expression in an obese population, independent of increased lactate and cortisol levels.

Hormonal, Steroidal and Inflammatory Responses in Collegiate Male Soccer Players and Female Cross-Country Runners

William M. Adams[1], Ryan M. Curtis[2], Courteney L. Benjamin[2], Abigail T. Colburn[2], Virgilio Lopez[2], Elaine C. Lee[2], Douglas J. Casa, FACSM[2]. [1]*University of North Carolina at Greensboro, Greensboro, NC.* [2]*University of Connecticut, Storrs, CT.* (Sponsor: Douglas J. Casa, FACSM)
(No relevant relationships reported)

PURPOSE: To examine hormonal, steroidal and inflammatory responses in collegiate male soccer players (M$_{SOC}$) and female cross-country runners (F$_{XC}$) over the course of a competitive season. **METHODS:** 22 M$_{SOC}$ (mean±SD; age, 20±1y; height, 181.2±6.5cm; body mass, 79.4±6.9kg; VO$_{2max}$, 50.9±4.4 ml•kg^{-1}•min^{-1}) and 11 F$_{XC}$ (mean±SD; age 19±1y; height 168.4±7.7cm; body mass, 58.7±9.6kg; VO$_{2max}$, 53.5±2.0 ml•kg^{-1}•min^{-1}) participated in this study. Participants provided a blood sample at 4 time points: before preseason (PS$_{PRE}$), following preseason (PS$_{POST}$), week 4 (W4, F$_{XC}$), week 8 (W8, M$_{SOC}$), and following the competitive season (RS$_{POST}$). Blood samples were assessed for the following biomarkers: testosterone (T), cortisol (C), testosterone:cortisol ratio (T:C), human growth hormone (HGH), estradiol (E), progesterone (P), insulin-like growth factor-1 (IGF-1), Interleukin-6 (IL-6) and Vitamin D (VitD). Significant differences were assessed via repeated measures ANOVA and subsequent post hoc testing (p<0.05). **RESULTS:** Compared to PS$_{PRE}$ (M$_{SOC}$, 23.71±13.16 pg•ml^{-1}; F$_{XC}$, 21.19±1.38 pg•ml^{-1}), IL-6 was significantly lower at PS$_{POST}$ (M$_{SOC}$, 20.44±11.58 pg•ml^{-1}; F$_{XC}$, 15.41±3.47 pg•ml^{-1}) and W4 (16.68±4.71 pg•ml^{-1}) (p<0.05). IL-6 was significantly greater at RS$_{POST}$ (20.27±4.97 pg•ml^{-1}) compared to PS$_{POST}$ for F$_{XC}$ only (p=0.04). In M$_{SOC}$, C was significantly greater at PS$_{POST}$ (84.76±15.70 ng•ml^{-1}) and W8 (84.34±16.68 ng•ml^{-1}) compared to PS$_{PRE}$ (74.59±14.65 ng•ml^{-1}) (p<0.05). VitD was significantly lower at RS$_{POST}$ (55.86±26.20 ng•ml^{-1}) compared to both PS$_{PRE}$ (74.30±33.28 ng•ml^{-1}) and PS$_{POST}$ (68.26±33.18 ng•ml^{-1}) for M$_{SOC}$ (p<0.05), with no significant differences in VitD in F$_{XC}$ at any time point (p>0.05). P, HGH, IGF, C (F$_{XC}$), T (M$_{SOC}$), T:C (M$_{SOC}$) and E (F$_{XC}$) were not significantly different at any time point (p>0.05). **CONCLUSION:** Our results detected a reduction in IL-6 following preseason in M$_{SOC}$ and F$_{XC}$ that returned to baseline at the conclusion of the competitive seasons. Over time, regular season training allowed for sufficient recovery from exercise stress in both male soccer and female cross-country athletes. Future research is needed to examine the relationship between changes in training volume and training intensity on changes in the anabolic and catabolic response in male and female collegiate athletes.

1957   Board #218   May 31 3:30 PM - 5:00 PM

Correlation Between Proinflammatory Cytokines And Cortisol In Female Soccer Players Carriers Of Premenstrual Syndrome

Mauro W. Vaisberg[1], Roberta Foster[1], André L. Bachi[2], Zsuzsanna I. Di Bella[1], Juliana de Melo Batista dos Santos[1]. [1]*Universidade Federal de São Paulo, São Paulo, Brazil.* [2]*Universidade Cruzeiro do Sul, São Paulo, Brazil.*
(No relevant relationships reported)

PURPOSE: The aim of this study was to evaluate cytokines production and its relation with cortisol in female soccer players with premenstrual syndrome (PMS) and without premenstrual syndrome PMS (nPMS), in pre-game evaluating the two phases of the menstrual cycle: follicular and luteal. PMS causes physical and emotional discomfort to women, so that this study can be of great importance in female athletes training scheme.
METHODS: Fifty-two eumenorreic soccer players were evaluated (age: 19.8 ± 4.7 years). The PMS and phases of the menstrual cycle were determined by monitoring for 3 consecutive months, using the Daily Symptom Report (DSR). Evaluation of cortisol and cytokines IL-1β, IL-6, IL-8, IL-10, IL-15, IL-17 and TNF-α were performed in urine and quantified by Flow cytometry method. Study approved by the Ethics Committee in Research from Universidade Federal de São Paulo (Brazil) (No.1604/10). ANOVA and Pearson correlation with significance level of 5% were used for data analysis.
RESULTS: No statistical significant results were found in cortisol and cytokines IL-1β, IL-8, IL-10, IL-15, IL-17 and TNF-α between groups PMS and nPMS. The concentration of IL-6, in pre-game during the luteal phase, showed an increased in the group with PMS (p=0.04) compared to the nPMS group. The results of correlation between cortisol and the cytokines evaluated also showed positive correlations in the pre-game of the luteal phase with IL-17 (p<0.001, r= 0.77), IL-1β (p<0.001, r= 0.63) and IL-6 (p<0.001, r= 0.55).
CONCLUSIONS: Our results allow us to conclude that female soccer athletes PMS carriers, even in the pre-game period, presented an increased inflammatory status. The increase of proinflammatory cytokines is of great importance, since it is associated with an increased incidence of musculoskeletal lesions and a decrease in aerobic

capacity. Therefore, the importance of our work is to alert female athletes, coaches and team physicians about the effects of PMS on health and performance, in order to provide these athletes with adequate training in the premenstrual period.

1958   Board #219   May 31 3:30 PM - 5:00 PM

Cd28 Expression On Cd4+ T Cells Is Not Affected By Strenuous Exercise In Untrained Individuals

Samantha A. Bianchi, Alexander K. Holbrook, Allyson Ihlenfeldt, Brad W. Macdonald, Hunter D. Peterson, Eric C. Bredahl, Michael A. Belshan, Jacob A. Siedlik. *Creighton University, Omaha, NE.* (Sponsor: Joseph P. Weir, FACSM)
(No relevant relationships reported)

Optimal T cell activation requires a two-signal process. The first signal is engagement of the TCR-CD3 complex and the second, or costimulatory, signal is the classical binding of a T cell CD28 receptor with an APC-bound CD80 or CD86. A marker of senescent T cells is a lack of CD28 expression and it has been posited that CD28 expression may decrease following strenuous exercise. **PURPOSE:** To quantify exercise induced changes in CD28 expression on CD4$^+$ cells obtained from human subjects. **METHODS:** Utilizing a cross over design, untrained subjects completed a control and exercise visit. The control visit consisted of 30 min of seated rest while the exercise session entailed 3 sets x 10 reps squat at 70% 1-RM, 3x10 leg press at 70% 1-RM, and 3x10 leg extensions at 70% 1-RM with 2 min rest between sets. Venous blood samples were obtained pre and post each visit. CD4$^+$ T cell isolation from peripheral blood was conducted through negative selection using a Human CD4$^+$ T cell enrichment kit. CD4$^+$ T cells were plated at 1.5 x 10^6 cells/ml in 200 μl of ImmunoCult T-cell expansion media directly after isolation and costimulated through CD3+CD28 or no stimulation. Cells were incubated for 1 and 3 d at 37°C in a humidified incubator with 5% CO$_2$ and then analyzed by flow cytometry. Data were analyzed using two-way RMANOVAs. **RESULTS:** There were no significant differences in CD28 expression between the exercise and control conditions in either the stimulated (p = .27) or non-stimulated (p = .62) samples. These data suggest that suppression of CD4$^+$ cell activation following strenuous exercise is likely not a result of dysfunction in CD28, a major costimulatory receptor. **CONCLUSIONS:** Changes in T cell activation following strenuous exercise are likely derived from a plurality of sources, but without direct assessment of discrete elements of the activation cascade we will be unable to understand how exercise changes immune function. Future work should focus on elements upstream of T cell clonal expansion in order to identify mechanisms for exercise induced changes in immunocompetence.

Neutrophil Extracellular Traps Engaged in Strenuous Exercise Induced Hyperfunction of Innate Immunity System

Shi Yue, Chen Peijie, Wu Die, Wei Hongzhan. *SHANGHAI UNIVERSITY OF SPORT, SHANG HAI, China.*
(No relevant relationships reported)

There is robust evidence that strenuous exercise is pro-inflammatory and inclined to impair the function of innate immunity. Neutrophil extracellular traps (NETs) is a novel cell death pathway through which neutrophils release chromatin and granule enzymes to capture and kill invaders. However, the components of NETs can also be harmful to host cells. Overproducing cell-free DNA (cf-DNA) and reactive oxygen species (ROS) through strenuous exercise are commonly proved. Much less is known about the origin of cf-DNA and whether ROS participate in strenuous exercise induced NETs formation. **Purpose:** Based on the doubt, we hypothesize that 1) strenuous exercise increase NETs formation and the high level of NETs is related to the imbalance of immunity function; 2) mitochondrial antioxidants suppress strenuous exercise induced NETs formation and reduce the adverse consequences to host. **Methods:**24 C57/bl mice were divided to three groups: Control group (C, n=8), strenuous exercise group (E, n=8) and mitoTempo+ strenuous exercise group (ME, n=8). E group and ME group were adapted to the treadmill for three days with a low speed. 30 minutes before formal experiment, ME group were injected with mitochondrial antioxidant mitoTempo (0.7mg/kg), then E group and ME group peform 90 minutes 85% VO2max speed running exercise. Immediately after exercise, 3 groups of mice were anesthetized and the circulating blood was collected into anticoagulant tube. Plasma cf-DNA, MPO-DNA complexes, IL-6, IL-10 and TNF-αwere tested according to the manufacture introduction of Elisa Kit; innate immunity cell function, such as phagocytosis and oxygen burst were test by flow cytometry. **Results:** Plasma cf-DNA and MPO-DNA complexes were two-fold increase in E group compared to C group (P<0.05), while there is no difference between C group and ME group; IL-6 and TNF-αlevel in E group were higher than C group and ME group, IL-10 level show the adverse result. Monocytes and neutrophils in E group show a stronger phagocyte and

ROS produce function than C group and ME group.**Conclusion:** An acute single bout of strenuous exercise increases NETs formation and cause hyper-function of innate immunity function.
Mitochondrial antioxidants suppress strenuous exercise induced NETs formation and balance innate immunity cells function.

Effects Of Exercise On The Expansion Of Myeloid-derived Suppressor Cells

Jacob Garritson, James M. Haughian, Nicholas A. Pullen, Reid Hayward. *University of Northern Colorado, Greeley, CO.*
(No relevant relationships reported)

Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of immune cells that expand in response to cancer and various other pathological conditions. MDSCs are characterized by their suppression of T-cells and their involvement in metastasis. Aerobic exercise protects against tumor growth and metastasis, yet the mechanisms behind this protection are still largely unknown. **PURPOSE**: To examine the effects of exercise on the expansion of MDSCs and suppression of immune function in a murine breast cancer model. **METHODS**: Female mice, 8 weeks of age, were randomly assigned to one of the following groups: exercise tumor (EX+TUM), sedentary tumor (SED+TUM), exercise control (EX) or sedentary control (SED). Animals in both TUM groups were inoculated with 1x10^4 4T1 murine mammary carcinoma cells in the mammary fat pad. Both EX groups were given access to running wheels for 4 weeks, beginning on the day of inoculation, and SED groups were restricted to normal cage activity. Following completion of the 4-week training period, blood and spleen samples were collected for analysis via flow cytometry. MDSC expansion was measured as the percentage of CD11b$^+$Ly6C$^+$ and CD11b$^+$Ly6G$^+$ cells in the population. Spleen cytotoxic T-cells were measured as the number of CD8$^+$ cells and expressed as a percentage of the total population. **RESULTS**: MDSCs in the blood of SED+TUM (15.3% ± 7.1%) were significantly higher (p < 0.05) than SED (0.8% ± 0.2%) indicating tumor-dependent expansion of MDSCs. EX+TUM (10.1% ± 0.7%) was not significantly different from EX (0.5% ± 0.1%) or SED (0.8% ± 0.2%) suggesting MDSC expansion did not occur to the same extent in the blood of exercised animals. The percentage of CD8$^+$ T-cells in SED+TUM (5.6% ± 1.7%) was significantly lower (p < 0.05) than EX (13.1% ± 1.1%) and SED (13.4% ± 0.9%) indicating a tumor-induced suppression of immune function. In contrast, EX+TUM (7.7% ± 1.0%) was not significantly different from EX (13.1% ± 1.1%) or SED (13.4% ± 0.9%). **CONCLUSION**: These data suggest that exercise may have a protective effect against the immunosuppression that results from expansion of MDSCs in tumor bearing animals. MDSCs have been shown to create a premetastatic niche at the site of metastasis and exercise may protect against distant metastases by attenuating increased numbers of MDSCs in the blood.

Acute Effects of Exhaustive Exercise and Cardio-Respiratory Fitness on Regulatory T Cell Homeostasis.

Christina Koliamitra, Philipp Zimmer, Alexander Schenk, Wilhelm Bloch. *Cardiovascular Research and Sports Medicine, Cologne, Germany.* (Sponsor: Prof. Dr. Steinacker Jürgen Michael, FACSM)
(No relevant relationships reported)

Regulatory T (T$_{Reg}$) cells are central anti-inflammatory regulators of the immune response and crucial for the maintenance of immune homeostasis. They exert anti-inflammatory effects and are central regulators of the immune responses to self- and foreign antigens. Increased T$_{Reg}$ cell populations can result in a state of immunosuppression, as has been shown in tumor-induced immunosuppression, whereas dysfunction of T$_{Reg}$ cells can result in autoimmune diseases. Acute physical exercise is known to have immune modulatory properties and has been previously described in professional athletes.
Purpose: The aim of this investigation was to examine the immune modulatory properties of acute exhaustive exercise on T$_{Reg}$ cell homeostasis and to examine whether there is a direct link between cardiovascular fitness status (VO$_{2\,peak}$) and T$_{Reg}$ cell population.
Methods: A total of 20 middle-aged healthy female subjects (age of 55, 2 ± 5, 7) were asked to perform a spiroergometry on a cycle ergometer. The spirometry protocol (1 minute rest measurement, 3 minutes warm-up with 50 Watts, increase of 25 Watts every 2 minutes) was performed until exhaustion of the subject. The evaluation of VO$_{2\,peak}$ served as a parameter of the healthy subjects' cardiovascular fitness. Before (T0) and after (T1) spiroergometry test, venous blood was collected. The T$_{Reg}$ cell evaluation was assessed using antibodies against CD3, CD4, CS25 and CD127 through multicolor flow cytometry.
Results: The T$_{Reg}$ cell population significantly decreased after single exercise load (T0 vs T1, p=.001). There was a positive correlation found between VO$_{2\,peak}$ and T$_{Reg}$ cell frequency (p= .005).

Conclusion/Significance: The T_{Reg} proportion decrease indicates an acute effect of intense physical exercise on T_{Reg} cell homeostasis. This could represent a rapid distribution to other tissues or a compensatory attempt to restore immune homeostasis and limit excessive damage. The correlation between peak oxygen uptake and T_{Reg} proportions could be seen as a chronic response of the anti-inflammatory capacity of healthy subjects to repeated bouts of exercise (short-term inflammatory stimuli).

Fatigue Influence On King-devick Test

Adrian Aron, Rachel Andrews, Erica Boggs, Andrea Stanley, Olivia Willson, Brent Harper. *Radford University, Radford, VA.* (Sponsor: Trent Hargens, FACSM)
(No relevant relationships reported)

One of current sideline, post-injury assessment tools used for screening concussion include the King-Devick Test (K-D) which measures cognitive processing speed, rapid eye movement, and visual tracking. As a post-exercise test it is unclear if the K-D is truly sensitive enough to rule-out concussion in the presence of fatigue. **PURPOSE:** To examine the impact of whole-body fatigue on King-Devick test performance. **METHODS:** The test was administered to 24 subjects (age = 23.2 ± 1.7 years, BMI = 24.9 ± 2.2 kg/m^2) at baseline, after a fatigue protocol and on ensuing time at least 3 weeks later. The fatigue protocol was performed on a Concept 2 rower at an initial metronome pace of 75 bpm with an increase of one bpm every two minutes until the subject reached fatigue. Fatigue was determined when three of four criteria were met: 90% or higher of predicted MaxHR, inability to maintain metronome pace for three consecutive pulls to the abdomen, 17/20 or higher on the RPE scale, and inability to maintain proper form. **RESULTS:** Post-fatigue, 41.7% of the subjects were positive on the K-D test. Among subjects that reported a history of dizziness, 57.1 % were positive on the post-fatigue K-D test compared to 35.3% who did not reported dizziness (P = 0.2). The time spent on the rower was not different (P = 0.2) between subjects that were positive on the K-D test (14.8 ± 12.0 minutes) and the ones that were negative (44.8 ± 23.2 minutes). A positive K-D test is determination when the time to complete the test increases on a posttest or an error is recorded. Follow-up testing (3 weeks) showed that 20.8% of subjects had K-D scores indicative of further evaluation (P = 0.09). Of these, 60% K-D scores were positive by less than 1 second (0.64 sec.). If a positive K-D was defined as a score ≥ 1 second, only 8.3% of subjects will be categorized as positive for K-D (P = 0.01 compared to baseline). **CONCLUSIONS:** The present data demonstrate that whole-body fatigue may worsen the K-D scores, questioning its construct validity and limiting its use as a sideline screening for concussion. Scoring definitions can also be improved to better depict the positive results. The K-D test can show an improved validity when used in conjunction with pre-concussion symptom history.

Differences in Reporting: The Concussed Student Versus the Concerned Parent

Gianna D. Maragliano[1], Ifeoma C. Agwuenu[1], Margaret E. Bristow[1], Vincent C. Nittoli[1], Adam W. Shunk[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]Saint Vincent Hospital, Indianapolis, IN.*
(No relevant relationships reported)

In the last decade, incidence of sport-related concussion has doubled. Optimal care requires an accurate diagnosis of symptoms and severity. Many student-athletes attempt to disguise symptoms and downplay severity to hasten their return to play. A concerned parent is less likely to participate in the downplaying. An accurate portrayal of symptoms may require both perspectives. Data comparing the reporting by parents and students are needed and limited. **PURPOSE:** To evaluate differences in the reporting of concussion symptoms between those who suffer them and the parents who observe them. **METHODS:** Over a 7-year period, 80 students were admitted for psychiatric evaluation owing to persistent post-concussion symptoms. Our study sample consisted of 72 of patients who completed the Behavior Assessment System for Children, 2nd Edition (BASC) as a component of their evaluation. The BASC assesses emotional, social, and behavioral functioning via self-report forms that are completed by adolescents and their parents. There are 13 questions that are unique to adolescents, 18 that are unique to parents, and 7 that are asked in both. The overlapping questions address atypicality, anxiety, depression, somatization, hyperactivity, anger control, and internalizing problems. We performed paired-samples t-tests on these domains to measure equivalence in reporting between students and parents. We used multiple linear regression to identify variables that explained differences in reporting.

RESULTS: Student/parent differences were found in atypicality (p=0.002), depression (p=0.012), anger control (p=0.006), and internalizing problems (p=0.017); students reported lower scores in each category. Averaging all 7 categories, parents reported 6.7% higher scores (p=0.031). Sex did not explain this difference (p=0.184), but grade in school was a trending predictor: each additional grade associated with a 1.2-point reduction in parental overestimation (p=0.064). **CONCLUSIONS:** Following a concussion, adolescents are likely to perceive the severity of emotional, social, and behavioral symptoms more modestly than their parents. The discrepancy was widest among elementary school students, it narrowed in middle and high school, and college students reported symptoms more severely than their parents.

Depression Severity in Adolescent Male and Female Athletes Following Sports-Related Concussion

Nikki Niewold, Stephanie Kliethermes, Timothy McGuine. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*
(No relevant relationships reported)

PURPOSE: Concussions are a growing concern in adolescent sports medicine. However, there is no prospective data demonstrating an association between sustaining a sports-related concussion (SRC) and depression in adolescents. This study prospectively assessed changes in depressive symptoms in high school athletes following an SRC. **METHODS**: This longitudinal cohort study consisted of 1701 adolescent athletes (grades 9-12) who were monitored for SRC. 99 athletes sustained a concussion during the study period (38 females, 61 males). Participants completed the Patient Health Questionnaire-9 (PHQ-9) survey to measure depressive symptoms at baseline (enrollment, pre-SRC), 24-72 hours post-SRC, and 7 days, 3 months, and 6 months post-SRC. Clinically relevant depressive symptoms were defined as a PHQ-9 score >4, or some depressive symptoms most days and most of each day. To evaluate changes in PHQ-9 scores from baseline, linear mixed-effect models adjusting for sex and time were used; least-square means and standard errors are reported. GEE models assuming a binomial distribution and logit link were used to model the association between depressive symptoms and time since concussion, stratified by sex. **RESULTS**: When compared to baseline, females reported PHQ-9 scores that were, on average, 1.53(0.56) points higher at 24-72 hours post-SRC and 1.62(0.57) points higher at 7 days post-concussion than at baseline (p=0.007; p=0.004). PHQ-9 scores were lower (i.e. better) than baseline for both males and females at 3 months post-SRC (M: - 1.19(0.48); p=0.01, F: -1.14(0.66); p=0.09). Females were 7.6 times more likely to have a PHQ-9 >4 at 24-72 hours post-concussion (95% CI: 1.47, 39.08) than they were at baseline (p=0.02) and 10.36 times more likely at 7 days post-concussion (95% CI: 1.90, 56.59) than at baseline (p=0.007). By 3 months, no difference from baseline is noted. There is no evidence to suggest that males experience increased depressive symptoms post-SRC. **CONCLUSIONS**: In the week following an SRC, athletes experience a transient increase in depressive symptoms, with females being more likely to experience clinically relevant depressive symptoms compared to male athletes at the same time points. We found no evidence that SRCs have a long-lasting impact on depression symptoms in adolescent athletes.

Are Subconcussive Impacts Harmless in Youth Soccer Players?

Luis R. Lopez-Roman[1], Yarimar I. Diaz-Rodriguez[2]. *[1]Universidad del Sagrado Corazon, San Juan, PR. [2]Universidad del Turabo, Gurabo, PR.*
(No relevant relationships reported)

In United States at least 3.5 million children play soccer yearly. Head Impact (concussive and subconcussive) in youth players have a growing concern throughout their short or long-term career. A subconcussive impact may induce a traumatic alteration of function of the cerebrum without associated imaging abnormalities or loss of consciousness. Accelerometers can measure the magnitude and quantity of the subconcussive impacts in the field. The SIM-G™ accelerometer is a small portable device that measures change in velocity during an impact and provides estimates of magnitude (G) and angles. The ImPACT Pediatric® is a neurocognitive test that provide information of cognitive changes. **PURPOSE:** To evaluate if a subconcussive impact could lead to negative cognitive functions in youth soccer players. **METHODS:** A group of 30 youth soccer athletes (15 males, 15 females) between 9 to 11 years old wear a head accelerometer in a specialize headband. Each participant was encouraged to perform normally in the game. Descriptive statistics was used to assess subconcussive impacts. T-test was used for the neurocognitive pre and post-test to assess differences in sequential memory, word memory, visual memory and rapid processing. **RESULTS:** Mean age of female and male athletes (9.9 ± 0.6 years) was not different (P > 0.05). A total of 42 impacts were receive by both genders in three games. Range of acceleration was from 16g to 60g (Ave= 23.8 ± 9.1g). T-Test showed differences in sequential memory for female (p = 0.02) and rapid processing for males (p = 0.01). There were no differences between pre and post test in word

THURSDAY, MAY 31, 2018

memory for females and males (p = 0.97, p = 0.11; respectively) and visual memory (p = 0.30, p = 0.34; respectively). **CONCLUSION:** These results suggest that females that play soccer and receive a subconcussive impact can reflect changes in their education and social activities at short term in their word recognition, oral reading and reading comprehension (sequential memory) and males in their auditory processing and language skills (rapid processing). Parents, coaches, trainers, exercise physiologist, and speech-language pathologists (SLP) should receive education to take precautions after a game with children that received at least one sub concussive impact and do not perceived any notable changes.

