[7]Medical College of Wisconsin, Milwaukee, WI.* (Sponsor: Steven P Broglio, FACSM)

(No relevant relationships reported)

Purpose: Examine the relative risk of concussion between males and females across three U.S. Service Academies based on level of sport competition, participation in physical education classes, military training, and free time activities.
Methods: We conducted a prospective cohort study using data from the Concussion Assessment, Research and Education (CARE) Consortium at three U.S. Service Academy sites (U.S. Military, U.S. Air Force, U.S. Coast Guard). Between August 2014 and June 2017, 10,603 participants were enrolled across the three sites. Participants were actively followed for incident concussions following enrollment. Incidence proportions, risk ratios (RR), and 95% confidence intervals (CI) were calculated by sex for concussions sustained by level of sport participation, physical education, military training, and free time activities.
Results: Of the 10,603 participants enrolled, 10,599 (n=2521 female) had complete data for the current analysis and 639 sustained a concussion during the follow-up period. The overall incidence of concussion across all sites was 6.03 (95%CI: 5.58-6.50) per 100 subjects. Females were nearly twice as likely (RR=1.93, 95%CI: 1.65-2.25, p<0.001) to sustain a concussion across all three academies regardless of activity. Females participating in club sports (RR=1.52, 95%CI: 1.06-2.19, p=0.022), physical education classes (RR=2.06, 95%CI: 1.49-2.86, p<0.001), military training (RR=2.32, 95%CI: 1.49-3.60, p<0.001) and free time activities (RR=2.83, 95%CI: 1.91-4.20, p<0.001) were also at significantly higher risk for injury. There were no differences in concussion risk among males and females participating in NCAA varsity (RR=1.11, 95%CI: 0.81-1.55, p=0.499) or intramural athletics (RR=1.04. 95%CI: 0.48-2.28, p=0.902). This held true even when football athletes and injuries were removed from the analysis for NCAA varsity athletes (RR=1.38, 95%CI: 0.96-1.98, p=0.077).
Conclusions: These preliminary findings suggest that the risk of concussion among females is nearly twice as high when compared to males at U.S. Service Academies. This increased risk ranges from 1.5 to nearly 3 times higher when compared to males across a number of activities. Further analysis is needed to better understand the factors associated with this sex discrepancy.

Trends In Concussion Incidence In High School Sports, 2008-09 To 2015-16

John D. Reynolds[1], Andrew E. Lincoln[2], Shane V. Caswell[3], Reginald E. Dunn[2], Lisa H. Hepburn[2]. *[1]Fairfax County Public Schools, Fairfax, VA. [2]MedStar Health, Baltimore, MD. [3]George Mason University, Manassas, VA.*

(No relevant relationships reported)

Although many studies have documented the effects of concussions in high school athletes, few recent studies have analyzed incidence rates of concussions in high school contact sports.
PURPOSE: To explore recent trends in sports concussion at the high school level for the period 2008-09 to 2015-16 in light of changes in concussion-related legislation, educational requirements, and public awareness.

METHODS: Sport-related concussion data were prospectively reported in an electronic medical record-keeping program by certified athletic trainers for 25 high schools in a large public school system over a consecutive eight-year period (academic years 2008-09 to 2015-16). The population included 115,439 student athletes over the study period in six boys' sports (football, soccer, lacrosse, wrestling, baseball, and basketball) and six girls' sports (soccer, lacrosse, basketball, cheerleading, softball, and field hockey). Incidence rates and rate ratios were calculated.
RESULTS: Over the eight years, there were 7,419 concussion injuries in 7,789,818 Athlete-Exposures (AEs), for an overall incidence rate of 0.95 concussions per 1000 AEs. Football (n=3118, 1.85 per 1000 AEs) accounted for 42% of all concussions and had a concussion rate nearly 9 times greater than baseball (n=108, 0.21 per 1000 AEs). Among girls' sports, cheerleading experienced the highest number of concussions (n=587, 0.89 per 1000 AEs), while girls' soccer had the highest incidence rate (n=525, 0.97 per 1000 AEs). The overall (12-sport) concussion rate increased 39% from 0.54 per 1000 AEs in 2008-09 to 0.76 per 1000 AEs in 2015-16. During this time, there was a 149% rise in overall concussion rate from 2008-09 to its peak in 2011-12 (1.35 per 1000 AEs), followed by a 44% decline to 2015-16.
CONCLUSION: This study presents the first evidence of a significant decline in high school sport-related concussion rates, which occurred from 2011-12 to 2015-16. The decline may reflect the combined effects of local school district policy changes and education programs, passage of a state concussion education law, nationwide rule changes within individual sports, more effective protective equipment, and changes in player behavior and technique.

Concussion Incidence in United States High School Boys' Ice Hockey, 2008/09-2015/16 School Years

Juleah M. Heath[1], Lauren A. Pierpoint[2], John M. Rosene[1], Zachary Y. Kerr[3]. *[1]University of New England, Biddeford, ME. [2]Colorado School of Public Health, Aurora, CO. [3]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

(No relevant relationships reported)

In recent years, the sport of ice hockey has grown in participation and popularity. Subsequently, there is a greater interest in the risk of injuries associated with participation, particularly concussions at the high school level. **PURPOSE:** To examine the concussion rates and mechanisms in high school boys' ice hockey in the 2008/09-2015/16 school years. **METHODS:** Data were obtained from the National High School Sports-Related Injury Surveillance System (HS RIO) during the 2008/09-2015/16 school years. HS RIO used a convenience sample of high school boys' ice hockey programs. Athletic trainers provided detailed reports on injuries and athlete-exposures (AE). Injury rates per 1,000AE, injury rate ratios (IRR), and injury proportion ratios (IPR) with 95% confidence intervals (CI) were calculated. **RESULTS:** Overall, 323 concussions were reported during the 2008/09-2015/16 school years, of which most occurred during competition (85.4%) and in-season (92.9%). These concussions were reported across 467,278AE, for a concussion rate of 0.69/1,000AE. The concussion rate was higher in competition than practice (1.75 vs. 0.15/1000AE; IRR=11.51; 95%CI: 8.45, 15.68). Most concussions were due to contact with another player (47.1%), followed by contact with the boards/glass (31.6%). Concussions occurred while being checked (36.5%), skating (28.2%), and chasing a loose puck (10.5%). Most concussions occurred in wings (47.1%), followed by defensemen (28.5%) and centers (11.5%). When comparing injury mechanism distributions between being checked and checking, the proportion of concussions due to contact with another player was higher in checking than being checked (68.8% vs. 41.5%; IPR=1.66; 95%CI: 1.12, 2.45). Of the seven concussions sustained by goalies, 42.9% were due to contact with the puck; in comparison, no concussions among all other competition positions had concussions reported to be due to contact with the puck. **CONCLUSION:** Concussions in high school boys' ice hockey occur mainly in competition and result from player contact. These concussions appear to be position dependent with the highest incidence occurring to wings. Examination of adaptations to the checking rule or teaching the checking technique may lead to a reduction in concussive events.

The Effect of Concussion on Subsequent Musculoskeletal Risk in High School Athletes

Alex Nusbickel, Ashley Zapf, Brady Tripp, Terrie Vasilopoulos, Daniel Herman, FACSM. *University of Florida College of Medicine, Gainesville, FL.*

(No relevant relationships reported)

PURPOSE: Prior studies in collegiate and professional athletes have noted an increased risk of musculoskeletal (MSK) injury after concussion; however, the effect in younger athletes at lower levels of competition is unknown. This study compared the risk of MSK injury in concussed high school athletes after return to play to that of non-concussed athletes.

METHODS: High school athletic training room electronic medical records from the 2010-2011 to the 2014-2015 seasons were queried for time-loss concussion and MSK injury in football, volleyball, basketball, soccer, lacrosse, baseball, and softball athletes from twelve local high schools. Concussed athletes were assessed for presence of MSK injury within 365 days prior to and subsequent to the concussion. Non-concussed athletes who experienced MSK injury were assessed for the presence of a second MSK injury within 365 days. Non-injured athletes were recorded for every year without injury. Chi-square analyses were conducted to compare the frequency of subsequent musculoskeletal injury in the athlete-years with prior concussion, prior concussion with prior musculoskeletal injury, and neither prior musculoskeletal injury or concussion. Odds ratios with 95% confidence intervals were calculated, and significance was set a-priori at P = 0.05.
RESULTS: Of the total number of athlete-years in this study (n=14461), 1.8% sustained a concussion and 8.3% experienced a MSK injury within a year of concussion. MSK injury was significantly associated with previous concussion (p < 0.001), and athletes with a concussion displayed nearly three times the likelihood of subsequent MSK injury in the following year when compared to those without previous concussion (OR=2.9, 95%CI: 1.9-3.7). This relationship proved similar in both male (OR=2.9, 95%CI: 2.1-4.0) and female (OR=2.8, 95%CI: 1.3-6.3) athletes. However, no difference in rates of later MSK injury was observed in the athletes with prior MSK injury or a combination of prior MSK injury and concussion (p= 0.34).
CONCLUSIONS: High school athletes who sustain a concussion display an elevated risk of subsequent MSK injury at rates comparable to higher-level concussed athletes and to athletes who have sustained a prior MSK injury. Neuromechanical rehabilitation during concussion recovery may be needed to moderate this effect.

Risk of Lower Extremity Musculoskeletal Injury after Concussion: A Meta-Analysis

April McPherson[1], Takashi Nagai[1], Kate Webster[2], Timothy Hewett, FACSM[1]. [1]Mayo Clinic, Rochester, MN. [2]LaTrobe University, Melbourne, Australia.
(No relevant relationships reported)

Estimates of the incidence of sport-related concussions range from 1.6 to 3.8 million cases per year. Short- and long-term consequences of concussion are continued topics of intensive research. In addition to an increased risk of suffering a second concussion or musculoskeletal (MSK) injury upon return to sport (RTS), long-term term sequelae include increased risk of mild cognitive impairment to severe neurodegenerative disease. Several recent studies have investigated the effect of concussion on lower extremity MSK injury.
PURPOSE: To perform a systematic review and meta-analysis to determine the risk of lower extremity MSK injury after concussion.
METHODS: A comprehensive search of electronic databases through to September 2017 was performed by two independent reviewers and supplemented by manual searches of the reference lists of included studies. Two search concepts were used; the first terms were 'cognition', 'brain', and 'brain injuries'; the second were 'athletic injuries' and 'lower extremity.' Studies were included if they reported the number of lower extremity injuries in athletes after RTS from a concussion diagnosis. Nine studies were included for data extraction and analysis. Data regarding number of injuries after concussion were combined via odds ratio (OR) and incidence rate ratio (IRR) meta-analysis using a random effects model. 95% confidence intervals (CI) were also calculated.
RESULTS: Seven of the nine included studies individually reported higher rates of lower extremity MSK injury after concussion, while two reported no significant difference in injury risk between concussed athletes and non-concussed control athletes. Results of the meta-analysis show that athletes who suffered a concussion had 2.06 times the odds of sustaining a lower extremity injury after RTS compared to a control group (OR = 2.06, 95% CI 1.48-2.88). Athletes who suffered a concussion had a 1.67 times higher incidence rate of lower extremity injury per athletic exposure after RTS (IRR = 1.67, 95% CI 1.42-1.96).
CONCLUSION: Based on the evidence of higher risk of lower extremity MSK injuries after concussion, concussed athletes should be examined not only for their cognitive function prior to RTS, but also screened for neuromuscular risk factors associated with lower extremity MSK injuries.

Concussion Symptom Clusters And Return-To-Play Time In College Athletes With Sports-Related Concussions: 2009-2010, 2013-2014 DISC

Adrian J. Boltz[1], Marc H. Feinberg[2], Terry D. Smith[1], Tammie M. Johnson[1], Michael R. Richardson[1], James R. Churilla, FACSM[1]. [1]University of North Florida, Jacksonville, FL. [2]Florida Atlantic University, Boca Raton, FL. (Sponsor: James R. Churilla, FACSM)
(No relevant relationships reported)

PURPOSE: Examine the relationship between Concussion Symptom Clusters (CSCs) and return-to-play time using a representative sample of college athletes with sports-related concussions. **METHODS:** Data from the 2009-2010 and 2013-2014 academic years (n=1670) were obtained from the Datalys Center for Sports Injury and Prevention Inc. database. Exploratory factor analytic methods were applied, and the resulting factors were used in multinomial regression modeling to identify associations between CSCs and return-to-play time. **RESULTS:** A 4-factor solution accounted for 48.8% of the variance and included an audio-vestibular, somatic, amnesic, and affective factor structure. Audio-vestibular symptoms were associated with increased odds of prevented participation at 7-13 days, 14-29 days, greater than 30 days, and out for remainder of season, respectively (p<0.05). Somatic symptoms were associated with decreased odds of prevented participation at 7-13 days and greater than 30 days, respectively (p<0.05). Amnesic symptoms were associated with decreased odds of prevented participation at 1-6 days, 7-13 days, 14-29 days, and greater than 30 days, respectively (p<0.05). Affective symptoms were associated with decreased odds of prevented participation at 7-13 days, 14-29 days, greater than 30 days, and out for remainder of season, respectively (p<0.05). **CONCLUSIONS:** Specific CSCs were significantly associated with return-to-play time in college athletes, (p<0.05).

Longitudinal Study Of Concussion In 6-14 Year Old Football Players Measuring Incidence, Risk Factors And Duration Of Symptoms

Sara P. Chrisman[1], Wren L. Haaland[2], Stanley A. Herring, FACSM[3], Emily Kroshus[2], Teah R. Hoopes[2], Shannon K. Higgins[2], Frederick P. Rivara[1]. [1]Seattle Children's Research Institute and University of Washington, Seattle, WA. [2]Seattle Children's Research Institute, Seattle, WA. [3]University of Washington, Seattle, WA. (Sponsor: Stan Herring, FACSM)
(No relevant relationships reported)

Football is a popular sport, but is not without risk. Concern has been raised about concussion in youth football. However, there is little data regarding concussion risk or natural history of concussion for youth younger than high school. **PURPOSE:** To collect prospective data regarding: 1) incidence of concussion, 2) risk factors for concussion, and 3) natural history of concussion in 6-14 year old football athletes. **METHODS:** We conducted a prospective cohort study with youth football athletes and their parents during a 10-week season. Youth who sustained a concussion were contacted weekly to determine mechanism of injury and time to return to: 1) school 2) sport and 3) baseline concussion symptoms. Logistic regression was used to estimate odds of sustaining a concussion based on baseline demographic factors. Baseline measures of mental health and concussive symptoms were compared between concussed and non-concussed youth using Student's t-tests. Time to return to school, sport and baseline symptoms were examined using survival curves. **RESULTS:** 610 youth were followed and 38 sustained a concussion, for a one season athlete-level concussion incidence of 5.9%. Two-thirds occurred during games and approximately half from head to head collisions. Youth with a history of concussion had a 3-fold increased risk for sustaining an incident concussion, and those with history of depression had a 5-fold increased risk. No other demographic factors were associated with increased risk for concussion. Following a concussion, 50% of athletes returned to school by 3 days, 50% returned to sport by 10 days, and 50% returned to a baseline level of symptoms by 2.5 weeks. Two youth returned to sport before their symptoms had returned to baseline levels, but no complications were noted with these youth. **CONCLUSIONS:** Concussion rates in this study were higher than previously reported, affecting 6 out of every 100 youth playing for one season. History of prior concussion and history of depression were both associated with greater risk. Further research is needed to explore ways to continue to improve safety in youth football. Funding for this project was provided by Seattle Pediatric Concussion Research Collaborative and the University of Washington Sports Health and Safety Institute.

94   Board #8   May 30 9:30 AM - 11:30 AM

Concussion Is Associated With Adverse Health Outcomes: A 15-Year Follow-Up Of Former College Football Players

Zachary Y. Kerr[1], Leah C. Thomas[1], Janet E. Simon[2], Michael McCrea[3], Kevin M. Guskiewicz, FACSM[1]. [1]University of North Carolina at Chapel Hill, Chapel Hill, NC. [2]Ohio University, Athens, OH. [3]Medical College of Wisconsin, Milwaukee, WI. (Sponsor: Kevin Guskiewicz, FACSM)
(No relevant relationships reported)

Previous research has found an association between concussion and adverse health outcomes in former professional football players. Less is known about such an association in former players without professional football experience. **PURPOSE:** Examine whether concussion history - without professional football exposure - was associated with adverse health outcomes in former college football players, 15 years following their collegiate playing career. **METHODS:** A sample of 204 former collegiate football players that played at least one season of football in 1999-2001 and did not play professional football completed an online questionnaire. Data included: lifetime concussion history; Physical Composite Score (PCS) and Mental Composite Score (MCS) from the Veterans RAND 36 Item Health Survey; the depression module of the Patient Health Questionnaire (PHQ-9); and the CAGE alcohol dependence questionnaire. Multivariable binomial regression models estimated prevalence ratios (PR) with 95% confidence intervals (CI) while controlling for demographics/playing history covariates through forward selection model building. **RESULTS:** Overall, 84.3% reported a concussion history; 22.1% and 39.2% of participants reported PCS and MCS scores <50, respectively (i.e., worse health than US national averages); 19.1% reported PHQ-9 scores ≥10 (i.e., moderate/severe depression) and 24.8% reported CAGE scores ≥2 (i.e., alcohol dependence). The prevalence of having MCS <50 was higher in those reporting ≥3 versus 0 concussions (PR=2.5; 95% CI: 1.3, 4.9). Controlling for body mass index (BMI), the prevalence of moderate/severe depression was higher in those reporting ≥3 versus 0 concussions (PR=4.2; 95% CI: 1.0, 16.3). Controlling for BMI, the prevalence of having PCS <50 was higher in those reporting ≥3 versus 1-2 concussions (PR=2.6; 95% CI: 1.3, 5.0), but not 0 concussions (PR=1.5; 95%CI: 0.6, 3.6). No associations were found for alcohol dependence. **CONCLUSION:** Associations between multiple concussions and adverse health outcomes were found in former collegiate football players without professional football exposure, but were limited to those reporting ≥3 concussions. Continued examination within non-professional football populations is needed, but findings highlight a need for concussion prevention efforts.

Cell-free, Circulating Dna As A Novel Marker For Player Load In Soccer

Nils Haller, Susanne Helmig, Pascal Taenny, Julian Petry, Sebastian Schmidt, Perikles Simon. *Sports Medicine, Mainz, Germany.*
(No relevant relationships reported)

PURPOSE: The relevance of biomarkers reflecting internal player load in intermittent sports such as football is questionable, so far. Increased levels of circulating DNA (cfDNA) have been demonstrated in a variety of exercise settings. Recently, it has been shown that cfDNA increased depending on intensity and duration during aerobic running. In this context, cfDNA was suggested to be applied in intermittent exercise, however the effects of short repeated sprinting as an essential feature of intermittent sports on cfDNA values are unknown. For the first time, we assessed both alterations of cfDNA due to repeated sprinting and due to a professional football game. **METHODS**: First, nine participants were subjected to a standardized sprint training session in a cross-over design of five maximal sprints of 40 meters with either "short" (1 minute) or "long" pauses (5 minutes) in between. Capillary cfDNA and lactate were measured after every sprint and venous cfDNA before and after each series of sprints. In addition, capillary cfDNA and lactate values were monitored in 23 professional football players during the course of a training week at rest (baseline) and in all 17 enrolled players following a regular season game. Game data in terms of total distance, sprints and intense runs was recorded for each player using the OPTA-System. **RESULTS**: Venous cfDNA and lactate increased in "short" (2.8-fold, p<0.0001 and 5.6-fold, p<0.0001) and less pronounced during "long" (1.9-fold, p=0.0051 and 3.6-fold, p<0.0001). The season game increased cfDNA 22.7-fold (p<0.0001) and lactate 2.0-fold (p=0.09) compared to baseline. CfDNA increases correlated with distance covered during game (spearman's r=0.87, p=0.0012), while no correlation between lactate and the tracking data could be found. **CONCLUSIONS**: Here we show for the first time that cfDNA could be an objective marker for player load in intermittent sports reflecting total distance covered during professional soccer.

97   Board #2   May 30 9:30 AM - 11:30 AM

Detection of Functional Overreaching in Endurance Athletes Using Proteomics

David C. Nieman, FACSM[1], Arnoud Groen[2], Artyom Pugachev[2], Gianmarco Vacca[3]. [1]Appalachian State University, Kannapolis, NC. [2]ProteiQ Biosciences GmbH, Berlin, Germany. [3]Università degli Studi di Milano-Bicocca, Milan, Italy.
(No relevant relationships reported)

There is a strong demand for diagnostic tools to identify athletes in various training states. **PURPOSE:** To determine if a cluster of proteins could be identified through proteomics procedures that are linked to functional overreaching (FOR) in male endurance athletes. **METHODS:** Participants (N=10, age 38.3±3.4 y, VO_{2max} 41.3±1.7 ml·kg^{-1}·min^{-1}) served as their own controls and in random, counterbalanced order either ran/cycled 2.5 h (70.0±3.7% VO_{2max}, 79.6±6.3% HR_{max}) three days in a row (FOR) or sat in the lab (rest) (separated by three weeks) (7:00 - 9:30 am, overnight fasted state). Participants provided fingerprick samples for dried blood spot samples (DBS) pre- and post-exercise/rest each of the three days, and then at 7:00 am during two additional recovery days. Participants also completed the Training Distress Scale (TDS) (19-items) at 7:00 am each of the five mornings during each trial (FOR and rest). Proteins were solubilized from DBS, digested into peptides and measured with nanoLC-MS in data independent acquisition mode (Q-Exactive, Thermo Fisher Scientific, Waltham, MA). The RAW MS data files were processed using Spectronaut™ software (Biognosys, Schlieren, Switzerland). Following data independent acquisition (DIA method), 594 proteins were identified and quantified. Proteins were considered for the FOR cluster if they were elevated during one of the two recovery days but not more than one of the exercise days (compared to rest). The Generalized Estimating Equation (GEE) was used to identify proteins linked to FOR (between trial contrasts, P≤0.05 for proteins with CV<15%, P≤0.01 with CV>15%). **RESULTS:** TDS scores differed between FOR and rest trials, peaking on the first recovery day (9.8±3.8, 3.5±2.6, respectively, P=0.029). A total of 13 proteins was linked to FOR and of these, 11 were related to the immune system, and two to exercise-induced physiological responses. Immune-related proteins included those associated primarily with the acute phase response, complement activation, and granulocyte function. **CONCLUSIONS:** This study utilized targeted, DIA proteomics procedures to identify a cluster of 13 proteins linked to FOR (7.5 h of high intensity exercise over three days), and 85% of the proteins were related to immune system activation during the 2-day recovery period.