1966   Board #227   May 31 3:30 PM - 5:00 PM

No Relationship Between Head Impact Kinematics and Concussion Clinical Assessment Performance

Thomas A. Buckley[1], Katherine M. Breedlove[2], Melissa S. DiFabio[1], Jessie R. Oldham[1]. [1]University of Delaware, Newark, DE. [2]Univeriity of Wisconsin - Eau Claire, Eau Claure, WI.

Reported Relationships: T.A. Buckley: *Salary; Applied Cognitive Engineering.*

Repetitive head impacts (RHI), independent of concussions, are speculated to be associated with later life neurological impairments. While football has received the majority of the attention, RHIs are commonplace in ice hockey. A multifaceted concussion clinical assessment battery assesses diverse neurological systems in clinically feasible manner.
PURPOSE: To examine relationship between head impact kinematics and performance on a multifaceted concussions assessment.
METHODS: Eleven male collegiate ice hockey players (age: 20.3 ± 0.8 years, Ht: $1.79 + 0.06$m, Wt: 80.9 ± 6.6 kg) wore a triaxial accelerometer (Triax Technologies, Norwalk, CT.) for all home games and practices. Participants completed the clinical assessment battery twice: pre-season (PRE) and post-season (POST). The test battery included the Standard Assessment of Concussion (SAC), Balance Error Scoring System (BESS), Trails A and B, Tandem Gait (TG), and Dual Task Tandem Gait (DT-TG). Independent variables were the head impact outcome measures: number of impacts, mean peak linear acceleration (PLA), and mean peak rotational acceleration (PRA). Linear regression analyzed the effects of head impact kinematics on change scores (calculated as positive is improved performance) of clinical measures.
RESULTS: Participants experienced 107.6 ± 57.8 impacts over the course of the season with mean PLA of 38.9 ± 2.5 g's and PRA of 3.9 ± 0.5 krad/sec^2. There was no relationship between head impact kinematics and SAC (change: 0.7 ± 2.0, p=0.067), BESS (change: 4.9 ± 10.5 errors, p=0.607), Trails A (change: 9.2 ± 7.3 sec, p=0.951), Trails B (change: $13.7 + 12.7$ sec, p=0.370), TG (change: 2.0 ± 2.4 sec, p=0.986), and DT-TG (change: $3.1 + 2.7$ sec, p=0.990).
CONCLUSIONS: The results of this study suggest that ice hockey related RHI do not adversely affect neurological health on a multifaceted concussion assessment battery. Performance on all tests improved over the course of the season suggesting a learning effect secondary to repeat administration influenced the outcomes. While changes have been identified in neuroimaging studies, these results are consistent with previous studies in other collision sports which failed to identify differences on clinical measures of neurological health.

Test Setting and ADHD Influence Baseline Concussion Testing Neurocognitive Performance in Collegiate Student-Athletes

Caroline A. Kelly, Caroline J. Ketcham, Kirtida Patel, Eric E. Hall, FACSM. *Elon University, Elon, NC.* (Sponsor: Eric Hall, FACSM)

(No relevant relationships reported)

Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT) is a widely used neurocognitive test for assessing and managing concussion injuries. There is inconclusive data on how test administration and environment influence baseline results for student-athletes. It has been well established that individuals with Attention Deficit Hyperactivity Disorder (ADHD) perform worse on the ImPACT, but little research has examined the effect of group test administration on neurocognitive performance and symptom reporting in student-athletes with ADHD. **PURPOSE:** To compare baseline neurocognitive performance and symptom scores in group versus individual administration settings in NCAA division 1 collegiate student-athletes. **METHODS:** 260 student-athletes completed two ImPACT baseline tests, test 1 was completed when they entered as first-year students or transfers and test 2 was completed this past summer. Of these participants, 205 athletes took test 1 individually and 55 participants took it in a group setting. All student-athletes took test 2 in a group setting. 21 of the 260 student-athletes had a diagnosis of ADHD. A 2 (time) x 2 (environment) x 2 (ADHD) Multivariate ANOVA was conducted. Time (test 1 and test 2) was within subjects and Environment at test 1 (individual and group) and ADHD (yes or no) were between subject variables. **RESULTS:** There was a significant increase in total number of symptoms reported when participants went from individual

testing to group testing (p<0.05). Time x Environment Interaction for visual memory (p<0.05) with scores increasing from test 1 to 2 if in the group setting for both, but staying the same if in the individual setting for test 1. A similar effect was found for visual motor processing speed (p<0.05). Participants with ADHD performed worse on all measures no matter the setting (p<0.05). Symptom scores significantly differed for ADHD participants depending on the setting (p<0.05). **CONCLUSIONS:** A group setting has inherent distractions and seems to influence performance on visual memory, visual motor processing speed and symptom scores. Student-athletes with ADHD may be more affected by these distractions. This should be considered in baseline concussion testing and interpreting post-injury neurocognitive performance.

Ninds/nih And Dod Sport-related Concussion Common Data Elements: A Common Language For Clinical Research

Anthony P. Kontos[1], Steven Broglio, FACSM[2], Kathryn Schneider[3], Elisabeth Wilde[4], Kristen Joseph[5], Sherita Ala'i[5], Joy Esterlitz[5], Katelyn Gay[5], Patrick Bellgowan[6]. [1]University of Pittsburgh, Pittsburgh, PA. [2]University of Michigan, Ann Arbor, MI. [3]University of Calgary, Calgary, AB, Canada. [4]Baylor College of Medicine, Houston, TX. [5]Emmes Corporation, Rockville, MD. [6]National Institute of Neurological Disorders and Stroke, Bethesda, MD. (Sponsor: Steven Broglio, FACSM)

Reported Relationships: A.P. Kontos: *Contracted Research - Including Principle Investigator; GE-NFL Head Health Initiative, ElMindA, Ltd, Abbott Laboratories.*

Purpose: In 2016, the National Institute of Neurological Disorders and Stroke (NINDS)/National Institutes of Health (NIH) and the Department of Defense (DOD) began development of Sport-related Concussion (SRC) Common Data Elements (CDEs) to develop data standards for all funded clinical research in neuroscience with goal of increasing the effectiveness of clinical research studies and treatment by facilitating data sharing across studies. The purpose of this abstract is to report the findings from the SRC-CDEs. **Methods:** The initial NINDS Traumatic Brain Injury (TBI) CDE recommendations created in 2010 included limited sport-related brain injury recommendations. In August 2016, a new SRC-specific CDE working group (WG) began developing and identifying CDEs, template case report forms (CRFs), data dictionaries and guidelines to assist investigators initiating and conducting SRC-specific clinical research studies. Comprised of 34 experts from around the world, the WG met regularly to review current collection of SRC data. The WG was divided into three subgroups to examine SRC over time: (1) Acute Subgroup (time of injury until 72 hours); (2) Subacute Subgroup (after 72 hours to 3 months); and, (3) Persistent/Chronic Subgroup (3 months and greater post-concussion). **Results:** The SRC CDEs were released to the NINDS CDE website in June 2017. The recommendations include Core and Supplemental - Highly Recommended CDEs for cognitive measures and symptom checklists, as well as other outcomes and endpoints (e.g., vestibular, oculomotor, balance, anxiety, depression) and sample case report forms (e.g., injury reporting, demographics, history of concussion, concussion history) across acute, sub-acute and persistent/chronic. **Conclusion:** NINDS encourages the use of SRC CDEs by the clinical research community to standardize data collection and reporting. The NINDS CDEs are a continually evolving resource, and these newly developed SRC CDEs serve as valuable starting points for investigators to streamline research that informs treatments for SRC. This material is based upon work supported by the U.S Army Medical Research and Materiel Command's Combat Casualty Care Research Program and funded by NIH contracts HHSN271201700064C and HHSN271201200034C.

Cardiovascular and Cerebrovascular Responses to Central Hypervolemia in Recently Concussed College Athletes

Blair D. Johnson, Morgan C. O'Leary, James R. Sackett, Zachary J. Schlader, John J. Leddy. *University at Buffalo, Buffalo, NY.*

(No relevant relationships reported)

Many concussion patients demonstrate exercise intolerance which has been posited to be due to dysfunctional cerebral blood flow regulation. Lower body positive pressure (LBPP) increases central blood volume and blood pressure in healthy controls and challenges cerebral blood flow regulation. **PURPOSE:** Test the hypothesis that recently concussed college athletes (CA) have exaggerated cardiovascular and cerebrovascular responses to LBPP versus healthy controls (HC). **METHODS:** Three symptomatic CA (age: 20 ± 1 years; 1 woman) within 6 days of a diagnosed concussion and three HC (age: 22 ± 3 years; 1 woman) underwent 5-min of LBPP (20 mmHg). Heart rate (HR; ECG), mean arterial pressure (MAP; photoplethysmography), end-tidal carbon dioxide tension ($PETCO_2$; capnography), and middle cerebral artery blood velocity (MCAv; transcranial Doppler) were measured continuously. Cerebral

vascular conductance (CVC) was calculated. Mean values were obtained over 60 s intervals. Data are expressed as the mean ± SD as a change from baseline. **RESULTS**: Baseline HR (CA: 54 ± 6; HC: 63 ± 10 bpm; P = 0.27), MAP (CA: 87 ± 5; HC: 90 ± 11 mmHg; P = 0.75), PETCO$_2$ (CA: 44 ± 3; HC: 47 ± 1 mmHg; P = 0.20), and CVC (CA: 0.48 ± 0.13; HC: 0.69 ± 0.09 cm/sec/mmHg; P = 0.09) did not differ between groups. Baseline MCAv was lower in CA (41 ± 11 vs. 61 ± 2 cm/sec; P = 0.04). HR did not change across time (P = 0.35) and was not different between groups (P = 0.51). MAP in CA did not increase from baseline (peak increase: 6 ± 2 mmHg; P = 0.16), whereas MAP increased in HC at the 4th (9 ± 9 mmHg; P = 0.02) and 5th min (10 ± 9 mmHg; P < 0.01) of LBPP. PETCO$_2$ did not change across time (P = 0.57) and was not different between groups (P = 0.29). MCAv was greater in CA throughout the entire LBPP protocol (peak difference at 5th min: 11 ± 3 vs. -13 ± 7 cm/sec; P < 0.01). CVC was greater in CA throughout the entire LBPP protocol (peak difference at 5th min: 0.10 ± 0.09 vs. -0.19 ± 0.04 cm/sec/mmHg; P < 0.01). CVC decreased in HC at the 3rd (-0.17 ± 0.03 cm/sec/mmHg; P = 0.05) and 5th min (-0.19 ± 0.04 cm/sec/mmHg; P = 0.02) of LBPP. **CONCLUSIONS**: Despite blunted MAP responses to LBPP, CA exhibit exaggerated increases in MCAv and CVC during LBPP. These preliminary data indicate that CA who are symptomatic demonstrate abnormal cerebral blood flow regulation during central hypervolemia.

Concussion Knowledge and Understanding in Guardians Following Administration of Standardized Education Form.

Tamerah N. Hunt, FACSM, Chloe Salway, Steve Patterson, Jody Langdon. *Georgia Southern University, Statesboro, GA.*

Reported Relationships: T.N. Hunt: *Royalty; SLACK Inc..*

Concussion legislation has established education as the cornerstone of prevention. Georgia legislation requires guardian completion and acknowledgement of concussion education via a standardized concussion information sheet. However, the effectiveness of this standardized form has not been examined. **Purpose:** Examine the knowledge and understanding in guardians of Georgia High School Association (GHSA) student-athletes that completed the GHSA concussion awareness form versus additional concussion education. **Methods:** 102 GHSA guardians completed a 34 item paper-based survey that included demographic questions, concussion knowledge questions, and scenario questions to assess concussion understanding. Participants were divided into groups based upon concussion education (GHSA form only: n=54; Additional education: n=48). Independent sample t-tests were calculated to evaluate differences in concussion knowledge, understanding, and overall score. A Pearson correlation examined the correlation between knowledge and understanding score. All statistical analyses were conducted using SPSS 23.0. Significance levels were set *a priori* at p ≤ 0.05. **Results:** No statistically significant differences were found between groups on knowledge (t(100) =1.74, p=.085), understanding (t(100)=.83, p=.41), and total scores (t(100)=1.88, p=.06).The Pearson correlation revealed a non-significant weak correlation between concussion knowledge and understanding (r = .03; p = .76). **Conclusions:** Guardians of high school student-athletes displayed moderate knowledge and understanding of concussion regardless of additional educational experiences. Despite a clinicians' desire for more comprehensive educational tools, the results of this study indicate that the state issued standardized form provides guardians with sufficient knowledge. This knowledge and understanding will help guardians in the recognition and management of a student-athlete with a concussion. Further, a multifaceted approach to concussion education could be utilized in order to most effectively reach every guardian regardless of education level.

Differences in Serial DTI Between 72 hours and 2 Weeks Following Sports Related Concussion

Sophia Pollalis[1], Michael Torry[1], Wen Liu[2], Dzung Dinh[2], Michael Zagardo[2], Lawrence Jiang[2], Cristin Rassi[2], Peggy Flannigan[2]. *[1]Illinois State University, Normal, IL. [2]OSF HealthCare Saint Francis Medical Center, Peoria, IL.*
(No relevant relationships reported)

While clinical assessments may aide to identify a concussion, there is no conclusive diagnosis via these assessments alone. Moreover, the progression and recovery of SRC is difficult to quantify. This is because the pathophysiological development of the injury occurs at the cellular processes level which clinical assessments may not be sensitive to nor can they be identified through standard structural imaging. fMRI-DTI scalars such as fiber tractography, Fractional Anisotrophy (FA), and Mean Diffusivity (MD) analyses have shown promise in identifying concussion as they can quantify axonal microstructure integrity via disturbances in Brownian water diffusion. PURPOSE: The purpose of this study was to compare fMRI-DTI scalars of FA and MD taken serially between acutely (<72 hrs.) concussed individuals with healthy controls. METHODS: Male athletes (n=6) between the ages of 14 and 23 who presented with a sports-related concussion received an fMRI studying specific regions of the brain using BOLD to assess FA and MD within 72 hours of injury and at 2

weeks post-injury. RESULTS: A significant difference (p<0.05) was observed in the right cingulum projecting to the hippocampus in the MD scan. No significant results were identified in the FA scan. CONCLUSION: While whole brain analysis showed significant differences between scan 1 and scan 2, only one identified region was significantly different. Objectively measuring concussion recovery through FA and MD may be possible, but further research is needed.

Effect of Soccer Headgear on Likelihood and Severity of Non-concussive Injuries in High School Athletes

Mikayla Gallenberger, Tim McGuine. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*
(No relevant relationships reported)

Purpose: In response to the rising awareness and concern over sports related concussions (SRCs) in high school soccer players, some athletes are choosing to wear protective headgear (HG) as a form of defense. One criticism of HG use is that it encourages more aggressive play, potentially increasing the incidence or severity of non-concussive injuries. The purpose of this study was to assess associations between use of HG and non-concussive injury in high school athletes. **Methods**: In a randomized control study of n=1577 Wisconsin high school soccer players, athletes were assigned to a HG group (n=925), or a control group, without the use of HG (n=652) for the 2016-2017 interscholastic seasons. Each athlete provided an SRC history and baseline survey of their concussion symptoms. Athletic trainers at each school recorded the SRCs and non-concussive injuries weekly, as well as additional information about the injuries such as days lost to play. Chi-square tests and logistic regression methods were used to assess for potential associations using intention to treat analyses. **Results**: 440 non-concussive injuries were reported, affecting 352 (22%) unique athletes. No difference in the likelihood of obtaining at least one non-concussive injury between the control group (21.9%) and the HG group (22.8%) was detected (p=0.157). Further, no difference was detected in the number of days lost between the control group (mean=11.46 days) and the HG group (14.83 days) (p=0.234). While girls were 2.53 (95% CI: 1.80, 3.55) times more likely to sustain a non-concussive injury than boys (p=0.001), after adjusting for HG use there was no significant interaction between the sex of the player and use of headgear on sustaining a non-concussive injury (p=0.21). **Conclusion**: Wearing HG designed to prevent SRCs does not influence the likelihood of obtaining a non-concussive injury, or the severity of that injury as defined by number of days lost, both of which would be expected if players with HG were competing more aggressively.

1973   Board #234   May 31 3:30 PM - 5:00 PM

Neuromechanical Factors Associated with Self-Reported Concussion History among Elite Athletes

Gary B. Wilkerson[1], Dustin C. Nabhan[2], William J. Moreau[2]. *[1]University of Tennessee at Chattanooga, Chattanooga, TN. [2]United States Olympic Committee, United States Coalition for the Prevention of Illness and Injury in Sport, Colorado Springs, CO.* (Sponsor: Daniel C. Herman, FACSM)

Reported Relationships: G.B. Wilkerson: *Consulting Fee; Traq Global, Ltd..*

PURPOSE: This study assessed various indices of neuromechanical responsiveness for possible identification of persisting concussion effects. METHODS: A cohort of 48 Olympic athletes (34 males: 23.8 ±4.4 years; 14 females: 25.4 ±4.5 years) performed 3 different 60-s visuomotor reaction time (VMRT) tests involving rapid manual contact with 64 randomly illuminated target buttons arranged in a pattern of 5 concentric rings on a height-adjustable board, and a whole-body reactive agility (WBRA) test requiring side-shuffle movements in response to 20 randomly presented left or right visual targets. An initial VMRT test trial was limited to manual button contacts, immediately followed by trials that involved 2 different dual-task conditions. A centrally located screen displayed scrolling text (VMRT+ST) that the athletes orally recited while also performing the basic VMRT test. The other dual-task condition displayed the Eriksen flanker test (VMRT+FT), which required the athletes to orally state the right or left direction indicated by the center arrow of a 20 5-arrow displays (10 congruent and 10 incongruent arrow sets). Measurements of WBRA reaction time, speed, acceleration, and deceleration were derived from a motion analysis system. RESULTS: Concussion occurrence was reported by 21 athletes at 2.0 ±2.3 years prior to testing (range: 2 weeks to 7.5 years). Strong univariable associations were found for VMRT+FT left minus right VMRT difference ≥15 ms (OR=7.14; 90% CI: 2.44, 20.90), VMRT+ST outermost 2-ring to innermost 3-ring average VMRT ratio ≥1.28 (OR=4.58; 90% CI: 1.51, 13.92), and WBRA speed asymmetry ≥7.7% (OR=4.67; 90% CI: 1.63, 13,36). A large VMRT+FT X VMRT+ST interaction effect was identified (OR=25.00; 90% CI: 6.00, 103.32), which had 88% positive predictive value (14/21) and 78% negative predictive value (25/32). Recursive partitioning identified a 3-way

VMRT+FT X VMRT+ST X WBRA interaction that had 100% positive predictive value (8/8) for identification of athletes with concussion history, whereas negative status on all 3 factors provided 90% negative predictive value (21/23). **CONCLUSIONS**: Metrics derived from the VMRT and WBRA tests provided clear evidence of neuromechanical responsiveness deficiencies among Olympic athletes who reported a history of at least one concussion.

1974   Board #235   May 31 3:30 PM - 5:00 PM

Preliminary Normative Baseline Data for the Sport Concussion Assessment Tool 5 (SCAT 5) in Adolescent Athletes

Morgan N. Anderson, Tracey Covassin, Abigail C. Bretzin, Kyle M. Petit, Jennifer L. Savage. *Michigan State University, East Lansing, MI.*

(No relevant relationships reported)

Approximately 1.6 - 3.8 million sports related concussions (SRCs) occur annually in the United States. Current consensus statements recommend using a multifaceted assessment for sideline evaluation after SRC. Following systematic review of current research and expert panel review, the Sport Concussion Assessment Tool 5 (SCAT5) was developed from the Sport Concussion Assessment Tool 3 (SCAT3). The SCAT5 includes additional assessments and addresses limitations of the SCAT3. Given the updated edition, there is a need to examine baseline normative data for the SCAT5. **PURPOSE**: To examine preliminary normative baseline data for the SCAT5 in adolescent soccer players. **METHODS**: In this cross sectional study, adolescent soccer players were administered the SCAT5 prior to practice. The SCAT5 is a sport concussion sideline evaluation that contains observable signs, Maddocks questions, Glasgow Coma Scale, cervical spine assessment, background information, symptom evaluation, cognitive evaluation (Standardized Assessment of Concussion [SAC]), neurological screening and the modified balance error scoring system (mBESS). Means and standard deviations were evaluated for total number of symptoms (out of 22), symptom severity (out of 132), orientation (out of 5), immediate memory (out of 30), concentration (out of 5), delayed recall (out of 10), total SAC score (out of 50) and mBESS (out of 30). **RESULTS**: The final sample consisted of 91 adolescent soccer players (23 males, 68 females; 13.78 ± 1.2 years old). The average total number of symptoms reported was 1.79 ± 2.9 and the average symptom severity score was 2.93 ± 6.4. The average scores of the individual components of the SAC included an: orientation score of 4.96 ± 0.2, immediate memory score of 19.97 ± 3.4, concentration score of 3.00 ± 1.2 and delayed recall score of 6.88 ± 1.7, equaling an average total SAC score of 34.80 ± 5.2. Finally, the average mBESS score was 3.21 ± 3.0 errors. **CONCLUSIONS**: Establishing normative baseline data for the SCAT5 may help sports medicine professionals better screen and evaluate athletes for SRC on the sideline. Future researchers should continue to collect baseline data to establish normative SCAT5 values. In addition, researchers should focus on age and sex baseline and post-injury data in high school and collegiate athletes for the SCAT5.

A Portrait of the Concussed Student-Athlete: Grade and Sex Affect Presentation of Symptoms

Joseph W. Mayhan[1], Cali A. VanValkenburg[1], Vincent C. Nittoli[2], Adam W. Shunk[2], Courtney D. Jensen[1]. [1]*University of the Pacific, Stockton, CA.* [2]*St. Vincent Sports Performance, Indianapolis, IN.*

(No relevant relationships reported)

It is important to appreciate the enormous diversity in the presentation and prognosis of sport-related concussions (SRC) in athletes. Duration of recovery is highly variable and partly attributable to injury severity, but a comprehensive evaluation must also include age and sex. Research on the interaction of these variables among youth athletes is limited. **PURPOSE**: To evaluate the effect of age and sex on the presentation of SRC symptoms in student-athletes undergoing prolonged recovery. **METHODS**: A sample of athletes from middle school to college (n=76) were evaluated for persistent symptoms of SRC. Cognitive function was measured using the ImPACT test; behavior and attitudes were collected via the Behavior Assessment System for Children (BASC) questionnaire. Independent-samples t tests, chi-squared tests, and multivariate analyses with a Bonferroni correction measured differences between sexes and scholastic grades on cognitive, behavioral, and functional assessments. **RESULTS**: Subjects were 16.2 ± 2.3 years of age; 56.6% of patients were male. Men and women expressed no differences in age (p=0.780), number of previous concussions (p=0.231), or duration of current symptoms (p=0.445). Men tested higher in verbal memory (p=0.036), visual motor speed (p=0.003), and cognitive efficiency (reaction time and accuracy; p=0.007). Women reported better attitudes toward school (p=0.005) and teachers (p=0.043). College athletes sustained more previous concussions (2.6) than middle school (1.0) and high school (1.0) athletes (p=0.016), but high school athletes expressed a trend for more co-occurring diagnoses (1.4) than middle school (0.9) and college (0.6) athletes (p=0.057). The difference between high school and college was significant (p=0.029). Regarding performance,

there was a difference between grade levels in the cognitive efficiency index with middle school athletes scoring significantly lower than high school and college athletes (p=0.022). **CONCLUSIONS**: When youth athletes experience SRC, the sex and age of the athlete is associated with important differences in attitudes, memory, and functional capacities. Proper evaluation of a concussed athlete must consider the role that age and sex play on the diagnosis of injury severity and the expectations of recovery.