Changes In Functional Activation Of Memory T Cells Following Exercise: A Pilot Study

Hunter D. Peterson, Alexander K. Holbrook, Allyson Ihlenfeldt, Brad W. Macdonald, Samantha A. Bianchi, Eric C. Bredahl, Michael A. Belshan, Jacob A. Siedlik. *Creighton University, Omaha, NE.* (Sponsor: Joseph P. Weir, FACSM)
(No relevant relationships reported)

Memory T (T_M) cells function to provide long-lasting protection against re-exposure to pathogens. The recall response of T_M cells to foreign antigen is quicker and of a greater magnitude than a naïve T cell. How functional activation is altered in T_M cells following a bout of exercise is not well known. **PURPOSE:** To quantify exercise induced changes in surface markers of early, middle, and late stage activation in memory T cells (CD4$^+$CD45RO$^+$CD45RA$^-$) obtained from human subjects. **METHODS:** Utilizing a cross over design, untrained subjects completed a control and exercise visit. The control visit consisted of 30 min of seated rest while the exercise session entailed 3 sets x 10 reps squat at 70% 1-RM, 3x10 leg press at 70% 1-RM, and 3x10 leg extensions at 70% 1-RM with 2 min rest between sets. Venous blood samples were obtained pre and post each visit. CD4$^+$ T cell isolation from peripheral blood was conducted through negative selection using a Human CD4$^+$ T cell enrichment kit. CD4$^+$ T cells were plated at 1.5 x 10^6 cells/ml in 200 µl of ImmunoCult T-cell expansion media directly after isolation and costimulated through CD3+CD28 or no stimulation. Cells were incubated for 1 and 3 d at 37°C in a humidified incubator with 5% CO$_2$ and then analyzed by flow cytometry. Early (CD69), middle (CD25),

and late (HLA-DR) markers of activation within the CD45RO$^+$CD45RA$^-$ subset were quantified at days 0, 1, and 3. Data were analyzed using two-way RMANOVAs. **RESULTS:** There were no significant differences in any markers of activation at the pre measure (p > .05). Preliminary data suggests exercise does not alter functional activation in non-stimulated CD45RO$^+$CD45RA$^-$ cells. There does appear to be a functional impact related to the T_M cells ability to respond to stimuli post-exercise with two-fold increases observed in HLA-DR expression for cells co-stimulated through CD3+CD28. **CONCLUSIONS:** Exercise-induced alterations in functional activation of T_M cells will need to be better quantified to determine not only the magnitude of change, but also to identify a kinetic profile of marker expression. Quantification of changes in this subset of cells will aid in our understanding how immune responses following vaccination are affected by exercise stress.

PURPOSE: To examine the influence of the Ultraman triathlon (3 days of non-continuous racing; stage 1: 10 km swim and 144.8 km cycle; stage 2: 275.4 km cycle; stage 3: 84.4 km run) on circulating plasma concentrations of whole-body (CRP, IL-6, and IL-10) and gut-specific inflammatory markers (IL-17 and IL-23) in trained participants (N = 17; 14 men, 3 women), and determine whether these variables influence performance. **METHODS:** Fourteen triathletes (age: 39 ± 8 yrs) were evaluated pre-race and post-race for circulating concentrations of CRP, IL-6, IL-10, IL-17, and IL-23. Blood samples were drawn two days prior to stage 1 (1600 h) and one day after stage 3 (1200 h). Plasma biomarker concentrations were determined by ELISA according to manufacturer's instructions. Data were analyzed with SPSS and significance was accepted at p < 0.05. Values are reported as means ± SD. Data points (for blood biomarkers) greater than 2 SD from the mean were removed as outliers. **RESULTS**: Plasma CRP significantly increased from pre-race (266.27 ± 276.18 ng/mL) to post-race ($25,891.94 \pm 12,888.65$ ng/mL; p < 0.001). Plasma IL-10 increased from pre-race (3.46 ± 2.98 pg/mL) to post-race (5.15 ± 1.89 pg/mL). Pre-race concentrations of IL-6 were below detectable limits; post-race IL-6 concentrations were 4.00 ± 3.74 pg/mL. Both pre-race and post-race concentrations of IL-17 and IL-23 were below detectable limits. Pearson's correlation between mean finish time and post-race CRP and post-race IL-10 was 0.35 and 0.54 (p < 0.05), respectively. **CONCLUSIONS**: The significant increase in CRP during the race may have been due to muscle damage. The greater anti-inflammatory capacity of the athletes likely led to increased clearance of IL-6, IL-17, and IL-23 the day after the race; the increase in IL-10 concentrations during the race reflect this anti-inflammatory response. A significant positive correlation between post-race IL-10 concentrations and mean finish time may indicate that a relationship between anti-inflammatory responses and performance exists.

Development Of A Consumer-Oriented Microbiome Tracker

Shawn M. Talbott, FACSM[1], Marc P. Oddou[2], Bret J. Stephens[2]. [1]*EQQIL, Draper, UT.* [2]*Wasatch Scientific Services, Murray, UT.*
Reported Relationships: **S.M. Talbott:** *Ownership Interest (Stocks, Bonds); Partner in development of BiomeTracker.*

Background: Interest in and knowledge of the gut microbiome has increased exponentially in the past decade. This once overlooked component of the gastrointestinal tract is now implicated in multiple aspects of human health, including mental wellness (e.g. depression, anxiety, stress), metabolic (e.g. diabetes, obesity), neurologic (e.g. Alzheimer's, autism), gastrointestinal (e.g. irritable bowel syndrome, Crohn's), and immunologic (e.g. inflammation, cancer), among others. **Purpose/Objectives:** Currently, most laboratory methods to test the microbiome rely on 16S ribosomal RNA sequencing. This testing method has several drawbacks, including: slow turnaround time, inconclusive quantification of low abundance species, labor intensive library preparation, and relatively high cost. Furthermore, the output is generally geared toward the scientific community, and are not particularly intuitive for the general public (e.g. consumers, patients). **Methods:** Herein, we have developed a consumer-facing microbiome test and scoring system (BiomeTracker) that provides an attractive alternative to 16S rRNA-based testing services. This system allows samples to be processed quickly at low cost, and provides an easy to understand

score for bacterial composition and health. **Results:** BiomeTracker analysis was performed in parallel with 16S sequencing for human fecal samples, with similar abundance quantification for major phyla through families of bacteria. As a proof of concept, patient baseline and final samples following microbiome intervention (diet and supplementation) were tested, and BiomeTracker was able to accurately assess changes of low abundant species known to function in a healthy gut. **Conclusions:** We envision that this system can be used by scientists and consumers alike to more quickly and easily evaluate the efficacy of dietary interventions on microbial composition and function.

CD4$^+$ T Cell Activation Markers Altered Following Resistance Training In Untrained Subjects: A Pilot Study

Brad W. Macdonald, Alexander K. Holbrook, Allyson Ihlenfeldt, Hunter D. Peterson, Samantha A. Bianchi, Eric C. Bredahl, Michael A. Belshan, Jacob A. Siedlik. *Creighton University, Omaha, NE.* (Sponsor: Joseph P. Weir, FACSM)
(No relevant relationships reported)

Assessment of immune function in response to exercise is commonly done via proliferative assays. These assays are often performed on mixed cell populations and fail to quantify discrete activation elements upstream of the proliferative response. Together these factors limit our ability to understand how subsets of immune cells respond to exercise and hinder our ability to target interventions towards a specific cellular response. **PURPOSE:** To quantify exercise-induced changes in surface markers of early, middle, and late stage activation in CD4$^+$ cells. **METHODS:** Utilizing a cross over design, untrained subjects completed a control and exercise visit. The control visit consisted of 30-min seated rest while the exercise session entailed 3 sets x 10 reps squat at 70% 1-RM, 3x10 leg press at 70% 1-RM, and 3x10 leg extensions at 70% 1-RM with 2 min rest between sets. Venous blood samples were obtained pre and post each visit. CD4$^+$ T cell isolation from peripheral blood was conducted through negative selection using a Human CD4$^+$ T cell enrichment kit. CD4$^+$ T cells were plated at 1.5×10^6 cells/ml in 200 μl of ImmunoCult T-cell expansion media directly after isolation and costimulated through CD3+CD28 or no stimulation. Cells were incubated for 1 and 3 d at 37°C in a humidified incubator with 5% CO$_2$ and then analyzed by flow cytometry. Purity of cell samples was assessed following T cell isolation (day 0) by staining with anti-CD4. Data analyses utilized two-way RMANOVAs. **RESULTS:** There were no significant differences in any markers of activation at the pre measure (p > .05). Preliminary data suggests there exists two separate effects: 1) An exercise alone effect with alterations in CD25 expression observed in the non-stimulated cells, and 2) An exercise effect on the ability of cells to respond to stimuli with changes in CD25 and HLA-DR expression observed in cells co-stimulated through CD3+CD28. **CONCLUSION:** Exercise induced alterations in T cell activation likely need to be quantified on a subset basis. Using mixed cell populations limits the development of exercise strategies targeting improvements in specific factors of immune function, and possibly leading to misinterpretation of exercise-derived immunological data.

The Effects of Resistance Exercise Training on Depressive Symptoms: A Meta-Analysis of Randomized Controlled Trials

Brett R. Gordon[1], Cillian P. McDowell[1], Mats Hallgren[2], Jacob D. Meyer[3], Mark Lyons[1], Matthew P. Herring[1]. [1]*University of Limerick, Limerick, Ireland.* [2]*Karolinska Intitutet, Stockholm, Sweden.* [3]*Iowa State University, Ames, IA.*

(No relevant relationships reported)

The physical benefits of resistance exercise training (RET) are well documented. Less is known regarding the effects of RET on mental health outcomes. Recent meta-analytic evidence supported the anxiolytic effects of RET, but no quantitative synthesis of the effects of RET on depressive symptoms has been conducted.
Purpose: To estimate the effect of RET on depressive symptoms, and to determine whether variables of logical, theoretical, and/or prior empirical relation with depressive symptoms account for significant variation in the overall effect.
Methods: Fifty-four effects were derived from 33 articles published before August 2017, located using Google Scholar, MEDLINE, PsycINFO, PubMed, and Web of Science. Trials involved 1,877 participants (mean age=52 ± 18 years) and included both randomization to RET (n=947) or a non-active control condition (n=930) and a validated measure of depressive symptoms assessed at baseline, mid-, and/or post intervention. Hedges' d effect sizes were computed and random effects models were used for all analyses. Meta-regression was used to examine participant and trial characteristics as moderators of the overall mean effect.
Results: RET significantly reduced depressive symptoms by a moderate-sized mean effect Δ of 0.66 (95%CI: 0.48-0.83; z=7.35; p<0.001). Significant heterogeneity was indicated ($Q_{T(53)}$=216.92, p<0.001, I^2=76.03%, 95%CI: 72.67%-78.97%), and sampling error accounted for 32.9% of observed variance. Total volume of prescribed RET, participant health status, and strength improvements were not significantly associated with the overall effect of RET on depressive symptoms. However, smaller reductions in depressive symptoms were found in trials with blinded allocation and/or assessment (Δ=0.56, 95%CI: 0.40-0.71; z=7.03 p<0.001).
Conclusions: The available empirical evidence supports the antidepressant effects of RET. RET significantly reduced depressive symptoms in otherwise healthy participants and those with a physical or mental illness. Improvements were not moderated by total prescribed volume of RET or significant improvements in strength. Higher quality randomized controlled trials that blind both allocation and assessment and compare RET to other empirically-supported treatments for depressive symptoms are needed.

The Relationship Between Affect And Enjoyment During High-intensity Interval Training In Overweight Sedentary Adults

Marcus W. Kilpatrick, FACSM, Andrew M. Rice, Jacob D. Stankich, Shelbey E. Lane. *University of South Florida, Tampa, FL.*

(No relevant relationships reported)

Intense exercise is well-established as a methodology for improving metabolic health and performance parameters, both via continuous and high-intensity interval training (HIIT). Research to date has demonstrated that more intense exercise tends to produce less favorable affective and enjoyment responses but the relationship between these two variables has not been established. **PURPOSE:** Assess the relationship between affective and enjoyment responses during HIIT and moderate continuous exercise among overweight and insufficiently active adults. **METHODS:** 48 overweight-to-obese participants (mean BMI = 28, mean VO2 peak = 29 ml/kg/min) completed four counterbalanced trials comprised of a 30-minute continuous trial at 33% peak power (CONT) and three 20-minute interval trials that alternated between 85% and 15% peak power using 1:1 work-to-recovery ratios: 15 secs (HIIT-15), 30 secs (HIIT-30), and 60 seconds (HIIT-60). Affect was measured using the Feeling Scale (FS) and enjoyment was measured using the Exercise Enjoyment Scale (EES). **RESULTS:** Data was submitted to RM ANOVA and correlational analyses. Findings indicated that affect and enjoyment declined during HIIT-60 but was preserved during all other trials. All correlations for assessments taken at the same point during exercise

were significant (p < 0.05) ranging from 0.31 to 0.70. Inspection of the correlation values indicate that the correlation decreased during the CONT trial (0.62 to 0.31) but remained relatively constant for all three HIIT trials. Additionally, correlations were slightly higher in the HIIT-60 trial than other HIIT trials. **CONCLUSIONS:** Findings indicate that correlations between affect and enjoyment are strong during HIIT and continuous moderate exercise. The finding that correlations decreased over time during the moderate continuous condition suggests a dissociation between the processes that underlie affect and enjoyment. Likewise, the maintenance of similar correlations throughout all of the HIIT trials suggests that within this particular exercise context that the underlying processes are not considerably unique. Collectively, the findings indicate that HIIT produces affective and enjoyment responses that are generally positive and therefore appropriate for overweight, sedentary populations.

Affective Responses To High-Intensity Interval Training In The Severe Domain

Robert W. Pettitt, FACSM[1], Zachery A. Roloff[2], Luke M. Krynski[2], Mark E. Hartman[3], Panteleimon Ekkekakis, FACSM[3], Nathan D. Dicks[4]. [1]*Rocky Mountain University of Health Professions, Provo, UT.* [2]*Minnesota State University, Mankato, Mankato, MN.* [3]*Iowa State University, Ames, IA.* [4]*North Dakota State University, Fargo, ND.*

(No relevant relationships reported)

High-intensity interval training (HIIT) has been used to enhance critical power (CP); yet, research on prescriptions using the CP concept is limited. The dual-mode theory (DMT) of affective responses suggests that participants would report homogenous reduction in pleasure above CP; but, supporting research is based predominantly upon incremental exercise responses. **Purpose**: We investigated affective responses to HIIT prescriptions of different intensities and durations derived using CP and the finite work capacity >CP (W'). **Methods:** Eight competitive cyclists completed a 3-min all-out exercise test with a verification bout for determining peak oxygen uptake (VO_{2peak}). On separate occasions, HIIT bouts were performed on a cycle affixed to a CompuTrainer. The Feeling Scale (FS) was administered each minute. **Results:** VO_{2peak} (ml·kg⁻¹·min⁻¹) values from the verification bout (58.7 ± 6.9), 4 X 3-min 60%W' condition (57.4 ± 8.2), 3 X 3-min 80% W' condition (58.3 ± 5.7), 4 X 5-min 60% W' condition (54.3 ± 8.0), and the 4 X 5-min 80% W' condition (55.7 ± 7.4) did not differ (F = 2.10, p = 0.25). Strong measurement agreement was observed for VO_{2peak} across conditions (ICC$_a$ = 0.85, typical error = 2.37 ml·kg⁻¹·min⁻¹, coefficient of variation = 4.6%). Time- and interval-dependent reductions in FS were observed with each interval condition, culminating with negative FS ratings (i.e., displeasure). **Conclusion**: The 60% and 80% W' HIIT conditions for either the 3 or 5 min durations evoked consistent VO_{2peak} values and negative ratings of affect. These data provide empirical support for the CP concept to standardize HIITs and provide more stable conditions for systematic affective responses to severe exercise using the FS.

Relationship Of Exercise Intensity Tolerance To Cardiometabolic Risk Factors And Body Composition In Healthy Females

Elise C. Brown, Mary A. Elsesser, Samantha C. Orr, Timothy A. Rengers, Ryan T. Tyler, Evan Eschker, Tamara Hew-Butler, FACSM, Charles R.C. Marks, Myung D. Choi, Kristen R. Landis-Piwowar. *Oakland University, Rochester, MI.*

(No relevant relationships reported)

When compared with moderate-intensity exercise, high-intensity exercise has been found to result in superior or equal improvements in cardiometabolic (CMB) health and body composition. However, individual differences exist in one's ability to tolerate higher intensities of exercise which may put those with a lower tolerance at risk for less favorable CMB health and body composition. **PURPOSE:** Therefore, the purpose of this study was to examine the associations of exercise intensity tolerance and individual CMB risk factors and body composition variables in young adult females. **METHODS:** The sample consisted of 25 non-obese [body mass index (BMI) < 30 kg/m2] apparently healthy females aged 22.6 ± 4.2 years examined in a cross-sectional study. After obtaining informed consent, each participant had measures of exercise intensity tolerance using The Preference for and Tolerance of the Intensity of Exercise Questionnaire, individual CMB risk factors, and body composition including anthropometric and imaging variables assessed. Spearman's rho (ρ) was computed to examine the bivariate correlations between exercise intensity tolerance and CMB risk factors and body composition variables. Statistical significance was set a priori at P≤0.05. **RESULTS:** Exercise intensity tolerance was associated with a number of CMB risk variables including resting heart rate (ρ = -0.56, P < 0.01), systolic (ρ = -0.48, P = 0.01) and diastolic (ρ = -0.57, P < 0.01) blood pressure, total cholesterol (ρ = -0.53, P < 0.01), triglycerides (ρ = -0.52, P < 0.01), and low-density lipoprotein (LDL) cholesterol (ρ = -0.48, P = 0.02). For body composition, exercise intensity tolerance was correlated with waist-to-height ratio (WHtR) (ρ = -0.48, P = 0.02),

bone mineral content ($\rho = 0.42$, P = 0.04), bone mineral density ($\rho = 0.47$, P = 0.02), bone density T-score ($\rho = 0.49$, P = 0.02), and bone density Z-score ($\rho = 0.46$, P = 0.02). **CONCLUSIONS:** Exercise intensity tolerance was negatively associated with resting heart rate and blood pressure, total cholesterol, triglycerides, LDL, and WHtR, and positively associated with bone density variables. These findings suggest that as exercise intensity tolerance increases, so does the favorability of CMB health and bone density in young adult females.

A Follow-up Study on the Rehabilitation Effect of Tai Chi for Female Individuals with Substance Abuse

Dong Zhu[1], Guobin Dai[1], Ding Xu[2]. [1]Shanghai University of Sport, Shanghai, China. [2]Shanghai Drug Administration, Shanghai, China.
(No relevant relationships reported)

PURPOSE: The aim of this study was to investigate the relapse of female amphetamine type stimulants (ATS) dependents who had received rehabilitation treatment after 4 years.
METHODS: Eighty female individuals with ATS dependence were randomly assigned to Tai Chi intervention (TC) and standard care (SC) for 6 months. The TC group was tutored for exercise intervention based on a simplified 24-Form Tai Chi, and the exercise activities in the SC group included 5 minutes of recreation activity (Guang Bo Ti Cao), 5 minutes of gesture language exercises, and self-study. Outcome measurements were applied with Pittsburg Self-Rated Sleep Quality Index (PSQI), Self-rated Depression Scale (SDS), and fitness evaluation at the baseline, 3 months and 6 months. A follow-up relapse investigation was also conducted. The investigation content was relapse of ATS dependents who had completed treatment from Shanghai mandatory detoxification and rehabilitation center (SMDRC). Pearson chi-square test was applied for categorical variables and independent sample t-test was applied for continuous variables at the baseline comparison, repeated measures analysis of variance was applied with year of drug dependent as the covariate.
RESULTS: 4 ATS dependents in TC and 10 ATS dependents in SC were found relapse, the relapse in the TC group was 9.5% and in the SC group was 26.3%. The cessation duration of ATS dependents from left SMDRC to be found relapse was 517 days in TC and 219 days in the SC group, the numbers of relapse in TC was significantly less than that of in SC group tested by chi-square test. The PSQI scores of sleep duration, need for sleep medications, daytime dysfunction were found to have a significant difference by time × group interaction after 6 month. The SDS showed no significant difference between the two groups, but the score of SDS in TC decreased after 6 months intervention and no changes in SC. The pulse rate was significantly decreased in the TC group compared to the SC group after 6 months.
CONCLUSIONS: The 4 year follow-up study indicated that TC is a cheap and potential supplementary treatment for ATS dependents. The results provided an evidence that Tai Chi can reduce female ATS dependents relapse.