1976   Board #237   May 31 3:30 PM - 5:00 PM

Single and Dual-Task Tandem Gait Performance Throughout Concussion Recovery

Jessie R. Oldham[1], Melissa S. DiFabio[1], Kelsey Bryk[1], Ryan M. DeWolf[2], Thomas W. Kaminski, FACSM[1], Thomas A. Buckley[1]. [1]*University of Delaware, Newark, DE.* [2]*MGH Institute of Health Professions, Boston, MA.*

(No relevant relationships reported)

Impaired postural control is common following concussion and is traditionally assessed with the Balance Error Scoring System (BESS); however, the BESS has been criticized for numerous limitations. Alternatively, tandem gait (TG) is a clinically feasible dynamic postural control assessment recommended by The Sport Concussion Assessment Tool- 3rd Edition (SCAT3). Single-task (ST) and dual-task (DT) standard gait assessments have successfully identified postural control impairments following concussion; however, there is minimal literature on the translation to ST and DT TG. **PURPOSE**: To evaluate ST and DT TG performance throughout concussion recovery. **METHODS**: Eighteen NCAA Division I student-athletes (Age: 20.3 ± 1.3 years; Height: 173.6 ± 8.9 cm; Weight: 70.1 ± 11.3 kg) participated in this study. All student-athletes were diagnosed with a concussion by an athletic trainer, and the diagnosis was confirmed by a team physician. Participants were instructed to walk heel-to-toe down a 3-meter line and back as quickly as possible. In accordance with the SCAT3, each participant completed four TG trials with the best time recorded. All participants were baseline tested prior to the season (BL), within 48 hours post-concussion (Acute), on the first symptom-free day (Asymp), and on the day he or she returned to full sports participation (RTP). A one-way ANOVA with repeated measures was utilized to examine both ST and DT TG at the four different post-concussion time points. The alpha level was set at p= 0.05. **RESULTS**: Both ST (p=0.001, F= 5.402) and DT (p=0.001, F= 8.995) TG were significant across the four time points following concussion. There were more pronounced changes in time to complete DT TG (BL: 12.9 ± 3.0 seconds; Acute: 15.4 ± 4.7 seconds; Asymp: 12.5 ± 2.8 seconds; RTP: 11.3 ± 2.0 seconds) compared to ST TG (BL: 10.3 ± 1.4 seconds; Acute: 10.9 ± 2.1 seconds; Asymp: 9.8 ± 1.9 seconds; RTP: 9.2 ± 1.4 seconds) across the four time points. **CONCLUSION**: There were significant changes in time to complete ST and DT TG from BL to RTP following concussion, with more dramatic changes seen during the DT condition. These results suggest that TG, particularly during DT, is a useful measure of post-concussion recovery.

The Relationship Between Patient-Reported Visual Symptoms and Visual Deficits After Concussion

Eileen P. Storey, Matthew F. Grady, Christina L. Master. *The Children's Hospital of Philadelphia, Philadelphia, PA.*

(No relevant relationships reported)

Previous reports in the literature have identified that visual deficits are common yet often undetected after pediatric concussion. Few studies have evaluated tools available to detect visual dysfunction after concussion. **PURPOSE**: To investigate the association between patient-reported and physician-detected visual deficits after concussion.
METHODS: We conducted a prospective cohort study of 69 subjects, ages 5-20 years old and 64% female, who reported both pre- and post-injury vision-specific symptoms on the Convergence Insufficiency Symptom Survey (CISS), a validated 15-question instrument used to assess for changes in visual symptoms in patients with convergence insufficiency, and underwent a comprehensive visio-vestibular examination in a pediatric sports medicine clinic a median of 34 days after injury (IQR 22-48). The relationship between patient-reported symptoms on the CISS and clinical findings were examined using chi-square analysis for categorical data and Mann-Whitney analysis for nonparametric data.
RESULTS: Forty-six (67%) subjects reported an abnormal CISS score of 16 or greater. However, only 31 (44%) reported the presence of visual problems when asked as one of 21 concussion-related symptoms on the Post-Concussion Symptom Inventory (PCSI). Even fewer reported symptoms on the near point of convergence (NPC) (31%) and accommodation (15.3%) testing completed as part of the visio-vestibular exam. However, those with an abnormal CISS score were significantly more likely to have abnormal clinical measures of NPC (p=0.002) and accommodation (p=0.003). Females were significantly more likely to have abnormal CISS scores than males after injury

(p<0.001), but were not significantly more likely to have abnormal scores before injury (p=0.509) or abnormal findings on NPC (p=0.309) or accommodation testing (p=0.179).
CONCLUSIONS: Those with detectable vision deficits may not recognize that they have visual problems using standard concussion symptom scales, making physician identification even more essential. Visual symptoms may also be more prevalent and severe among females compared to males. The CISS may be a useful screening tool specific to visual symptoms that are not captured by symptom provocation on the visio-vestibular exam or commonly used concussion symptom scales.

Reliability of Five Novel Reaction Time and Cognitive Load Protocols

Kelsey Picha, Carolina Quintana, Amanda Glueck, Nicholas Heebner, John Abt, FACSM, Scott Lephart, FACSM. *The University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

A common side effect from a concussion is slowed reaction time. When returning to play, reaction time should be at preinjury levels to ensure a safe return to activity and to prevent further injury. The Dynavision D2 system may be utilized as an assessment and rehabilitation tool to aid in the determination of reaction time following concussion. Previous research has demonstrated good intersession reliability when assessed following a 24-48 hour test-retest window. Determining reliable test-retest intervals for novel reaction time protocols is necessary for future use as a diagnostic and rehabilitation tool. **Purpose:** To investigate the test-retest (intra- and intersession) reliability of a battery of five reaction time protocols. **Methods:** A total of 28 nonclinical participants completed a battery of five protocols increasing in difficulty in terms of reaction speed requirement and cognitive load. Prior to testing, participants were instructed to stand approximately 30.5 cm from the board and allowed three familiarization opportunities. All protocols required participants to hit as many lights as quickly as possible in 60 seconds. After completing the initial testing session (Time 1), participants waited an hour before completing the second session (Time 2). Between 10-14 days later, the participant completed the same battery of tasks for the third session (Time 3). The intraclass correlation coefficient (ICC) and repeated measures ANOVA were calculated. **Results:** The ICC values for each of the five protocols illustrated good to excellent reliability between Time 1 and Time 2 (0.66- 0.90) and between Time 2 and Time 3 (0.71-0.89). There were no significant differences across time points (F<0.105, p>0.05). **Conclusion:** The one hour and two-week test-retest intervals are reliable for clinical assessment, expanding the timeframe of when assessments can be completed reliably. Although these protocols have application both as an assessment and rehabilitation tool, it is important to identify optimal intervention windows to improve reaction time post-concussion. Future research should focus attention on identifying optimal intervention windows and how effective the Dynavision D2 system is for rehabilitation purposes.

Normative Values and Effects of Fatigue on the King Devick Test in Wheelchair Athletes

Angela Mickle, J.P. Barfield. *Radford University, Radford, VA.* (Sponsor: Hank Williford, FACSM)

(No relevant relationships reported)

The King-Devick (KD) test of rapid eye movement is a common assessment of concussion in able-bodied (AB) sport but data are unavailable on disability sport athletes. **PURPOSE:** The purpose of this study was to establish normative KD values for wheelchair rugby and wheelchair basketball sport participants. The secondary purpose was to examine the effect of submaximal and maximal effort on baseline values. **METHODS:** Fifty wheelchair rugby (*n* = 22) or wheelchair basketball (*n* = 28) players (47 males, 3 females) completed baseline KD assessments via an iPad application approximately 10 minutes before a scheduled practice or competition. Because some athletes had limited or impaired grip, iPads were placed on music stands at a standardized height and distance from each participant. To assess the effect of submaximal effort on baseline score, 24 athletes completed a general warm-up, a sport-specific warm-up, and a 6-set sprinting session of 30 meters (15 down, 15 back) starting every 30 sec. To assess the effect of maximal effort, 18 different participants completed sprints until an RPE of 18 was reached (level between "very hard" and "extremely hard"). Final measurements of perceived exertion using the Borg RPE scale and a final KD test completed within 30 sec of the last sprint. **RESULTS:** Mean KD baseline score was 51 sec and no significant difference on mean KD baseline score existed between sports, impairment types, or gender. Specific to submaximal effort, mean KD score decreased by 3.5% after 6 maximum effort sprints (Post-test RPE = 13; perceived between "light" and "somewhat hard" effort). Specific to maximal effort (Post-test RPE = 18), mean KD score increased by 1.7% despite the fact that 8 of 12 players demonstrated an improvement. **CONCLUSSIONS:** KD normative scores were meaningfully higher than previously reported norms in AB sport. Consistent with AB sport, exertion typically caused an improvement (decrease) in KD score time.

The Effect of Intradialytic Exercise Training on Cardiac and Arterial Health in Hemodialysis Patients

Jin hee Jeong[1], Pei-tzu Wu[2], Annabel Biruete[1], Brandon Kistler[3], Peter Fitschen[1], Hae Ryong Chung[4], Emily Tomayko[5], Bo Fernhall, FACSM[6], Kenneth Wilund[1]. *[1]University of Illinois at Urbana-Champaign, urbana, IL. [2]University of California at Los Angeles, Los Angeles, CA. [3]Ball State University, Muncie, IN. [4]Clayton State University, Morrow, GA. [5]Oregon State Univeristy, Corvallis, OR. [6]University of Illinois at Chicago, Chicago, IL.* (Sponsor: Bo Fernhall, FACSM)

(No relevant relationships reported)

Introduction and Aims:
Patients with kidney failure undergoing chronic hemodialysis (HD) treatment have excessively high rates of cardiovascular (CV) morbidity and mortality. Exercise training as a part of a comprehensive treatment program has been shown to reduce the risk of CV events in patients with established CV disease. However, much less is known about the CV effects of exercise training in HD patients. The aim of this study was to determine the effect of 12 months of intradialytic exercise with concomitant protein supplementation on CV health in HD patients.
Methods:
This is a secondary analysis of CV parameters measured from a subset of patients participating in the IHOPE trial (NCT#01234441). This analysis includes data from 98 HD patients (54±12 yrs; 59% male) randomized either to usual care (CON) or intradialytic exercise training + protein supplementation (EX) for 12 months. Patients in the EX group performed supervised moderate intensity exercise (RPE = 12-14) on cycle ergometers for 30-45 minutes with a concomitant oral protein supplement (30g whey) during treatment. Ultrasound exams were performed to measure cardiac systolic function (ejection fraction), diastolic function (early diastolic filling pressure; E, early diastolic tissue velocity; E') and carotid arterial wall thickness (intima-media thickness, IMT). Outcomes were assessed at baseline, 6, and 12 months.
Results:
There were no significant changes in any CV parameter between groups at 12-months (*Group x Time* interaction, p > 0.05 for all measures). However, there was a significant main effect of *Time* for EE' in the overall study population, indicating a general worsening of left ventricular filling capacity at 12-months that was larger in CON compared to EX (p< 0.05). There was a similar trend for an increase in carotid IMT at 12-months in CON (p<0.05), that was not evident in EX.
Conclusion:
These data indicates that declines in cardiac diastolic function and increases in carotid IMT that manifest over time in HD patients may be attenuated by intradialytic exercise training. Surprisingly few studies have investigated the effects of exercise on CV structure and function in HD patients, thus, these findings warrant further investigation.

Predictors Of Performance At Anaerobic Threshold (AT) In Patients With Chronic Liver Disease (CLD)

Jillian K. Price[1], Carey Escheik[2], Patrick Austin[2], Lynn Gerber[2], Zobair M. Younossi[3]. *[1]George Mason University, Herndon, VA. [2]Inova Health System, Falls Church, VA. [3]Inova Fairfax Hospital, Falls Church, VA.* (Sponsor: Walter R. Frontera, FACSM)

(No relevant relationships reported)

PURPOSE: Determine which baseline assessments are most predictive of AT performance in non-alcoholic fatty liver disease (NAFLD) and hepatitis C (HCV) subjects. **METHODS:** At baseline prior to Modified Bruce cardiopulmonary exercise testing (CPET), clinical, laboratory, and questionnaire self-report data were collected for NAFLD, HCV and non-CLD subjects participating in prospective research measuring performance (CPET), activity level (HAP), and fatigue (FSS). Data were analyzed via ANOVA, t-test, Pearson correlation, and both linear and step-wise regression. **RESULTS:** 28 subject's baseline clinical data and self-reports were analyzed (39.3% female, 57.1% Caucasian, 14.3% African American, 10.7% Hispanic, 14.3% Asian, 50.0% NAFLD, 25.0% HCV, 25.0% Non-CLD, age 40.9 ± 13.3**,** BMI 29.1 ± 5.9, 42.9% obese, 35.7% overweight, 14.3% diagnosed with hypertension (HTN), 28.6% hyperlipidemia (HYP), 7.1% diabetes mellitus, 7.1% metabolic syndrome, resting heart rate 70.0 ± 11.8, systolic blood pressure (SBP) 121.3 ± 11.5, diastolic blood pressure (DBP) 73.6 ± 10.1, liver enzymes: AST 35.1 ± 22.3 IU/L,

---

ALT 46.7 ± 29.8 IU/L). Frequently at baseline, subjects had elevated SBP (57.1%), DBP (28.6%) or both SBP and DBP (14.3%). In the 14.3% of the cohort diagnosed with hypertension (3 NAFLD, 1 HCV), 100% had both SBP and DBP outside of the normal ranges. The non-CLD group was significantly younger (p=.0001), had higher VO2 (p=.019) and METs (p=.020) at AT than NAFLD, scored higher on HAP sub-measures (p=.001-.004), and had exercised longer at AT onset than both NAFLD (p=.010) and HCV (p=.027) cohorts. Per stepwise regression age (AT HR r=.816, p=.014, AT exercise duration r=.728, p=.007) and age with elevated AST (AT HR r=.971, p=.001) was most predictive of AT performance in the NAFLD cohort. In the HCV cohort, HTN was most predictive of AT performance (AT VO2 r=.857, p=.029, AT metabolic equivalents (METs) r=.864, p=.027, and AT exercise duration r=.900, p=.014). **CONCLUSION:** Regardless of formal hypertension diagnosis, elevated blood pressures were common in the HCV and NAFLD cohorts. Hypertensive blood pressures at baseline are most indicative of poorer performance at AT in HCV subjects, while elevated liver enzymes (AST) were most indicative of performance at AT in NAFLD subjects.

1982   Board #243   May 31 3:30 PM - 5:00 PM

Long-term Effects of Tai Chi on Muscle Strength and Physical Function in Patients with Peripheral Neuropathy

Arturo A. Arce-Esquivel, Joyce E. Ballard, FACSM, Melinda L. Hermanns, Linda R. Rath, Brittany Murley, Yong T. Wang, FACSM, Barbara K. Haas. *The University of Texas at Tyler, Tyler, TX.* (Sponsor: Joyce E. Ballard, FACSM)
(No relevant relationships reported)

An estimated 20 million people in the U.S. suffer from peripheral neuropathy (PN). Patients with PN develop gait abnormalities, and foot pain is one of the factors affecting walking ability. As a result, a large number of individuals with PN suffer from a reduction in daily physical activity. Tai Chi appears to be safe and effective in promoting strength and functional capacity in older patients with PN and other chronic disabilities. **PURPOSE**: To assess the long-term effects on muscle strength and physical function among patients with PN enrolled in a Tai Chi exercise program. **METHODS**: Eleven participants (men=5, women=6; age: 73 ± 6.96 years) participated in this study. These participants have been engaged in a Tai Chi exercise program over the past one and a half years. The progressive Tai Chi (i.e., Yang Style) program was offered 2 times per week, 60 minutes each time. Before and after training, muscle strength [One repetition maximum (1RM) for leg extension and leg curl], and physical function [i.e., six-minute walk test (6MW) and 8-foot up-and-go] were evaluated. **RESULTS**: After the 18 months of training, muscle strength increased significantly [leg extension: pre = 24.33±16.88; post = 34.71±18.66 kg; leg curl: pre = 29.81±16.50; post = 37.81±16.46 kg; (*p<0.05*)]. The performance of 6MW was improved significantly by 26.16% [pre = 367±118; post = 463±159 m, (*p<0.05*)]. Finally, the time of 8-foot up-and-go decreased significantly by 21% [pre = 11.98±5.52; post = 9.46±3.84 sec, (*p<0.05*)]. **CONCLUSIONS**: These findings demonstrate that long-term Tai Chi exercise program is capable of increasing lower extremity muscle strength and physical function among patients with PN. Interestingly, the exercise training program was able to reduce the risk for loss of functional mobility (i.e., decreased 8-foot up-and-go time) among the participants with PN.

Muscular Impairment In Brazilian Adults With Neurofibromatosis Type 1

MARCIO LR SOUZA, ANN K. JANSEN, DARLENE LS VILELA, ALINE S. MARTINS, LUIZ OC RODRIGUES, NILTON A. REZENDE. *FEDERAL UNIVERSITY OF MINAS GERAIS, BELO HORIZONTE, Brazil.*
(No relevant relationships reported)

Neurofibromatosis type 1 (NF1) is a genetic neurocutaneous disorder, autosomal dominant, with multisystemic manifestations, including a predisposition to tumor formation, bone dysplasias, neuromuscular and exercise capacity impairment and motor deficits, such as poor coordination, low muscle tone, and easy fatigability. Recent studies have illustrated a primary role for the *NF1* gene product in muscle growth, strength and metabolism.
PURPOSE: To evaluate body composition and muscle strength in Brazilian individuals with NF1.
METHODS: 26 individuals with NF1 (14 male), aged 18-45 years, were compared to 26 controls, matched by sex, age, body mass index (BMI) and physical activity level. The following anthropometric parameters were measured: weight, height and waist circumference. Body composition was assessed by dual energy X-ray absorptiometry (DXA). The muscular strength was evaluated by the handgrip test using a dynamometer and presented as maximum muscle strength (Fmax) and per unit area (Farea). The physical activity level were evaluated by IPAQ short form. Statistical analyses used: Kolmogorov-Smirnov and T of Student paired.

RESULTS: The mean age was 34.31 ± 6.05 and 32.92 ± 6.14 years old in the NF1 and control groups, respectively (p=0.316). Stature was lower in individuals with NF1 (1.61 ± 0.10 vs. 1.68 ± 0.08 meters, p=0.003). There were no differences in weight, BMI, waist circumference, fat mass, fat percentage and body fat index. Appendicular lean mass adjusted by BMI was lower in the NF1 group (0.743 ± 0.190 vs. 0.828 ± 0.161, p=0.048). Individuals with NF1 also presented reduction of Fmax (31.09 ± 12.20 vs. 37.47 ± 10.66 kg, p=0.035) and Farea (13.26 ± 4.17 vs. 15.62 ± 3.58 kg, p=0.028).
CONCLUSION: The NF1 group in this study have lower lean mass adjusted for BMI and lower maximal muscle strength. It may indicate an early sarcopenia in this population, which requires further investigation about the mechanisms of these changes and the role of nutrition and exercise on these results.

Feasibility Of A Low Volume HIIT Intervention In HIV+ Hispanic Women With Neurocognitive Impairment

Amarilys Romero-Reyes, Farah A. Ramirez-Marrero, FACSM, Marcos Amalbert-Birriel, Annette Medina-Encarnacion, Jorge Santana-Bagur, Walter Frontera, FACSM, Valerie Wojna. *University of Puerto Rico, San Juan, Puerto Rico.*
(No relevant relationships reported)

High intensity interval training (HIIT) is safe and improves cardiorespiratory fitness and other health characteristics in people living with chronic diseases. However, the feasibility of such intervention among HIV+ women with neurocognitive impairment (NCI) have not been tested. **PURPOSE:** To determine feasibility (attendance and percent completion) of a low-volume HIIT (LV-HIIT) intervention among HIV+ Hispanic women with and without NCI compared with HIV- women. Also, to evaluate between group differences in HR response during the intervention. **METHODS:** 30 HIV+ with and without NCI (19 and 11, respectively), and 13 HIV- women volunteered for a 6-week, 3-days/week LV-HIIT intervention on a cycle ergometer. During the first 2-weeks, participants completed 8-intervals (1-min intense, 1-min active resting) of cycling at 80% of their HR reserve (HRR) determined in a maximal exercise test. During the last 4-weeks, they completed 10-intervals at 90% of their HRR. Workloads prescribed to reach target HR ranged from 60 to 115, and 40 to 135 W in HIV+ and HIV- participants, respectively (P=0.54). Each session began with a 5-min warm-up on a cycle ergometer with no resistance, and ended with a 5-10 min cool-down with stretching exercises. NCI was determined with a battery of neuro-psychological testing (7-domains). Kruskal-Wallis non-parametric test was used to determine between group differences. **RESULTS:** 14 HIV+ with NCI (74%), 5 HIV+ without NCI (45%), and 11 HIV- (85%) Hispanic women completed the intervention; all with 100% attendance. Mean workload and percent target HR achieved were not different between HIV+ and HIV- participants (94±20 vs. 92±27 W, P=0.54; 95±6 vs. 100±17 %, P=0.69). Mean HR during the first 2-weeks were: 117±21 bpm for the HIV+ with NCI, 120±9 bpm for the HIV+ without NCI, and 124±13 bpm for the HIV- (P= 0.34). During the last 4-weeks, HR was: 129±21 bpm for the HIV+ with NCI, 132±8 bpm for the HIV+ without NCI, and 142±21 bpm for the HIV- (P=0.36). **CONCLUSION:** Attendance and percent completion suggest the feasibility of the LV-HIIT intervention among HIV+ Hispanic women with NCI. Similar HR response between groups further suggest the feasibility and safety of the HIIT exercise intervention in these patients. The study was supported by NIMHD S21MD001830, R21MH095524, U54-MD007587-04, R25MD007607.

Cardiopulmonary Profile Of Individuals With Intellectual Disabilities During Maximal Exercise

Thessa Hilgenkamp[1], Anne Boonman[2], Elizabeth Schroeder[3], Maria Hopman[2], Bo Fernhall, FACSM[3]. [1]*Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands.* [2]*Radboudumc Nijmegen, Nijmegen, Netherlands.* [3]*University of Illinois at Chicago, Chicago, IL.*
(No relevant relationships reported)

Individuals with intellectual disabilities (ID) often live a sedentary life and present with low fitness levels. Exercise intolerance has been shown in individuals with Down syndrome, but in individuals with non-syndromic ID, the parameters derived from cardiopulmonary exercise tests (CPET) relating to exercise intolerance have not yet been thoroughly investigated. **PURPOSE:** Our purpose was to assess potential differences in the maximal oxygen uptake and full cardiopulmonary profile during CPET in individuals with non-syndromic ID and healthy controls. **METHODS:** Participants performed a treadmill CPET using an incremental protocol until exhaustion. Differences between groups in peak heart rate (HRpeak), peak oxygen uptake (VO2peak), peak minute ventilation (VEpeak), peak CO2 expired (VCO2peak), oxygen uptake efficiency slope (OUES), relationship between VE and VCO2 (VE/VCO2 slope), relationship between VO2 and HR (O2 pulse), heart rate reserve (HRR), and peak respiratory exchange ratio (RERpeak) were tested with students t-test and

Mann Whitney-U tests. **RESULTS**: Nine individuals with ID (4 male, 32.3 ± 7.7 yrs, 23.0 ± 8.7 kg/m2) and nine age and sex matched controls (24.3 ± 2.9 kg/m2) were included. Individuals with ID demonstrated significantly lower values (p<0.05) in all outcomes compared to controls, except for VE/VCO_2 slope (p=0.06) and RERpeak (p=0.34). **CONCLUSION**: Even with similar effort (RERpeak) between groups, individuals with non-syndromic ID had lower heart rate related parameters and altered integration of cardiovascular, muscular and respiratory function. This likely partially explains the lower exercise capacity compared to matched controls. This project has received funding from the Marie Curie International Outgoing Fellowship within the 7th European Community Framework Program under grant agreement No 625455-ID Physiology.