108   Board #6   May 30 9:30 AM - 11:30 AM

Cognitive Reappraisal Improves Psychological State During Endurance Exercise

Grace E. Giles[1], Julie A. Cantelon[1], Marianna D. Eddy[1], Tad T. Brunyé[1], Heather L. Urry[2], Holly A. Taylor[2], Caroline R. Mahoney[1], Robin B. Kanarek[2]. [1]U.S. Army Natick Soldier Research, Development, and Engineering Center, Natick, MA. [2]Tufts University, Medford, MA.
(No relevant relationships reported)

Topic 702: Cognition and Emotion
Title: Cognitive reappraisal improves psychological state during endurance exercise
Giles, G.E.[1,2,3], Cantelon, J.A.[1,2,3], Eddy, M.D.[1,2,3], Brunye, T.T.[1,2,3], Urry, H.L.[1,3], Taylor, H.A.[1,3], Mahoney, C.R.[1,2,3], Kanarek, R.B.[3]
[1]US Army Natick Soldier, Research, Development, and Engineering Center [2]Center for Applied Brain and Cognitive Sciences [3]Tufts University
PURPOSE: To determine whether emotion regulation strategies, specifically cognitive reappraisal and distraction, influence psychological state and prefrontal cortex oxygenation during endurance exercise.
METHODS: Twenty four individuals (15 female; age 18-33 years) participated. All ran regularly: at least 30 miles per week, with at least one run per week of 9 miles or more. On three separate occasions, participants ran for 90 minutes at 75-85% age-adjusted maximum heart rate while employing one of three emotion regulation strategies: no instruction, cognitive reappraisal, i.e. reevaluating the running experience to reduce felt negative emotions, and distraction, i.e. re-directing attention by focusing on neutral thoughts unrelated to the running experience. Participants completed subjective measures of valence (on a scale from "very bad" to "very good"), arousal ("low arousal" to "high arousal") and perceived exertion ("no exertion at all" to "maximal exertion") before, every 30 minutes during, and after exercise. Functional near-infrared spectroscopy (fNIRS) was used to quantify changes in prefrontal cortex oxygenation (O_2Hb).

RESULTS: Participants felt lower emotional arousal and physical exertion when instructed to utilize cognitive reappraisal than when given no emotion regulation instruction, but not when instructed to utilize distraction. Emotion regulation strategies did not influence emotional valence or prefrontal cortex oxygenation.
CONCLUSION: Emotion regulation strategies benefit psychological state during endurance exercise, independent of reductions in prefrontal cortex oxygenation.

Effect Of Continuous Exercise At Self-selected Intensity And Hiit On Psychophysiological Responses In Overweight Women

Sergio G. da Silva[1], Sandro S. Ferreira[1], Lucio Follador[1], Erick D. Garcia[1], Ragami C. Alves[1], Vinicius FS Andrade[1], Sara C. Barbosa[1], Leticia M. Oliveira[1], Carlo Baldari, FACSM[2]. [1]Universidade Federal do Parana, Curitiba, Brazil. [2]IUniversity of Rome "Foro Italico", Rome, Italy.
(No relevant relationships reported)

PURPOSE: To compare the effects of continuous exercise at self-selected intensity and high-intensity interval training (HIIT) on physiological, perceptual, and affective responses in overweight women. **METHODS:** Twenty-eight overweight or obese women were randomly assigned to 1 of 2 groups: continuous exercise at self-selected intensity (SS, n = 14) or high-intensity interval training (HIIT, n = 14; 10 x 60 s). Both groups underwent 4 weeks of training, 3 days/week, 20 min each session, on a cycle ergometer. Rating of perceived exertion (RPE; OMNI-Cycle), affective responses (pleasure/displeasure; Feeling Scale), and heart rate (HR) were recorded during each session. Peak oxygen uptake (VO_{2peak}), body mass, and maximal power were assessed pre- and post-intervention. **RESULTS:** A two-way ANOVA revealed no effect of the intervention on BMI and maximum power output in both groups. VO_{2peak} increased similarly in both groups (SS pre: 22.9 ± 2.9 ml.kg^{-1}.min^{-1}, post: 25.4 ± 4.5 ml.kg^{-1}.min^{-1}; HIIT pre: 24.8 ± 3.9 ml.kg^{-1}.min^{-1}, post: 26.9 ± 4.2 ml.kg^{-1}.min^{-1}) ($p < .05$). Across the 4 weeks of the intervention, %HR (week 1: 77.7 ± 7.1; week 2: 75.9 ± 7.6; week 3: 75.4 ± 8.2; week 4: 76.6 ± 6.3) and RPE (week1 : 4.7 ± 1.2; week 2: 4.8 ± 1.2; week 3: 4.5 ± 1.6; week 4: 4.5 ± 1.7) were lower compared to HIIT (week 1: 83.3 ± 5.6; week 2: 82.1 ± 5.5; week 3: 82.4 ± 6.2; week 4: 81.7 ± 6.1) and (week 1: 5.4 ± 1.6; week 2: 5.7 ± 1.5; week 3: 5.4 ± 1.6; week 4: 5.1 ± 1.6) ($p < .05$). **CONCLUSION:** Four weeks of SS or HIIT had similar effects on cardiorespiratory fitness. SS was perceived as less strenuous, however, both groups exhibited similar affective responses.

110   Board #8   May 30 9:30 AM - 11:30 AM

Examining The Effects of Functional Resistance Training on Affect, State Anxiety and Enjoyment in College-Age Females

Jamie Faro[1], Phil Gona[1], Marisa Hastie[2], Laura L. Hayman[1], Julie Wright[1], Jessica Whiteley[1]. [1]University of Massachusetts Boston, Boston, MA. [2]Lasell College, Newton, MA.
(No relevant relationships reported)

College-aged females, who are less likely to meet ACSM resistance training (RT) guidelines than males, face a number of barriers to RT adoption and maintenance. Females experience more perceived barriers to RT (such as enjoyment, pleasure, embarrassment and anxiety) suggesting that programs could be developed to address these barriers. Functional RT (FRT) uses multi-joint exercises similar to activities of daily life and has yet to be compared to traditional RT using machines (TRT) to determine the effects of acute sessions in this population. **PURPOSE:** To compare the effects of an acute bout of both a functional and traditional RT program on affect, state anxiety (SA) and enjoyment. **METHODS:** Female students (n=27) ages 18-35 years (26±4.3 years; BMI=25.2±5.3 kg/m²) not currently meeting RT guidelines completed 4 trainer-led RT sessions (2 FRT, 2 TRT) within 4-weeks (2-7 days apart) in a randomized crossover design. Session 1 of each RT type familiarized participants to the exercises, while session 2 consisted of 2 sets of 10 repetitions at a moderate intensity (using RPE scale) and collection of assessment measures. Affect and SA were assessed pre, post, and 15 minutes post, while enjoyment was assessed at post. **RESULTS:** RPE did not differ significantly between types of training (FRT 5.8±1.2; TRT 6.2±1.1; p=0.09). Repeated measures ANOVA revealed no significant differences in change scores pre to post or 15 minutes post in affect (both p>0.05) nor SA (both p>0.05) between FRT and TRT; however, pre to post-exercise changes in affect were positive and greater in FRT (d=+.87) compared to TRT (+.77), and greater in decreases in SA (FRT, d=-.53; TRT, d= -.43). Between group results indicate enjoyment levels were significantly greater following FRT compared to TRT (p<0.05). Secondary outcomes reveal within-group increases in positive affect and decreases in SA pre to post and 15 minutes post-exercise (all p<0.05) in both types of RT. **CONCLUSION:** While no differences in affect or SA were found between types of RT, participants had significantly greater enjoyment levels following the FRT session.

Though both FRT and TRT sessions increased affect and decreased SA, higher levels of enjoyment following FRT may lead to increased adoption rates acutely and possibly increase the percentage of college-females meeting ACSM RT guidelines.

The Influence of Oral Contraceptive Use on Skeletal Characteristics of Female Collegiate Rowers

Breanne S. Baker, Ivy E. Brown, Michael G. Bemben, FACSM, Allen Knehans, Debra A. Bemben, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Dr. Debra Bemben, FACSM)

(No relevant relationships reported)

Physical activity promotes an osteogenic response leading to greater bone mineral density (BMD). Previous studies suggest women who use oral contraceptives (OC) may not experience the same magnitude of skeletal benefits from exercise compared to women not using OC. These findings are important for athletes competing in sports with a high prevalence of low BMD and fracture, such as rowing. **PURPOSE:** To examine skeletal health, OC usage, and injury rates in collegiate competitive female rowers. **METHODS:** Data from two cross-sectional studies were used to investigate body composition and skeletal attributes in 49 NCAA Division I female rowers. DXA was used to measure body composition and areal BMD (aBMD) of the total body, lumbar spine, and dual femur. pQCT was used to measure bone geometry of the 4%, 38%, 66% tibiae sites. **RESULTS:** There were no significant differences between OC users (n=14) and non-users (n=35) for age, height, weight, fat mass, bone free lean body mass, age at menarche, calcium intake, training volume, or years of rowing experience (p≥0.340). OC users had significantly greater total body aBMD, dual femoral neck (FN) aBMD, and dual total hip (TH) Z-Scores (p≤0.05). Bone strength index was greater in the non-dominant tibia of OC users at the 4% site (p=0.017). For tibiae 38% and 66% sites, OC users had greater cortical area and thickness, while non-users had greater endosteal circumference (p≤0.047). Rowers who reported fractures had significantly lower rib aBMD, non-dominant trochanter Z-Scores, and 66% tibiae muscle cross-sectional area compared to rowers who did not report fractures (p≤0.049). **CONCLUSIONS:** Rowers who use OC had greater bone density and quality at most sites as compared to non-users. Our findings suggest that in this population OC usage does not impair skeletal health.

Table 1. Skeletal differences between OC users and non-users.

Variable	OC Users (n=14)	Non-users (n=35)
Total Body aBMD (g/cm²)	1.305 ± 0.029*	1.241 ± 0.014
Dual FN aBMD (g/cm²)	1.206 ± 0.028*	1.132 ± 0.018
Dual TH Z-Score	1.008 ± 0.249*	0.358 ± 0.148
Mean 38% vBMD (mg/cm³)	966.63 ± 10.47**	914.77 ± 9.15
Mean 38% Cort Thickness (mm)	6.33 ± 0.10**	5.71 ± 0.09

T Cells Accumulate In Skeletal Muscle Following Contraction-induced Damage To A Greater Degree In Women

Michael R. Deyhle, Kaitlyn Evans, Chris Sutton, Seth Hampton, Jacob Parmley, Jacob R. Sorensen, 84602, Allen Parcell, FACSM, Robert Hyldahl, 84602. *Brigham Young University, Provo, UT.*

(No relevant relationships reported)

Immune cells, such as macrophages and monocytes are active participants in muscle repair/regeneration following damage. Recent studies have identified T cells as important mediators of effective muscle regeneration following traumatic injury. A few studies have reported that T cells also accumulate in muscle following damaging contractions, suggesting that they may also be involved in muscle repair and adaptation following contraction-induced damage. However, it is not clear: 1) when T cell accumulation peaks in following contraction-induced damage and 2) whether muscle T cell accumulation is different between men and women. The **PURPOSE** of this study was to identify the time course of CD8+ T cell accumulation following contraction-induced damage in men and women. **METHODS:** Six men and three women (22.2 ± 2.4 years of age) did 300 (30 sets of 10 reps) maximal-effort lengthening contractions (LC) of the knee extensor muscles using an isokinetic dynamometer. Maximal isometric torque of the knee extensors was measured before LC and at 5min, 24h and 72h-post. Muscle biopsies (vastus lateralis) were taken before LC and at 3h, 24h, and 72h-post LC. Intermuscular CD8+ T-cells were counted with immunohistochemistry and fluorescence microscopy. **RESULTS**: Compared to baseline values (207.2 ± 37 Nm), maximal isometric torque was significantly reduced 5min after (106 ± 45.7 Nm), 24h after (107 ± 50 Nm), and at 72h after LC (112 ± 70 Nm) (p<0.05). Torque loss between men and women was not different (p>.05), suggesting a similar degree of muscle damage. Intermuscular CD8+ cells were increased at 72h-post LC compared to baseline (5 fold, p=0.0008), 24h-post LC (3.2 fold, p=0.0016), and 3h-post LC (3.1 fold, p=0.018). T cell content before LC was not different between men and women, but accumulation following LC was significantly greater in women compared to men (Sex*Time, p=0.01). **CONCLUSIONS**: Following contraction-induced damage, muscle CD8+ T cell content peaks at or later than 72h, and the accumulation appears to be more robust in women than men.

Sex-Related Differences in Muscle Composition and Motor Unit Firing Rates of the First Dorsal Interosseous.

Mandy E. Wray, Adam J. Sterczala, Jonathan D. Miller, Hannah L. Dimmick, Trent J. Herda. *University of Kansas, Lawrence, KS.*

(No relevant relationships reported)

PURPOSE: To determine sex-related differences motor unit (MU) firings during a high intensity contraction and muscle composition of the first dorsal interosseous (FDI) in recreationally trained individuals. METHODS: Nine males (mean±SD: age = 22±3 yr, height = 180.0±6.3 cm, weight = 73.4±10.3 kg, BMI = 22.5±3.3 kg/m²) and 11 females (mean ± SD: 164.23.7 cm, weight = 63.65.3 kg, BMI = 23.6± 2.1 kg/m²) recreationally active individuals volunteered for this study. The FDI was isolated and measured during abduction of the index finger against a metal force plate. A 5-pin electromyographic (EMG) sensor array was placed over the FDI to record muscle activity. EMG signals collected during the submaximal muscle actions were decomposed to extract action potentials and firing events of single MUs. Subjects completed isometric trapezoidal muscle action at 70% maximal voluntary contraction (MVC). Recruitment thresholds (RTs) and mean firing rates (MFR) at the targeted steady force were calculated for each MU and analyzed with a linear relationship for each subject. Normalized EMG amplitude was recorded for each subject at the targeted steady force. In addition, ultrasound scans of the FDI were completed prior to the experimental visit in order to determine the muscle cross-sectional area (CSA), echo intensity (EI), and subcutaneous fat (SF). Independent samples t-tests were analyzed to compare mean differences between males and females. RESULTS: Males had a significantly larger CSA (p<0.001) and peak torque during the MVC (p<0.001), while females had significantly higher y-intercepts from the MFR vs. RT relationship (p=0.036) with no differences in the slopes (p=0.398). No differences were found in normalized EMG (p=0.398), EI (p=0.423), and SF (p=0.400). CONCLUSION: Males have greater CSA, more contractile area, and generated more force. During the 70% MVC, females had significantly greater y-intercepts from the MFR vs. RT relationships, but slopes were similar. These relationships indicated greater MFRs of MUs with RTs from 25.1 to 59.2 in females. Greater MFRs for females may have been necessary to achieve the targeted force as a result of weaker higher-threshold MUs.

Effects of Estrogen Receptor Alpha and Progesterone on Skeletal Muscle Fatigue and Recovery

Christine A. Cabelka[1], Brittany C. Collins[2], Cory W. Baumann[1], Espen E. Spangenburg[3], Dawn A. Lowe, FACSM[1]. *[1]University of Minnesota, Minneapolis, MN. [2]University of Utah, Salt Lake City, UT. [3]East Carolina University, Greenville, NC.*

(No relevant relationships reported)

Skeletal muscle function declines with aging, most notably at the time of menopause. Human and rodent research indicates that estrogen-based hormone therapy can attenuate the declines. However, the role of the major estrogen receptor in skeletal muscle (ER α) remains unclear. While estrogen appears to play a predominant role in maintenance of muscle strength the other key ovarian hormone, progesterone, has been implicated in protection against muscle fatigue. **Purpose:** We hypothesized

1) voluntary wheel running would not protect mice lacking estrogen receptor α in skeletal muscles (skmERαKO) against fatigue and 2) treatment with progesterone after ovariectomy would protect against fatigue. **Methods:** Study 1: 32 skmERαKO mice and WT (Flox) littermates were randomized into 4 groups: skmERαFlox-Run, skmERαKO-Run, skmERαFlox-Sed, and skmERαKO-Sed. Run groups were given free access to wheels for 20 wk. Sedentary mice remained in standard cages. *In vivo* and *in vitro* muscle contractility was measured at wk 20. Study 2: 40 female C57Bl/6J mice ran on wheels for 2 wk and then randomized into 4 treatment groups: E2, P4, E2+P4, or OVX. All mice underwent OVX, ran for another 2 wk, hormone pellets were implanted, and then mice returned to running wheels for 6 wk before *in vitro* soleus muscle contractility testing was completed. **Results:** Study 1: *In vivo* isometric, concentric and eccentric torque was low in skmERαKO groups compared to WT (p< 0.029). Additionally, muscles of skmERαKO mice had greater fatigue (p<0.001) and did not recover strength as well as WT (p<0.001). Study 2: After 60 fatiguing contractions, soleus muscles of the OVX+E2+P4 group maintained greater submaximal force than those of other groups (p<0.05). Immediately after the fatiguing contractions, OVX+E2+P4 muscles had greater maximal force production than the OVX+E2 group (p=0.027). **Conclusion:** SkmERαKO mice produce less force regardless of physical activity. Although 20 wks of wheel running partially prevented force loss during fatigue in skmERαKO mice, force production during recovery remained low, indicating that estrogens function through ERα in skeletal muscle. A combined treatment of E2+P4 protected soleus muscles against fatigue, suggesting both hormones have roles in preventing muscle fatigue. This work was supported by NIH grant R01-AG031743.

Increased Quadriceps Muscle Attenuation Correlates With Reduced Cellular And Whole Muscle Function In Older Women

Chad R. Straight[1], John D. Chase[1], Philip A. Ades[2], Michael J. Toth[2], Mark S. Miller[1]. [1]*University of Massachusetts Amherst, Amherst, MA.* [2]*University of Vermont, Burlington, VT.*
(No relevant relationships reported)

PURPOSE: Adiposity adversely affects physical function in older adults, but the mechanism underlying this relationship remains unknown. The aim of this study was to examine ectopic fat located in or around muscle fibers, as reflected in the measurement of muscle tissue attenuation derived from computed tomography, and its relationship with skeletal muscle function in older adults from the molecular to the whole muscle level.
METHODS: Healthy older men and women had their body and thigh composition characterized by dual-energy X-ray absorptiometry and computed tomography, and their knee extensor function by dynamometry. Isometric tension (force per cross-sectional area) and myofilament stiffness properties were measured on single muscle fibers obtained from biopsies of the vastus lateralis.
RESULTS: Older women had greater absolute and relative body and thigh fat (all p < 0.05). However, quadriceps muscle attenuation was similar between sexes (51.4 ± 50.3 HU for men and women, respectively; p = 0.33). In women, lower quadriceps attenuation, representing greater fat deposition, was related to decreased whole muscle isometric torque (r^2 = 0.21; p < 0.05) and isokinetic power (r^2 = 0.18; p < 0.05), but no association was evident in men. In older women, lower quadriceps attenuation was associated with decreased isometric tension in myosin heavy chain (MHC) I (r^2 = 0.17) and IIA (r^2 = 0.36) muscle fibers (both p < 0.05). At the molecular level, lower quadriceps attenuation was associated with reduced myofilament lattice stiffness of MHC IIA fibers in older women (r^2 = 0.26; p < 0.05), but not men. Greater myofilament lattice stiffness, in turn, was strongly associated with higher isometric tension in MHC I (women r^2 = 0.30; men r^2 = 0.17) and IIA (women r^2 = 0.53; men r^2 = 0.40) fibers in both sexes (all p < 0.05); however, relationships were stronger in women.
CONCLUSIONS: Despite similar quadriceps muscle attenuation between sexes, impairments in force generation at the cellular and whole muscle levels were present only in older women. Our results suggest that greater quantities of fat in the muscle microenvironment alter skeletal muscle ultrastructure in ways that decrease myofilament stiffness, leading to reduced myosin-actin cross-bridge force transmission, and ultimately impaired cellular and whole muscle function.

Myosin Super-relaxed State is Affected by Aging in Female But Not Male Skeletal Muscle

Sira M. Karvinen[1], Lien A. Phung[2], Brett A. Colson[3], David D. Thomas[2], Dawn A. Lowe, FACSM[2]. [1]*University of Jyväskylä, Jyvaskyla, Finland.* [2]*University of Minnesota, Minneapolis, MN.* [3]*University of Arizona, Tuscon, AZ.* (Sponsor: Dawn A. Lowe, FACSM)
(No relevant relationships reported)

Muscle weakness is consistently reported as an independent risk factor for high mortality in aged individuals. In aging females, ovarian hormone deficiency that occurs during menopause has a role in the loss of skeletal muscle strength. At the molecular level, the loss of muscle force production may be attributed to the slowing of myosin-actin cross-bridge kinetics and different structural states of the myosin head is key. There are three distinct functional states of the myosin head: active state, relaxed state (RX) and super-relaxed state (SRX). The SRX state is emerging as an important factor in muscle mechanics and regulation, yet its possible role in aging process has remained elusive. A previous study showed that estradiol-mediated signaling reversibly regulated ATP turnover in SRX state, which in turn may contribute to the age-related decline in muscle strength and function in females. **PURPOSE**: To further evaluate the role of ovarian hormones in SRX regulation during aging, we measured the SRX population and ATP turnover rate in skeletal muscle fibers from female and male mice during natural aging process. **METHODS**: The population of myosin heads in the SRX state and ATP turnover rate were measured in chemically skinned skeletal muscle (psoas) fibers from young (3-4 months old) and aged (28 months old) C57BL/6 female and male mice. Quantitative confocal microscopy of fluorescent MANT-ATP turnover was used to detect and quantitate myosin SRX in the fibers. **RESULTS**: In female mice, fibers from aged animals had faster SRX and RX myosin ATP turnover rates compared to those from young mice (SRX: 94 ± 6s vs 117 ± 9s, p = 0.033 and RX: 18 ± 1s vs 25 ± 2s, p < 0.001). There was no difference in turnover rates between fibers from young and aged male mice (SRX: p = 0.804 and RX: p = 0.202). We found no differences in the population of myosin heads in RX and SRX states between young and aged fibers in either sex (p ≥ 0.100). **CONCLUSION**: Our results indicate that ovarian hormones rather than aging process per se influence the myosin SRX state. This work was supported by R01-AR032961, R37-AG26160, T32-AR007612, and R01-AG031743.