	ID	Controls	p-value
HRpeak (bpm)[a]	182.0 ± 19.50	194.6 ± 7.54	0.003[b]
VO_2peak (L/min)	1.8 ± 0.86	2.7 ± 0.50	0.014

Associations of Sleep Patterns with Physical Functioning and Physical Activity in Adults with Down syndrome

Stamatis Agiovlasitis, FACSM[1], Mallory Chapman[1], Benjamin Carlson[1], Jasmine S. Curtis[1], Marquell Johnson[2]. [1]*Mississippi State University, Mississippi State, MS. [2]University of Wisconsin-Eau Claire, Eau Claire, WI.*
(No relevant relationships reported)

People with Down syndrome (DS) have low sleep quality, physical functioning, and physical activity, and high levels of sedentariness and body mass index (BMI). It is not known, however, if sleep patterns are associated with physical activity, sedentariness, physical functioning, and BMI in adults with DS. **PURPOSE**: To examine if sleep variables are associated with physical functioning, physical activity, sedentariness, and BMI in adults with DS.
METHODS: Fifteen persons with DS (8 women and 7 men; age 29 ± 14 y; BMI 32.8 ± 8.7 kg·m[-2]) participated in this study. Participants attended a session where time during the timed-up-and-go test and distance covered during the 6-min walk test were measured. Participants then wore for 7 days on their right wrist an accelerometer (wGT3X+, Actigraph) which provided sleep, physical activity, and sedentariness variables. We calculated descriptive statistics and we used Spearman's rho to examine associations of sleep with physical functioning and physical activity variables, and BMI.
RESULTS: Mean ± SD of sleep, physical functioning, physical activity, and sedentariness variables were: total time in bed 557 ± 61 min·day[-1]; total sleep time 407 ± 54 min·day[-1]; latency 26.8 ± 21.0 min; efficiency 73.9 ± 12.0%; wake after sleep onset 123 ± 65 min; number of awakenings 21.0 ± 6.2; average length of awakenings 6.1 ± 3.0 min; timed up-and-go 10.3 ± 3.1 s; 6-min walk distance 255.6 ± 89.6 m; moderate-to-vigorous physical activity accumulated in 10 min bouts 91.3 ± 173.0 min·week[-1]; total sedentary time 3165 ± 527 min·week[-1]; total sedentary time in 15-min bouts 731 ± 560 min·week[-1]. Six-minute walk distance was significantly associated with average length of awakenings (rho = -0.69; p = 0.005) and total sleep time (rho = 0.58; p = 0.024), and moderately, but non-significantly, with efficiency, latency, and number of awakenings (rho = 0.50, 0.45, and 0.40, respectively). There were no other significant correlations between sleep variables and physical activity, sedentariness, and BMI.
CONCLUSIONS: Adults with DS experience difficulties in sleeping and have low physical activity and physical functioning levels, and high sedentariness levels. Indices of sleep are associated with performance during the 6-min walk test, but not with physical activity or sedentariness.

Metabolic And Cardiovascular Effects Of Body Weight Support Treadmill Walking In Healthy Adults

Robert S. Van Zant, Wick Colchagoff, Michael Kunish, Tamara Kunz, Mark Marshall, Sara McDermott, Trevor Myers, Byron Sunga. *The University of Findlay, Findlay, OH.*
(No relevant relationships reported)

PURPOSE: The use of body weight support treadmill (BWST) training for rehabilitation of patients with brain injuries, as well as musculoskeletal and neuromuscular impairments, is an emerging clinical treatment method. Because of the limited evidence of physiological stress of BWST training, the purpose of this study was to describe the metabolic and cardiovascular response to varying levels of BWST walking in healthy adult subjects.
METHODS: A total of 21 subjects (10 females; 34±6.7 yr; 74.6±14.3 kg; 170.8±6.9 cm; 26.1±5.3 kg/m²) provided their informed consent to participate in three 5-minute walking trials at a self-selected treadmill speed, with body weight support (BWS) of 0, 15, and 30%. Test order was randomized for each subject. Subjects rested for a minimum of 5 minutes between each trial, and did not begin a subsequent trial until HR was verified to be ≤ 5 bpm of HR rest. Mean HR (12-lead ECG), BP (auscultation), oxygen uptake (continuous indirect calorimetry), and RPE (Borg ratio scale) were determined from the last 3 minutes of each trial. Mean values for all variables were assessed for difference between trials using repeated measures analysis of variance (SPSS ver. 24, New York, NY).
RESULTS: At rest, HR was 78.2±11.5 bp and BP was 121.2±7.9 / 76.9±8.0 mmHg. Mean walking speed of subjects was 64.2 m/min. HR and systolic BP significantly (p<0.05) increased from rest to exercise at all BWS levels, with no significant difference in diastolic BP seen from rest to exercise at all BWS levels. There was no statistical difference among levels of BWS for HR, BP, RPE, oxygen uptake, respiratory exchange ratio, respiratory rate, tidal volume, and METs.
CONCLUSIONS: Metabolic and cardiovascular responses to treadmill walking at 3 levels of BWS (0, 15, 30%) were similar in apparently healthy adult subjects.

Myotonic Dystrophy Alters Peripheral And Central Adaptations Involved With Movement Control

Aaron T. Buelow, Michael A. Petrie, Jinhyun Lee, Peg Nopoulos, Laurie Guttmann, Richard K. Shields. *The University of Iowa, Iowa City, IA.*
(No relevant relationships reported)

Myotonic dystrophy type 1 (DM1) is the most common inherited muscular dystrophy in adults. The clinical manifestations of myotonia, muscle weakness, and muscle wasting are characteristic symptoms of DM1. However, "upstream" effects of myopathy on spinal cord function and overall movement control is not well established. **Purpose**: To determine the effect of DM1 on peripheral muscle properties, spinal cord excitability, and neuromuscular movement control. **Methods:** Sixteen DM1 and sixteen control subjects participated in this study. Subjects received a battery of 4 tests; 1) assessment of spinal cord excitability via suppression using paired H-reflexes (H2/H1), 2) soleus muscle single (S) and double pulse (D) twitches, 3) fatigue via a repetitive 3 Hz stimulation, and 4) a global motor accuracy movement score (coherence) during a novel weight bearing task. We used a split plot repeated measures analysis of variance to test for differences within and between DM1 and control for each test. **Results:** H-reflex suppression was not different between DM1 and control (0.40 and 0.31; p=0.52). The soleus single twitch amplitude was less for DM1 compared to control (0.59 and 0.72; p=0.03). The double pulse to single pulse (D/S) ratio, a measurement of excitation-contraction coupling, trended higher for DM1 compared to control subjects (1.96 and 1.8; p=0.08). The weight bearing task error analysis (coherence) was less for DM1 group as compared to the control group(0.42 and 0.66; p=0004). Coherence was correlated to the MIRS score (r=0.7; p<0.05). The reproducibility of all within session measurements were high (r>0.87). **Conclusion:** The reduced twitch amplitudes for DM1 group is consistent with the extensive atrophy and provides a reproducible measurement to monitor disease progression. The enhanced D/S ratio for the DM1 group is consistent with impaired excitation contraction coupling, suggesting that calcium release is functionally compromised in people with DM1. The human performance weight bearing task accuracy (coherence) was the most robust measurement and highly correlated to disease severity. These findings support that people with genetically identified myopathy also have significant upstream effects that may influence human performance. Supported by NIH Grant R01NS094387-03

Bioimpedance Spectroscopy Measurements Comparing Different Body Positions and Electrode Types in Men and Women

Jordan R. Moon[1], Michael T. Lane[2], Lee A. Doernte[2], Ryan M. Bean[2], April M. Spears[2], Zackary S. Cicone[3], Clifton J. Holmes[3], Bailey A. Welborn[3], Todd Freeborn[3], Michael R. Esco, FACSM[3]. [1]*Impedimed, Inc., Carlsbad, CA.* [2]*Eastern Kentucky University, Richmond, KY.* [3]*University of Alabama, Tuscaloosa, AL.*
(No relevant relationships reported)

PURPOSE: To evaluate how BIS measurements are affected by metal electrodes and different body positions (sitting and standing) compared to the traditional supine, gel-backed electrode method. **METHODS**: Forty-nine subjects (m=24, w=25) participated in the study (24 +/- 6 years, 172 +/- 11 cm, 74.2 +/- 15.4 kg). Whole body, right side measurements were taken sitting with metal electrodes (SiM), standing with metal electrodes (StM), and supine with gel-backed electrodes (SuG). Supine measurements were taken with a traditional lead-based device while standing and sitting measurements were taken using a fixed metal electrode device. Both devices independently calculated R0 and Rinf. **RESULTS**: Significant correlations were identified between all measurements (r > 0.88, p < 0.001). The highest correlations were observed between SiM and StM as well as StM and SuG for Rinf in the women (r > 0.949, p < 0.001) and between SiM and StM R0 as well as SiM and StM for Rinf in the men (r > 0.973, p < 0.001). Significant differences (p < 0.05) were observed in both R0 and Rinf for men and women comparing all measurements apart from R0 between SiM (764.95 ohms) and StM (773.18 ohms, p = 0.116) and R0 between SiM (764.95 ohms) and SuG (755.2 ohms, p = 0.172) in women. Compared to SuG, (women: R0 = 755.20, Rinf = 517.43 ohms; men: R0 = 599.30, Rinf = 384.70 ohms) SiM (women: R0 = 764.95, Rinf = 553.61 ohms; men: R0 = 613.31, Rinf = 417.54 ohms) was less effected than StM (women: R0 = 773.18, Rinf = 572.06 ohms; men: R0 = 623.58, Rinf = 434.40 ohms). **CONCLUSIONS**: Successful BIS measurements and calculations using complex Cole models were obtained from all measurements (sitting with metal electrodes, standing with metal electrodes, and lying supine with gel-backed electrodes). High (significant) correlations were observed between each measurement. Compared to the traditional supine gel-backed electrodes, both standing and sitting measurements taken with metal electrodes resulted in slightly (< 55 ohms) higher R0 and Rinf values. An R0 and Rinf correction factor should be applied when utilizing standing or sitting BIS measurements using metal electrodes for the calculations of fluid volumes or tissue masses when using the same calculations and resistivity coefficients as traditional supine measurements using gel-backed electrodes.

Predicting Basal Metabolic Rate After Spinal Cord Injury

Ashraf S. Gorgey, FACSM, Thomas E. Nightingale. *Hunter Holmes McGuire VA Medical Center, Richmond, VA.*
(No relevant relationships reported)

PURPOSE: To assess the accuracy of existing basal metabolic rate (BMR) prediction equations in men with chronic (> 1 year) spinal cord injury (SCI). The primary aim is to develop new SCI population-specific BMR prediction models, based on anthropometric, body composition and/or demographic variables that are strongly associated with BMR.
METHODS: Thirty men with chronic SCI (Paraplegic; n = 21, Tetraplegic; n = 9), aged 35 ± 11 years (mean ± SD) participated in this cross-sectional study. Criterion BMR values were measured by indirect calorimetry. Body composition (dual energy X-ray absorptiometry; DXA) and anthropometric measurements (circumferences and diameters) were also taken. Criterion BMR values were compared to values estimated from six commonly used prediction equations. Multiple linear regression analysis was performed to develop new SCI-specific BMR prediction models.
RESULTS: Existing equations that use information on stature, weight and/or age, significantly (P < 0.001) over-predicted measured BMR by a mean of 14-17% (187-234 kcal/day). Equations that utilised fat-free mass (FFM) accurately predicted BMR. The development of new SCI-specific prediction models demonstrated that the addition of anthropometric variables (weight, height and calf circumference) to FFM (Model 3; $r^2 = 0.77$), explained 8% more of the variance in BMR than FFM alone (Model 1; $r^2 =$

0.69). Using anthropometric variables, without FFM, explained less of the variance in BMR (Model 4; $r^2 = 0.57$). However, all the developed prediction models demonstrated acceptable mean absolute error ≤ 6%.
CONCLUSIONS: BMR can be more accurately estimated when DXA derived FFM is incorporated into prediction equations. Utilising anthropometric measurements provides a promising alternative to improve the prediction of BMR, beyond that achieved by existing equations in persons with SCI.

Effects of Resistance Training on Vascular and Hemodynamic Responses to Standardized Workloads in Coronary Patients

Kerstin Grafe, Phillip Bendick, Margaret Burr, Judy Boura, Diedre Brunk, Barry Franklin, FACSM. *Beaumont Health, Royal Oak, MI.* (Sponsor: Barry Franklin, PhD, FACSM)
(No relevant relationships reported)

PURPOSE: To determine the impact of superimposed resistance training (RT) in aerobically trained coronary patients on systolic blood pressure (SBP), heart rate (HR), rating of perceived exertion (RPE; 6-20 scale), and rate pressure product (RPP) at fixed submaximal workloads following a 12-week RT intervention. Additionally, pre and post RT measures of brachial artery reactivity, an index of endothelial function, were obtained. **METHODS:** Fifteen low risk coronary patients (13 men, 2 women; mean ± SD age = 66.1 ± 5.1yrs) completed a progressive 12-week RT program that complemented their regular aerobic training regimen. Prior to training, SBP, HR, RPP, and RPE were obtained while subjects performed 1 set (10 repetitions) of 3 different exercises (bicep curl [BC], shoulder press [SP], leg press [LP]) at an intensity ~ 60-80% of 1-repetition maximum. After the training period, testing was repeated while subjects lifted the identical pre-training loads for each exercise following a standardized protocol. Vascular function was assessed by flow-mediated vasodilation (FMD) testing prior to and immediately following the 12-week RT training intervention. **RESULTS:** Lifting the same pre-training loads evoked attenuated responses for all variables (HR, SBP, RPE, RPP). A statistically significant decrease was shown for RPP ([HR x SBP]/100) during BC (106 ± 27 to 91 ± 22, *P* < 0.007) and SP (102 ± 24 to 86 ± 17, *P* < 0.007), whereas the RPP decrease during LP (116±22 to 109 ± 26) did not achieve statistical significance (*P* = 0.18). RPE for all 3 exercises decreased significantly (*P* < 0.0001) following the RT intervention: BC (14.3 ± 2.3 to 9.7 ± 1.6), SP (13.9 ± 1.6 to 9.2 ± 1.5), LP (14.3 ± 1.4 to 10.3 ± 1.6). Pre versus post RT measurements for resting HR and resting SBP were unchanged. Peak FMD responses for the 15 subjects were 12.8% and 10.3% dilation pre- and post-training, respectively (*P* = 0.332). However, 5 of the 15 subjects showed modest improvements in their post-training time to achieve maximum dilation from a mean of 117 seconds to 81 seconds (*P* = 0.156). **CONCLUSION:** Among aerobically trained coronary patients, a superimposed resistance training program resulted in decreased hemodynamic and RPE responses to lifting fixed submaximal workloads and improved FMD responses in 5 of the 15 participants.

The Effects Of Multi-directional Exercise Training On Body Composition, Physical Fitness, And Mobility In Stroke Patients

Eunkyung Park[1], Younsun Son[2], James Johnson[3], Kyungock Yi[4], Jung-Il Oh[1]. [1]*University of Texas Rio Grande Valley, McAllen, TX.* [2]*University of Houston, Houston, TX.* [3]*3Baylor College of Medicine, Houston, TX.* [4]*Ewha Womans University, Seoul, Korea, Republic of.*
(No relevant relationships reported)

PURPOSE: The aim of this study was to compare the effects of multi-directional exercise training with conventional uni-directional stroke rehabilitation training on body composition, lower body strength and endurance, flexibility, balance, and mobility in stroke patients.
METHODS: Twenty-three male patients with chronic stroke were randomly assigned either a multi-directional exercise training group (MET) or a uni-directional exercise training group (UET). All participants in both groups underwent 12 weeks of exercise training (3 times/week, 60 mins/day). The MET group utilized a half-ball balance device and the UET group utilized a treadmill. The following tests were administered pre- and post-intervention: chairstand test, up and down test, single-leg balance test, sit and reach test, 6m walking test, and 6min walking test. Data were analyzed using T-test and ANCOVA with a significance level of 5%.
RESULTS: Twenty participants completed the exercise regimen (MET, n=10, 53.9 ± 8.3 yrs; UET, n=10, 58.3 ± 12.1 yrs). There was a significant increase between pre- and post-intervention values in the sit and reach test (-6.50 ± 9.52 vs -4.45 ± 11.06, t=-2.13, p<.05) and up and down test (10.30± 2.91 vs -12.1±2.60, t=-9.00, p<.05) in MET, and although up and down values did improve in the UET the results did not meet criteria for statistical significance. Significant increases of single-leg balance test ($F_{(1, 17)} =$

THURSDAY, MAY 31, 2018

4.73, p<.05)) and up and down test (F(1, 17) = 14.03, p<.05) values were found in the post-intervention MET group compared to the UET group using ANCOVA analysis. No significant effects were found on body composition or mobility.
CONCLUSION: The 12-week multi-directional exercise training regimen utilizing half-ball balance devices improved lower limb strength, endurance, and balance compared with uni-directional conventional training in patients with chronic stroke. Therefore, this multi-directional exercise regimen may have therapeutic advantages in a clinical rehabilitation setting.

Blood Pressure in Subjects under Treatment for Knee Osteoarthritis: Role of Physical Activity Status

José Messias Rodrigues da Silva[1], Marcia Uchoa de Rezende[2], Emmanuel Gomes Ciolac[3]. *[1]São Paulo State University (UNESP), School of Sciences, Campus Bauru, São Paulo, Brazil. [2]Traumatology,School of Medicine, University of São Paulo, São Paulo, Brazil. [3]. São Paulo State University (UNESP), School of Sciences, Campus Bauru, Bauru, Brazil.*
(No relevant relationships reported)

PURPOSE: Physical exercise and educational programs promote several benefits for patients with knee osteoarthritis (OA). However, little is known about their effects on blood pressure (BP) of this population. Our purpose was to assess the role of physical activity on BP of subjects under treatment for knee OA submitted to an interdisciplinary educational program.
METHODS: One hundred and thirty six sedentary subjects (25/111 men/women; age = 67.6 ± 9.6, BMI = 30.6 ± 4.4 kg/m^2), under treatment for primary knee OA, were submitted to an interdisciplinary educational program emphasizing the recommendation for regular practice of physical exercise, and have their BP, six minute walking test (6MWT), body mass index (BMI) and daily living physical activity (IPAQ -short version) assessed before (pre) and after 12 months of follow-up. Subjects were then classified, according to their physical activity status during follow-up, in sedentary-to-sedentary (SED-SED, sedentary/insufficiently active at pre and post follow-up), sedentary-to-active (SED-ACT, sedentary/insufficiently active at pre follow-up and active/very active at post follow-up), active-to-sedentary (ACT-SED, active/very active at pre follow-up and sedentary/insufficiently active at post follow-up) and active-to-active (ACT-ACT, active/very active at pre and post follow-up) groups and have their BP and physical 6MWT compared.
RESULTS: : Systolic BP increase (11 ± 3 mmHg , $P < 0.01$) and maintenance in diastolic BP were found in SED-SED, whereas tendency toward increase in systolic BP (12 ± 6 mmHg , $P = 0.07$) and increase in diastolic BP (5 ± 1 mmHg , $P < 0.01$) were found in ACT-SED during follow-up. On the other hand, maintenance in systolic BP and reduction in diastolic BP (5 ± 2 mmHg , $P < 0.01$) were found in SED-ACT, whereas maintenance in systolic BP and tendency toward reduction in diastolic BP (3 ± 2 mmHg , $P < 0.07$) were found in ACT-ACT during follow-up. The positive effects on BP in SED-ACT and ACT-ACT were accompanied by improvements ($P < 0.05$) on 6MWT (SED-ACT = 8.5 ± 2.7 %; ACT-ACT = 9.3 ± 3.6 %) and BMI (SED-ACT = 2.9 ± 0.9 %; ACT-ACT = 3.8 ± 2.0 %), whereas no changes were found in SED-SED and ACT-SED.
CONCLUSIONS:This results suggest that high levels of physical activity may have a positive role on prevention /management of high BP in subjects under treatment for knee OA.

Endothelial Function Correlates With Aerobic Fitness In Adults With Fasting Hyperglycemia Plus Impaired Glucose Tolerance

Stephanie L. Miller, Natalie Z.M. Eichner, Nicole M. Gilbertson, Emily M. Heiston, Arthur Weltman, FACSM, Eugene J. Barrett, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steve Malin, FACSM)
(No relevant relationships reported)

Background: Impaired glucose tolerance (IGT) elevates type 2 diabetes and cardiovascular disease (CVD) risk above and beyond impaired fasting glucose (IFG) alone. Endothelial dysfunction and arterial stiffness have been implicated in chronic disease and linked to reduced aerobic fitness. However, it is unknown if the presence of IGT attenuates vascular function in people with IFG. We tested the hypothesis that adults with IFG+IGT have endothelial dysfunction and arterial stiffness in relation to low aerobic fitness when compared with IFG counterparts. **Methods:** Middle-aged, obese adults with IFG (n=11, 58.3 ± 10yrs; 34.0 ± 7.4 kg/m^2; (FBG: 105.6 ± 6.1mg/dl, 2-hr glc: 120.7 ± 28.1mg/dl) and IFG+IGT (n=14, 61 ± 8.1yrs; 33.1 ± 3.3 kg/m^2; FBG: 104.2 ± 10.5mg/dl, 2 hour glc: 165.4 ± 2mg/dl) were compared in this cross-sectional study following a 75g OGTT screening based on ADA criteria. Aerobic fitness (VO$_2$peak) was assessed with a cycle ergometer via indirect calorimetry, and body fat was determined by BIA (InBody®). After an overnight fast, brachial artery flow mediated dilation (FMD) was used to assess endothelial function by ultrasound and

arterial stiffness was determined via augmentation index (AI) and pulse wave velocity (PWV) via applanation tomography. A 180-min OGTT was also performed to assess glucose tolerance. **Results:** Although there was no significant difference between IFG and IFG+IGT for body fat (P=0.94), VO$_2$peak (P=0.46), FMD (P=0.42), AI (P=0.71), or PWV (P=0.95), elevated VO$_2$peak was strongly correlated with a higher FMD in people with IFG+IGT (r=0.57, P=0.04), but not IFG (r=0.1, P=0.99). Moreover, elevated postprandial blood glucose at 180 min was associated with lower VO$_2$peak (r=-0.51, P=0.06) and FMD (r=-0.54, P=0.05) in IFG+IGT, but not IFG (r=-0.19, P=0.57; r=-0.22, P=0.52, respectively). **Conclusion:** Endothelial function was significantly related to aerobic fitness in adults with IFG+IGT but not IFG. These data highlight that post-prandial hyperglycemia may modify vascular function and training adaptation uniquely between prediabetes phenotypes. Additional research is needed to determine the effect of training across exercise doses on skeletal muscle vascular glucose regulation to optimize diabetes and/or CVD prevention.