The Effects Of Whole-body Vibration On Posture, Balance, And Mobility In Women With Multiple Sclerosis

Eduardo Freitas, Christine Frederiksen, Ryan M. Miller, Aaron D. Heishman, Japneet Kaur, Karolina J. Koziol, Bianca A. R. Galletti, Debra A. Bemben, FACSM, Michael G. Bemben, FACSM. *University of Oklahoma, Norman, OK.* (Sponsor: Michael G. Bemben, FACSM)
(No relevant relationships reported)

PURPOSE: To investigate the effects of acute and chronic WBV on postural control, balance, and mobility in women with relapsing remitting multiple sclerosis (RRMS). **METHODS**: Twenty-one women were divided into a whole-body vibration (WBV: n=12) and a control (CON: n=10) group. WBV was submitted to 5 sets of vibration (30 Hz of magnitude and 3 mm of amplitude) for 30 s each with 1 min between trials maintaining a squat position with slight flexion of knees, hips, and ankle. CON group was not submitted to any vibration, but mimicked the vibration exposure by standing on the platform in a squat position. For the acute response, all measures were performed immediately pre and post for both testing conditions at week 1 and week 5. For the chronic adaptation, measurements were performed at baseline and after 5 weeks of WBV once a week. Participant's postural sway and balance were measured using a NeuroCom Balance Master. Field tests were used to measure mobility, fatigue, and flexibility and included timed-up and go test, 500 m walk, and seat reach flexibility. Two-way repeated measures ANOVA were used to test for group and time main effects. **RESULTS**: Acutely, no significant differences were observed for the field tests at week 1 or 5 (p>0.05); but, significant group*time interactions (p<0.05) revealed that WBV induced more stability as results from the sensory organization test improved from pre to post for the WBV group while it decreased for CON, at week 1 and 5. However, there was also a significant group*time interaction for the unilateral stance test, in which the CON group was significantly more stable (p>0.05) than the WBV group, at week 5. Chronically, WBV group presented greater stability as a significant group*time interaction (p>0.05) showed that participants in the WBV group improved their scored in the modified clinical test for sensory integration of balance, while CON decreased. Additionally, a significant group*time interaction (p>0.05) reviewed that WBV also increased walking speed, as CON decreased. Finally, a significant group*time interaction (p=0.05) reviewed that CON improved flexibility, when pre to post percent changes were calculated from week 1 to 2. **CONCLUSION:** Acute WBV did not improve postural balance, stability or mobility any in women with RRMS. However, chronic exposure improved stability and mobility.

Decreased Gait Variability Following Anterior Cruciate Ligament Reconstruction Negatively Impacts Patient Function

Terry L. Grindstaff[1], Meredith Chaput[1], Brooke Farmer[1], Kayla Anderson[2], Amelia S. Lanier[2], Amelia S. Lanier[2], Brian A. Knarr[2], Christopher Wichman[3], Kimberly A. Turman[4]. [1]*Creighton University, Omaha, NE.* [2]*University of Nebraska at Omaha, Omaha, NE.* [3]*University of Nebraska Medical Center, Omaha, NE.* [4]*GIKK Ortho Specialists, Omaha, NE.* (Sponsor: Joan Eckerson, FACSM)

(No relevant relationships reported)

Limited knee motion and increased movement variability during gait occurs following anterior cruciate ligament reconstruction (ACL-R). Previous study findings have limited clinical application since they only included male participants and did not describe impairments in context to patient function. **PURPOSE:** To quantify differences in nonlinear measures of sagittal plane movement variability during running in individuals within 2 years of ACL-R compared to a healthy group. A secondary purpose was to determine the relationship between movement variability and patient-reported outcome measures. **METHODS:** Nineteen individuals with a history of ACL-R (13 female, 6 male; mean±SD age= 20.1±5.6 y; height= 172.9±8.0 cm; mass= 70.3±13.6 kg; time since surgery= 12.2±5.2 months; International Knee Documentation Committee subjective knee scale [IKDC]= 87.7±13.4) and twenty healthy participants (11 female, 9 male; age= 20.2±4.2 y; height= 175.6±9.6 cm; mass= 69.4±12.1 kg; IKDC= 97.2±4.3) performed 2 minutes of running. The primary outcome measures were sagittal plane movement variability (sample entropy) and IKDC subjective scores. A mixed model ANOVA was used to determine differences between sides (involved/uninvolved; nondominant/dominant) and groups. The relationship between movement variability and IKDC scores was quantified using a Pearson product moment correlation. **RESULTS:** There was a significant group x side interaction (F= 7.95, p= .01). The ACL group had significantly lower (F= 10.82, p= .002) sagittal plane movement variability compared to healthy individuals (nondominant= .3665±.0147; dominant= .3656±.0173) with significantly greater (t= -2.81, p= .01) deficits in the involved limb (.3406±.0265) relative to the uninvolved limb (.3550±.0169). There was a moderate relationship (r= .598, p= .007) between IKDC scores and sagittal plane movement variability during running. **CONCLUSIONS:** Individuals with a history of ACL-R demonstrate decreased sagittal plane movement variability during running compared to healthy individuals. Decreased movement variability manifests as more predictable movement in the involved relative to the uninvolved limb and negatively impacts patient function. Future studies should determine interventions to address movement variability impairments.

Biomechanics of Walking in Healthy Adults at Different Gait Speeds

Matt Prebble[1], Siddhartha Sikdar[1], Oladipo Eddo[1], Stuart McCrory[1], Shane Caswell[1], Ana M. Azevedo[2], Nelson Cortes[1]. [1]*George Mason University, Manassas, VA.* [2]*University of Lisbon, Lisbon, Portugal.*

(No relevant relationships reported)

Lower extremity biomechanical parameters during gait are of interest in degenerative pathologies, such as knee osteoarthritis. However, few investigations have looked at the effect of walking speed on knee biomechanics (e.g., moments). **Methods**: 10 healthy volunteers (25.6 ± 5.0 years, 1.68 ± 0.11 m, 70.3 ± 18.0 kg) completed 3 trials each of walking at 4 different speeds [preferred (PS), fast (FS), slow (SS), & very slow (VSS)]. The range for each speed was determined by measuring a percentage of the participants PS: FS = (120 ± 5%), SS = (80 ± 5%), and VSS = (50 ± 5%). Speed was determined using timing gates (Power Systems Brower) placed 2.4 meters apart. Data was collected using a motion capture system (VICON, 200Hz) while participants walked across a ~6-meter walkway; 4 in-line force plates (Bertec, 1000Hz) captured ground reaction force. Sagittal and frontal plane kinematics and kinetics at the knee were calculated for the 4 speeds using Visual 3D. Differences between the 4 speeds were analyzed using a repeated-measures GLM with pairwise comparisons (p<0.05).

Results: Average speed for the 4 conditions were: PS = 1.06 ± .17 m/s, FS = 1.29 ± .21 m/s, SS = .90 ± .16 m/s, and VSS = .73 ± .11 m/s. There was a significant main effect for speed ($F_{2, 8}$ = 28.7, p = 0.034). Pairwise comparisons indicated a statistically significant difference in knee flexor moment for PS versus FS (PS = .181 ± .019, FS = .079 ± .015, p < .05) as well as in knee internal adductor moment for FS versus PS, SS, and VSS (FS = .026 ± .083, PS = -.437 ± .068, SS = -.579 ± .170, VSS = -.363 ± .112, p < .05). Knee flexor moments were smaller for FS versus PS, while FS was also smaller than PS, SS, and VSS for the knee adductor moment. **Conclusion**: Our findings agree with previous research that identified differences in knee flexor and adductor moments at different gait speeds. For pathological populations it is important to understand the effect of gait speed on knee adductor moment since it is a surrogate measure for joint loading. However, our sample size was small; therefore, the effect of gait speed on knee flexor and adductor moments should be further investigated. Future studies will seek to understand the relative contribution of the quadriceps's muscles at different speeds and its impact on knee joint loads.

Impact of Lower-Extremity Gait Mechanics on Energy Cost of Walking in Younger and Older Adults

Dain P. LaRoche, FACSM, Victoria A. Gregory, Morgan P. Baumgartner, Breanna M. Bozzuto, Victoria M. Libby, Brittany N. Marshall. *University of New Hampshire, Durham, NH.*

(No relevant relationships reported)

The energy cost of walking (Cw) has been shown to be 20% greater in older adults than young, and the difference may be due to the adoption of different lower-extremity gait mechanics with age. **PURPOSE:** To determine if lower-extremity vertical stiffness (K_{vert}), joint range of motion, spatiotemporal gait parameters, and muscle activation explain the difference in Cw between young and old adults. **METHODS:** Twenty younger (29 ± 11 yr, 84.1 ± 17.4 kg, 28.6 ± 4.9 kg m[-2]) and twenty older men and women (78 ± 9 yr, 78.7 ± 12.8 kg, 27.1 ± 4.4 kg m[-2]) performed a four-minute, steady-state walk on an instrumented treadmill at 1.25 m s[-1]. Concurrently, Cw was measured via indirect calorimetry, muscle activation of vastus lateralis (VL) and gastrocnemius lateralis (GL) was measured by electromyography, and lower-extremity kinematics and kinetics were measured by a 3D optical motion system and the treadmill's force plates. Maximal isokinetic knee extensor strength was measured on a dynamometer at 60 deg s[-1]. Multivariate analysis of variance was used to compare younger and older groups and Pearson correlation was used to relate variables. **RESULTS:** Knee extensor strength was 37% lower in older adults (1.47 ± 0.33 vs. 2.34 ± 0.56 Nm kg[-1], p < 0.001, respectively). Cw was not different between old and young (3.06 ± 0.34 vs. 2.91 ± 0.24 J m[-1] kg[-1], p = 0.129). Older adults had 18% lesser K_{vert} (23.1 ± 5.6 vs. 28.0 ± 6.8 kN m[-1], p = 0.019), 20% narrower stride width (11.4 ± 3.0 vs. 14.3 ± 3.6 cm, p = 0.008), 39% lesser ankle range of motion (28 ± 5 vs. 39 ± 13 deg, p = 0.002), and greater VL (35 ± 23 vs 10 ± 6 % peak, p < 0.001) and GL (78 ± 58 vs. 47 ± 24, p = 0.025) activation than young. Cw was inversely related to knee range of motion (r = -0.43, p = 0.031), but only in older adults. In both groups, K_{vert} was inversely related to stride length (r = -0.36, p = 0.012) and positively related to stride frequency (r = 0.35, p = 0.012). **CONCLUSIONS:** When walking at a standard speed, at steady-state, the gross Cw was similar between older and younger people. While K_{vert} was not related to Cw as we hypothesized, it did differ between young and old, and varied in proportion to stride length and frequency.

Increased Loading Rates During Walking in those with Chronic Ankle Instability Relative to Uninjured Controls

Erik A. Wikstrom, FACSM[1], Kyeongtak Song[1], Chris J. Hass, FACSM[2]. [1]*UNC - Chapel Hill, Chapel Hill, NC.* [2]*University of Florida, Gainesville, FL.*

(No relevant relationships reported)

Chronic ankle instability (CAI) is a multi-factorial condition linked with ankle post-traumatic osteoarthritis. Research has shown that CAI patients ambulate with altered kinematic patterns relative to uninjured controls. CAI patients also have increased loading rates relative to controls during running but little is known about how CAI effects loading rates while walking. **PURPOSE:** To compare the loading characteristics of CAI and control participants while walking. **METHODS:** 18 CAI (age:20.6±1.8 years, height:165.8±9.2cm, weight:67.3±12.7kg) and 18 healthy controls (age:20.6±1.0 years, height:168.7±10.3cm, weight:71.6±21.6kg) participated. CAI participants had a history of a lateral ankle sprain that required immobilization or non-weighting bearing for at least 3 days (10.1±8.5 days), experienced at least one episode of giving way within the past year (8.6±6.9 episodes) and experience at least one recurrent sprain between three and six months prior to participation. Each participant completed five walking trials at a self-selected speed. Vertical ground reaction forces (vGRF) were collected at 1200Hz from two adjacent force plates in the middle of the 5m walkway. Gait velocity, peak vGRF, time to peak vGRF, and loading rates were compared between groups. Normalized peak vGRF and loading rates,

---

relative to body weight and gait velocity, were also compared. Independent t-tests assessed group differences with an alpha level of p<0.05. **RESULTS**: Gait velocity did not differ between the groups (CAI:1.27±0.11m/s, Control:1.23±0.08m/s, p=0.18). However, time to peak vGRF (CAI: 148.47±17.9s, Control:162.48±15.86s, p=0.018) and the normalized loading rate (CAI:5.69±0.62N/kg/s, Control: 5.29±0.44N/kg/s, p=0.034) were significantly different between the groups. No other group differences were noted (p>0.05). **CONCLUSION:** Those with CAI have less time to peak vGRF relative to uninjured controls while walking. Increased loading rates, when normalized to body weight and gait velocity, were also higher in CAI participants relative to controls. These altered loading patterns may play a role in the degeneration of talar articular cartilage following acute and recurrent lateral ankle sprains. This project was supported by a grant from the SouthEastern Athletic Trainers' Association.

Spatiotemporal Comparisons Between Male and Female Soldiers While Walking With Heavy Loads

Joseph F. Seay, Victoria A. Gregory, Peter N. Frykman, Nathaniel I. Smith, Rebecca E. Fellin. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

(No relevant relationships reported)

U.S. Army Soldiers have carried average loads of 45 kg in past conflicts. With the recent decision permitting women to enter Combat Arms roles, knowledge of whether men and women are affected differently by military load carriage has become more operationally relevant. Some studies have reported lighter loads have shown no differences in spatiotemporal (S-T) parameters between men v. women, while limited work comparing the effect of heavier carried loads (>30 kg) has resulted in observed S-T sex differences. However, none of these studies have systematically controlled for anthropometric differences. which may have contributed to those discrepancies. **PURPOSE**: To examine the effect of carrying light to heavy loads on S-T parameters in anthropometrically matched male and female Soldiers. **METHODS**: Eight male and 8 female Soldiers were matched on height and body weight (differences < 2.54 cm and 4.54 kg). All participants walked unloaded (BW), and with vest-borne loads of 15, 35 and 55 kg. Each load was carried for 10 min while walking on a level treadmill at 1.34 m·s⁻¹, with kinematics collected after 5 min. 2-way ANOVA RM compared the effects of load carriage on S-T variables between men and women. **RESULTS**: Several significant differences were observed as a function of increasing load (stride rate and % double support increased, stride length decreased), but no significant differences between men and women were observed (Table 1). **CONCLUSIONS**: Our results did not show the same discrepancies at the heaviest loads as reported in previous studies, suggesting that S-T differences may disappear at higher loads when anthropometry is tightly matched. **Disclaimer:** The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government.

Table 1. Spatiotemporal parameters for different loads and genders.

Parameter	Gender	BW	15 kg	35 kg	55 kg	
Gait cycle	M	1.04 ± 0.04	1.04 ± 0.03	1.04 ± 0.05	1.03 ± 0.04	*
(sec)	F	1.07 ± 0.04	1.07 ± 0.05	1.06 ± 0.05	1.05 ± 0.05	
% Dbl Sup	M	19.23 ± 1.43	21.47 ± 1.91	24.01 ± 2.38	27.40 ± 1.49	* +
(% Stance)	F	18.81 ± 1.48	21.65 ± 1.94	24.39 ± 1.88	26.91 ± 2.45	#
Stride rate	M	57.58 ± 2.38	57.73 ± 1.92	57.72 ± 2.58	58.54 ± 2.53	* +

Relationship Between First Metatarsal Motion and Metatarsal Load Distribution During Walking

Christopher Casillas, James Becker. *Montana State University, Bozeman, MT.*

(No relevant relationships reported)

Hypermobility of the first metatarsal (M1) has been theorized to alter plantar loading, and thus be one contributing factor in the development of second (M2) and third (M3) metatarsal stress fractures. To date, most studies examining these relationships have used static measures of M1 mobility. However, it has been shown that there is poor agreement between static measures of M1 mobility and M1 mobility during gait. **PURPOSE**: To quantify the relationship between sagittal plane M1 range of motion (ROM) during walking gait and vertical load distribution among the metatarsals. **METHODS**: Participants were 10 physically active individuals (sex: 5 M, 5 F; age: 21.8 ± 3.0 years). A 12-camera motion capture system recorded foot kinematics during walking while plantar pressures were recorded concurrently with a plantar pressure

mat located over the force plate. Participants completed 3 trials with both left and right feet (total: 60 trials). A multi-segment foot marker set was used to calculate movement of M1 relative to the midfoot. The plantar pressure data was used to identify the entire metatarsal region, as well as each individual metatarsal. Peak load in the metatarsals and percent of peak carried in each metatarsal were then calculated. A linear regression was used to determine the relationship between M1 ROM and percent peak load carried in each metatarsal. **RESULTS**: Peak load in the metatarsals was 1.25 (± 0.25) % body weight. At peak loading, M1, M2, M3 carried 19.14 (± 7.89), 24.53 (±3.92), and 28.37(±4.09) % of the load, respectively. Average ROM for M1 relative to midfoot was 7.84 (± 2.60°). There was not a significant relationship between M1 ROM and percent load under M1 ($R^2 = 0.05$, $p = 0.22$), M2 ($R^2 = 0.01$, $p = 0.70$), or M3 ($R^2 = 0.02$, $p = 0.25$). **CONCLUSION:** Our results do not support the hypothesis that M1 hypermobility increases loading of M2 and M3. Future studies should examine whether other aspects of dynamic M1 mobility instead of simple ROM may be related to increased loading of M2 and M3.

126   Board #7   May 30 9:30 AM - 11:30 AM

Gait Biomechanics at Different Time Periods Following Anterior Cruciate Ligament Reconstruction

Christopher Johnston, Jonathan Goodwin, Brian Pietrosimone, FACSM, Troy Blackburn. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

(No relevant relationships reported)

Aberrant gait biomechanics following anterior cruciate ligament reconstruction (ACLR) are hypothesized to contribute to the increased risk of developing knee osteoarthritis (OA). It remains unclear how time since ACLR influences gait biomechanics.
Purpose: To determine how time since ACLR influences loading characteristics during walking gait following ACLR. **Methods:** Ninety-five (64 F, 31 M; 73.4±11.5 kg) individuals at least 6 months removed from unilateral ACLR and 25 (20 females, 5 males; 62.8±11.0 kg) uninjured controls volunteered for the study. The ACLR cohort was categorized into four groups based on time since ACLR: 6 months (n=24); 7-12 months (n=24); 13-36 months (n=21); >36 months (n=26). Kinetics and kinematics were sampled during walking gait at a self-selected speed with peak vertical ground reaction force magnitude (vGRF), peak instantaneous loading rate (ILR; first time derivative), and linear loading rate (LLR; slope), and peak internal knee extension, valgus, and varus moments identified during the first 50% of the stance phase. vGRF, ILR, and LLR were normalized to body weight (xBW) and moments were normalized to the product of BW and height (BW*ht). Outcomes were compared between groups via one-way ANOVA with Bonferroni corrections.
Results: vGRF was significantly lower in the 6 month (1.04±0.07 xBW) group compared to the uninjured (1.12±0.09 xBW; p=0.03) and 13-36 month (1.13±0.10 xBW; p=0.005) groups. LLR was significantly less in the 6 month (6.88±1.5 xBW/s) group compared to the 13-36 (9.02±2.0 xBW/s; p=0.005) and >36 month (8.57±2.2 xBW/s; p=0.038) groups. The internal knee extension moment was significantly larger in the 7-12 (-0.059±0.02 xBW*ht; p=0.006) and >36 month (-0.057±0.02 xBW*ht; p=0.01) groups compared to the uninjured group (-0.038±0.015 xBW*ht).
Conclusion: Based on these results, walking gait biomechanics fluctuate following ACLR as representative of lower loading early and increasing over time. Continued research should be conducted to determine the necessary ranges for joint loading during walking gait to preserve joint health following injury and take into consideration the changes in walking gait over time to establish how these alterations influence risk of OA.

A-26   Clinical Case Slide - **Hip and Pelvis I**

Wednesday, May 30, 2018, 9:30 AM - 11:10 AM
Room: CC-200E

127   **Chair:** Angela Smith, FACSM. *Nemours Children's Health System, Bryn Mawr, PA.*

(No relevant relationships reported)

130   May 30 9:30 AM - 9:50 AM
Recurrent Hip Pain in a Preadolescent Soccer Athlete

Megan Fraker, Greg Canty. *Childrens Mercy, Kansas City, MO.*
(No relevant relationships reported)

HISTORY: 11yo male soccer player has worsening right hip pain vaguely localized to his groin. He has had right hip pain for 3-4 months which did not resolve with physical therapy following his initial visit. Recently progressed and unable to play with friends. Any activity, even walking, makes it worse. He also has a rash on his right knee and scrotal area that has not improved with antifungal or topical steroid treatment.
PHYSICAL EXAMINATION:Afebrile. Well appearing male. Erythematous plaque over his right patella and follicular papules on his scrotum. Full, passive range of motion both hips but pain with flexion and external rotation. His hip girdle strength was decreased: 4/5 flexion and abduction; 4+/5 hip adduction and extension. Antalgic gait and refuses single leg hop or squat attempts secondary to pain. Spine exam was normal. No other MSK swelling, tenderness, or limitations with active ROM.
DIFFERENTIAL DIAGNOSIS: 1. Stress fracture 2. Myositis 3. Juvenile Arthritis 4. Chronic infectious osteomyelitis 5. Chronic relapsing multifocal osteomyelitis(CRMO) 6. Neoplasm 7. Amplified pain syndrome 8. Chronic hip strain 9. Femoral-acetabular abnormalities/impingement
TEST AND RESULTS: -AP and frog view pelvis xray: no bony abnormality -MRI right hip with and without IV contrast: increased T2 signal right pubic ramus. Patchy edema in ilium near acetabula as well as in the introchanteric femoral neck -Lab(CBC, CMP, CK, ESR, CRP): all normal with exception of Hgb 12.5, Hct 36.7, ESR 31
FINAL WORKING DIAGNOSIS: Chronic relapsing multifocal osteomyelitis (CRMO)
TREATMENT AND OUTCOMES: 1. Ibuprofen 400mg TID initially-mild improvement 2. Rheumatology consult - whole body MRI with repeat labs plus vitamin D, immunoglobulin, UA with urine creatinine and urine calcium, TSH, ANA, HLA B27, SS A/SSB antibodies, and Quantiferon TB testing. 5. Started indomethacin 25mg BID and discontinued ibuprofen. Pain resolved, fatigue improved, and appetite increased. 6. CRMO officially diagnosed after full body MRI showed increased T2 signal in multiple bony sites and remaining lab was negative. 7. Dermatology consult diagnosed plaque psoriasis which can be associated with CRMO. Improved with topical calcipotriene and higher potency topical corticosteroid. 8. Two months after beginning indomethacin returned to soccer drills.

131   May 30 9:50 AM - 10:10 AM
Hip Pain Post Pregnancy

Sarah T. Yang. *Schwab Rehabilitation Hospital/University of Chicago, Chicago, IL.*
(No relevant relationships reported)

HISTORY: 28 year old woman with PMH Type 1 Diabetes Mellitus and hypothyroidism presented to clinic with severe right-sided groin pain 1 week after prolonged delivery resulting in C-section of a healthy infant. She received 2 weeks of PT per her OB with only temporary relief. She was then referred to PM&R . In clinic, she reported localized pain to her right groin and difficulty walking. Symptoms were exacerbated by sitting or lifting her R leg. She denied numbness, radiation, or bowel/bladder symptoms. Tylenol and tramadol provided minimal relief.
PHYSICAL EXAMINATION: She has considerable difficulty getting out of the chair to the bed. She ambulates with an antalgic gait. No specific tightness or tenderness surrounds the right pelvis or upper leg. Overall painful active ROM of the right hip, particularly with internal rotation. Supine PROM: flexion 115, ER 40, IR 15. Strength

4+/5 hip flexion and adduction, 4/5 abduction glut max, 4-/5 abduction glut medius. Leg lengths are equal. Neurovascular examination of the bilateral lower extremities is normal.
DIFFERENTIAL DIAGNOSIS: 1. Avascular necrosis 2. Labral injury 3. Sacroiliac joint dysfunction 4. Fracture
TEST AND RESULTS: **Xray of Hips and Pelvis** - No gross abnormalities. No acute fracture or subluxation. **MRI Hip wo cst** - Transient osteoporosis of the femoral head and neck with subchondral insufficiency fracture. Non-displaced anterior superior labral tear **DEXA** - lowest Z-score with a bone mineral density of 0.999 g/cm^2 and Z score of -1.8 (within age-expected range) **MRI Hip wo cst, 1 month later** - overall decrease in T2 bone marrow signal in the right femoral head and neck with persistent focus of subchondral fracture. Grade 2-3 right hip chondral thinning with small spur formation. Labral tear similar to prior exam **FINAL WORKING DIAGNOSIS**: Subchondral fracture secondary to Transient osteoporosis of the hip **TREATMENT AND OUTCOMES**: 1. Conservative treatment - protected weight-bearing with crutches, analgesia, and supportive PT.
2. Calcium and vitamin D supplementation. 3. On 4 week follow-up, she was upgraded to WBAT. 4. On 2 month follow-up, strength 5/5. Negative FABER and FADIR. Went for a walk for the first time. 5. On 3 month follow-up, no pain with passive ROM of hip. Strength normal. No TTP. Able to ascend/descend stairs without pain.

132   May 30 10:10 AM - 10:30 AM
Pubic Pestilence-Cross Country

Keirsten E. Smith, James B. Robinson, Earl R. Stewart, Brett C. Bentley. *University of Alabama Sports Medicine, Tuscaloosa, AL.*
(No relevant relationships reported)

HISTORY: An 18-year-old female collegiate cross-country runner presented with complaints of acute abdominal pressure for 3 days. Initially evaluated by ED treated for an UTI but her pain has persisted. The athlete did extra core work for 30 minutes prior to the onset of symptoms and does not usually do core-work. Her pain was peri-umbilical and LLQ, radiating to the left flank. The pain was relieved by ibuprofen and aggravated by movement and bending. Associated symptoms include bloating, decreased appetite, nausea. She denies back pain, fever, chills, dysuria, vaginal bleeding or discharge. She has no significant PMH.
PHYSICAL EXAMINATION: Examination revealed a thin female in pain. Abdomen soft, normal bowel sounds, severe tenderness to palpation over her rectus abdominis insertion LLQ with inability to leg-lift or sit-up. No CVA tenderness. Normal neurological exam.
DIFFERENTIAL DIAGNOSIS:
1. Exercise induced rhabdomyolysis
2. Rectus abdominis tear/hematoma
3. Osteitis pubis
4. Pubic osteomyelitis
5. Stress fracture pubic ramus
TEST AND RESULTS:
LABS: leukocytosis, elevated ESR/CRP, normal CMP, CK, UA
XR Pelvis revealed no acute osseous abnormality.
MRI pelvis showed moderate edema in the distal left rectus abdominis musculature, adductor group, and subcutaneous tissue. Signal changes of the left pubic ramus with some cortical discontinuity.
CT pelvis without contrast showed symphysis appearance most suggestive of osteitis pubis rather than fracture with cortical erosions on the left.
NM bone scan three-phase revealed mild increased activity in the pubis and symphysis.
FINAL/WORKING DIAGNOSIS: Pubic Osteomyelitis
TREATMENT AND OUTCOMES:
1. Operative left pubis debridement with deep bone debridement, cultures and pubic symphysis lavage performed
2. Prolonged antibiotic course was initiated initially with Vancomycin IV which was later changed to Clindamycin IV after surgical cultures grew back Propionibacterium Acnes and Methicillin Resistant Staphylococcal Epidermidis.
3. Returned to sports as tolerated after suture removal from surgical debridement with Groshong catheter in place. Her pelvis continued to hurt after long-distance exercises but she had no severe resting pain; therefore, inflammatory markers (ESR and CRP) were monitored as surrogate markers of the progress toward cure.

133   May 30 10:30 AM - 10:50 AM
Novel Treatment of Anterolateral Thigh Pain-Triathlon

Ciara Johnson, McCasey Smith, Neil Segal. *University of Kansas Medical Center, Kansas City, KS.*
(No relevant relationships reported)

HISTORY: A 49-year-old male, active duty Army, presented with a 4-month history of right anterolateral thigh pain and paresthesias. Pain was described as numb-like, stabbing, burning, and sharp. Symptoms began while cycling during a triathlon. After the race, there was increasing numbness and pain in left anterolateral thigh. Symptoms worsened with sitting, yoga, and flexion of the hip past 90°. He noted

Abstracts were prepared by the authors and printed as submitted.

increased weakness with running. Pregabalin, naproxen, tramadol, physical therapy, and inversion table were ineffective. He underwent 6 lateral femoral cutaneous nerve blocks under ultrasound guidance that provided positive diagnostic benefit, but temporary therapeutic benefit. At presentation, Visual Analogue Scale pain score was 6-8/10.**PHYSICAL EXAMINATION**:
Patient demonstrated allodynia of the right thigh 4-6cm lateral to the midpoint of the inguinal ligament from Pubic symphysis to ASIS that increased with resisted hip flexion. There was also diminished sensation over the right anterolateral thigh. Neurological and musculoskeletal examination was otherwise unremarkable.
DIFFERENTIAL DIAGNOSIS: 1. Meralgia Paresthetica 2. Lumbar Plexopathy3. L1, L2 Lumbar Radiculopathy **TEST AND RESULTS**: Lumbosacral MRI --Right L5-S1 disc protrusion resulting in mild lateral recess stenosis.
FINAL WORKING DIAGNOSIS: Meralgia Paresthetica **TREATMENT AND OUTCOMES**:
1. Cryoablation of Lateral Femoral Cutaneous Nerve under US guidance 2. Immediate, complete resolution of anterolateral thigh pain.3. Post-procedural pain score was 0/10, decreased from Pre-procedure pain score of 6/10. 4. Complete resolution of pain for 1.5 months post-procedure with return to activity. Continues to have 60-70% relief.5. Patient was able to return to running, cycling, and swimming.

134   May 30 10:50 AM - 11:10 AM
Groin Pain Following Spin Class in a Personal Trainer
Joseph Dadabo, Prakash Jayabalan. *Shirley Ryan AbilityLab/ Northwestern University, Chicago, IL.* (Sponsor: Joseph Ihm, FACSM)
(No relevant relationships reported)

History:
A 41 year old G3P1 woman 3 months postpartum presented with 2 days of groin pain that started after riding a stationary cycle. She also reported night sweats and fevers. She had left hip dysplasia and left femoral and obturator nerve palsy since birth. Now she described constant stabbing pubic symphysis pain with radiation into her right medial thigh. Pain intensity was 9/10 and worse with hip flexion, adduction, and walking. She required a walking stick for ambulation.
Physical Examination:
Tenderness to palpation over pubic symphysis and adductor muscles bilaterally, worse on right due to baseline sensory deficits on left. Strength 5/5 bilaterally for ankle dorsiflexion, plantar flexion, inversion, eversion, and EHL. Right hip flexion, hip abduction, and TFL strength 3/5, all with significant pain. Passive right hip adduction caused severe pain. Left hip flexion 2/5, hip adduction 1/5, and light touch sensation over left lateral thigh diminished, her baseline due to known nerve palsy. Reflexes 1+ on right and absent on left. Stinchfield's and scour tests positive on the right. FABER and log roll negative bilaterally.
Differential Diagnosis:
1. Athletic pubalgia
2. Hip flexor strain
3. Hip adductor tear
4. Hip labral tear
Tests and Results:
XR Hips: Left acetabular dysplasia and sclerosis. Avulsion fracture left inferior pubic ramus.
WBC: 16.0 (H)
ESR: 121 (H)
CRP: 9.9 (H)
MRI Pelvis: Avulsion fracture left medial pubic bone at origin of adductor muscles. 4.6 cm hematoma over left adductor muscles. Grade 1 strain proximal right adductor muscles. Bilateral sacral insufficiency fractures. Bilateral pubic reactive marrow edema.
Ultrasound-guided aspiration of adductor and pubic symphyseal fluid: Serosanguinous fluid, cultures negative.
Final Working Diagnosis:
1. Left pubic avulsion fracture at origin of adductor muscles with secondary hematoma
2. Grade 1 strain proximal right adductor muscles
3. Bilateral sacral insufficiency fractures
Treatment and Outcomes:
1. NWB left leg for 2 weeks
2. Tylenol PRN for pain. Stop NSAID's
3. Therapy - pelvic floor and lower extremity strengthening, stretching, gait stability, and balance upon return to full weight bearing
4. DEXA Scan: Normal bone mineral density
5. Calcium and vitamin D: Within normal limits
6. Normalization of WBC, ESR, and CRP on serial monitoring

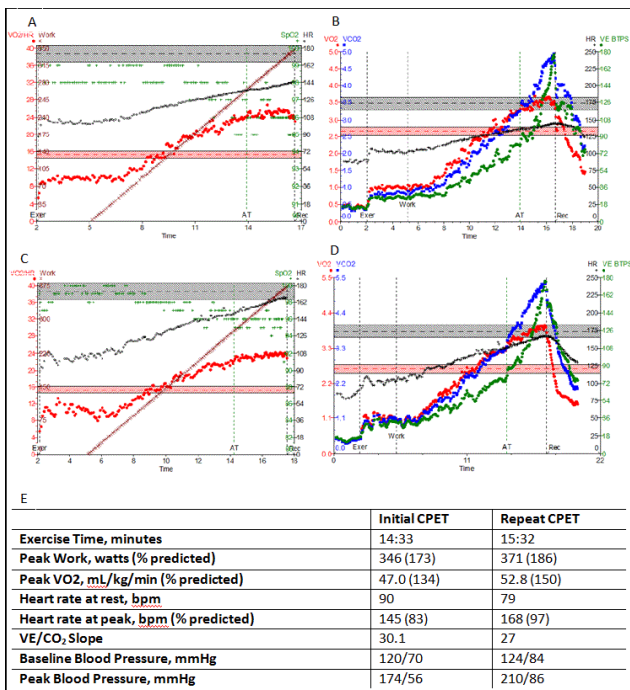
A-27   Clinical Case Slide - **Medical Issues I**
Wednesday, May 30, 2018, 9:30 AM - 11:10 AM
Room: CC-200F

135   **Chair:** Kenneth P. Barnes, FACSM. *Elon University / Kernodle Clinic Orthopedics & Sports Medicine, Elon, NC.*
(No relevant relationships reported)

136   **Discussant:** Hallie Labrador. *NorthShore University HealthSystem, Gurnee, IL.*
(No relevant relationships reported)

137   **Discussant:** Suzanne S. Hecht, FACSM. *University of Minnesota, Minneapolis, MN.*
(No relevant relationships reported)

138   May 30 9:30 AM - 9:50 AM
Avoiding Grave Cardiac Outcomes in an Athlete with Grave's Disease
Sander Rubin, Robert Kiningham, FACSM. *University of Michigan, Ann Arbor, MI.*
(No relevant relationships reported)

HISTORY:
A 20yo male college football player presented to the athletic training room with 15 pounds of unexplained weight loss over a two-week period. He reported decreased appetite, increased general fatigue and muscle fatigue over the past two weeks. His review of systems was otherwise negative. He had no chronic medical problems or current medications. His family history was significant for asthma, hypertension, and diabetes mellitus type 2.
PHYSICAL EXAMINATION:
General - No acute distress, well-appearing
HEENT - Sclera anicteric, tympanic membranes normal
Neck - Supple. Thyroid palpable, no enlargement or nodules
Lymph nodes - No axillary, cervical, or supraclavicular lymphadenopathy
Respiratory - Clear to auscultation bilaterally, no dyspnea
Cardiovascular - Regular rate and rhythm, no murmur
Abdomen - Soft, non-tender, non-distended, no mass, bowel sounds present
GU - No testicular mass
DIFFERENTIAL DIAGNOSIS:
1. Mononucleosis
2. Neoplasm
3. Hyperthyroidism
4. HIV
5. Vitamin B12 or D Deficiency
6. Diabetes mellitus
TESTS AND RESULTS:
Initial Labs:
TSH - <0.01
Urinalysis - Normal
CMP - Na 139, K 3.9, Cl 105, CO2 29, UN 23, Cr 0.93, Glu 101, Ca 10, Pro 6.7, Alb 4, AST 48, ALT 83, Alk Phos 81, Bil 0.6
CBC - Wbc 8.1, Hgb 13.3, Hct 39, Plt 238
CK - 675
ESR - 20
CRP - 0.2
Monospot - Negative
Vitamin B12 - 782
Vitamin D (25HD) - 25
Follow-Up Labs:
Free T4 - 4.65
Free T3 - >20
Thyrotropin Receptor Ab - 11
Thyroid Stimulating Ig - 5.8
Hepatitis Panel - Negative
FINAL/WORKING DIAGNOSIS:
1. Hyperthyroidism due to Grave's Disease
TREATMENT AND OUTCOMES:
The patient was held from practice and referred to endocrinology for further evaluation and management. His increased liver enzymes were likely due to the hyperthyroidism. He was started on methimazole 20mg daily and inderal 10mg three times per day, with a plan to check thyroid and liver function tests every 2-4 weeks. He returned to football activities and did well until he started to lose weight and methimazole dosage had to be lowered due to elevated alk phos. A baseline EKG will be obtained to ensure he is not


in atrial fibrillation. Given the increased risk of atrial fibrillation in his hyperthyroid state, he will be instructed to keep his heart rate target below 120bpm. Once his thyroid levels return to normal, he plans to undergo radioactive iodine ablation, likely after the football season.

---

139   **May 30 9:50 AM - 10:10 AM**

Exercise Intolerance in an Endurance Athlete with Depression

Ankit B. Shah, Aaron L. Baggish, FACSM, Meagan M. Wasfy. *Massachusetts General Hospital, Boston, MA.*
(No relevant relationships reported)

HISTORY: A 46-year-old male competitive cyclist with a history of depression presented with concerns of decreased exercise tolerance. Over the past year, he has had difficulty maintaining as high a level of effort for a sustained period of time as he was accustomed. A year ago, his heart rate using a chest strap monitor during maximal perceived exertion was 170 beats per minute (bpm). This year, with similar effort, his heart rate does not rise above 150 bpm. Upon further questioning, he was started on two new medications in the last year, buproprion 200mg twice daily and desipramine, a tricyclic antidepressant (TCA) 150mg daily.**PHYSICAL EXAMINATION**: Resting heart rate was 65 bpm, he was normotensive and oxygen saturation was 100% on room air. Cardiopulmonary examination was normal.**DIFFERENTIAL DIAGNOSIS**: 1. Sinus node dysfunction 2.Myocardial Ischemia 3.Heart Failure 4. Medication side effect 5. Hypothyroidism**TEST AND RESULTS**: Thyroid panel, basic metabolic panel and complete blood count were within normal limits. Electrocardiogram showed normal sinus rhythm, left axis deviation with normal PR and corrected QT intervals. Exercise testing confirmed his subjective limitations and revealed chronotropic incompetence. We hypothesized that TCAs' previously described impact on central nervous system (CNS) B1 adrenergic receptors was the cause of his limitations. Desipramine was safely weaned off and repeat exercise testing revealed improved VO2 and normalization of peak heart rate. TCAs are known to reduce the sensitivity and/or density of B1 receptors in the CNS, and we propose that this side effect is likely due to similar impact on cardiac B1 receptors.

FINAL WORKING DIAGNOSIS: Desipramine use is a reversible cause of chronotropic incompetence and associated exertional limitation.**TREATMENT AND OUTCOMES**: His depression is well controlled on a different antidepressant regimen prescribed by his psychiatrist. He has not had recurrence of his exertional intolerance.

	Initial CPET	Repeat CPET
Exercise Time, minutes	14:33	15:32
Peak Work, watts (% predicted)	346 (173)	371 (186)
Peak VO2, mL/kg/min (% predicted)	47.0 (134)	52.8 (150)
Heart rate at rest, bpm	90	79
Heart rate at peak, bpm (% predicted)	145 (83)	168 (97)
VE/CO₂ Slope	30.1	27
Baseline Blood Pressure, mmHg	120/70	124/84
Peak Blood Pressure, mmHg	174/56	210/86

140   **May 30 10:10 AM - 10:30 AM**

Exercise Intolerance-cycling

Devon E. Hutton, Sean C. Robinson. *Oregon Health and Science University, Portland, OR.* (Sponsor: Diane L Elliot, FACSM)
(No relevant relationships reported)

HISTORY: A 55-year-old competitive male cyclist presented with one year of progressive exercise intolerance, increased dyspnea on exertion, and four weeks of

bilateral ankle edema. He also reported chest discomfort with exertion, orthostasis, and weight gain. On review, he initially reported exercise intolerance with fatigue eight months earlier with EKG showing sinus arrhythmia and normal labs except low total protein. Cycling stress test with VO2 max showed ST depression in inferior leads and VO2 max of 27.6ml/kg/min. Follow up stress echo was negative for wall motion abnormality. **PHYSICAL EXAMINATION**: Examination revealed regular rate and rhythm without extra sounds, clear lungs bilaterally, and 1+ pitting edema up to shins. **DIFFERENTIAL DIAGNOSIS**: Ischemic cardiomyopathy, Hypothyroidism, Malignancy **TEST AND RESULTS**: Labs: Cr 0.81mg/dL, Total protein 5.9g/dL, Albumin 3.0g/dL, Hgb 15.0g/dL, Hct 43.5%, Ferritin 111ng/mL, TSH 2.05mlU/L, Testosterone 434ng/dL, Cortisol 14.6ug/dL, 24hr Urine protein 2773mg/24hr Echocardiogram: LV size and LVEF normal. Severe LV hypertrophy by area length method 144g/m2. RV size and RVEF normal. RV hypertrophy present. Moderate biatrial enlargement. Suggests infiltrative cardiomyopathy. **FINAL WORKING DIAGNOSIS**: AL Amyloidosis with infiltrative cardiomyopathy **TREATMENT AND OUTCOMES**: Ordered MR Cardiac w/wo: *Biventricular hypertrophy with preserved right and left ventricular systolic function. Dilated right atrium. Mild to moderate mitral and moderate tricuspid regurgitation. Small pericardial effusion. Abnormal late gadolinium enhancement of basal LV myocardium and both atria. Suggests cardiac amyloidosis.* Ordered UPEP/SPEP--*UPEP: Urine protein conc 82 mg/dl, Urine monoclonal protein free lambda light chains; SPEP: Serum lambda light chain 1230mg/L, Serum kappa/lambda ratio 0.008;* Referred to Heme/Onc--*Bone marrow biopsy: Monoclonal plasmacytosis, negative for amyloid deposition; Kidney biopsy: Amyloidosis, AL-lambda type, with predominant glomerular involvement; Started Andromeda Clinical Trial—Cyclophosphamide, Bortezomib, Dexamethasone (CyBorD), and Daratumamab;*

141   **May 30 10:30 AM - 10:50 AM**

Left Lower Quadrant Abdominal Pain in a Division 1 Discus Thrower

Alyssa M. Neph[1], Tracy Bras[2], Kentaro Onishi[1]. *[1]University of Pittsburgh Medical Center, Pittsburgh, PA. [2]Maine General Orthopedics/Evergreen Sports Medicine Fellowship, Augusta, ME.* (Sponsor: Brian A. Davis, FACSM)
(No relevant relationships reported)

HISTORY: A 19-year old female Division 1 discus thrower with a history of ruptured left ovarian cyst presents with intermittent left lower quadrant abdominal pain that started 8 months ago. Focal pain is located superior and medial to the left anterior superior iliac spine and there is an associated bulge, reportedly brought by heavy activity, although not clinically reproducible. Physical therapy for core and lumbopelvic strengthening did not provide improvement. As CT and MRI were unremarkable, she was referred to our sports ultrasound clinic for a diagnostic ultrasound of the left lower abdominal region.
PHYSICAL EXAM: Non-antalgic gait with full lumbar and left hip range of motion. Mild tenderness to palpation medial to the iliac crest in the left lower quadrant without guarding or rebound. No palpable muscle defect is appreciated at rest or with valsalva maneuver. Transition from FABER to hip extension does not reproduce pain or snapping. Resisted sit up, Stinchfield, FAIR, and hip hyper flexion impingement tests were negative.
DIFFERENTIAL DIAGNOSIS
1. Sports hernia/athletic pubalgia
2. Ovarian cyst
3. Endometriosis
4. Inguinal hernia
5. Intra-articular hip pathology
6. Spigelian hernia
TEST AND RESULTS:
-Pelvic ultrasound and CT abdomen/pelvis: normal
-X-ray lumbar spine and pelvis: dextroscoliosis of lumbar spine, normal left hip and pelvis
-MRI pelvis: Right adnexal cyst measuring 4.9 x 4.2 cm. No inguinal hernia, edema, or fascial defect over the lower abdominal wall
-Left lower quadrant musculoskeletal ultrasound: 11 mm gap within transversalis fascia on the lateral edge of the left rectus abdominis muscle, just deep to the inferior epigastric vessels. Herniation was seen deep to the intermediate investing fascia and was exacerbated with coughing, laughing, and half sit-ups
FINAL/WORKING DIAGNOSIS
Type 1 Spigelian hernia
TREATMENT AND OUTCOMES:
1. Diagnostic laparoscopy identified a 12-15 mm area of defect in the left Spigleian fascia with pre-peritoneal fat herniation as seen on the diagnostic ultrasound. The defect was repaired in an open fashion with four sutures.
2. Gradual return to activity 12 weeks post repair with decreased pain during heavy weight lifting and participation in discus throwing.
3. Repeat ultrasound 4 months after surgical repair was normal with no visible abdominal wall defect.