Six Weeks of Aerobic Exercise Improves Markers of Insulin Sensitivity and Metabolic Endotoxemia: Correlations with the Gut Microbiota

Lucy Mailing, Jacob Allen, Grace Niemiro, Josh Cohrs, Hannah Holscher, Michael De Lisio, Jeffrey Woods. *University of Illinois at Urbana-Champaign, Urbana, IL.*
(No relevant relationships reported)

PURPOSE: Research from our laboratory indicates that six weeks of aerobic exercise alters the gut microbiota and microbial-derived short chain fatty acids (SCFAs) in both lean and obese humans. SCFAs directly modulate inflammation, insulin sensitivity and gut barrier function. Thus, the objectives of the present study were to (1) determine the effects of aerobic exercise training on circulating metabolic and inflammatory parameters indicative of inflammation, insulin sensitivity, and gut barrier function and (2) determine whether changes in these parameters paralleled shifts in the microbiota and its metabolites.
METHODS: Previously sedentary but otherwise healthy adults (n=16 lean; n=11 obese) underwent a six-week aerobic exercise intervention. Blood samples collected before and after the intervention were analyzed for C-reactive protein (CRP), lipopolysaccharide binding protein (LBP), and insulin resistance by the homeostatic model assessment (HOMA-IR). Fecal samples were analyzed for microbiota composition (16S rRNA gene sequencing) and SCFA concentrations (gas chromatography).
RESULTS: At baseline, obese individuals had significantly higher CRP, LBP, insulin, and HOMA-IR compared to lean individuals (p < 0.05) There were no changes in CRP as a result of exercise training. However, LBP and HOMA-IR were significantly reduced by exercise in the obese group (p < 0.05). Change in CRP over the 6-week intervention positively correlated with change in abundance of *Erysipelotrichaceae* (r = 0.610, p = 0.009), a microbe previously shown to be associated with metabolic syndrome. Change in abundance of *Anaerostipes*, a genus of known butyrate-producers, negatively correlated with change in LBP (r = -0.727, p = 0.007*)* and HOMA-IR (r = -0.471, p = 0.036). Both CRP and LBP levels after the intervention were negatively correlated with post fecal acetate, butyrate, and propionate levels (p < 0.01).
CONCLUSIONS: Six weeks of aerobic exercise improved markers of insulin sensitivity and metabolic endotoxemia in obese individuals. These improvements may be related effects on the gut microbiota, as metabolic and inflammatory markers correlated with changes in several important microbial genera and post-intervention SCFAs.

Cardio-Ankle Vascular Index (CAVI) And Leisure-Time Physical Activity In Men With Type 1 Diabetes

Iisa K. Alho[1], Anne S. Koponen[2], Antti-Pekka E. Rissanen[1], Jyrki M. Aho[2], Juha E. Peltonen[2], Harri J. Lindholm[1], Heikki O. Tikkanen[3]. *[1]University of Helsinki, Helsinki, Finland. [2]Foundation for Sports and Exercise Medicine, Helsinki, Finland. [3]University of Eastern Finland, Kuopio, Finland.* (Sponsor: Robert Petrella, FACSM)
(No relevant relationships reported)

Diabetes is known to amplify the vascular changes that result in arterial stiffening. Individuals with type 1 diabetes (T1D) may also have impaired cardiorespiratory fitness which may influence their leisure-time physical activity (LTPA). Cardio-Ankle Vascular Index (CAVI) is a noninvasive method used to assess arterial stiffness. Currently there are few studies investigating the relationship between arterial stiffness and LTPA in individuals with T1D. **PURPOSE**: To determine CAVI and its associations with LTPA and cardiorespiratory fitness (VO$_{2max}$) in young men with T1D. **METHODS**: As a part of a larger study investigating early signs of cardiovascular disease in T1D 12 men with T1D (33 ± 7 y, 181 ± 7 cm, 81 ± 11 kg, T1D duration 13 ± 7 y) and 17 healthy age- and anthropometry-matched men (CON) (33 ± 6 y, 181 ± 5

cm, 83±10 kg) participated in the study. CAVI was assessed using VaSera VS-1500 (Fukuda Denshi Co. Ltd., Tokyo, Japan). Self-reported LTPA (min/wk) was obtained through a questionnaire. The subjects also performed incremental cycling exercise test until volitional fatigue to determine maximal oxygen uptake (VO_{2max}). Group comparisons were made using independent samples t-test and relationships were determined using Pearson correlation coefficient. All parameters are presented as mean ± SD. **RESULTS**: CAVI was higher in T1D (7.1±0.5 for right, 7.1±0.4 for left) compared to CON (6.5±0.6 for right, 6.4±0.6 for left) (p<0.01). LTPA did not differ between the groups, whereas VO_{2max} was lower in T1D than in CON (35.9±4.8 ml/kg/min vs. 42.7±7.5 ml/kg/min, p<0.05). LTPA was inversely associated with right CAVI (r=-0.72, p<0.01) and left CAVI (r=-0.68, p<0.05) in T1D but not in CON. VO_{2max} was not associated with CAVI in T1D or in CON. **CONCLUSIONS**: Young men with T1D have increased arterial stiffness determined by CAVI which may be an early sign of cardiovascular disease. Our finding of the inverse association between CAVI and LTPA in men with T1D suggests that LTPA may be especially important in modifying arterial stiffness in T1D.

The Influence Of Physical Inactivity On Risk Of Type 2 Diabetes In University Staff

Ever Espino-González, María de Jesús Muñoz-Daw, Elsa Hinojos-Seáñez, José Luis Santiesteban-Parra, José Buenaventura Pardo-Rentería. *Autonomous University of Chihuahua, Chihuahua, Mexico.*
(No relevant relationships reported)

There is now comprehensive evidence that physical inactivity is a primary cause of most cardiovascular and metabolic diseases. The Finnish Diabetes Risk Score (FINDRISC) questionnaire has demonstrated to be an effective tool for predicting the development of cardio-metabolic disorders, such as type 2 diabetes mellitus (T2DM) and metabolic syndrome (MetS). Importantly, one FINDRISC question is related with physical activity. **PURPOSE**: Thus, the present study aimed: (i) to determine the influence of physical inactivity on the risk of developing type 2 diabetes in university staff; and (ii) to determine possible connections between health parameters and the questionnaire responses. **METHODS**: A cross-sectional, descriptive study was conducted with 252 professors and administrative staff (139 women: 42±11 yr; 113 men: 45±13 yr) from the Autonomous University of Chihuahua (UACH) who underwent a health check including anthropometric measurements (height, weight, and waist circumference), blood pressure, and the FINDRISC questionnaire. The association between physical activity and the risk of T2DM was measured by contingency tables. **RESULTS**: There was a significant association between physical inactivity and the risk of T2DM (p<0.000). Waist circumference and body max index were also associated with physical inactivity (p=0.01 and 0.03, respectively). Cardiovascular risk measured by waist circumference was 33% for women and 31% for men. Around 42% of men and 40% of women did at least 30 minutes of physical activity daily. **CONCLUSIONS**: Lack of physical activity measured by the FINDRISC questionnaire showed a robust association with the risk of development cardio-metabolic disorders, as well as with health parameters.

Subjects categorized to type 2 diabetes risks according to FINDRISC				
	Women		Men	
FINDRISC	Frequency	%	Frequency	%
Low (<7 points)	34	24.1	18	16.2
Slightly elevated (7-11 points)	61	43.3	36	32.4
Moderate (12-14 points)	22	15.6	29	26.1
High (15-20 points)	19	13.5	21	18.9
Very high (>20 points)	5	3.5	7	6.3

Association Between Cardiovascular Markers And Physical Activity In Patients With Obstructive Sleep Apnea

Marcos Mônico-Neto, MSc, Hanna Karen Moreira Antunes, PhD, Ronaldo Vagner Thomatieli dos Santos, PhD, Vânia D'Almeida, PhD, Lia Rita Azeredo Bittencourt, PhD, Sergio Tufik, PhD. *Federal University of Sao Paulo, Sao Paulo, Brazil.*
(No relevant relationships reported)

The combined effect of intermittent hypoxemia and sleep fragmentation induced by obstructive sleep apnea (OSA) is associated with high cardiometabolic risk. In contrast, high levels of physical activity (PA) decrease proinflammatory markers related to cardiovascular diseases, improve glycemic control and sleep quality. **PURPOSE**: To observe the association between PA levels with sleep parameters and a range of cardiometabolic profile in a population sample, and to assess the OSA effect on association between PA level and cardiometabolic markers.

METHODS: A cross-sectional study, the Sao Paulo Epidemiologic Sleep Study, assessed 1042 individuals aged between 20 and 80 years of age through polysomnography, self-report PA level (MET's/week) and cardiometabolic profile such as C-reactive protein (CRP), homocysteine, folic acid, vitamin B12, tumor necrosis factor-alpha (TNF-α), interleukin-6 (IL-6), leptin, ghrelin, insulin and blood glucose. **RESULTS**: In the 993 individuals included in the analyses, PA level had a negative association with apnea and hypopnea index (B= -0.016, P<0.001). Compared to the non-apneic group (P=0.013), the MET level was 20.9% lower in the mild apnea group, 39.9% lower in the moderate group (P<0.001), and 57.7% lower in the severe apnea group (P<0.001). There was a negative association between PA level, CRP (B=-0.34, P=0.001) and insulin (B=-0.011, P=0.023) when analyzed whole sample. A negative association between PA level and homocysteine was only observed in non-apneic subjects (B=-0.027, P=0.02). There was no association between PA level, and CRP and insulin when apneic individuals only were analyzed. **CONCLUSIONS**: A high PA level is negatively associated with OSA severity. Although PA level was negatively associated with CRP and insulin in the whole sample, this association was not found when only OSA individuals were considered.

Obesity, Lower Extremity Soft Tissue Pain & Physical Functioning

Geoffrey E. Moore, FACSM[1], Deborah L. King[1], Jake Veigel[2]. [1]Ithaca College, Ithaca, NY. [2]Utah Sports Medicine, Salt Lake City, UT.
(No relevant relationships reported)

Loss of physical functioning due to non-surgical lower extremity soft tissue pain (LESTP) is not well studied, but LESTP have been linked to difficulty completing activities of daily living. Obese patients have high incidences of musculoskeletal pain in the back, knee, ankle, and feet as barriers to a physically inactive lifestyle. The American College of Sports Medicine (ACSM) recently published simple methods to assess physical functioning for adults with a chronic disease or disability. **PURPOSE**: To see if the ACSM methods can be implemented in a medical practice, and to examine the relationships between lower-extremity exertional symptoms, BMI and biomechanical abnormalities with poor physical functioning. **METHODS**: 15 subjects (12 female, 3 male) completed informed consent and underwent a brief medical history and physical exam for symptoms and signs of LESTP. Weight and height were recorded; knee and ankle alignments were measured (Ingham's knee mal-alignment and foot rotation instruments). Dynamic stability was assessed by Trendelenberg test, 2-legged half-squats and 1-legged squats. Functional performance was assessed by gait speed, sit-to-stand, and stair climb tests. Associations between LESTP, biomechanical burdens, and poor physical functioning were examined with Fischer's Exact test and Spearman's rank correlation. **RESULTS**: Fisher's Exact test revealed significant relationships between BMI vs abnormal gait (p<0.01), as well as BMI vs two-legged squat mechanics (p<0.05). There were strong associations between physical functioning measures: sit to stand vs stair time r=-0.64, p<0.05; gait speed vs sit to stand r= 0.60, p<0.05; gait speed vs stair climb time r=-0.65, p<0.05. Strong associations were also seen between BMI and dynamic instability score r=0.71, p<0.005, as well as dynamic instability and poor physical functioning r=0.50, p<0.05. Significant correlation was found between BMI and biomechanical burdens (r^2=0.27, p<0.05). **CONCLUSION**: In this study, BMI was associated with dynamic instability, and dynamic instability was associated with poor physical functioning. The findings support the concept of sarcopenic obesity, wherein body mass outstrips musculoskeletal ability to provide normal biomechanical functioning and impairs independence and activities of daily living.

Special Rehabilitation Treatment of Patients with Low Back Pain

Michaela Tomanová[1], Lee Cabell[2]. [1]Rehabilitation Institute Brandýs nad Orlicí, Brandýs nad Orlicí, Czech Republic. [2]Arkansas Tech University, Russellville, AR.
(No relevant relationships reported)

Special rehabilitation treatment and exercises by INFINITY method® (IM) use active movement and passive therapy. The three-dimensional rehabilitation therapy and movements stabilize and centralize the posture and also lumbar region. The IM is used as a treatment of patients with low back pain (LBP) and also preventive exercise program.
PURPOSE: To test efficacy of the rehabilitation method IM in patients with LBP.
METHODS: This was a quasi-experimental and non-randomized study with repeated measures design in a rehabilitation clinic. The participants with LBP (n = 15, age 66.2 ± 18.8 yr) volunteered in the study. All patients received a 60-minute IM therapy per day for twenty days for four weeks. We measured the area of center of force (COF) (cm^2), anterior-posterior (A-P) and medial-lateral (M-L) sway components of COF (cm) before and after the treatment. Patients were standing for 30 seconds with eyes

closed to measure postural control on a pressure mat system MatScan, before and after the rehabilitation treatment. Another dependent variable, the visual analog scale (VAS) of low back subjective pain scores (1 - pain free; 10 - unimaginable, unspeakable), was measured before and after the treatment. Data were analyzed using a Paired t-test and Wilcoxon signed-ranks test. $P < .05$.
RESULTS: The mean COF before treatment (M = 4.89, SD = 0.91) was significantly greater than the mean after treatment (M = 2.81, SD = 1.77), t (14) = 2.14, p < .05. The sway was reduced in both directions after treatment. M-L instability had larger effects on sway compared to A-P instability. The mean A-P before and after (M = 2.95, SD = 1.08) and (M = 2.81, SD = 1.21) showed only small, non-significant difference, t (14) = 0.42, p > .05; however, the mean M-L score before and after treatment (M = 3.69, SD = 1.37) and (M = 2.71, SD = 1.24) revealed significant difference, t (14) = 2.63, p < .05. VAS pain scores for pre- and post-treatment indicated significant difference (Mdn = 5.00) and (Mdn = 4.00), z = -3.32, p < .01.
CONCLUSIONS: The study revealed a significant decrease in pain and the area of COF, A-P and L-R sway components of COF. Out of all these parameters study shows that over 70% of patients with LBP improved at least in three dependent variables. The results of this study present the efficacy of IM in treatment of patients with LBP.

Exercise Effects On Health, Fitness, And Cardiometabolic Risk Factors Among Firefighters: A Meta-analysis

Katie L. Andrews, Stephen Gallagher, Matthew P. Herring. *University of Limerick, Limerick, Ireland.*
(No relevant relationships reported)

Exercise training may reduce cardiovascular disease (CVD) risk among at risk populations. Firefighters are a high-stress occupational group at increased risk for CVD. However, the effects of exercise training on risk factors of CVD among firefighters remain unclear. **PURPOSE** To estimate the population effect size of exercise on health, fitness, and physiological/biological risk factors for CVD among firefighters. **METHODS** Eleven randomized controlled trials and seven experimental studies published before August 2017 were located using Google Scholar, MEDLINE, PsycINFO, PubMed, and Web of Science. Trials involved 1,428 (27 females) participants aged 36.7± 8.5 years, included firefighters, aimed to increase physical activity and/or improve fitness/health, and included a validated measure of ≥1 biological CVD risk factor(s). Hedges' d effect sizes were computed to quantify the magnitude of the effects of exercise compared to control conditions. Random effects models were used for all analyses. **RESULTS** Exercise interventions included aerobic exercise training, resistance exercise training, and combined training that varied in frequency (3±1 sessions/wk), intensity (moderate to intense), supervision (n=10), and duration (16.5 ± 10 weeks). Exercise resulted in significant, small-to-moderate effects on body weight (Δ=0.29, [0.02-0.56], $p≤0.05$, k=12), body composition (Δ=0.34, [95% CI: 0.14-0.54], $p≤0.001$, k=21), body fat percentage (Δ=0.53, [0.20-0.86], $p≤0.001$, k=5), strength (Δ=0.33, [0.11-0.54], $p≤0.05$, k=15), and occupational fitness (Δ=0.59, [0.20-0.99], $p≤0.05$, k=8). Significant, large effects were found for fitness (Δ=0.85, [0.58-1.12], $p≤0.001$, k=45), aerobic capacity (Δ=1.21, [0.47-1.95], $p≤0.001$, k=8), and endurance (Δ=1.53, [0.79-2.28], $p≤0.001$, k=11). Exercise training resulted in small-to-moderate non-significant effects on cholesterol, heart rate, psychological outcomes, BMI, flexibility, and systolic blood pressure. **CONCLUSIONS** The available evidence supports positive effects of exercise interventions on risk factors of CVD, including health outcomes (i.e., body composition, weight, and body fat percentage), and relevant measures of fitness (i.e., aerobic capacity, endurance, strength, and occupational fitness).

Morphometric Parameters in Somatic and Branchiomeric Muscles of Mdx Mice

Mariana Cruz Lazzarin, Hananiah Tardivo Quintana, Vivianne Izabelle de Araújo Baptista, Flavia De Oliveira. *Federal University of Sao Paulo, Santos, Brazil.*
(No relevant relationships reported)

Duchenne muscular dystrophy is a neuromuscular disorder characterized by progressive muscle degeneration. A common histological alteration in dystrophic muscle is variation in fiber size. However, muscles with somatic and branchiomeric embryological origins have different responses to muscular dystrophy. **Purpose:** To investigate morphometric parameters in somatic and branchiomeric muscle of mdx

mice, an experimental model of Duchenne muscular dystrophy. **Methods:** Male sixteen-week-old C57BL/10 (Control group; n=5) and C57BL/10-Dmd^{mdx} (Mdx group; n=5) mice (Ethical protocol number 8165240614). After euthanasia, the *gastrocnemius* (somatic muscle) and *masseter* (branchiomeric muscle) were dissected, sectioned, and stained with Hematoxylin-Eosin (H&E). Five fields from one section have been chosen and photographed with 40x objective, through computerized imaging equipment attached to a binocular microscope. The frame with area known was used to measure all cells ($μm^2$) in this area. Analysis of distribution frequency of the muscle fiber areas was presented in a histogram. **Results:** In *gastrocnemius* muscle, fibers areas revealed greater of heterogeneity in Mdx group when compared with Control. Mdx group showed muscle fiber area values between 70 and 3,000$μm^2$ and Control group had a lower numerical range between 190 and 2,000$μm^2$. Furthermore, we observed that the groups presented difference between frequency peaks of muscle fiber area. Control group presented two peaks of frequency: 500/600$μm^2$ and 1,000/1,100$μm^2$. In contrast, Mdx groups showed only one peak of distribution frequency between 400/600$μm^2$. In masseter muscle, Control and Mdx groups had similar values between muscle fiber areas (70-100$μm^2$ and 2,000-2,200$μm^2$), with the same frequency peaks in 600$μm^2$. **Conclusion:** Morphometric parameters are different in somatic and branchiomeric muscles of mdx mice. Muscle with somatic embryological origin was most affected by variability of muscle fiber sizes than muscle with branchiomeric embryological origin.

Exercise Training Alleviates Murf1-mediated Muscle Atrophy By Activating The Sirt1-AMPK Pathway In Diabetic (db/db) Mice

HUNG-WEN LIU. *National Taiwan Normal University, Taipei, Taiwan.*
(No relevant relationships reported)

Nuclear factor-κ B (NF-κB) pathway activation in conjunction with stimulated ubiquitin-proteasome pathway, especially E3 ubiquitin ligases MuRF1, leads to muscle loss in diabetes. Aerobic exercise training stimulates oxidative energy production via activation of sirtuin 1 (SIRT1) and AMP-activated protein kinase (AMPK) which could inhibit NF-κB signaling and suppress inflammation. **PURPOSE:** The study examined the underlying mechanisms of aerobic exercise training on attenuating diabetes-related muscle loss. **METHODS:** Eight weeks moderate-intensity exercise (5m/min, 60min/day, 5days/week for a total of 8weeks) on the skeletal muscle size and transcription factors such as NF-κB involved in regulation of MuRF1 were investigated in diabetic db/db (C57BL/KsJ-lepr^{db}/lepr^{db}) mice (n=10/per group). The statistical significance of the differences between two groups was determined by independent sample t-test ($P < 0.05$). **RESULTS:** No differences in fasting glucose and serum insulin levels and the areas under the curve (AUC) of intraperitoneal glucose tolerance test were observed in db/db mice with and without exercise training. The wet weights of gastrocnemius (64.25 vs. 74.64 mg) and tibialis anterior muscles (21.56 vs. 27.14 mg) were significantly increased in db/db mice with exercise training. The average cross-sectional area of tibialis anterior muscle was significantly increased by 1.2-fold in db/db mice with training compared with untrained mice (676.5 vs. 830.6 μm²). Prevention of muscle loss by exercise training was associated with downregulation of MuRF1 (-44%, P=0.014) and K48-linked poly-ubiquitination (-24%, $P < 0.01$) in db/db mice with exercise training. Decreases in phosphorylation of IκBα (-68%, P = 0.015) and NF-κB were observed in db/db mice with training compared with untrained mice (-64%, P = 0.017). Upregulation of SIRT1 (+33%, P < 0.01) and AMPKα activity (+165%, P = 0.015) were observed in db/db mice with exercise training. **CONCLUSION:** Aerobic exercise training inhibits NFκB signaling pathway via activation of the SIRT1/AMPKα pathway, thereby alleviating MuRF1-mediated muscle atrophy.

Ceramide Accumulation and Insulin Resistance During Hindlimb Suspension In Wheel-Running Mice Is TLR4 Dependent

Alec I. McKenzie, Paul T. Reidy, Jade L. Mulvey, Nikol M. Yonemura, Trevor S. Tippets, Aspen F. Johnson, Micah J. Drummond. *University of Utah, Salt Lake City, UT.*
(No relevant relationships reported)

Short term skeletal muscle inactivity (i.e. hospitalization, bed rest) impairs muscle size, function, and insulin sensitivity. We have suggested that muscle inflammation (TLR4 signaling) and accumulation of the bioactive sphingolipid, ceramide, are potent determinants of muscle health following inactivity periods. **Purpose:** To study specific inflammatory mediated effects on skeletal muscle of physically active mice, following 7-days of inactivity. **Methods:** In efforts to build on our recent findings and to study rapid inactivity induced changes, we provided 8-week old C57BL/6 mice access to running wheels for 5-weeks. Mice were then hindlimb suspended for 7-days (HS, n=10) or continued running wheel activity (Con, n=10) during this 7-day period. An additional group of HS mice were given daily injections of TAK242, a TLR4 specific inhibitor (HS+TAK242, n=10), in an attempt to protect muscle health during

7-days of inactivity. Primary outcomes were soleus-specific ceramide content, muscle Akt signaling, insulin sensitivity, and muscle size. **Results:** Muscle total ceramide abundance was greater (45%, p<0.01) in HS vs. Con, while TLR4 inhibition prevented ceramide accumulation during HS (HS+TAK242 vs. Con, p=0.87). Muscle ceramide increases during inactivity were largely driven by ceramide carbon chain lengths C16:0 & C18:0. Soleus mass declined (27%, p<0.01) in both HS and HS+TAK242. HOMA-IR, an estimate of peripheral insulin sensitivity, was significantly impaired (53%, p<0.01) in HS vs. Con, while TLR4 inhibition provided partial protection (HS+TAK242 vs. Con, p=0.19; HS+TAK242 vs. HS, p=0.24). Muscle Akt ^{S473} and AS160 ^{S588} phosphorylation was not different across the groups. **Conclusions:** These data extend the body of evidence implicating the connection between TLR signaling, muscle ceramide accumulation, and impaired metabolic health. Follow-up analyses in other tissues (i.e. liver) are warranted, in order to understand the peripheral insulin sensitivity discrepancies compared to muscle.