142   May 30 10:50 AM - 11:10 AM

Effects Of An Exercise Program On Quality Of Life On A Rheumatoid Arthritis Patient: A Case Study

Diego A. Alonso-Aubin[1], Iván Chulvi-Medrano[1], Moisés Picón[1], Tamara Rial[2], Juan M. Cortell-Tormo[1]. [1]University of Alicante, Alicante, Spain. [2]International Hypopressive & Physical Therapy Insititute, Vigo, Spain. (Sponsor: Avery D. Faigenbaum, FACSM)

(No relevant relationships reported)

HISTORY: A woman 34-years-old, after 8-weeks of cardiac surgery (tricuspid surgery) wheelchair bound due to evolutioned Rheumatoid Arthritis (RA) since she was 9-years-old. **PHYSICAL EXAMINATION:** Height 1.40 meters, weight 36.1 kg, body mass index 18.41kg/m². Limited range of motion (overall ankylosis) and an overall and clinical muscular atrophy. **DIFERENTIAL DIAGNOSIS:** Diagnosis RA and CVD (tricuspid surgery). **TEST AND RESULTS:** Rheumatoid Arthritis Impact of Disease (RAID) scored 3.72 and SF-36 Health Survey (SF-36) total score 1730. Muscular function in handgrip was 1 in Oxford-scale. **FINAL/ WORKING DIAGNOSIS:** Rheumatoid Arthritis. Musculoskeletal pain and motor deficit. **TREATMENT AND OUTCOMES:** Specific pharmacologic treatment. 8-weeks of multicomponent physical exercise. 5 days/week. Multicomponent physical exercise: combined aerobic and resistance exercise program, including electrical nerve stimulation. Intensity associated with pain tolerance (tonification program), was used as monitoring the training. After 8weeks of multicomponent physical exercise she improves scores in RAID (3.57) and SF-36 (1865). The handgrip muscular function has increased to a 2.

The Retaining Effects of Running Training Combined with Blood Flow Restriction on VO₂max and Muscular Strength after Detraining

Yun-Tsung Chen[1], Mong-Da Hsu[1], Yao-Yi Hsieh[1], Jung-Charng Lin[2]. [1]National Taiwan Normal University, Taipei, Taiwan. [2]Chinese Culture University, Taipei, Taiwan.

(No relevant relationships reported)

Purpose: Concurrent improvements in maximal oxygen uptake (VO_2max) and muscle strength in aerobic (e.g., walking and running) training combined with blood flow restriction (BFR) has been reported. However, the retain effects of aerobic training combined with BFR on VO_2max and muscular strength is still unknown. Therefore, this study investigated the effects of 2 weeks detraining on VO_2max and muscle strength performance following running training combined with BFR. **Methods:** Twenty male athletes were recruited and pair matched into: (1) running training with thigh BFR group (RT-BFR, n=10), or (2) running training only group (RT, n=10). Before detraining, all subjects in both groups performed eight weeks of running training (24 sessions). RT-BFR group performed running sessions with pressure cuff belts. The occlusion pressure was 1.3 x resting systolic blood pressure. VO_2max, all out time (AOT), muscular strength and hamstring/quadriceps (H/Q) ratio were assessed before and after the detraining. **Results:** There were no differences ($p > .05$) between groups in VO_2max (-3.5 ± 3.6 vs. -0.8 ± 6.3 %), AOT (-3.4 ± 3.6 vs. -1.6 ± 4.0 %), isokinetic knee extensor (60º/s, -3.5 ± 8.5 vs. -1.2 ± 9.7 %; 180º/s, -0.2 ± 7.1 vs. 4.0 ± 10.8 %), flexor strength (60º/s, -2.9 ± 8.4 vs. 0.9 ± 8.9 %; 180º/s, -7.8 ± 11.4 vs. 1.6 ± 12.9 %) and H/Q ratio (60º/s, 0.9 ± 9.4 vs. 2.9 ± 11.1 %; 180º/s, -7.3 ± 11.6 vs. -2.2 ± 7.8 %) after 2 weeks detraining. However, the RT-BFR decreased H/Q ratio from 0.75 to 0.69, which may alleviate the training-induced injury protective effects in hamstring. **Conclusions:** There were similar retaining effects on aerobic capacity and muscular strength between groups after 2 weeks detraining. However, only RT-BFR group was shown to have higher VO_2max (65.1 ± 5.2 vs. 64.3 ± 4.7 ml/kg/min), AOT (15.9 ± 1.7 vs. 15.4 ± 1.4 min), knee extensor (60º/s, 2.5 ± 0.5 vs. 2.3 ± 0.4 Nm/kg; 180º/s, 1.9 ± 0.2 vs. 1.6 ± 0.2 Nm/kg) and flexor strength (60º/s, 1.5 ± 0.2 vs. 1.4 ± 0.3 Nm/kg; 180º/s, 1.3 ± 0.2 vs. 1.2 ± 0.2 Nm/kg) performance when compared with pre-training. Thus, the findings suggest that RT-BFR may be considered as a practical training strategy for concurrent increase in VO_2max and muscular strength performance. In addition, the training effects are maintained within 2 weeks of detraining in athletes.

Exercise with Blood Flow Restriction and Power Development of the Lower Body

Justin Faller[1], Susan Sotir[2], Kristen Ouellette[2], Vicent J. Paolone, FACSM[2], Brian Thompson[2]. [1]Skidmore College, Saratoga Springs, NY. [2]Springfield College, Springfield, MA. (Sponsor: Vincent J. Paolone, FACSM)

(No relevant relationships reported)

Sixty to eighty percent of one repetition maximum (1 RM) is generally recommended to elicit improvements in muscular fitness, however these intensities may not be appropriate for all populations and situations. A new training technique has been reported to elicit increases in musle strength and size uses low intensity resistance training (~ 20% 1RM) in combination with blood flow restriction (BFR) to the working muscle. BFR training has also been reported to reduce atrophy experienced during immobilization. Muscular power can improve due to increases in muscular strength and size, which can be beneficial to athletic performance. Acute changes in power output have been observed following near maximal resistance exercise efforts, however this has not been examined extensively in BFR training. **PURPOSE:** To determine the acute effects low intensity resistance exercise with BFR has on power output of the lower body. **METHODS:** Resistance trained males (n = 14) completed three experimental sessions in which lower body power output and vertical jump height were measured pre and post exercise protocol. Exercise protocols consisted of the barbell back squat with either 20% 1 RM and blood flow restriction (BFR) for 15 repetitions, or a high load (90% 1 RM) without restriction for 3 repetitions, and no exercise (control). Vertical jump height and lower body power output were assessed using a portable force plate before and following the barbell back squat. A two-way repeated measures ANOVA was utilized to examine exercise protocol and vertical jump height as well as exercise protocol and power output. **RESULTS:** Vertical jump height following BFR exercise was reduced when compared to vertical jump height before BFR exercise (46.4±5.6 cm vs. 43.6±4.6 cm, p <0.05). No differences in vertical jump height were observed with 90% 1 RM (45.4±4.7 cm vs. 46.2±4.9 cm, p>0.05) or in the control group (47.6±5.9 cm vs. 45.6±5.7 cm, p>0.05). Power output was unaffected by condition but decreased from pre to post exercise (62.2±7.5 w/kg vs. 60.9±7.7 w/kg, p<0.05). **CONCLUSION:** A decrement in vertical jump height was experienced after an acute bout of BFR with low load resistance exercise. Low load resistance exercise with BFR or high intensity resistance exercise may not be beneficial as part of a warm up to acutely enhance vertical jump or power output.

The Effect of Blood Flow Restriction Training on Body Composition and Muscular Strength in College-Aged Individuals.

Zachary R. Salyers, Jame Larkin, Michael Lane, Aaron Sciascia. *Eastern Kentucky University, Richmond, KY.*

(No relevant relationships reported)

Scientific Abstract SampleBFR training utilizes workloads between 20-30% of an individual's one repetition maximum, with one set of 30 reps, followed by 3 sets of 15 reps while incurring little to no muscle damage. Future research should be conducted to determine if BFR training is an effective training method. **PURPOSE:** To determine the effects of practical blood flow restriction training on body composition and muscular strength in college-aged individuals when compared to a traditional resistance training protocol. **METHODS:** This study consisted of two randomized groups, an experimental group (BFR), and a traditional resistance training (TRT) control group. The subject's characteristics were (mean ± SD, N=9, 8 males, 1 female) age, 22.3 ± 1.6 years; height, 68.9 ±2.7 inches; weight, 183.7±40.4 lbs.; body fat percentage, 21.2±8.6. All participants completed pre-testing measures of girth of both arms and legs, upper chest, and shoulders. Body composition was determined using air displacement plethysmography via BodPod (COSMED USA, INC., Concord, CA) to determine fat free mass and body fat percentage. Maximal strength was assessed on the bench press and back squat to determine workloads during the training programs. Both groups completed a four-week training program consisting of both upper and lower body training. The BFR program consisted of four sets (1 set x 30 repetitions and 3 sets x 15 repetitions). Loads progressed from 20 to 32% of each person's 1RM over the four weeks. The TRT program consisted of four sets with progressive loads of 65%, 75%, 80% and 85% with 15, 10, 8, and 6 repetitions respectively. Post testing measures followed the pre-testing regimen .regimen. Within and between group differences from pre topre-to post testing were determined via paired and independent t-tests. . **RESULTS:** No significant differences were found among any of the body composition measurements as well as squat performance. The BFR group demonstrated significantly greater increases in bench press performance (pre: 198 ±79 lbs.; post: 211±83 lbs.) after the training program (p=0.004) compared to the TRT group.

CONCLUSION: In a limited sample, BFR training was shown to be a comparable training method when compared to traditional hypertrophy training. The findings were specific to increases in bench press performance.

Early Adaptations In Strength As A Result Of Blood Flow Restriction Training Is Not Mode-specific

Ethan C. Hill, Terry Housh, FACSM, Cory Smith, Joshua Keller, Richard Schmidt, Glen Johnson, FACSM. *University of Nebraska - Lincoln, Lincoln, NE.* (Sponsor: Terry Housh, FACSM)
(No relevant relationships reported)

PURPOSE: Low-intensity blood flow restriction training has been demonstrated to elicit increases in muscle strength comparable to training at high intensities of exercise without blood flow restriction. Eccentric muscle actions are a key component to induce favorable adaptations in muscle, but there is limited information regarding the effects of eccentric (Ecc-BFR) versus concentric (Con-BFR) blood flow restriction training. The purpose of this investigation was to examine Ecc-BFR versus Con-BFR training on muscle strength. **METHODS:** Twenty-four untrained women (mean age ± SD = 21.9 ± 1.4 years) were randomly assigned to 2-wk of Ecc-BFR (n = 12) at 30% of their eccentric peak torque (PT) or 2-wk of Con-BFR (n = 12) at 30% of their concentric PT. Training was performed 3 times per week for 2-wk and consisted of 75 repetitions each training session performed over 4 sets (1×30, 3×15) and each set was separated by 30-s of rest. All training and testing procedures were performed on an isokinetic dynamometer at a velocity of $120° \cdot s^{-1}$. At baseline and after 2-wk of training, indices of muscle strength (eccentric PT, concentric PT, and maximal voluntary isometric contraction [MVIC]) were assessed. Training-induced changes in muscle strength were examined using a 2 (Time [baseline, 2-wk]) × 2 (Group [Ecc-BFR, Con-BFR]) × 3 (Mode [eccentric PT, concentric PT, MVIC]) mixed factorial ANOVA. **RESULTS**: There were no significant ($p > 0.05$) interactions, but there were significant ($p < 0.05$) main effects for Time and Mode, but not for Group. Muscle strength increased 12.0% (collapsed across Group and Mode) from baseline (24.2 Nm) to 2-wk (27.1 Nm), and eccentric PT (34.6 Nm) was greater than concentric PT (20.4 Nm) and MVIC (22.0 Nm), but concentric PT and MVIC were not different (collapsed across Time and Group). **CONCLUSIONS:** These findings indicated that low-intensity Ecc-BFR and Con-BFR training elicited comparable increases in muscle strength following 2-wk of resistance training. In addition, the increases in muscle strength were not mode-specific and increased for all modes of testing (eccentric PT, concentric PT, and MVIC) regardless of the training modality (Ecc-BFR or Con-BFR). Collectively, these results suggested that Con-BFR training resulted in comparable increases in muscle strength when compared to Ecc-BFR training.

Acute Effects Of Resistance Training With And Without Blood Flow Restriction On Muscle Thickness

Iván Chulvi-Medrano[1], Moisés Picón[1], Juan M. Cortell-Tormo[1], Diego A. Alonso-Aubin[1], Tamara Rial[2], José Fernández-Sáez[1], Daniel Alonso[3], Yasser Alakhdar[3]. *[1]University of Alicante, Alicante, Spain. [2]International Hypopressive and Physical Therapy Institute, Vigo, Spain. [3]University of Valencia, Valencia, Spain.*
(No relevant relationships reported)

Low-intensity resistance exercise associated with blood flow restriction (LI-BFR) has demonstrated to be an effective strength training methodology with similar hypertrophy gains than conventional resistance exercise (RE). **PURPOSE:** To compare the acute effects of high intensity RE (HI), low intensity RE (LI) and low intensity RE with blood flow restriction (LI-BFR) on muscle thickness in healthy subjects. **METHODS:** 52 subjects (27.3 ± 7 years; BMI: 27.3 ± 3.1) were randomly assigned into three groups: High intensity (HI, 75%-1RM; n=15); low intensity (LI, 30%-1RM; n=13); and low intensity with blood flow restriction training (LI-BFR, 30%-1RM and 30% of total vascular restriction; n=24). All participants performed four sets of plantar flexion in the leg press machine with 1 set of 30 repetitions following 3 sets of 15 (for LI and LI-BFR group) or 10 repetitions (HI group). An inflated cuff at 30% of total vascular restriction of each individual (mean: 47.6 ± 19.8 mmHg) was attached at the calf of the dominant leg. The muscle thickness of gastrocnemius (G) and anterior tibial (AT) was measured before, immediately after the fourth set, 60min post-exercise and 24h post-exercise with ultrasound. **RESULTS:** Significant muscle thickness increase of the G and AT was observed in the LI-BFR group (p<0.001) after the fourth set (G: pre: 1.91 ± 0.26 cm; post: 2.10 ± 0.23 cm; AT: pre: 1.89 ± 0.36 cm; post: 2.15 ± 0.49 cm) and 60min post-exercise (G: pre: 1.91 ± 0.26 cm; post: 2.14 ± 0.23 cm; AT: pre: 1.89 ± 0.36 cm; post: 2.20 ± 0.48 cm). HI and LI groups also promoted significant muscle thickness increase (p<0.05) in the G after the fourth set (HI: pre: 1.83 ± 0.37 cm; post: 2.03 ± 0.32 cm; LI: pre: 1.70 ± 0.26 cm; post: 1.81 ± 0.27 cm) and 60min post-exercise for LI group (pre: 1.70 ± 0.26 cm; post: 1.83 ± 0.23 cm). Significant intergroup differences were observed in G muscle thickness after the fourth set (p=0.011) and 60min post-exercise (p=0.004) and also in AT muscle thickness after the fourth set (p=0.001), 60min (p=0.006) and 24 hours post-exercise (p<0.001). **CONCLUSION:** LI-BFR group showed the highest increase in muscle thickness of the G when compared to HI and LI groups. Only LI-BFR group was able to achieve significant increase of AT muscle thickness.

Acute Cardiovascular Responses To Resistance Training With And Without Blood Flow Restriction

Moisés Picón[1], Iván Chulvi-Medrano[1], Juan M. Cortell-Tormo[1], Diego A. Alonso-Aubin[1], Tamara Rial[2], José Fernández-Sáez[1], Daniel Alonso[3]. *[1]University of Alicante, Alicante, Spain. [2]International Hypopressive and Physical Therapy Institute, Vigo, Spain. [3]University of Valencia, Valencia, Spain.*
(No relevant relationships reported)

Recently, it has been suggested that resistance exercise (RE) can be applied for cardiovascular function, maintenance and/or for rehabilitation purposes. **PURPOSE:** To compare the acute effects of high intensity RE (HI), low intensity RE (LI) and low intensity RE with blood flow restriction (LI-BFR) on heart rate (HR) and blood pressure (BP) in healthy subjects. **METHODS:** 52 subjects ($(27.3 \pm 7$ years; BMI: 27.3 ± 3.1) were assigned into three groups: High intensity (HI, 75%-1RM; n=15); low intensity (LI, 30%-1RM; n=13); and low intensity with blood flow restriction training (LI-BFR, 30%-1RM and 30% of total vascular restriction; n=24). All participants performed 4 sets of plantar flexion in the leg press machine with 1 set of 30 repetitions following 3 sets of 15 (for LI and LI-BFR group) or 10 repetitions (HI group). Blood flow restriction was achieved using a cuff positioned on the dominant calf. The cuff was inflated at 30% of total vascular restriction of each individual (mean: 47.6 ± 19.8 mmHg). Cardiovascular variables were obtained during and after the session. **RESULTS:** Results indicated that HR increased significantly during the 4 exercise set for all groups (p <0.05), although the highest increases were found during the last set for the HI group (pre: 70.0 ± 10.0 bpm; post: 81.6 ± 11.7 bpm; p<0.001) and during the first set for the LI-BFR group (pre: 66.1 ± 12.9 bpm; post: 73.7 ± 15.1bpm; p<0.001). There were no significant differences in BP for any group. However, significant intergroup differences were observed in systolic BP during the first set for HI and LI-BFR groups when compared to LI group (p=0.03). HI and LI-BFR promoted significant systolic BP reductions (p<0.001) 30min post-exercise (pre: 126.1 ± 11.7 mmHg; post: 112.3 ± 14.0 mmHg), 45min post-exercise (pre: 126.1 ± 11.7 mmHg; post: 113.1 ± 10.2 mmHg) and for HI group post-15min (pre: 123.6 ± 15.7 mmHg; post: 115.0 ± 15.9 mmHg), post-45min (pre: 123.6 ± 15.7 mmHg; post: 114.4 ± 16.7 mmHg) and post-60min (pre: 123.6 ± 15.7 mmHg; post: 113.3 ± 14.7 mmHg). There were no significant changes (p>0.05) for diastolic BP and HR of the LI-BFR group. **CONCLUSION:** LI-BFR resistance training is able to generate an acute hemodynamic and cardiovascular response similar to HI and LI resistance exercise. HI and LI-BFR seem to promote a hypotensive post-exercise response.

Blood Flow Restriction During Barbell Squats does not Alter Performance or Muscular Damage

Teresa Wiczynski, Joseph Badinger, Cody E. Morris, Ray VanWye, Scott Arnett, Lee J. Winchester. *Western Kentucky University, Bowling Green, KY.* (Sponsor: Scott Lyons, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if an acute bout of blood flow restriction (BFR) during barbell squat training at 75% of 1 Repetition Maximum (1RM) would hinder performance or enhance muscular damage and inflammation when compared to traditional resistance training.
METHODS: 13 recreationally resistance trained men and women between the ages of 18 and 30 were recruited for this study. Participants were asked to complete 3 separate sessions for the course of this study. During session 1, the individuals 1RM on a bench press was assessed. During sessions 2 and 3, participants were asked to perform 5 sets of barbell squats until failure for each set at 75% of their tested 1RM. Half of the participants performed traditional resistance training during session 2 and blood flow restricted resistance training during session 3. This was reversed for the other half of the participants to avoid the possibility of a training effect. Perceived limb pain and number of repetitions performed were evaluated for each set. Venous blood samples were collected at each time point to assess muscular damage and inflammation, through ELISA analysis of myoglobin and IL-6, respectively. All 3 sessions occurred at least 7 days apart.
RESULTS: No significant differences were observed in the total number of repetitions performed between traditional and BFR resistance training (47.0 ± 14.7 vs 44.9 ± 10.8; p = .289). However, BFR training resulted in a significantly elevated average perceived pain rating when compared to traditional training (6.58 ± 1.35 vs 7.18 ± 1.23; p = .011). Myoglobin was elevated in the plasma during both traditional (4.47 ± 3.31) and

BFR (4.99 $\pm$ 3.5) training when compared to baseline (2.73 $\pm$ 2.48; p for both < .05), but there was no significant difference in myoglobin between the two conditions (p = .398). IL-6 is currently being assessed.