Muscle Activation Patterns of Lower Body Musculature Among Three Traditional Lower Body Exercises in Trained Women

Adam Korak[1], Max R. Paquette[2], Dana K. Fuller[3], Jennifer L. Caputo[3], John M. Coons[3]. *[1]University of St. Thomas, St. Paul, MN. [2]University of Memphis, Memphis, TN. [3]Middle Tennessee State University, Murfreesboro, TN.*
(No relevant relationships reported)

ABSTRACT
The deadlift, back and front squat are common multi-joint lower body resistance exercises that are promoted to train similar musculature. To our knowledge, muscle activity measured via surface electromyography (EMG) has never been analyzed among these three exercises. Furthermore, most literature examining this topic uses all male participants creating a void in the literature for the female population. Knowledge of lower body muscle activation among these three exercises can aid coaches, trainers, and therapists for training and rehabilitative purposes. Therefore, the purpose of this study was to compare peak muscle activity of five lower body muscles among the back squat, front squat, and deadlift in trained women. Thirteen trained women completed two days of testing including a one repetition maximum (1RM) estimation, an actual 1RM, and 3 repetitions at 75% 1RM load for the deadlift, back and front squat. Muscle activity during the three repetitions at 75% 1RM load of each muscle during the total exercise period were averaged and normalized as a percentage of the peak signals obtained during the 1RM lifts. A repeated measures within subject analysis indicated muscle activity of the gluteus maximus (GM) differed among exercises ($p = .01$, $\eta_p^2 = .39$). Specifically, post hoc analysis indicated greater muscle activity during the front squat ($M = 94\%$, $SD = 15\%$) compared to the deadlift ($M = 72\%$, $SD = 16\%$; $p < .05$) in the GM. No significant differences were observed among the lifts in the vastus medialis, vastus lateralis, biceps femoris, and rectus femoris. These findings suggest that coaches and athletes may consider utilizing the front squat exercise for training focused on the GM involvement in female athletes.

Effect of the In Vitro Mechanical Loading of Myotubes on their Myogenic Lineage Progression

Athanasios Moustogiannis, Anastassios Philippou, Orjona Taso, Evangelos Zevolis, Michael Koutsilieris. *National and Kapodistrian University of Athens, Attiki, Greece.*
(No relevant relationships reported)

Mechanical loading of differentiated myotubes mimics the loading pattern of mature skeletal muscle and alterations in signaling and gene expression responses have been reported upon mechanical loading applied on skeletal muscle myotubes. **PURPOSE:** This study investigated the effects of the mechanical loading of terminally differentiated myoblasts (myotubes) on signaling and gene expression responses associated with the progression of their myogenic lineage. **METHODS:** C2C12 myoblasts were cultured on elastic membranes up to the day 10 of their differentiation and then underwent a passive, cyclic stretching (2.2% elongation, at a frequency of 0.25Hz, for 12h). Cells were harvested and lysed 24 hours after the completion of the stretching protocol. Phosphorylation of signaling proteins ERK1/2 and Akt and the expression of the key myogenic factor MyoD were determined by immunoblotting of cell lysates derived from stretched and non-stretched myotubes. Real Time-PCR was utilized to measure changes in expression levels of the myogenic regulatory factors (MRFs; MyoD, Myogenin, MRF4), as well as growth (IGF-1 isoforms: IGF-1Ea, IGF-1Eb), apoptotic (Foxo, Fuca) atrophy (Murf1, Atrogin, Myostatin) and inflammatory factors (Il-1b, Il-6, INF-γ) in response to mechanical loading of the differentiated C2C12 cells.
RESULTS: Mechanical loading of the myotubes resulted in significantly increased activation of Akt and of MyoD protein levels (422%; p<0.05), while no significant differences were found in ERK1/2 phosphorylation. Gene expression levels of IGF-

1 isoforms (IGF-1Ea: 2.1-fold, IGF-1Eb: 1.2-fold) and MRFs (MyoD: 5.8-fold, Myogenin: 3.3-fold, MRF4: 2.3-fold) increased significantly (p<0.05), while the apoptotic (FOXO: 0.7-fold, FUCA: 0.3-fold) and atrophy factors (Atrogin: 0.09-fold, Myostatin: 0.7-fold, Murf1: 0.09-fold) decreased (p<0.05). On the contrary, an upregulation of the inflammatory factors (IL-1b: 4.6-fold, IL-6: 7.5-fold) was depicted (p<0.05), along with a downregulation of the (INF-γ: 0.5-fold) levels (p<0.05).
CONCLUSIONS: It was demonstrated that mechanical loading of myotubes can further promote the progression of their myogenic lineage by upregulating myogenic and anabolic factors and signaling, and downregulating apoptotic and atrophy genes.

Glycogen Enhancement Augments Overload-Induced Protein Synthesis, Growth, and Myogenesis in Aged Skeletal Muscle.

Marcus M. Lawrence[1], Josh R. Huot[1], Bailey Peck[2], Yuan Wen[2], Michael Shields[1], Raahil Madhiwala[1], Alexander Skurat[3], Peter J. Roach[3], Eric Kane[1], Adam Reitzel[1], Benjamin F. Miller[4], Karyn L. Hamilton[4], Susan T. Arthur[1], Scott E. Gordon, FACSM[5]. *[1]UNC Charlotte, Charlotte, NC. [2]University of Kentucky, Lexington, KY. [3]Indiana University, Bloomington, IN. [4]Colorado State University, Fort Collins, CO. [5]Kennesaw State University, Atlanta, GA.* (Sponsor: Scott E. Gordon, PhD, FACSM)
(No relevant relationships reported)

Age-related skeletal muscle (SkM) wasting is associated with elevated 5'-AMP-Activated Protein Kinase (AMPK) activity, which inhibits overload-induced (OI) SkM protein synthesis (MPS) and growth. Glycogen, an inhibitor of AMPK, is reduced in aged SkM. **PURPOSE**: To examine the effects of manipulating glycogen on AMPK, MPS and related signaling, and OI-growth in aged SkM. **METHODS**: Mutant glycogen synthase (GS; designed to enhance SkM glycogen content [GC]) or empty-vector plasmids were electrotransferred into fast-twitch plantaris muscles prior to 21-day synergist ablation-induced unilateral overload in young adult (8 mo.; empty vector; YE, n=9) and old (33 mo.; empty vector, OE, n=11; or mutant GS, OM, n=13) male FBN rats. Contralateral limbs underwent SHAM ablations with no plasmid. **RESULTS**: As expected, mutant GS expression and GC were significantly higher in OM overloaded muscles (the only muscles receiving the mutant GS plasmid) vs SHAM OM muscles or vs both SHAM or overloaded YE and OE muscles. There were significant increases in OI-(all vs SHAM) MPS and hypertrophy in all groups and OM was greater than OE. Markers of AMPK activity and other signaling intermediates affecting MPS were largely unaltered by glycogen enhancement. However, there was a strong and significant effect of enhancing GC (via mutant GS vs empty vector plasmid) on myogenic regulatory factors MyoD and myogenin, embryonic myosin heavy chain-positive fibers, and total fiber number in aged muscle under conditions of overload. **CONCLUSIONS**: Thus, enhancing GC may lead to enhanced MPS and OI growth in aged SkM. This effect may be due, in part, to an enhanced myogenesis.

High versus Low doses of Anti-inflammatory Drugs Do Not Differentially Affect Muscle Molecular Response to Acute Resistance Exercise

Mats Lilja[1], Marcus Moberg[2], Mirko Mandić[1], Thomas Gustafsson[1], Tommy R. Lundberg[1]. *[1]Karolinska Institutet, Stockholm, Sweden. [2]The Swedish School of Sport and Health Sciences, Stockholm, Sweden.*
(No relevant relationships reported)

PURPOSE: We recently reported that high doses of non-steroidal anti-inflammatory drugs (NSAIDs) attenuate resistance exercise-induced muscle hypertrophy in young adults. Yet, little is known about the molecular mechanisms behind this effect. The current study aimed to examine acute muscle molecular responses to resistance exercise during co-ingestion of high and low doses of anti-inflammatory drugs. **METHODS**: Thirty one young (age 18-35 years) healthy men and women were randomly assigned to daily consumption of high doses of ibuprofen (IBU; 1200 mg; n=15) or low doses of acetylsalicylic acid (ASA; 75 mg; n=16) during an 8-week training intervention. During this period, subjects performed 20 supervised resistance training sessions (4 x 7-12 repetitions) involving the knee extensor muscles. Gene expression and protein signaling of key muscle growth regulators were analyzed from skeletal muscle biopsies obtained before training/treatment and 3 hours after an acute resistance exercise session during week 4 of the intervention. Real-time qPCR procedures were employed to determine mRNA expression. Protein signaling was assessed using western blots. **RESULTS**: Gene expression of myostatin (0.4-fold; p>0.0005), MuRF-1 (0.8-fold; p=0.015) and FoxO3 (0.6-fold; p>0.0005) decreased in response to the resistance exercise bout, with no difference across groups. Gene expression of IL-6 and STAT3

were unaltered. Protein phosphorylation of p70S6K increased (24-fold, $P>0.0005$) in response to the resistance exercise bout, with no difference across groups. Protein phosphorylation of STAT3 remained unchanged. **CONCLUSIONS**: These results show that high and low doses of NSAIDs do not differentially affect exercise-induced changes in gene expression and protein signaling for key markers of muscle growth in young adults. We therefore conclude that these acute markers do not seem to explain the negative effects of high doses of NSAIDs on muscle hypertrophy.

ULK2 Regulates Autophagic Cargo Recognition Impacting Contractile Function In Skeletal Muscle

Jordan D. Fuqua, Caleb Mere, Jay Bloome, Dam Bae, Vitor de Melo, Estevão Scudese, Kristen Turner, Ana Kronemberger, Christopher M. Adams, Vitor A. Lira. *University of Iowa, Iowa City, IA.*

(No relevant relationships reported)

Autophagy is an anciently conserved pathway responsible for the degradation of long-lived proteins, protein aggregates, and organelles, thereby contributing to efficient protein homeostasis. Autophagy is stimulated by nutrient deprivation and is required for certain beneficial adaptations of exercise. Insufficient autophagy is a common feature of muscle diseases, obesity, type 2 diabetes, and aging. However, regulation of autophagy is incompletely understood at the molecular level. **PURPOSE:** Define the role of unc-51 like autophagy activating kinase 2 (ULK2), and contrast with that of its close homolog ULK1, in regulation of autophagy and contractile function in skeletal muscle. **METHODS: 1)** DNA plasmids encoding either Ulk1 or Ulk2 pre-micro RNAs (miR) were electroporated into the tibialis anterior (TA) muscle of one leg, and a control miR plasmid into the contralateral leg of wild type mice. Muscles were harvested 7-8 days afterwards, either at basal conditions or after 24h of starvation. **2)** ULK2$^{fl/fl}$ differentiated primary mouse myotubes were infected with Ad-Cre-GFP or Ad-GFP (control) viruses, and harvested up to 96h afterwards. **3)** Maximal force of hindlimb dorsiflexors was assessed in adult ULK2 skeletal muscle knockout mice (ULK2$^{fl/fl}$, Myogenin-Cre$^{+/-}$; ULK2mKO) via stimulation of the fibular nerve, and compared to control littermates (ULK2$^{fl/fl}$, Cre$^{-/-}$). **RESULTS:** ULK2 is expressed at ~2-fold higher levels than its close homolog ULK1 in skeletal muscle. ULK2 deficiency, but not ULK1, leads to ubiquitin and autophagy receptor protein accumulation (p62, NBR-1), suggesting impaired cargo recognition in adult skeletal muscle and primary myotubes, independent of lysosomal function. Preliminary findings indicate that maximal force is reduced in adult ULK2mKO. **CONCLUSION:** Here, we demonstrate a novel and fundamental role for ULK2 in regulating cargo recognition, an essential aspect of selective autophagy, which is commonly impaired in conditions of muscle dysfunction. These results reveal ULK2 as a potential therapeutic target for skeletal muscle contractile and metabolic dysfunction, and serve as basis for future studies dissecting the mechanisms of autophagic cargo recognition in skeletal muscle.
Supported by AHA (16SDG30360001) and Dept. of Health & Human Physiology, University of Iowa.

Mathematical Modeling of Skeletal Muscle Focal Adhesion Kinase Signaling in Response to Contraction

Sida Zhao, David C. Clarke. *Simon Fraser University, Burnaby, BC, Canada.*

(No relevant relationships reported)

Force is a stimulus of resistance exercise (RE) that prompts adaptations to muscle size. Force acts at the molecular level on mechanotransducers such as focal adhesion kinase (FAK), which is a tyrosine kinase that undergoes a conformational change in response to force and subsequently activates a signaling cascade that controls the rate of protein synthesis. The dynamics by which FAK signaling transduces mechanical forces into chemical signals to induce hypertrophy are unclear.
PURPOSE:
The purpose of this study was to develop and analyze a mathematical model of skeletal-muscle FAK signaling in response to contractions.
METHODS:
The model was expressed as a system of ordinary differential equations incorporating signaling proteins involved in the control of protein translation (the FAK/ERK1/2/TSC2 axis). Intracellular biochemical reactions were represented by mass-action or Michaelis-Menten kinetics. We constructed the model by amalgamating a published model of FAK signaling [Zhou et al. (2015) *PLoS Comput Biol*] and ERK1/2 signaling [Hatakeyama et al. (2003) *Biochem J*]. We calibrated the kinetic parameters of the Zhou et al. and Hatakeyama et al. models to reflect skeletal muscle cells.
RESULTS:
Our model outputs qualitatively agreed with published time-course data for FAK, ERK1/2, and TSC2 following the simulation of muscle force contraction profiles. Specifically, we simulated thirty contraction cycles featuring 15-pN contractions and

3 sec per contraction followed by 7 sec of rest [Ato et al. (2016) *Physiol Rep*], which led to increased ERK1/2 signaling lasting ~3.5 hrs. Parameter sensitivity analysis determined that the model was most sensitive to parameters that described the force-induced rate of conformational change for FAK. We also simulated various force inputs for the contraction protocol described above and observed that ERK1/2 signaling was responsive to forces between 8-15 pN, achieving a plateau for higher forces.
CONCLUSION:
Our model provides a working quantitative hypothesis of the dynamics of protein translational control in skeletal muscle induced by mechanical factors. Going forward we will use the model to study the effects that different RE variables (repetitions, sets, loads, rest, etc.) have on FAK signaling dynamics by simulating different contraction profiles.

Mathematical Modeling of Mammalian Target of Rapamycin following Leucine Ingestion

Taylor J. McColl, David C. Clarke. *Simon Fraser University, Burnaby, BC, Canada.*

(No relevant relationships reported)

The mammalian target of rapamycin complex 1 (mTORC1) is a regulatory protein for several cell processes and is critical in the control of muscle protein synthesis and hence muscle size. Its activity is primarily regulated by nutrition (i.e., protein) and growth factors (i.e., insulin); however, how the whole-body dynamics of these factors translate into protein translational signaling in skeletal muscle cells is poorly understood.
Purpose: The purpose of this study was to develop and analyze a simple mathematical model of the signaling controlling protein translation in human skeletal muscle following leucine ingestion.
Methods: The model was expressed as a system of ordinary differential equations (ODEs) incorporating the signaling proteins involved in the control of protein translation (e.g., IR/PI3K/AKT/mTOR axis). Intracellular biochemical reactions were represented by mass-action kinetics. We constructed the model by modifying amalgamated published models of mTOR signalling [Pezze et al. (2012) *Sci Signal*] and skeletal-muscle leucine kinetics [Tessari et al. (1995) *Am J Physiol*]. The Pezze model was specific to HeLa cells, so we calibrated the kinetic parameters using signaling data from human skeletal muscle following leucine ingestion. The ODEs were solved using the ODE23s solver in MATLAB.
Results: The model outputs qualitatively agreed with published time-course data for plasma leucine, plasma insulin, and phosphorylation of Akt^{S473}, mTORC1^{S2448}, and p70S6K^{T389} following the ingestion of a single leucine bolus or multiple, pulsatile leucine doses. Parameter sensitivity analysis determined that mTORC1 activity was most sensitive to total mTORC1 concentration and highly sensitive to the rate of leucine transamination to alpha-ketoisocaproate.
Conclusion: Our model represents a working quantitative hypothesis of the dynamics of protein translational control in skeletal muscle by nutritional and hormonal factors.

Short-term Effect Of Ultrasound-guided Iliopsoas Peritendinous Injection In Athletes With Iliopsoas Tendonitis

Julie Han, Dai Sugimoto, Maxwell McKee-Proctor, Andrea Stracciolini, FACSM, Pierre d'Hemecourt, FACSM. *Boston Children's Hospital, Boston, MA.* (Sponsor: Pierre d'Hemecourt, FACSM)

(No relevant relationships reported)

BACKGROUND: Iliopsoas injury is the second most common cause of groin pain in athletes. Treatment includes ultrasound (US)-guided iliopsoas peritendinous injection. Evidence regarding US-guided iliopsoas injection efficacy is lacking in athletes with intra-articular hip abnormalities. **PURPOSE**: To examine short-term efficacy of US-guided iliopsoas corticosteroid injection in athletes with and without intra-articular hip pathology. **METHODS**: Prospective study design to evaluate athletes 12-50 years with iliopsoas tendonitis. Participants completed a Hip Disability and Osteoarthritis Outcome Score (HOOS) questionnaire prior to US-guided iliopsoas injection and 6-weeks after injection. Outcome measures included change in HOOS subcategory scores. Independent variables included normal hips vs. hips with intra-articular pathology (labral tear, femoroacetabular impingement, osteoarthritis, and dysplasia).

Two-way repeated measures analysis of variance (ANOVA) with effect size (η^2) was used to determine effects of injection on HOOS scores of patients at baseline and 6-weeks following injection. **RESULTS**: 180 patients analyzed; 85.6% (N154) female, mean age: females 20.5±7.5, males 21.5±7.6 years. Time effects were found for both normal and abnormal hips in all five HOOS score subcategories: symptoms (p=0.041, η^2=0.050), pain (p=0.001, η^2=0.184), activity of daily living (ADL) (p=0.011, η^2=0.076), sports/recreation (p=0.001, η^2=0.151), and quality of life (QOL) (p=0.001, η^2=0.193). Significant differences between normal vs. abnormal hips were found in sports/recreation (p=0.032, η^2=0.056) and QOL scores (p=0.001, η^2=0.135). Interaction was found for QOL scores only (p=0.031, η^2=0.056). **CONCLUSIONS**: US-guided iliopsoas injection appears to improve outcomes over the 6 week study period regardless of pre-existing intra-articular hip pathology. Athletes without intra-articular pathology showed greater improvement in sports/recreation and QOL when compared to athletes with abnormal hip pathology. QOL was significantly better in athletes with normal hips than those with hip pathology during 6 weeks. US-guided iliopsoas injections may serve to help patients with iliopsoas tendonitis to advance care and continue with non-surgical treatment regimes.

Pediatric and Adolescent Figure Skating Injuries: A 15-year Retrospective Chart Review

Agnieszka Kowalczyk, Dai Sugimoto, Bridget Dahlberg, Lyle Micheli, FACSM, Ellen Geminiani. *Boston Children's Hospital, Boston, MA.*
(No relevant relationships reported)

BACKGROUND
According to our literature review, there is a paucity of studies published over the last four decades, examining figure skating injuries in the pediatric and adolescent populations. **PURPOSE**: To analyze the characteristics of injuries sustained by young figure skaters, who were evaluated at a regional pediatric sports medicine clinic. **METHODS**: Retrospective chart review was conducted over the study period from 2003 to 2017. Figure skaters were identified by entering key words 'figure skating' and 'figure skater' into search engine, *HoundDog*. Eligible figure skaters were between the ages of 9 and 19 years and had been evaluated at least once at the sports medicine clinic by a physician. All skating disciplines and both sexes were included. Injuries unrelated to figure skating were excluded. Descriptive statistics were used to report injured body areas, type of injury (acute or overuse), number of injuries and time to seek medical attention. Data were stratified by sex. **RESULTS**: Of 382 figure skaters identified during the preliminary search, 296 met eligibility criteria with a total of 822 injuries (273 female and 23 male, age: 14.2±2.3 years, height: 158.8±9.68 cm, weight: 52.2±10.7 kg, BMI: 20.6±3.0, BMI percentiles: 54.5±23.2%). Approximately 31.5% were acute and 67.5 % were overuse injuries. Mean number of injuries sustained was 2.78 per female figure skater and 2.65 per male figure skater. Mean time to seek medical attention was 62.3±143 days (range, 0-1825 days) by female figure skaters and 23.4±28.5 days (range, 0-150 days) by male figure skaters. In female figure skaters, the most frequently injured body areas were, foot/ankle (30.1%), knee (19.5%), back (16.2%), hip (10.5%) and wrist/hand (4.3%). In male figure skaters, they were foot/ankle (27.9%), back (14.8%), knee (13.1%), hip (13.1%), pelvis (6.6%), and lower leg (6.6%). **CONCLUSIONS**: Pediatric figure skaters most commonly sustain foot/ankle (29%), knee (16.3%) and back (15.5%) injuries in both females and males. Approximately two-thirds of their injuries are overuse in nature while about one-third stem from acute mechanisms. This study indicates that not only are pediatric and adolescent figure skaters at risk of injuries, but that they also sustain multiple injuries requiring medical attention from sports medicine physicians.

Feasibility of a Novel Strategy for Cardiovascular Screening During the Preparticipation Physical Examination

Roberta Dennison[1], Deanna Kerkhof[2], Trent Honda[2], Renato Calatroni[2], Gianmichel Corrado[1]. *[1]Boston Children's Hospital, Boston, MA. [2]Northeastern University, Boston, MA.*
(No relevant relationships reported)

Sudden cardiac death (SCD) in athletes is a devastating event in which young, seemingly healthy individuals meet an untimely death, usually without warning. Best screening practices for SCD are highly debated; they vary around the globe and with level of play. **PURPOSE:** To determine the feasibility of simultaneously conducting history and physical (H&P), limb-lead ECG, and preparticipation echocardiography by frontline providers (PEFP) at one screening station. **METHODS:** A cross-sectional study design compared 2 preparticipation cardiovascular screening strategies. There were 31 participants screened in Year 1 and 53 screened in Year 2. Year 1 screening was conducted at three stations: screening H&P, 12-lead ECG, and limited PEFP. Time to complete each station was recorded and the total time for screening was the summation of times for each of the 3 stations. Year 2 screening was conducted at a single station by 2 frontline providers. Year 2 participants underwent screening H&P,

limb-lead ECG, and limited PEFP in simultaneous fashion. Timing of the single station began when the patient entered the room and ended when all three components of screening were complete. An unpaired t-test was used to compare the mean time difference between Year 1 and Year 2 screening stations. **RESULTS:** The Year 1 screening time was significantly longer than the time to complete cardiac screening using the Year 2 protocol (10.27 minutes vs 3.96 minutes, respectively; p<0.01). Zero athletes screened positive in Year 1. Three athletes were referred to cardiology for further evaluation from the Year 2 cohort; all athletes were ultimately cleared to participate. **CONCLUSIONS:** A comprehensive preparticipation cardiac screening examination can be completed in a timely fashion using a single screening station and limited ECG to improve efficiency, while still allowing providers to gather information on personal and family history, physical exam, heart rhythm, and heart structure. This strategy may serve as a potential solution in the longstanding debate over best practices for preparticipation cardiovascular screening for athletes.