CONCLUSIONS: Our current results indicate that blood flow restriction training results in an increase in perceived pain rating during acute bouts of resistance training. However, it does not impair muscular performance or enhance muscular damage when compared to traditional resistance training. Future studies are needed to address the mechanism behind the ability of BFR training to enhance muscular performance.

The Effect Of Different Exercises On Qt Dispersion In Sedentary Women.

Guner Cicek[1], Oguzhan Celik[2]. [1]hitit university, Corum, Turkey. [2]Mugla Sitki Kocman University, Mugla, Turkey. (Sponsor: Mark D. Peterson, FACSM)
(No relevant relationships reported)

The effect of different exercises on QT dispersion in sedentary women.
Background: QT dispersion (QTd) is a marker of myocardial electrical instability, and is a clinical metric known to predict ventricular arrhythmias and sudden cardiac death. Regular exercise has been shown to decrease both QTd and risk for cardiovascular mortality in various populations; however, the extent to which exercise modalities differ with respect to QTd adaptive response is less well-understood.
PURPOSE: The purpose of this study was to investigate the effect of different exercise modalities on QTd in sedentary women**. METHODS:** A total of 26 volunteers were recruited and randomized into an aerobic exercise group (n=16; 35±2.2 years) and a resistance exercise group (n=10; 36.3±2.8 years). In both groups, exercise took place 4 days per week, for 16 weeks, and with 60 minute session. Heart rate (HR) was monitored continuously during all sessions, with the goal of maintaining an intensity of 60-70% max HR. Before and after the interventions, a standardized 12-leadsurface ECGs and blood pressure, were recorded. Pre and post intervention changes were assessed within subjects and between groups.**RESULTS:** Following the exercise interventions, there was a decrease in the body mass, body mass index (BMI), and systolic and diastolic blood pressure in both intervention groups. There were also increases in the values of RR intervals, T wave, and P wave, and decreased resting HR for the aerobic exercise group (p<0.05), but not significantly in CSG. In addition, for the aerobic exercise group, QTd decreased in from 50±15.0 to 26.2±11.4 ms, and QTc decreased in from 17.3± 5.3 to 8.3±3.7 ms (p<0.01). For the resistance exercise group, QTc decreased from 16.3±4.5 to 11.3±3.9 ms (p<0.05). **CONCLUSION:** The results of this study indicate that aerobic exercise significantly reduces the indices of ventricular repolarization dispersion among sedentary woman. While there were improvements in QTc for the resistance exercise group, QTd parameters improved to a greater extent.
Key Words: Sedentary woman, exercise, ventricular repolarization

Heat Rate Variability:Meaningful Change and Reliability using a Heart Rate Sensor Chest Strap and an Android Phone Application

Nathan J. Hellyer, Sonya Blyakher, Sarah Costello, Kaitlin Wohnoutka. *Mayo Clinic College of Medicine, Rochester, MN.*
(No relevant relationships reported)

PURPOSE:Heart rate variability (HRV), or the beat-to-beat variance in heart rate, is an adjunct measure of stress and physiological fatigue. Physically active individuals and athletes may use HRV as a measure of recovery from physical exhaustion, but change in HRV naturally fluctuates and meaningful change has not been well described. Therefore, the purpose of our investigation is to investigate reliability and minimal detectable difference in HRV measurement.
METHODS:We employed a test-retest reliability design with five minute resting heart rate measurements taken one week apart in eleven male and eleven female subjects (23±1 years old; BMI 22.7±2.3 kg/m²) positioned in a supine posture. HRV was collected by a Polar H7 heart rate sensor strap with data collected by a commercially available HRV android application, HRV Elite. Artifact detection and HRV analysis was performed using ARTiiFACT software to generate the root mean square of the successive differences (RMSSD) values for each HRV measurement. Intraclass correlation coefficients (ICC) were calculated to examine reliability and a minimal detectable difference was calculated to examine change detectable beyond the limitations of error. **RESULTS**:: RMSSD means on trial one and two were 75.0

(s.d.=27.8) milliseconds and 68.3 (s.d.=28.8) milliseconds, respectively. We observed an ICC of 0.947 (95% confidence interval 0.803-0.987). We calculated the minimal detectable difference to be 18.4 milliseconds.
CONCLUSIONS:HRV measurements taken from a heart rate strap and android phone application appear reliable in young, healthy subjects at rest as indicated by a relatively high ICC. However, a daily change in RMSSD needs to be considered with respect to innate measurement error in order to reflect meaningful change, which for the Polar H7 sensor and HRV Elite application pairing appears to be slightly greater than eighteen seconds.

Chronic Effects of an Elevation Training Mask on Aerobic Capacity, Anaerobic Endurance, and Pulmonary Function

Tyler Heimdal[1], Lavan Rajan[1], Justin Vickery[1], Ujalashah Dhanani[1], Joshua Harris[1], Michael Moreno[2], David Huston[3], Patrick McCulloch[1], Bradley Lambert[1]. *[1]Houston Methodist Hospital, Houston, TX. [2]Texas A&M University, Houston, TX. [3]Texas A&M Health Science Center, Houston, TX.*
(No relevant relationships reported)

Elevation training masks (ETM) have become popular in professional & recreationally active populations to enhance performance via purported adaptations associated with high elevation training (HET) and respiratory muscle training (RMT). **PURPOSE**: To compare the effect of training with (TM) to without (CON) wearing the ETM. **METHODS**: 8 healthy recreationally active adults (TM: M=2, F=2; 26.25±1.50; 25.05±1.42 kg·m²| CON: M=3, F=1; 31.5±6.95 yr; 24.92±1.83 kg·m²) were recruited & provided consent for this study. VO$_2$max and time to exhaustion (TTE) were assessed (Bruce protocol GXT, w/ & w/o ETM). Anaerobic endurance was assessed using two consecutive 300-yrd shuttle sprints (separated by 5min). Pulmonary function was assessed using a metabolic cart (FVC, MVV, FEV1). Following group assignment (TM and CON), subjects trained 3d/wk for 12 wks alternating between steady state running (Progression: 65->85% VO2max, 30->45min) and intense sprint conditioning every other session with VO$_2$max reassessment following wk 6. The TM group performed all sessions wearing the ETM at manufacturer reported simulated altitude of 9,000 ft. A (2)group x (2)time ANCOVA followed by a Tukey's post-hoc test was used to detect within group and between group differences following training. Type I error set at α=0.05. **RESULTS:**

CONCLUSION: Preliminary data indicate that training w/ the ETM does not enhance either aerobic or anaerobic endurance beyond standard training and may produce adaptations that are less favorable in comparison. However, under conditions of restricted breathing (i.e. GXT performed wearing the ETM), the TM group showed greater improvement. While the ETM may not provide benefits to those whose breathing is not typically restricted, further study is required to determine if there may be adaptive benefits for those who typically perform under restricted breathing conditions. **Data collection is ongoing with final data (n=24) to be presented at the time of conference.

Exercise Mode Reduces Photoplethysmography Measured Heart Rate Validity

J. Luke Pryor, Jeremy Hudson, Alexis Zazueta, Reyoot Berry, Breanna Hernandez, Scott S. Sailor. *California State University, Fresno, Fresno, CA.*
(No relevant relationships reported)

The validity of photoplethysmography-measured heart rate (PPG-HR) during exercise with varying degrees of upper extremity movement is unknown. **PURPOSE**: To assess the concurrent validity of three popular, commercially available PPG-HR monitors during exercises requiring varying amounts of upper extremity movement. **METHODS**: Twenty-one subjects (11 women and 10 men; mean±SD: age=24±4y, height=1.71±0.06m, body fat=19.4±6.5%) donned PPG-HR devices at the forearm, wrist, and ear canal and researchers applied the 12-lead electrocardiogram (ECG; criterion standard). HR data were collected during 4 minutes each of treadmill exercise, cycling, rowing, and calisthenics. Exercise intensity progressively increased each minute from 9, 12, 15, to 19 on Borg's 6-20 ratings of perceived exertion scale during each exercise mode. Calisthenics consisted of one minute of each of the following: body weight step-ups, jumping jacks, lunges, and burpees. Three minutes rest was given between exercise modes. PPG-HR and ECG devices were time synced with raw device data logged approximately every 5 seconds using a commercially available cellular application. Lin's concordance correlation coefficients (r_c) and Bland-Altman plots with 95% limits of agreement and mean bias characterized validity. **RESULTS**: Modes with less arm movement such as cycling (wrist r_c = 0.68, forearm r_c = 0.87, ear canal r_c = 0.39) and treadmill exercise (wrist r_c = 0.77, forearm r_c = 0.91, ear canal r_c = 0.42) produced relatively higher agreement with the ECG than exercise modes with greater arm movement such as rowing (wrist r_c = 0.13, forearm r_c = 0.56, ear canal r_c = 0.18) and calisthenics (wrist r_c = 0.03, forearm r_c = 0.84, ear canal r_c = 0.01). Combining all exercise modes, mean bias was low in the forearm device (-5 bpm) and high for the wrist (15 bpm), and ear canal (-38 bpm) devices. The limits of agreement (device - ECG) fell between -35 to 25, -40 to 70, and -103 to 27 bpm for the forearm, wrist, and ear canal devices, respectively. In all three devices, HR data fell outside of these limits of agreement at all exercise intensities. **CONCLUSIONS**: Variable validity of PPG-HR devices was observed across all exercise intensities. Exercise modes with greater upper extremity movement (rowing, calisthenics) further diminished PPG-HR validity.

Changes in Vascular Function of Female University Students at Different Types of Walking

Peizhen Zhang[1], Xiangrong Shi, FACSM[2]. [1]*Beijing Sport University, Beijing, China.* [2]*UNT Health Science Center, Fort Worth, TX.*
(No relevant relationships reported)

PURPOSE: To reveal effect of different types of walking on vascular function of female university students at the same amount of exercise. **METHODS**: Thirty normal weight female university students (age: 20.9±1.5years) participated in the study. They were randomly divided into two groups (IW group and CW group). There were fifteen female students in each group. Each group did exercise at the intensity of 65% heart rate reserve. CW(continuous walking) group walked continuously for 30 minutes without rest. IW(intermittent walking) group had 3-minute rest between two 15-minute walking. The blood pressure, heart rate, pulse wave velocity (PWV) and ankle brachial index (ABI) were determined before exercise. After exercise above indexes were recorded every 5 minutes till 30 minutes. **RESULTS**: 30 minutes after intermittent walking, the blood pressure(SBP: 99.8±6.8 vs 104.8±7.5mmHg, DBP: 59.8±6.1 vs 65.3±9.9mmHg) and heart rate(62.1±7.6 vs 68.2±3.9bpm) of IW group decreased significantly compared with pre-exercise(P<0.05). 5 minutes(891.2±86.3 vs 1006.9±71.5cm/s) and 30 minutes (933.4±72.2 vs 1006.9±71.5cm/s) after intermittent walking, PWV of IW group declined significantly compared with pre-exercise(P<0.05). 30 minutes after continuous walking, the blood pressure(SBP: 100.8±4.8 vs 108.4±8.2mmHg, DBP: 59.6±6.1 vs 64.7±5.0mmHg) and heart rate(65.3±11.4 vs 70.3±9.7bpm) of CW group descended significantly compared with pre-exercise(P<0.05). 5 minutes and 30 minutes after continuous walking, PWV(978.1±93.8 vs 1012.5±91.5cm/s) and ABI(0.96±0.09 vs 1.04±0.08) of CW group decreased significantly compared with pre-exercise(P<0.05). 5 minutes after exercise, the SBP(109.0±7.9 vs 116.8±6.1mmHg) and DBP(61.2±6.2 vs 63.4±5.7mmHg) of CW group were significantly lower than those of IW group. **CONCLUSIONS**: Both intermittent walking and continuous walking do good to lower blood pressure and heart rate, ameliorate arterial stiffness and improve vascular elasticity of female university students. Continuous walking has better effect on improvement of blood pressure and ankle brachial index compared with intermittent walking, which contribute to reduce risk of lower extremity arterial stenosis. All those improvement are beneficial to prevent cardiovascular disease in early life.

Comparing the Effects of Yoga and Meditative Relaxation on Blood Pressure Among College Age Students

Stephanie M. Otto, Riley Viner, Nathanael R. Otto, Mitchell Feske. *Gustavus Adolphus College, St. Peter, MN.*
(No relevant relationships reported)

Blood pressure (BP) is an important ACSM risk factor when assessing cardiovascular health. Yoga practice addresses both movement related benefits for BP and also benefits related to an activation of the parasympathetic nervous system through the use of breath and meditation. Meditative relaxation emphasizes parasympathetic nervous system activation but does not include the movement component. **PURPOSE:** The purpose of this study was to compare the effects of yoga and meditative relaxation on BP among college students. **METHODS:** Sixty-seven men and women with an average age of 19.88 (±1.75) years participated. Participants were enrolled in a 13-week yoga (n = 35), meditative relaxation (n = 18), or a control group course (n = 14). BP was measured at the beginning and end of the 13-week semester. Participants were grouped based on hypertension classification. The ACSM hypertension guidelines were used to place participants in either a high or low hypertension group. A two-way ANOVA analysis ($p < .05$) was used to determine group differences by hypertension class on change in systolic and diastolic BP. **RESULTS:** Forty-four participants were placed in the low hypertension group (systolic below 140mmHg and diastolic below 90mmHg) and 23 participants were placed in the high hypertension group (systolic at or above 140 mmHg and/or diastolic at or above 90mmHg). Among the participants in the high hypertension group, independent sample t-test showed a significant drop in both systolic, $t(65) = 4.62$, $p = .00$, and diastolic, $t(65) = 2.78$, $p = .00$, BP across both

exercise groups and the control group. Furthermore, a significant interaction between hypertension class and group was found for diastolic BP, $F (2, 2,537) = 3.59$, $p = .034$ but not for systolic BP. When the data was analyzed separately by hypertension class, a one-way ANOVA no longer showed significant group differences among either hypertension class. **CONCLUSION:** Among this sample, high hypertensive participants significantly decreased both systolic and diastolic BP by the end of a 13-week academic semester. However, there was no significant difference in BP change between yoga, meditative relaxation, and the control group. Continued research is needed to uncover potential benefits for students engaging in movement and meditation courses over the course of an academic semester.

Physical Activity or Body Composition for Heart Health & Heart Rate Variability

Karen K. Dennis, Alex M. Wolfe, Samantha Ward. *Illinois State University, Normal, IL.* (Sponsor: Dale D. Brown, FACSM)

(No relevant relationships reported)

Previous research has established a relationship between physical activity (PA), sleep efficiency (S%) and heart rate variability (HRV). Our previous studies (Wolfe and Dennis, 2016) have further established this relationship, with significant findings when separating PA by intensity (Dennis and Wolfe, 2016). **Purpose:** The purpose of the current study was to further investigate the relationship between PA and HRV. Specifically the primary aim of the study was to investigate the difference between BMI, PA and HRV. **Methods:** Nineteen subjects (20 ± 1 yr.) from a Division I University volunteered for the study. All subjects voluntarily signed an informed consent and completed anthropometric measures including height, weight and BMI. Subjects were then fitted with a BodyMedia SenseWear Armband to assess PA and sleep efficiency for the duration of one week (7days). Upon returning the device, each subject had HRV assessed (CardioSoft software), utilizing a 12-lead EKG by assessing standard deviation of the mean R-R intervals (SDANN). Subjects were classified as "Normal" or "Overweight" according to their BMI and t-tests were utilized to compare the two groups. **Results:** Our results show that the "Overweight" category (mean BMI = 26.6 kg/m²) had fewer steps (79, 060) when compared to the "Normal" BMI category (mean BMI = 21.6 kg/m², steps 81,212). Our results also show that the "Overweight" category had a lower HRV score when compared to the "Normal" category. However, the results of the t-tests showed no statistical difference ($p < .05$) between the two groups. **Conclusion:** While there was no statistically significant relationship between BMI and HRV, based on the results of the current study and by previous results (Wolfe & Dennis, 2016; Dennis & Wolfe, 2016) PA and PA intensity appear to have a larger impact on HRV rather than weight status. In terms of improving health, increasing PA should be the focus of college aged adults rather than reducing weight status.

The Impact of Ballet and Modern Dance Performance on Cardiac Autonomic Function in Collegiate Dancers

Rohan C. Edmonds[1], Meaghan C. Wood[2], Patricia Fehling, FACSM[2], Sarah DiPasquale[2]. *[1]Creighton University, Omaha, NE. [2]Skidmore College, Saratoga Springs, NY.* (Sponsor: Patricia Fehling, FACSM)

(No relevant relationships reported)

Heart rate (HR) variability (HRV) is a useful tool for assessing cardiac autonomic function and identifying potential training maladaptation in athletic populations, but has yet to be investigated in ballet or modern dance populations. As such, HRV may be able to provide valuable insight into the preparedness of dancers and the demands of performance in a collegiate dance population.
PURPOSE: The purpose of the study was to examine acute fluctuations in cardiac autonomic function in a cohort of collegiate dancers over an intensive modern and ballet concert weekend.
METHODS: Female collegiate dancers (n=29, age=20.0+1.1 years) were monitored leading up to and following a dance performance. Along with HR, analysis of HRV focused on the square root of the mean squared differences of the successive RR intervals (RMSSD). Magnitude based inferences (MBI) with effect sizes (ES) were used to identify the practical significance of changes during the Winter Dance Concert. The Recovery-Stress Questionnaire for Athletes (RESTQ-Sport) measured the frequency of stress of dancers.
RESULTS: Mean HR was likely higher at the first (76.5±2.1bpm, 92/8/0, ES=0.35) and second (75.6±1.8bpm, 94/6/0, ES=0.33) pre-show recordings compared to baseline (69.8±1.7bpm). In contrast, RMSSD was most likely lower at the first (0/0/100, ES=-0.61) and second (0/0/100, ES=-0.58) pre-show recordings compared to baseline. Both HR and RMSSD returned to baseline values at the post-show recording. Additionally, as per the RESTQ-Sport dancers reported feeling increasingly stressed and lacking energy going into the performances, as well as significantly higher feelings of fatigue after the weekend of performances when compared to baseline values.
CONCLUSIONS: Dancers responded to concert performances in a comparable manner to other athletic populations approaching intense competition, exhibiting

decreased parasympathetic activity, while returning to baseline values within 24 hours of their performance. This is indicative of ideal preparation and recovery from the weekend dance performances.

Daily HRV Monitoring During Resistance Training Program in a Collegiate Athlete

Clifton J. Holmes, Michael R. Esco, FACSM. *University of Alabama, Tuscaloosa, AL.*

(No relevant relationships reported)

PURPOSE: Examine the relationship between total work (TW) and HRV in a collegiate athlete during an 18-week resistance training program.
METHODS: The program consisted of three 60-90 minute full-body exercise sessions per week with at least 24-hours of rest between each session. Daily 55-sec HRV measurements were taken immediately after waking using the ithlete™ smartphone application and the pulse-wave finger sensor. TW was a combination of total volume (TV) and total load (TL). TV was calculated from sets multiplied by reps of all exercises and TL was the sum of weight lifted in all exercises. HRV was separated into the weekly mean (HRV_M) and the coefficient of variation (HRV_{CV}).
RESULTS: No statistically significant correlations were found between HRV_M and TW, TL, or TV ($r = -.002$, $p = .993$; $r = -.273$, $p = .273$; $r = 0.39$, $p = .879$) but statistically significant correlations were found between HRV_{CV} and TW, TL, and TV ($r = .525$, $p = .030$; $r = -.559$, $p = 0.020$; $r = .705$, $p = .002$, respectively). A step-wise regression showed non-significant partial correlations for TW (-.232, $p = .388$) and TL (-.323, $p = -.232$).
CONCLUSIONS: No statistically significant correlations were found with HRV_M. However, statistically significant correlations were found between HRV_{CV} and TW, TL, and TV, with TV being the most important determinant. This study demonstrates that as intensity of resistance training increases or decreases from session to session through the manipulation of volume and load, HRV_{CV} increases or decreases proportionally, directly or inversely.

Heart Rate Variability in Marathon Runners During Steady State Exercise and a Graded Exercise Test

Christopher J. Lundstrom, Timothy J. Houghton, Kelsey Sutter, George R. Biltz. *University of Minnesota, Minneapolis, MN.* (Sponsor: Dr. Eric Snyder, FACSM)

(No relevant relationships reported)

Heart rate variability (HRV) analysis offers insight into health status, where greater HRV is associated with better cardiovascular function. Unlike most HRV techniques, which require stationarity of data (e.g., rest), detrended fluctuation analysis (DFA) does not. However, DFA may require a larger data set for reliable results. DFA captures both short- (DFAα1) and long-term fluctuations (DFAα2). A reliable technique to measure HRV using a brief, submaximal exercise session could serve as a simple method of assessing health and adaptability. **PURPOSE:** To compare HRV using DFA during a 3-min steady state (SS) run versus a longer graded exercise test (GXT). **METHODS:** Forty recreational runners (21.1 ± 1.6 years, 27f) completed a 2-mile (3.218-km) time trial (TT) prior to, and after 18 weeks of training for a 42.2-km marathon. Subjects performed a SS run at 75% of TT velocity for 6 min followed by an incremental GXT. Paired samples t tests were used to compare pre- and post-DFA measures, TT, and VO2max, and to compare DFA scores for the final 3 min of SS with the full GXT. Delta scores were calculated for all variables. Correlations between the changes were assessed using Pearson's r. **RESULTS:** When comparing SS and GXT, post-DFAα1 and α2 and pre-DFAα1 were different. ($p \le 0.001$). During SS, DFAα1 decreased from pre- to post-testing (0.947 ± 0.248, 0.835 ± 0.261; $p \le 0.018$) whereas DFAα2 did not change: (1.224 ± 0.188, 1.291 ± 0.207; p = 0.150). For the full GXT, neither DFAα1 or DFAα2 changed with training. Subjects improved in TT (15.5 ± 2.0, 14.3 ± 1.6; $p \le 0.001$) and VO2max (50.4 ± 7.2, 52.7 ± 7.0; p = 0.002). DFA scores for SS and GXT were significantly correlated (r = 0.59 to 0.70, $p \le 0.001$) with the exception of the DFAα2 post-test (r = 0.25, p = 0.122). The changes from pre- to post-test during SS and GXT were correlated (DFAα1: r = 0.60, $p \le 0.001$; DFAα2: r = 0.32, p = 0.044). **CONCLUSION:** DFAα1 during SS decreased with training, indicating increased short-term HRV. While SS and GXT yielded different DFA scores, the correlations between the scores during SS and GXT and the correlations between the changes suggest that the SS data captures information related to the larger data set. Further research is needed to determine whether the differences between SS and GXT scores are due to the smaller data set or the higher exercise intensity during GXT.