2015   Board #276   May 31 3:30 PM - 5:00 PM

Medical Utilization Patterns Among Division I Collegiate Athletes

Christopher Fox[1], Emily Miller[1], Joshua Goldman[1], Peter Awad[1], Nisha Batta[1], Montana Dunn[1], Glenda Marshall[1], Marissa Ogata[1], Phil Sundin[2]. *[1]UCLA, Santa Monica, CA. [2]UCLA, Westwood, CA.* (Sponsor: Aurelia Nattiv, FACSM)
(No relevant relationships reported)

PURPOSE: There are a multitude of medical care models for NCAA student athletes. At our Division I institution, student athletes have access to both primary care sports medicine physicians and sports medicine orthopedic surgeons on a daily basis. The purpose of our study was to determine athlete utilization patterns over the course of a single academic year.
METHODS: Using Presagia Sports, a web-based reporting system, medical visits from September 1, 2016 to August 31, 2017 were reviewed. Demographic information, team affiliation, physician type (primary care versus orthopedic surgery, fellow versus attending), and diagnosis were recorded. Encounter diagnoses were grouped into 12 categories ranging from chronic medical conditions to acute illness and operative orthopedic issues. Encounter diagnoses and categories were reviewed by two primary care sports medicine fellows and cross-referenced with athlete medical records. Poisson regression was used for statistical analysis.
RESULTS: A total of 2416 medical visits occurred during the study period, representing 517 of the 793 (65.2%) student athletes. Football (15% of athletes) represented 16.7% of total visits, followed by rowing (14.5% of athletes) with 10.9%, women's track and field (10.7%) with 9.4%, women's swim/dive (4.8%) with 8.9% and women's gymnastics (3.8%) with 7.1%. Female athletes (53.7% of student athletes) composed 62% of all visits, male athletes 38% (p<.001). 83.3% of all visits were with Primary Care Sports Medicine physicians versus 16.7% with Sports Surgery. When evaluating common diagnoses by sport the following trends were noted: football accounted for 38% of total concussion visits. Rowing had the highest percentage of mental health visits (48%), followed by swim/dive (11%) and women's water polo (7%). Women's cross country and track accounted for 58% of female athlete triad visits (amenorrhea, bone stress injuries or disordered eating) followed by gymnastics at 11% and rowing 10%.
CONCLUSIONS: A foundational understanding of current training room utilization and trends in the distribution of common sports medicine diagnoses, Sports Medicine physicians have the opportunity to prevent these diagnoses, mitigate their effects, and ensure athletes are receiving care designed to optimize their health and athletic performance.

2016   Board #277   May 31 3:30 PM - 5:00 PM

Youth Multi-sport Participation Is Associated With Higher Bone Mineral Density In Female Collegiate Distance Runners

Emily Miller[1], Michael Fredericson, FACSM[2], Andrea Kussman[3], Emily Krauss[2], Sonal Singh[4], Megan Deakins-Roche[2], Brian Kim[5], Adam Tenforde[6], Kristin Sainani[2], Aurelia Nattiv, FACSM[1]. *[1]University of California, Los Angeles, Los Angeles, CA. [2]Stanford University, Stanford, CA. [3]Stanford University, Los Angeles, CA. [4]UCLA, Los Angeles, CA. [5]University of California, Irvine, Irvine, CA. [6]Harvard University, Boston, MA.* (Sponsor: Aurelia Nattiv, FACSM)
(No relevant relationships reported)

PURPOSE:
Youth sport participation is encouraged as a way to promote health and social interactions. But specialization in a single sport at an early age is becoming increasingly common. Distance runners have lower bone mineral density (BMD) compared to athletes in other weight-bearing sports and a higher risk of bone stress

injuries (BSI). We sought to determine the effect of pre-college participation in sports other than cross country or track on BMD and BSI in collegiate middle and long-distance runners.

METHODS:
As part of a prospective study on bone health in collegiate distance runners, baseline data were collected on 81 male and 79 female NCAA Division 1 distance runners at two institutions, including prior sports participation. Baseline BMD was recorded for 55 men and 54 women. We followed athletes for up to 4 years and recorded prospective BSIs. Data were analyzed using t-tests or regression models adjusted for age and school (linear regression for BMD, Poisson regression for BSI).

RESULTS:
62 male runners (76.5%) and 47 female runners (59.5%) had participated in at least one sport in addition to running/track and field events prior to college. Soccer and basketball were the most common sports played in women and men. At baseline, women who participated in multiple sports had faster mile times (4:53 vs 5:11, p<.05), whereas male multi-sport athletes did not (4:12 vs. 4:14). All but 7 multi-sport athletes had participated in at least one high-impact or multi-directional sport. For women, prior participation in high-impact sports was associated with nearly a half-standard deviation increase in total body BMD (Z= .49, p=.047); in contrast, the effect in men was small (Z=.12, p=.65). In terms of prospective BSI risk for women, prior participation in basketball was associated with a relative risk (RR) of 0.50 (0.28-0.91, p=0.023) whereas participation in gymnastics was associated with a RR of 1.99 (1.21-3.26, p=0.007). For men, cycling was significantly associated with an increased risk of prospective BSI with a RR of 4.33 (2.1-8.95, p<0.001) however the N was small (N=6 male cyclists).

CONCLUSIONS: For female collegiate distance runners, prior participation in non-running sports was associated with higher baseline BMD. Thus, encouraging youth to participate in multiple sports may have skeletal benefits.

2017   Board #278   May 31 3:30 PM - 5:00 PM

Effects Of A 12-week Cycling Training Program On Clinical Parameters In Patients With Parkinson Disease

Zinta Zarins[1], Gary Smith[2], Robert Sallis, FACSM[1]. *[1]Kaiser Fontana, Fontana, CA. [2]Pomona College, Claremont, CA.* (Sponsor: Dr. Robert Sallis, MD, FACSM)
(No relevant relationships reported)

PURPOSE: We examined the effects of endurance training [12 week, 3 days/week, 45 min/session, 60-75% of age-adjusted maximum heart rate, targeted rpm of 80-90] on change MDS-UPDRS (Unified Parkinson's Disease Rating Scale) score in patients with mild to moderate Parkinson's Disease (n=12, 71±2.23 years, 1.5 ± 0.23 Hoehn and Yahr staging, 5.71± 0.62 years duration of Parkinson's Disease). We also looked at changes in body composition, resting blood pressure and heart rate, five-times sit to stand test, and timed up and go test. **METHODS:** The 12 subjects recruited for the study had an average BMI of 24.39± 1.13 and were weight-stable. The exercise intervention was supervised and consisted of pedaling on a stationary bike 3 days/week for 45 minutes and intensity of exercise training was gradually increased such that by the second week the subjects were exercising at 60-75% of their age-adjusted maximum heart rate and pedaling at a target rpm of 80-90. Body composition was analyzed using the InBody270. **RESULTS:** Subjects attended an average of 76.9% of the training sessions and trained at an average of 64.7% of their age-adjusted maximum heart rate and cycled at an average of 78.3 rpm. With regards to testing time, there was no significant difference in the time since the last levodopa dose. While all of the UPDRS components decreased after training, there was only a statistically significant decrease in UPDRS I (pre-training=11.5±1.31, post-training=9.50±1.58, p<0.01), UPDRS III (pre-training=20.83±4.17, post-training=7.91±2.22, p<0.01), and the total UPDRS (pre-training=51.0±7.56, post-training=32.4±6.75, p<0.01). Four of the 12 subjects in the study were unable to maintain the average target rpm goal of 80-90, but were still noted to have significant clinical improvements with training. There was no significant change in body composition, five times sit to stand, or get up and go testing. Diastolic blood pressure significantly decreased after training (pre-training=77.08±1.88, post-training=65.91±1.85, p<0.01). **CONCLUSION:** These results suggest that in patient's with mild to moderate Parkinson's Disease a cycling endurance training program 1) significantly improves the total UPDRS by 36% and UPDRS III by 62% 2) improvement in UPDRS III score was irrespective of the average rpm.

2018   Board #279   May 31 3:30 PM - 5:00 PM

Play Lifestyle And Activity Assessment In Children With Cerebral Palsy

Amy Rabatin, Rebecca Zwicker, Dai Sugimoto, Eric Nohelty, Jodie Shea, Benjamin Shore, Andrea Stracciolini, FACSM. *Boston Children's Hospital, Boston, MA.* (Sponsor: Andrea Stracciollini, FACSM)
(No relevant relationships reported)

BACKGROUND: The World Health Organization (WHO) recommends at least 60 minutes of moderate to vigorous physical activity (MVPA) for all children 5-17 years. Exercise Deficit Disorder (EDD), defined as reduced levels of MVPA, afflicts both typically developing (TD) children and children with disability. Currently there is a lack of knowledge surrounding factors that affect physical activity in children with disability.

PURPOSE: (1) To investigate knowledge and understanding, daily behavior, and motivation/attitudes surrounding physical activity in children with cerebral palsy (CP); (2) To compare TD and CP responses to Play Lifestyle & Activity in Youth (PLAY) questionnaire.

METHODS: **Study design:** cross sectional questionnaire study. **Study subjects:** children ages 6-11 with GMFCS level I and II CP or related diagnoses, and TD children in the same age group. **Main outcome measures:** answers to selected questions from PLAY questionnaire focusing on (1) family rules regarding screen-time/media-use (knowledge and understanding), (2) status of daily physical activity (daily behavior), (3) frequency of parents driving child to sporting events (motivation and attitudes). **Statistical analyses:** simple descriptive statistics and two-sided Fisher's exact test.

RESULTS: Nine children with CP (5 males, 4 females; mean age 7.9±1.4 years) and 11 TD children (4 males, 7 females; mean age 7.7±1.6 years) were enrolled. All TD children (100%) had screen-time/media-use rules in the household, as compared to 89% of CP children. Almost two thirds of TD children reported 60-min of MVPA daily, as compared to less than half of the children with CP (44%, *P*=.653). A greater proportion of parents of children with CP drove their children to sporting activities for each outing versus parents of TD children (67% and 56%, respectively, *P*=0.545).

CONCLUSIONS: The majority of CP and TD children in this study had screen time/media use rules in the household. Preliminary analyses found no significant differences between CP and TD children in knowledge and understanding, daily behavior, and motivation/attitudes surrounding physical activity. Continued research will strive to increase our understanding of physical activity barriers in all children.

2019   Board #280   May 31 3:30 PM - 5:00 PM

The Prevalence Of NCAA Division III Athletes With Positive Depression Screening: A Retrospective Cohort Study

Mary Iaculli, DO[1], Ula Lewandowski, MS III[2], Elizabeth Rothe, MD[3], Peter Sedgwick, MD, FACSM[3]. *[1]Evergreen Sports Medicine Fellowship, Augusta, ME. [2]Central Maine Medical Center, Lewiston, ME. [3]Evergreen Sports Medicine Fellowship, Lewiston, ME.* (Sponsor: Peter Sedgwick, MD, FACSM)
(No relevant relationships reported)

PURPOSE: Mental health is a growing area of concern for college athletes. A 2015 report from the NIMH estimated that 6.7% of all American adults experienced an episode of MDD within the past 12 months. Episodes were highest in college-age individuals and females. While there is currently no standardized protocol for screening student-athletes for depressive symptoms during pre-participation physical exams, it has been adopted by some. Our retrospective cohort study evaluates the prevalence of depressive symptoms in student-athletes at a division III college.

METHODS: The entire entire student-athlete population (N =729) of a single division III college was screened for depressive symptoms over the course of one year using the clinically validated questionnaires, PHQ-2 followed by PHQ-9 if positive. Screening was performed during routine pre-participation physicals for sport over a one-year period. Depression screening results were evaluated by gender, sport, class year, and time of year data was collected, and then compared to published national rates.

RESULTS: The prevalence of clinically significant depressive symptoms using the PHQ screening tools in our study was 4.1%, significantly lower than the prevalence of 23.7% cited by Wolanin et al in 2016 using CES-D screening (z= 12.45, p = <.001). Inconsistent with previously published data, there was no overall significant gender difference, $\chi2 = 1.58$, p =.21. However there was a statistically significant difference in women reporting moderate to severe depressive symptoms compared to men, $\chi2 = 16.36$, p =.001. There was no statistical difference with season of screening, $\chi2 = 4.52$, p = .61.

CONCLUSIONS: In this sample, PHQ screening revealed depressive symptoms in less than 5% of division III student-athletes from a single school. Female college athletes reported significantly more moderate-severe depressive symptoms than males. There was no statistical difference in the time of year screening was performed. Hypothesized explanations for the differences in results obtained through our study

and previously published data include, environment of screening, screening tool used, and level of collegiate play. More cross-sectional studies are needed to better elucidate rates of depression in our student-athlete population across all divisions.

2020   Board #281   May 31 3:30 PM - 5:00 PM
Comparison of Running Mechanics in Healthy Female Runners Versus Those with Sacroiliac Pain

Kristin E. Schwarz[1], Dai Sugimoto[1], Charles A. d'Hemecourt[2], Duncan A. d'Hemecourt[2], Pierre A. d'Hemecourt, FACSM[1]. *[1]Boston Children's Hospital, Boston, MA. [2]The Micheli Center for Sports Injury Prevention, Waltham, MA.* (Sponsor: Pierre d'Hemecourt, FACSM)
(No relevant relationships reported)

BACKGROUND: Injuries to the back, pelvis, hip, and thigh have been reported to account for 25-35% of all injuries sustained by runners. Repetitive torsional forces, shear stress, and inflammation can cause deleterious effects and pain in the sacroiliac (SI) joint. SI joint pain is more common among women, in part due to gender-related anatomic differences. Research on the gait mechanics of female runners with SI joint pain has been limited to date. **PURPOSE:** To identify running gait mechanical differences between healthy female runners and those with SI joint pain. **METHODS:** Retrospective case-control running gait video analysis was performed. Runners who had completed video gait analysis and who had been diagnosed as SI joint pain were identified by chart review. Diagnosis was made either by positive response to SI joint injection (i.e. resolution of pain after ultrasound-guided SI joint injection with a mixture of analgesic and steroid) and/or 2 or more positive physical exam provocative tests for SI joint pain. Based on the runner's age, height, mass, and BMI, matched healthy female runners were designated as control. Running mechanics at point of initial contact during the stance phase of the gait cycle were measured from side view (sagittal plane) of runners on a treadmill. Measurements included: foot strike angle, ankle angle, overstride angle, knee angle, hip angle, and trunk posture angles. Foot strike pattern (i.e. rearfoot, midfoot, or forefoot) was documented. Videos were analyzed by an experienced sports medicine physician. **RESULTS:** There were 19 female runners with SI joint pain and 63 healthy female runners in the control group. Runners with SI joint pain demonstrated significantly greater foot strike angles (p=0.001) than those without. Those with SI joint pain also had smaller ankle angles (p=0.001) than healthy runners. There were no significant differences between overstride angles, knee angles, hip angles, or trunk posture angles. There were no significant differences in foot strike patterns between the two groups. **CONCLUSIONS:** Female runners with SI joint pain demonstrated greater ankle dorsiflexion at the point of initial contact during stance phase compared to healthy runners. This suggests a potential role for gait retraining in the treatment and prevention of SI joint pain.

Room: Hyatt-Lakeshore C

2021   Board #1
Chest Pain and Palpitations - Lacrosse

Elizabeth E. Barton - (Sponsor: Kyle J. Cassas, FACSM), Vicki R. Nelson, Irfan M. Asif. *Steadman Hawkins Clinic of the Carolinas, Greenville Health System, Greenville, SC.*
(No relevant relationships reported)

HISTORY:
A 15-year-old female HS lacrosse player presented for episodes of chest pain and palpitations, initially at rest for minutes and then became exertional with SOB. She denied nausea, HA, and syncope. Family history was negative for congenital heart disease and sudden cardiac death, but her mother had atrial fibrillation and MGF died before age 60 from an MI.
PHYSICAL EXAMINATION:
T 97.7°F, HR 56, BP 116/68, RR 20, SpO$_2$ 98% RA, BMI 20.7
Well appearing with clear breath sounds. Cardiac exam: regular rhythm, normal S1 and S2, no S3 or S4, and a 2/6 low frequency systolic murmur best heard at the left upper sternal border. 2+ pulses. No peripheral edema, cyanosis, or hepatomegaly.
DIFFERENTIAL DIAGNOSIS:
1. arrhythmia - SVT, WPW, aflutter, afib, PACs
2. pulmonary valve stenosis, tricuspid valve regurgitation
3. cardiomyopathy—hypertrophic cardiomyopathy, ARVD
4. ASD
5. anemia
6. hyperthyroidism

TEST AND RESULTS:
-ECG- sinus bradycardia, no chamber enlargements or pre-excitation, normal QTc
-28 day event monitor- two episodes of chest pain and rapid heart beat correlate with nsr and sinus tachycardia
-Transthoracic echocardiogram- normal cardiac segmentation, valvular function, biventricular size, and systolic function. No effusion. There is a small coronary cameral fistula entering the main pulmonary artery.
-Exercise stress with 2D echocardiogram performed showed normal EF with no wall motion abnormalities, ischemia, or arrhythmias
FINAL WORKING DIAGNOSIS:
Coronary-cameral fistula
TREATMENT AND OUTCOMES:
1. The patient was cleared to play after symptoms spontaneously resolved and serial echocardiograms over a 5 year period demonstrated a stable coronary-cameral fistula.
2. Cardiology consultants recommended a rest/stress MRI to further determine the anatomical nature of the fistula given the symptom history. However, they believe that the fistula was an incidental finding and likely not the cause of her symptomatology.
3. Coronary-cameral fistula is a rare cause of congenital cardiac anomalies. Although most are small and asymptomatic, larger ones may cause MI or CHF, thus requiring intervention.
4. There are no published reports of this condition in athletes, highlighting provocative issues surrounding risks of incidental findings of unknown significance and return to play considerations.

2022   Board #2
Cotton Mouth In A Cross Country Runner

Jason A. Kirkbride - (Sponsor: John MacKnight, FACSM), Siobhan Statuta. *University of Virginia, Charlottesville, VA.*
(No relevant relationships reported)

HISTORY: A 21-year-old Division I cross-country runner presented to the athletic training room the day he was to leave for ACC championships, concerned about his intolerable dry mouth, leg heaviness and worsening fatigue. He had an unintended weight loss of 15 pounds despite working with Sports Nutrition over the summer due to a baseline BMI of 17.9 and a history of a sacral stress fracture the prior year. He endorsed normal eating pattern, but often felt full secondary to increased fluid intake from his dry mouth. Over the past few days, he also noted the onset of blurry vision. His only medication was an Omega-3 supplement and he denied a family history of autoimmune diseases, but did have an uncle with Type II diabetes mellitus.
PHYSICAL EXAMINATION: Temp. 36.9 °C (Oral) HR: 54 beats per minute Orthostatic blood pressure: Supine: 112/72 Standing: 108/65 Weight: 61.3 kg BMI: 17.36 kg/m2 GEN: No acute distress, Thin. Cachectic appearing. HEENT: Eyes prominent where conjunctiva is visible around entire iris, no thyromegaly. Tongue and uvula covered with white scrapable film, no cervical lymphadenopathy. CV: Normal S1, S2, normal rhythm. No murmurs. Bradycardic (baseline for patient). NEURO: Alert, oriented x3, speech fluent, sensation intact. PSYCH: Quiet, slower to respond compared to baseline. "Spacey," but logical thinking. No tangentiality.
DIFFERENTIAL DIAGNOSIS: Relative energy deficiency in sport Overtraining syndrome Thyroid disease Anemia Viral illness/ Mononoculeosis Diabetes Mellitus Type 1 Malignancy Diabetes Insipidus
TEST AND RESULTS: Urinalysis: Color yellow, Appearance Clear, Specific Gravity 1.035, pH 6.5, Protein Neg., Glucose 3+, Ketone Moderate, Bilirubin Neg., Blood Neg., Nitrite Neg., Leukocyte esterase neg. CBC: WBC 7.3, Hgb. 16.6, Hct. 46, Plt. 268 CMP: Na 130, K+ 5.6, Cl. 88, Bicarb. 27, BUN. 39, Cr. 0.8, Glc. 870, Alk phos. 183, ALT 67, AST 35, Anion Gap 15 TSH 0.27, Free T4 0.9, Free T3 1.5 CRP 0.2 ESR 7 Ferritin 224 HIV Non-reactive Hgb. A1c 13.6
FINAL WORKING DIAGNOSIS:New onset Diabetes Mellitus Type 1 in diabetic ketoacidosis
TREATMENT AND OUTCOMES:Urgent transport to the emergency department for DKA management including insulin and intravenous fluids with several day admission. Endocrinology work-up in process. Plan to follow weekly x 6 weeks and held from sport the remainder of the semester.

Going the Distance Makes Me Tired: Seizure in a Cross Country Runner

Caitlin G. Waters - (Sponsor: Pierre Rouzier, FACSM), James Broadhurst, John H. Stevenson. *UMass Memorial Medical Center, TEWKSBURY, MA.*
(No relevant relationships reported)

HISTORY: 21 y/o M collegiate cross country runner presents to team doctor with hand shaking and body cramping after a strenuous 12 mile run. Complained of generalized weakness, abdominal and leg cramping, nausea, diarrhea, slight shaking of his hands, and thirst. Felt well prior to the run. Endorsed increased thirst this week and had been drinking water. Sent to the ER for IV hydration. On his way to the ER, he suddenly became unresponsive with stiffness, shaking, and frothing at the mouth.

THURSDAY, MAY 31, 2018

PHYSICAL EXAMINATION: Temp: 36.9 Celsius, BP: 140/80, HR: 90-110, RR:21-27, SpO2: 100% on RA, GEN: Responsive, staring. Pale. NAD. Photosensitive. No rigidity. Clear speech. PSYCH: Answers "Yup." to most questions. Occ. confused. Alert. Oriented x3. HEENT: PERRL. EOMI. No LAD. Neck supple. No JVD. CARDIOPULM: CTA B/L. S1, S2, RRR, no MRG, ABD: Soft, NT, ND, no HSM, BS+ , EXT: No edema, capillary refill <2, SKIN: No rash, NEURO: CN II-XII testing limited, but grossly intact. Would not stick out tongue. Opens eyes on request. Normal grasp. Reflexes 2+ DTR's b/l.
DIFFERENTIAL DIAGNOSIS:Metabolic Derangement, Hyponatremia, Hypercalcemia, Hypoglycemia; Rhabdomyolysis/Dehydration; Toxic Encephalopathy; Drug Withdrawal; Intracranial Mass; CNS Infection; Epilepsy
TEST AND RESULTS:Initial Na 118, Anion Gap 17, Bicarbonate 15, Magnesium 1.5, initial CPK 917, CK rose to greater than 60,000 despite IV hydration, Toxicology Negative, CT head: questionable hypodensities in the medial temporal lobe, MRI Brain: normal, EEG: negative
FINAL WORKING DIAGNOSIS: Seizure induced by Hyponatremia Secondary to Psychogenic Polydipsia; Hyponatremia Induced Myopathy
TREATMENT AND OUTCOMES:Sodium corrected in the ICU over a few days. Patient drank a total of 48 oz prior to his run, and 160 oz post-run. Despite hydration and gentle correction of sodium, CK continued to rise. Rhabdomyolysis thought initially due to seizure and muscle breakdown in the setting of aggressive exercise; however, the delayed clearance of CPK raised concerns for glycogen storage deficiency vs genetic dysfunction. Referred to Genetics for a muscle biopsy to rule out glycogen storage deficiency, biopsy pending. Returned to cross country running with strict instructions regarding hydration, runs 5-8 miles without any issues.

2024   Board #4
Different Strokes for Different Folks - Football

Tu Dan Nguyen[1], Mark Chassay, FACSM[1], Jocelyn Szeto[1], Noor Alzarka[2]. [1]*University of Texas Health Science Center at Houston, Houston, TX. [2]Memorial Family Medicine Residency, Sugar Land, TX.*

(No relevant relationships reported)

History:
22-year-old D1 University Football Long Snapper presents to the training room for migraines. He's had migraines for 6-7 years and 4 concussions since HS. The night prior he had a migraine in the temporal region associated with transient left-sided vision loss & left arm numbness for 30-40 minutes. A diffuse headache lasting for 4-5 hours followed. Sumatriptan relieved the pain. He's had increased migraine frequency for the past 6 months. Episodes were described to his neurologist. MRI of the Brain & Cervical Spine were ordered.
Physical Examination:
AF VSS. NAD, well appearing. PERRLA, EOMI, NCAT
Cranial nerves intact, no nystagmus, normal face symmetry, tongue & palate midline
Sensation intact
Strength/tone normal bilaterally
Reflexes 2+
Coordination and gait intact
Differential Diagnosis:
Migraine (hemiplegic/retinal) with brainstem aura
Transient Ischemic Attack or Cerebrovascular Accident
Cerebral Aneurysm
Intracranial space-occupying lesion
Dissection Syndrome
Tests & Results:
MRI Brain w/o contrast: small subacute infarct in the right cerebellum. No mass effect or ICH.
MRI C-Spine: mild degenerative changes. No canal stenosis
Admitted to the hospital further work up. Labwork negative.
US LE w/ doppler - No DVT
CTA head/neck: Normal vessels. No dissection
MRA Neck: Common and internal carotid arteries w/ normal caliber and contour. Normal vertebral arteries. Left vertebral a. is dominant. No flow-limiting stenosis.
TTE: Small right to left shunt on agitated saline contrast study suggestive of a patent foramen ovale.
Transcranial Doppler US Bubble Study: Right to left shunting, showering bubbles
Final / Working Diagnosis:
Cryptogenic subacute right cerebellar infarct secondary to a PFO
Treatment and Outcomes:
Aspirin & Clopidogrel started inpatient. Discharged after workup.
PFO closure and transseptal left heart catheterization completed with Cardiovascular Surgery.
Continue ASA and Clopidogrel for 6 months post-op; ASA lifelong.
Retired from the football team.
Repeat TTE: well seated closure device.
Cardiac rehabilitation for first 2 months post-op.
4 months post-op: running about 1 mile daily, 6 days/week. Endurance and circuit training with low weights.

He's been migraine free since 2 months post-op. He takes Indomethacin as needed. Follow up scheduled for 6 months post-operation.

Forearm Pain- Gymnastics

Melissa Faubert[1], Holly Benjamin, FACSM[2], Daniel Mass[2]. [1]*NorthShore University HealthSystem/University of Chicago, Chicago, IL. [2]University of Chicago, Chicago, IL.*

(No relevant relationships reported)

HISTORY: 14 year old right handed level 8 gymnast presents with complaints of progressive right greater than left elbow and forearm pain over the past four months. Despite bracing, activity modification and three months of physical therapy she still reported progressive worsening of pain and development of tingling in her hands and forearms. She notes she has a constant feeling of tightness over her anteromedial forearms and pain and tingling of her arm occurs the worst while writing in school or vaulting. Pain and numbness resolve with a few minutes of rest and elbow extension. She does not have any nighttime pain. **PHYSICAL EXAMINATION**: - Well appearing female adolescent - Full ROM of elbow, forearm, wrist and fingers - Sensation intact to light touch in the radial, medial and ulnar nerve distribution bilaterally - 5/5 strength in the radial, medial, ulnar, anterior interosseous and posterior interosseous nerves bilaterally - Mild TTP of proximal forearm and medial elbow bilaterally - Positive compression test at the proximal forearm - Positive Tinel's test over the pronator teres - Positive Tinel's test over cubital tunnel - Negative Tinel's, Durkan's and Phalen's at the wrist bilaterally **DIFFERENTIAL DIAGNOSIS**:- Pronator syndrome - Cubital tunnel syndrome - Chronic exertional compartment syndrome of the forearm - Anterior interosseous nerve syndrome - Brachial plexus neuritis - Cervical radiculopathy **TEST AND RESULTS**: MRI elbow Left: MRI findings normal but noted presence of accessory anconeous epitrochlearis muscle. MRI elbow Right: Normal MRI. **FINAL WORKING DIAGNOSIS**: Pronator syndrome bilaterally. Left arm with accessory anconeous epitrochlearis muscle also causing ulnar neuropathy. **TREATMENT AND OUTCOMES**: Patient's older sister previously had pronator syndrome as well as chronic exertional compartment syndrome for which she underwent median nerve release and fasciotomy. Patient and her parents elected to forgo compartment testing suspecting she also had both conditions. She underwent surgery on her left elbow with a median nerve release, ulnar nerve release and fasciotomy. She is due to have surgery on her right arm for median nerve release and fasciotomy three weeks after her left.

Low Back Pain - Recreational Soccer Player

Sean Matsuwaka, Brian Liem. *University of Washington, Seattle, WA.*

(No relevant relationships reported)

HISTORY: A 21-year-old female recreational soccer player presented with intermittent right-sided low back pain for two years. She denied any trauma or inciting event. Pain was localized to the right lumbosacral region without radiating leg pain and was described as dull and aching. It was rated on average 5/10 on a numerical rating scale and associated with nausea when pain worsened. Symptoms were worse with prolonged sitting, and several times in the last month she reported worsening of typical pain with alcohol intake. She denied leg weakness, numbness, or bowel/bladder dysfunction. She participated in six weeks of physical therapy, which helped with nausea and pain with sitting, but she continued to have pain with alcohol consumption.
PHYSICAL EXAM: Full and symmetric strength, sensation, and reflexes. Mild lumbar dextroscoliosis. No palpable step-offs. Tenderness over right lumbar paraspinals and above right iliac crest. No tenderness over PSIS. Full, non-painful range of motion with lumbar flexion and extension. No pain with facet loading. Full, non-painful hip range of motion. Negative FABER, FADIR, and straight leg raise test bilaterally.
DIFFERENTIAL DIAGNOSIS: 1. Discogenic pain 2. Facet-mediated pain 3. Disc herniation 4. Muscular strain 5. Sacroiliac joint dysfunction 6. Intrabdominal/intrapelvic etiology 7. Neoplasm
TESTS AND RESULTS: 1. Lumbar spine X-rays: -Normal alignment, normal vertebral body and disc space height -Partial lumbarization of S1 vertebral body -Five degrees of lumbar dextroscoliosis 2. MRI lumbar spine: -Lumbarization of S1 vertebral body -Normal disc heights and signal -Normal central canal and neural foramen size throughout lumbar spine -T1/T2 hyperintensity within S2 vertebral body, likely lipoma -Increased T2 signal medial to right kidney suggestive of hydronephrosis 3. Renal ultrasound:-Moderate right hydronephrosis with extrarenal pelvis. No nephrolithiasis. 4. Renogram with furosemide: - Right kidney with blunted flow and delayed clearance improved slightly with furosemide, consistent with partial obstruction at right ureteropelvic junction
FINAL/WORKING DIAGNOSIS: Ureteropelvic junction obstruction causing Dietl's crisis
TREATMENT AND OUTCOMES: 1. Referral to urology 2. Resolution of pain and improvement in renal function after pyeloplasty

Chronic Medial Knee Pain in a Collegiate Basketball Player and Marching Band Member

Nicholas E. Anastasio-(Sponsor: Robert Wilder, MD, FACSM), David Hryvniak. *University of Virginia, Charlottesville, VA.*

(No relevant relationships reported)

History:
Patient 1:
A 17 year-old female collegiate basketball player presented with insidious onset right medial knee pain for the last 8 months. Pain waxed and waned with activity. No history of swelling, instability or locking. No numbness or weakness. Pain located diffusely over the medial knee and proximal medial tibia. Symptoms refractory to PT, patellofemoral kinesiotaping, medial arch support orthotics and NSAIDs. No relief following Medrol dose pack, intraarticular corticosteroid injection, or pes anserine bursa corticosteroid injection.
Patient 2:
A 19 year-old female collegiate marching band member presented with insidious onset right medial knee pain present for 4 years. Patient reported intermittent swelling but denied instability or locking. Symptoms were worse with walking and marching. Previous Rheumatologic consult unrevealing. Symptoms refractory to PT, knee sleeve, and patellar straps. No relief following right pes anserine bursa corticosteroid injection.
Physical Examination:
Patient 1 - Knee without effusion. Diffuse tenderness to palpation over the medial knee at and below mid medial joint line. ROM and strength normal. No laxity. Neurovascular intact.
Patient 2 - Knee without effusion. Tenderness to palpation over the medial joint line and distally over pes anserine. Tinel's sign positive over the medial femoral condyle. ROM and strength normal. No laxity. Neurovascular intact.
Differential Diagnosis:
1. Pes anserine bursitis
2. MCL bursitis
3. Patellofemoral syndrome
4. Medial meniscal tear
5. Medial patellar plica
6. Saphenous neuralgia
Test and Results:
Patient 1:
XR Knee - No fracture or joint effusion.
MRI knee - No meniscus tear. No internal derangement. Mild increased T2 signal within the superior lateral aspect of Hoffa's fat.
Diagnostic saphenous nerve block - 0.5% bupivacaine injected 2 inches cephalad to the medial joint line - 24 hours of relief.
Patient 2:
XR Knee - No fracture or malalignment.
MRI knee - Unremarkable MRI of the knee.
Labs - ESR 8, TSH 1.7
Final/Working Diagnosis:
Saphenous Neuralgia
Treatment and Outcomes:
Patient 1:
Saphenous nerve injection - 40 mg triamcinolone/0.5% bupivacaine - 5 months of relief.
US guided hydrodissection saphenous nerve - Full resolution for 1.5 years.
Patient 2:
US guided hydrodissection saphenous nerve - 6 months of relief.

Are Subconcussive Impacts Harmless in Youth Soccer Players?

Luis R. Lopez-Roman[1], Yarimar I. Diaz-Rodriguez[2]. [1]*Universidad del Sagrado Corazon, San Juan, PR.* [2]*Universidad del Turabo, Gurabo, Puerto Rico.*

(No relevant relationships reported)

In United States at least 3.5 million children play soccer yearly. Head Impact (concussive and subconcussive) in youth players have a growing concern throughout their short or long-term career. A subconcussive impact may induce a traumatic alteration of function of the cerebrum without associated imaging abnormalities or loss of consciousness. Accelerometers can measure the magnitude and quantity of the subconcussive impacts in the field. The SIM-G™ accelerometer is a small portable device that measures change in velocity during an impact and provides estimates of magnitude (G) and angles. The ImPACT Pediatric® is a neurocognitive test that provide information of cognitive changes. **PURPOSE:** To evaluate if a subconcussive impact could lead to negative cognitive functions in youth soccer players. **METHODS:** A group of 30 youth soccer athletes (15 males, 15 females) between 9 to 11 years old wear a head accelerometer in a specialize headband. Each

participant was encouraged to perform normally in the game. Descriptive statistics was used to assess subconcussive impacts. T-test was used for the neurocognitive pre and post-test to assess differences in sequential memory, word memory, visual memory and rapid processing. **RESULTS:** Mean age of female and male athletes (9.9 ± 0.6 years) was not different (P > 0.05). A total of 42 impacts were receive by both genders in three games. Range of acceleration was from 16g to 60g (Ave= 23.8 ± 9.1g). T-Test showed differences in sequential memory for female (p = 0.02) and rapid processing for males (p = 0.01). There were no differences between pre and post test in word memory for females and males (p = 0.97, p = 0.11; respectively) and visual memory (p = 0.30, p = 0.34; respectively). **CONCLUSION:** These results suggest that females that play soccer and receive a subconcussive impact can reflect changes in their education and social activities at short term in their word recognition, oral reading and reading comprehension (sequential memory) and males in their auditory processing and language skills (rapid processing). Parents, coaches, trainers, exercise physiologist, and speech-language pathologists (SLP) should receive education to take precautions after a game with children that received at least one sub concussive impact and do not perceived any notable changes.

Test Setting and ADHD Influence Baseline Concussion Testing Neurocognitive Performance in Collegiate Student-Athletes

Caroline A. Kelly, Caroline J. Ketcham, Kirtida Patel, Eric E. Hall, FACSM. *Elon University, Elon, NC.*

(No relevant relationships reported)

Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT) is a widely used neurocognitive test for assessing and managing concussion injuries. There is inconclusive data on how test administration and environment influence baseline results for student-athletes. It has been well established that individuals with Attention Deficit Hyperactivity Disorder (ADHD) perform worse on the ImPACT, but little research has examined the effect of group test administration on neurocognitive performance and symptom reporting in student-athletes with ADHD. **PURPOSE:** To compare baseline neurocognitive performance and symptom scores in group versus individual administration settings in NCAA division 1 collegiate student-athletes. **METHODS:** 260 student-athletes completed two ImPACT baseline tests, test 1 was completed when they entered as first-year students or transfers and test 2 was completed this past summer. Of these participants, 205 athletes took test 1 individually and 55 participants took it in a group setting. All student-athletes took test 2 in a group setting. 21 of the 260 student-athletes had a diagnosis of ADHD. A 2 (time) x 2 (environment) x 2 (ADHD) Multivariate ANOVA was conducted. Time (test 1 and test 2) was within subjects and Environment at test 1 (individual and group) and ADHD (yes or no) were between subject variables. **RESULTS:** There was a significant increase in total number of symptoms reported when participants went from individual testing to group testing (p<0.05). Time x Environment Interaction for visual memory (p<0.05) with scores increasing from test 1 to 2 if in the group setting for both, but staying the same if in the individual setting for test 1. A similar effect was found for visual motor processing speed (p<0.05). Participants with ADHD performed worse on all measures no matter the setting (p<0.05). Symptom scores significantly differed for ADHD participants depending on the setting (p<0.05). **CONCLUSIONS:** A group setting has inherent distractions and seems to influence performance on visual memory, visual motor processing speed and symptom scores. Student-athletes with ADHD may be more affected by these distractions. This should be considered in baseline concussion testing and interpreting post-injury neurocognitive performance.

Jump Training Improves Psychological Impairments and Facilitates Greater Sports Participation in Athletes with ACL Reconstruction

Ryan L. Mizner, Audrey R. Elias. *University of Montana, Missoula, MT.*

(No relevant relationships reported)

PURPOSE: About 35% of athletes with anterior cruciate ligament (ACL) reconstruction fail to return to their preinjury level of sports participation. Psychological factors, such as fear of reinjury, often prevent athletes who wish to return to their sport from achieving their goal. Limited evidence is available to direct patient care to target these psychological impairments. Most ACL injuries are non-contact in nature and typically occur during a deceleration task such as jump landing. We propose that training focused on improving jump landing performance will improve psychological factors and facilitate increased sports participation. **METHODS**: Forty-eight athletes completed screening tests an average of 2 years after unilateral ACLR (Wk0). Testing included the ACL-Return to Sport after Injury (ACL-RSI) scale as measure of psychological readiness for sports participation. Athletes (n = 25, 9 men, age = 23 ± 5 yr) who scored below normative ACL-RSI recovery standards (<65%) completed 8 weeks of twice-weekly jump landing training. Retesting occurred at midtraining (Wk4), posttraining (Wk8), and 2 months after training (Wk16).

Athletes answered a survey measuring perceived changes in sports participation at the end of training. Changes observed during training were determined via repeated measures ANOVA.
RESULTS: ACL-RSI scores improved substantially throughout treatment (mean ± SD; Wk0: 53 ± 18%, Wk4: 67 ± 15%, Wk8: 76 ± 16%; p<0.001). Treatment benefits were maintained over the retention period (Wk16: 81 ± 15%; p=0.052). Four out of 5 athletes trained report that they were more likely to participate in their sports activities after training and two thirds of the cohort described at least a moderate increase in their sports participation.
CONCLUSIONS: Progressively dosed jump training that focuses on correcting aberrant landing movements is effective at addressing psychological factors in athletes who self-identified as having limited readiness for sport. The training was also effective at facilitating increased sports participation. Clinicians should consider implementing similar jump training interventions to help athletes who are struggling to return to their desired sports participation because of limited confidence or high fear of reinjury. Funded in part by the Foundation for Physical Therapy.

2030b   Board #11

Long-term Functional Impact of Viscosupplementation Versus True Placebo in Symptomatic Hip Osteoarthritis; A Randomized Control Trial

Jane Konidis[1], Philippe Corbeil[1], Antoine Cantin-Warren[2], Sylvie Turmel[3], Emile Cardinal-Soucy[1], Remi Lacroix[3], Etienne Belzile[3]. *[1]University Laval, Quebec City, QC, Canada. [2]Center for Interdisciplinary Research in Rehabilitation and Social Intergration (CIRRIS), Quebec City, QC, Canada. [3]University Hospital Center of Quebec (CHUQ), Quebec City, QC, Canada.*
(No relevant relationships reported)

INTRODUCTION: Degenerative hip osteoarthritis (OA) is a common progressive disorder causing disability. The injection of exogenous hyaluronic acid (HA), or viscosupplementation (VS), can potentially help restore the properties of synovial fluid. There is little literature available evaluating the long-term effects and the functional impact of VS in hip OA. **PURPOSE:** To determine if a single intra-articular injection of a high-molecular weight (HMW) VS would improve function and decrease pain in persons suffering from hip OA. **METHODS:** A double-blinded randomized control trial was conducted at a University Hospital Center in Canada. Patients were randomly allocated to either the treatment group, an ultrasound guided single intra-articular injection of a HMW HA, or the placebo group, a single extra-articular injection of local anesthetic. Participants underwent evaluations at 2 weeks prior to the injection (T0), and at 1 month (T1), 3 months (T2) and 6 months (T3) post injection. Patients completed two questionnaires; the Hip Disability and Osteoarthritis Outcome Score (HOOS) and the 36-Item Short Form Survey (SF-36). Gait biomechanics were evaluated in a lab. **RESULTS:** Between May 2014 and September 2017, 38 participants were evaluated in this study over the course of 6 months. In the treatment group, N = 19 and in the placebo group, N = 18. The mean age at the time of injection was 55. On the HOOS symptom subscale, the placebo group worsened from T0 to T3 by 6.29% compared to the treatment group. The VS group improved their pain subtotal from T0 to T2 by 4.73%. The control group worsened by 1.22% during that same time and continued to deteriorate by 6.09% at T3. There were also improvements in the activities of daily living subscale from T0 to T3, with the treatment group improving by 5.29% while the placebo group worsened by 5.15%. The most important change occurred in the sports and recreational subscale of the HOOS. Between T0 and T3, the placebo group worsened by 7.611 points (- 17.82%). The treatment group improved by 6.67%. **CONCLUSION:** Our preliminary results suggest that a HMW VS hip injection for degenerative OA, when compared to true placebo, may lead to long-term improvements in pain relief, increase in function and in activity participation. NIH Clinical Trials Registry: NCT02086474

Lisa S. Krivickas Clinician/Scholar Travel Award - The Prevalence of Hypertension in a Population of Former Professional Football Players

Jaime Kaplan, Genevieve E. Smith, Gregory W. Stewart, FACSM. *Tulane University School of Medicine, New Orleans, LA.*
(No relevant relationships reported)

OBJECTIVE: There is substantial data suggesting that former professional football players have considerable cardiovascular disease risk. The objective of this study was to better understand the prevalence of hypertension, a major risk factor for cardiovascular disease, in former professional football players. **DESIGN:** Data including blood pressure, height, and weight were collected from 981 former professional football players between April 2015 and May 2017 during cardiovascular screening events held throughout the U.S. Demographic information was collected from all subjects, including age, race, previous hypertension diagnosis, and treatment. Means were analyzed using one-way ANOVA, Chi square, or paired T-tests where appropriate. **RESULTS:** Pre-hypertension was greatest for former players aged 20-59, with almost 50% of those aged 20-39 pre-hypertensive at screening. Hypertension was greatest in former players aged 60+, with more than 50% of these individuals hypertensive at screening; over 20% of those 20-39 were hypertensive. White former players aged 60+ had the lowest prevalence of pre-hypertension. Hypertension prevalence was only significantly different between age-specific racial groups at age 40-59. The majority of former players had a BMI ≥ 30 kg/m2, regardless of age; those with normal BMI were least likely to be hypertensive. Over 30% of former players reported previous hypertension diagnosis, with approximately 75% of those diagnosed reporting treatment. Of those former players that reported treatment, most had poorly controlled blood pressure at the time of screening. Of former players that reported no hypertension diagnosis, 41% had elevated blood pressure at screening. Former players aged 30-39 had the highest prevalence of previously undiagnosed elevated blood pressure at screening. **CONCLUSIONS:** Hypertension is a serious concern for former professional football players, even those considered to be younger and at decreased risk. This may be related to the high BMI typically associated with these athletes. Blood pressure control in those reporting diagnosis is also a concern, as the majority of those men had high blood pressure at screening.

THURSDAY, MAY 31, 2018

E-02   Highlighted Symposium - **The Respiratory System in Heart Failure**

Friday, June 1, 2018, 9:30 AM - 11:30 AM
Room: CC-101AB

The lungs have an intimate relationship with the heart. They are hemodynamically linked in series, accepting nearly all of the cardiac output, share a common surface area, compete for space in the thoracic cavity, are exposed to similar intrathoracic pressures and are neurally and humorally linked. Thus, as the heart remodels and function changes in patients with forms of chronic heart failure, the lungs become an important part of the heart failure syndrome. The interdependence is enhanced with exercise. This symposium will highlight current knowledge on the influence of heart failure on the pulmonary system and their interdependence at rest and during exercise.

Precapillary Pulmonary Hypertension in Heart Failure: Potential Cause and Consequences

Bryan J. Taylor[1], Barry A. Borlaug[2], Robert P. Frantz[2], Andrew D. Miller[2], Thomas P. Olson, FACSM[2], Bruce D. Johnson[2]. [1]*Mayo Clinic, Rochester, MN; University of Leeds, Leeds, United Kingdom.* [2]*Mayo Clinic, Rochester, MN.*

(No relevant relationships reported)

Combined pre- and post-capillary pulmonary hypertension (CpcPH) develops in 10-40% of heart failure (HF) patients and is a powerful predictor of short-term mortality. However, the mechanisms that underpin the pathophysiological development of CpcPH in HF remain elusive. In addition, the impact of CpcPH on the pulmonary haemodynamic response to exercise in HF requires further investigation. Purpose. To determine 1) the relationship between systemic oxygen levels and the presence of CpcPH; and 2) the impact of CpcPH on the pulmonary haemodynamic response to exercise in HF patients. Methods. Thirty-nine HF patients undergoing right-heart catheterisation were studied. Blood was drawn for the determination of PaO_2, SaO_2, PvO_2, SvO_2, and vasoactive neurohormones. Pulmonary arterial and wedge pressure (PAP; PWP), transpulmonary pressure gradient (TPG; PAP - PWP) and cardiac output (Q) were assessed at rest and throughout exhaustive incremental exercise. Results. Post catheterization, patients were classified as having no PH (n = 11), isolated post-capillary PH (IpcPH) (n = 11), or CpcPH (n = 17). At rest: PaO_2 and PvO_2 were lower in CpcPH compared to no PH and IpcPH (65 ± 9 vs 78 ± 11 mmHg and 75 ± 14 mmHg; 29 ± 4 vs 36 ± 3 mmHg and 33 ± 2 mmHg; P < 0.05). Also, SaO_2 and SvO_2 were lower in CpcPH vs. no PH ($93 \pm 3\%$ vs $96 \pm 3\%$; $51 \pm 11\%$ vs $68 \pm 4\%$; P < 0.05). TPG was inversely related to PaO_2, PvO_2, SaO_2, and SvO_2 in the CpcPH only ($r \le -0.557$; P < 0.05). Similarly, plasma endothelin-1 correlated with PaO_2, PvO_2, SvO_2 ($r \le -0.495$) and TPG (r = 0.662) (P < 0.05) in CpcPH only. With exercise: At peak exercise, mean PAP (mPAP) and mean PWP (mPWP) were greater in CpcPH compared to no PH and IpcPH. The slope of the mPAP-Q̇ and mPWP-Q̇ relationship during exercise was greater in CpcPH vs IpcPH vs no PH (mPAP-Q̇: 6.7 ± 3.2 vs 4.1 ± 3.9 vs 2.6 ± 1.7 mmHg/L/min; mPWP-Q̇: 4.2 ± 1.4 vs 3.3 ± 1.2 vs 2.9 ± 1.5 mmHg/L/min); however, only the differences between no PH and CpcPH were statistically significant. Conclusion. 1) Systemic hypoxaemia may play a role in the development of CpcPH in HF, potentially via a hypoxia-induced increase in endothelial release of the vasoconstrictor endothelin-1; and 2) the development of CpcPH is associated with greater pulmonary vascular pressures and a steeper pulmonary vascular pressure-to-Q̇ relationship in response to exercise in HF patients.