Leukocyte and Lactate Responses to Different Modes of Exercise at the Same Target Heart Rate

Pearl Law, Fadia Haddad, Frank P. Zaldivar, Annamarie Stehli, Sebastian Piombo, Shlomit Radom-Aizik. *UC Irvine, Irvine, CA.* (Sponsor: Barket Falk, FACSM)
(No relevant relationships reported)

Heart Rate (HR) is widely used for exercise intensity prescriptions and/or studies of exercise training. It is often assumed that exercising at a given HR results in similar metabolic stress, regardless of the mode of exercise. **PURPOSE:** To gauge the leukocyte and lactate responses following a submaximal exercise at an equivalent target HR on cycle ergometer (CE) and treadmill (TM). **METHODS:** Six healthy male adults (25.4 ± 3.2 y.o) completed 4 laboratory visits. Participants performed a progressive exercise test to exhaustion on CE and TM. On subsequent separate days, in a randomized order, participants performed a 30-min constant exercise challenge at 70% HR reserve (HRR) on CE or TM. Borg's Rating of Perceived Exertion (RPE) was recorded every 5 min. Blood was drawn before and immediately after the 30-min exercise. Paired t-test was used to evaluate within-person differences (before/after exercise) & between modes. Due to the small sample size, effect sizes were also calculated. **RESULTS:** We successfully "clamped" HR during the exercise in CE and TM (CE, 154.8 ± 0.7; TM 156.8 ± 0.8 bpm). During the first 10 minutes, all participants perceived the CE challenge as more strenuous compared to the TM (RPE; 13.9 ± 0.1 vs. 11.3 ± 0.4), with no significant difference between modes during the last 10-min (11.7 ± 0.5 vs. 12.5 ± 0.0). Immediately following the exercise, lactate was greater in CE (5.9 ± 1.4 mmol/L) vs. TM (3.1 ± 1.3, p =.032). Leukocytes were significantly elevated (p<.003) immediately after exercise for both CE and TM, with no difference between exercise modes (monocytes; CE 53.3 %, TM 62.5%, granulocytes; CE 33.5%, TM 42.7%, lymphocytes; CE 118.7%, TM 76.9%). However, a moderate effect size (d= .486) was seen for lymphocytes, with a greater increase in CE. **CONCLUSION:** Lactate response was lower on TM while leukocyte response was generally similar. The smaller lactate increase on TM may reflect lower reliance on anaerobic metabolism when using a larger muscle mass and/or greater lactate clearance by upper body muscles. The similar leukocyte response may reflect the fact that in both modes metabolic stress was moderate. HR is not sufficient in and of itself to fully assess the metabolic stress associated with a given mode of exercise. Supported by NIH P01HD-048721 & PERC Systems Biology Fund

Effects of Off-Season Training on In-Season Training Load and Time Spent in Heart Rate Zones

Jason A. Melnyk, Kimberly Kostelis. *Central Connecticut State University, New Britain, CT.* (Sponsor: Sean Walsh, FACSM)
(No relevant relationships reported)

Maximizing training in and out of season is essential for player development in college soccer. Maintaining and improving aerobic performance has been shown to be successful using high-intensity interval training (HIIT) and vigorous endurance exercise (END). Utilizing HIIT can be as much as half the time commitment, which among Division III who have limited contact time, becomes crucial for success of programs. **PURPOSE**: To compare the effects of two off season endurance-training protocols on Training Load (TL), as well as time spent in Heart Rate Zone (HRZ) during in season training. **METHODS**: During off seasons, players (N=19) were randomly assigned to either HIIT or END. The HIIT group performed five maximal 30-sec sprints with 4.5 minutes of recovery, twice per week, and the END group completed a 40-min run at 80% heart-rate reserve twice weekly. VO_{2max} was estimated pre vs post of the 5 week training intervention. Once athletes were in season, data was collected using Polar Team2 system for 6 sessions. TL and time in each of the 5 HRZs were recorded from 50% to 100% HR_{max}, in 10% increments. **RESULTS:** During off season, both groups significantly improved their VO_{2max} estimated by the Beep test; however, there was no significance between groups. When examining TL and HRZ during in season training, there were also no significant differences (p>0.05) among groups. Nevertheless, average TL for athletes in the HIIT group (190.27±41.92) was higher than athletes in the END group (180.29±60.70). Additionally, when examining HRZ, athletes in the HIIT group spent a larger percentage of time (39.70%) in 80% HRZ or higher as compared to the END group (35.72%). **CONCLUSIONS**: Soccer players may improve aerobic performance irrespective of training method thus saving significant time during self-directed off season training among Division III athletes . In-season analysis indicated neither training type impacted TL; however, the HIIT group spent on average an hour more in the 80-100% HRZ.

Resistive-based Walking Training For Individuals With Poststroke Hemiparesis

Christopher P. Hurt, Marcas M. Bamman, FACSM, Tara Pearce, Sarah dos Anjos, Jutaluk Kongsuk, David A. Brown. *University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Marcas M Bamman, FACSM)
(No relevant relationships reported)

Individuals poststroke exhibit reduced walking economy compared to age-matched nonimpaired individuals. Typical aerobic training-based walking programs may not improve economy.
PURPOSE:
This abstract describes the feasibility of applying backward directed resistive forces to individuals poststroke walking at their comfortable speed, at a vigorous level of aerobic intensity, within a novel treadmill environment.
METHODS:
We are reporting on two participants (49±9 yrs, >6 months post CVA) who have completed the resistive walk training within this ongoing pilot RCT (NCT03174392). Individuals visited the lab 3 days a week for 8 weeks and accumulated 30 minutes of walking per training session. The training bouts were broken up into 5-minute increments, if needed, and resistive force was added until a training intensity of at least 60% heart rate reserve was achieved. Resistive forces were provided by a novel exercise training device that delivered a constant backward-directed pulling force at the level of the center of mass. Participants did not use handrails while training, however they wore a safety harness to ensure safety. Comfortable walk speed, 6-minute walk, and the Functional Gait Assessment (FGA) were completed along with net gait economy, pre-and post-training. Average standing VO_2 consumption was subtracted from the final three minutes of a six-minute walking trial at the same speed pre- and post-assessment.
RESULTS:
One individual began walking against a constant 19 N resistive force and progressed to 57N. Walking economy improved 11.5% with a marginal change in walking speed, however this individual increased their 6-minute walk distance 10% while improving their FGA score by 33%. The other individual progressed from 33 N to 85 N of continuous force. A 37% increase in economy occurred upon completion of the training with marginal changes in comfortable walking speed and a 34% improvement in 6-minute walk distance along with an 11% increase in FGA.
CONCLUSION:
This preliminary data suggests that using horizontal resistive forces to generate an aerobic level of training during walking is a feasible approach to exercise training of individuals poststroke and may result in improved gait economy, balance, ability to sustain higher work at their comfortable speed, and endurance.

Cardiovascular Risk Markers in Firefighters: A Longitudinal Study

Steven Martin, Rachel Atchison, Kory Sealy, Kalen Johnson, Alison McGuire, Jason Lytle, John Green, FACSM, Stephen Crouse, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: Stephen F. Crouse, FACSM)
(No relevant relationships reported)

Purpose: To investigate changes in certain cardiovascular risk markers over an eight year period for a group of firefighters (n =52). Subjects were full time firefighters employed by a moderate-to-large municipality. **Methods:** As part of an annual physical exam, firefighters underwent evaluation of several cardiovascular risk factors including body weight, a graded exercise test (GXT; Bruce protocol), body composition (through DEXA), and fasting bloodwork. Maximal oxygen uptake (VO2max) was estimated using the Foster equation and functional aerobic impairment (FAI) was computed using both age predicted norms and the Foster equation estimation of VO2max. Resting systolic blood pressure (RSBP) and resting diastolic blood pressure (RDBP) were measured before the start of the GXT protocol. Blood analysis was performed by a College of American Pathologists-accredited laboratory. All blood samples were analyzed for total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and glucose (GLU). **Results**: A repeated measures analysis of variance was used to analyze the data. Significant negative changes across the eight-year assessment period occurred in all dependent variables measured. **Conclusion**: In general, these data suggest a negative trend in certain cardiovascular risk markers for a group of local firefighters over time. These findings support the need for required health and fitness programs for firefighting personnel.

Training Impulses And The Relation With Performance Improvement: Not That Straightforward

Kobe M. Vermeire, Gilles Vandewiele, Jan Bourgois, Jan Boone. *Ghent University, Ghent, Belgium.*
(No relevant relationships reported)

Purpose: To assess the relation between training load and performance improvement in a homogeneous group with a differentiated training programme.
Methods: Training data from 11 recreational cyclists (aged 38.5 ± 5.9 yr) were collected during a 12-week training period. Before and after the training period, subjects underwent a laboratory incremental exercise test with lactate measurements. Baseline metrics were the aerobic lactate threshold (ALT), the anaerobic lactate threshold (ANLT) and the maximum power output (MPO). Internal training load was calculated using individualized TRIMP (iTRIMP), Lucia TRIMP (LuTRIMP), Banister TRIMP (bTRIMP) and Edwards TRIMP (eTRIMP). The distribution of training load was calculated as the time in zone 1 (Z1), zone 2 (Z2) and zone 3 (Z3), being the zone below the ALT, between ALT and ANLT and the zone above ANLT respectively.
Results: 353 training sessions were analysed. All metrics improved ($p < 0.01$) from baseline to posttest (ALT from 161.4 W $\pm$ 20.8 to 179.4 W $\pm$ 25.6; ANLT from 221.6 W $\pm$ 25.8 to 240.4 W $\pm$ 25.0 and MPO from 273.5 W $\pm$ 23.7 to 290.9 W $\pm$ 26.0) All TRIMP calculations correlated very highly with one another (r= $0.88 - 0.99$, $p <$ 0.01). No significant correlations ($p < 0.05$) were found between the mean weekly TRIMP, for every calculated method, and the improvement in fitness variables. When looking at the distribution of training time, total minutes in Z2 correlated largely with the progression in the ANLT ($r = -0.63$, $p = 0.02$). The percentage of time trained in Z1 correlated with progress in MPO ($r = 0.58$, $p = 0.03$), percentage in Z2 correlated negatively with MPO ($r = -0.74$, $p < 0.01$) and percentage in Z3 shows a relation with the progress in ANLT ($r = 0.56$, $p = 0.04$). When combining the percentage and total time in each of the training zones in a regression analysis, there is a stronger relation with the improvement in ALT ($r = 0.29$), in ANLT($r = 0.74$) and MPO ($r = 0.81$).
Conclusion: Directly relating training impulses with training progression should be done with caution. Distribution of training time over the intensity zones should always be accounted for. It is improbable that one metric could directly relate to the overall progression of an athlete.

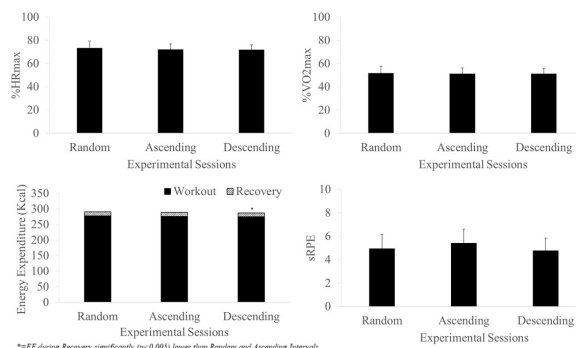
Indoor Cycling Energy Expenditure: Does Sequence Matter?

Cristina Cortis[1], Carl Foster, FACSM[2], Mich Cook[2], Scott T. Doberstein[2], Cordial Gillette[2], John P. Porcari, FACSM[2]. *[1]University of Cassino and Lazio Meridionale, Cassino, Italy. [2]University of Wisconsin-La Crosse, La Crosse, WI.*
(No relevant relationships reported)

Although during cycling class intensity is modified by changing interval intensity sequencing, it has not been established whether intensity order can alter physiological and perceptual responses within a workout. **PURPOSE:** To determine the effects of interval intensity sequencing on energy expenditure, physiological markers, and perceptual responses during indoor cycling. **METHODS:** 10 males (20.0 ± 0.8 yr) and 8 females (21.3 ± 2.7 yr) completed four cycle ergometer sessions. They performed 3 randomly ordered interval bouts (random intervals-RI, ascending intervals-AI, and descending intervals-DI) including three 3-minute work bouts at workloads corresponding to 50%, 75%, and 100% of peak power output (PPO) and three 3-minute recovery periods at 25% PPO. Heart rate (HR) and oxygen consumption (VO_2) were measured and expressed as percentages of maximal HR (%HRmax) and VO_2 (%VO_2max). Energy expenditure was considered for both the work bout (EE) and for the 5-minute recovery period (EE Rec). Session RPE (sRPE) and Exercise Enjoyment Scale (EES) were recorded. **RESULTS:** No significant differences were found for %HRmax (RI: 73.3 ± 6.1%; AI: 72.1 ± 4.9%; DI: 71.8 ± 4.5%), %VO_2max (RI: 51.8 ± 4.6%; AI: 51.4 ± 3.9%; DI: 51.3 ± 4.5%), EE (RI: 277.5 ± 39.9; AI: 275.8 ± 39.4; DI: 274.9 ± 42.1 kcal), EES (RI: 4.9 ± 1.0; AI: 5.3 ± 1.1; DI: 4.9 ± 0.9), and sRPE (RI: 4.9 ± 1.0; AI: 5.3 ± 1.1; DI: 4.9 ± 0.9). EE Rec was significantly ($p<0.005$) lower after DI (11.9 ± 3.2 kcal) with respect to RI (13.2 ± 2.5 kcal) and AI (13.3 ± 2.5 kcal). **CONCLUSIONS:** Although lower EE are observed during the recovery period in DI, interval intensity sequencing does not effect overall energy expenditure, physiological markers, and perceptual responses during cycling. This suggests that group cycling instructors can vary workout structure to promote adherence and maintain enjoyability, while achieving the same EE.

---


*=EE during Recovery significantly (p<0.005) lower than Random and Ascending Intervals

Comparison of Three Lactate Threshold Determination Methods in Trained Cyclists and in Non-Cyclists

Lisa Ferguson-Stegall[1], Rachael Nelson[1], Mallory Wirth[1], Anthony Wolfe[2]. *[1]Hamline University, Saint Paul, MN. [2]University of Texas at Austin, Austin, TX.* (Sponsor: Hirofumi Tanaka, FACSM)
(No relevant relationships reported)

While lactate threshold (LT) is a common laboratory test and is often used to design training plans and monitor fitness changes, there is no consensus as to which determination method should be used. Three of the most common are the break point (BREAK), 1 mmol.L^{-1} over baseline (+1 mmol), and reaching 4 mmol.L^{-1} (onset of blood lactate accumulation, OBLA). Currently, it is not clear if different determination methods could yield varying results in different populations. **PURPOSE:** We compared 3 most commonly used LT methods in trained cyclists and in athletes (soccer players) who were not accustomed to cycling exercise. We hypothesized that the BREAK and +1 mmol methods would yield similar results in both populations. **METHODS:** LT data were analyzed from 41 athletes [18 trained cyclists (15 males [m], 3 females [f]) and 23 female soccer players]. Tests were performed on a cycle ergometer using 5 min stages starting at 70 W (m)/50 W (f). Work rates were increased by 25 W (m)/15 W (f) for the first 3-4 stages, and by 15 W (m)/10 W (f) for the last 2-3 stages. Blood samples were obtained in the last min of each stage, and blood lactate was analyzed using a Lactate Plus device. For determinations of LT, 3 trained investigators independently analyzed the plots. **RESULTS**: In cyclists, LTs using BREAK and +1 mmol (247 ± 48 W vs. 250 ± 50 W, $p=0.52$) were not different but were significantly lower than that obtained with OBLA (270 ± 54 W). Correlational analyses indicate that LT using BREAK and +1 mmol were strongly related (R=0.99). Associations were strong between +1 mmol and OBLA (R=0.96) and between BREAK and OBLA (R=0.96). In non-cyclists, LTs obtained with all 3 methods were significantly different (BREAK: 125 ± 13 W; +1 mmol: 130 ± 11 W; OBLA, 134 ± 13 W; all $p<0.04$), although BREAK and +1 mmol were strongly associated (R=0.98). The associations between different LT methods were much weaker in non-cyclists (1 mmol and OBLA: R=0.90; BREAK and OBLA: R=0.85) compared with cyclists. **CONCLUSIONS**: Break point and +1 mmol.L^{-1} methods yield comparable results in trained cyclists but not in non-cyclists. Caution should be used when interpreting LT results obtained from different determination methods.

Assessing The Ability Of The Wattbike Cycle Ergometer To Predict Maximal Oxygen Consumption

Nicholas J. Hanson[1], Erin E. Kishman[1], Kyle D. DeRosia[1], Sarah C. Martinez[1], Sangwoo Lee[1], Cory M. Scheadler[2], Michael G. Miller[1]. *[1]Western Michigan University, Kalamazoo, MI. [2]Northern Kentucky University, Highland Heights, KY.*
(No relevant relationships reported)

The Wattbike is an electromagnetically and air-braked cycle ergometer that has been used for talent identification and elite development by British Cycling. It is paired with advanced software that includes a 3-min aerobic test meant to provide maximum minute power (MMP) and predict maximal oxygen consumption (VO_2peak). **PURPOSE**: To investigate the accuracy of the prediction by the Wattbike, and to determine the ability of the 3-min test to elicit a true VO_2peak. **METHODS**: This study included 13 cyclists (3 women, 10 men) with varying degrees of experience, a mean$\pm$SD age of 29.2 ± 10.0 years, height of 178.7 ± 8.3 cm, and mass of 75.1 ± 12.5 kg. At the first lab visit, a 10-min self-paced VO_2peak test (SPV) was performed. For the second visit, they were asked to complete a warm-up followed by the 3-min

test. The goal of the 3-min test, as stated in the manufacturer's instructional video, is to maintain as high of a power output as possible for three full minutes without a drop in performance. Subjects were shown the video, so that they were fully aware of the protocol and requirements. They were free to alter pedal cadence and resistance throughout the test. A metabolic cart was used to collect expired gases. 15-breath moving averages were calculated and the maximal value for each variable was used for analysis [VO_2, respiratory exchange ratio (RER) and ventilation (V_E)]. A one-way repeated-measures ANOVA was used to compare the VO_2peak (in ml·kg^{-1}·min^{-1}) given by the Wattbike to the values provided by the metabolic cart for the SPV and the 3-min test. Dependent t-tests were used to compare the heart rate (HR), V_E and RER between the two tests. To determine if the tests were truly maximal, the following criteria were used: HR within 10 bpm of apHR_{max} or RER of $\geq$1.10. **RESULTS**: There was no difference (p=.367) between the Wattbike-predicted VO_2peak (54.3±9.3) and the values provided by the metabolic cart during either test (3-min: 52.5±8.7, SPV: 54.0±9.7). There was a higher HR and lower RER in the SPV compared to the 3-min test (184.7±10.6 vs 180.9±6.3 bpm; p=.027 and 1.19±.06 vs. 1.29±.10; p=.001). There was no difference in V_E between tests (p=.474). The MMP for the 3-min test was 323.8±71.7 W. **CONCLUSIONS**: These results show that the Wattbike 3-min test elicited a VO_2peak value similar to that of the SPV, and it was able to successfully predict VO_2peak.

Validity and Reliability of the Lode Excalibur Sport Cycle Ergometer for the Wingate Anaerobic Test

William R. Lunn. *Southern Connecticut State University, New Haven, CT.* (Sponsor: Robert Axtell, FACSM)
(No relevant relationships reported)

The Wingate Anaerobic Test (WanT) has been used extensively for decades for lower-exremity anaerobic power determination in various populations. While multiple devices are advertised with WAnT capability, reliability and validity data are less available. **PURPOSE:** To determine if the Lode Excalibur Sport cycle ergometer (Groningen, Netherlands) is a reliable and valid instrument to conduct the 30-s WAnT compared to the Monark 894e Peak Bike (Vansbro, Sweden). **METHODS:** Recreationally active men with no history of cardiovascular disease or exercise impairment (n=33; 20.5 ± 2.6 y; 1.8 ± 0.1 m; 79.8 ± 10.2 kg) were recruited. Following familiarization to the WAnT, participants completed four (4) 30-s WAnTs within 2 weeks: two on the Lode (torque factor of 0.7) and two on the Monark (resistance = 0.075 kg·kg body mass^{-1}). Time of day, pre-test nutrition, and geometric fit on the cycle were duplicated for each test. Peak power (PP), mean power (MP), minimum power (MinP), and fatigue index (FI) were measured. Pearson's correlation coefficients, inter-day correlation coefficients (ICC), and one-way MANOVA were used to determine reliability and validity. Error rate was set at $p<0.05$. **RESULTS:** Reliability by ICC with 95% CI for Monark and Lode, respectively, was excellent to good for PP (0.96 (0.93-0.98), 0.91 (0.81-0.95)); MP (0.99 (0.98-0.99), 0.95 (0.91-0.98)); MinP (0.89 (0.78-0.95), 0.91 (0.81-0.95)); and moderate to excellent for FI (0.84 (0.67-0.92), 0.78 (0.52-0.89)). Correlation was strong for PP ($r = 0.87$; $p<0.001$), MP ($r = 0.90$; $p<0.001$), MinP ($r = 0.78$; $p<0.001$), and moderate for FI ($r = 0.59$; $p = 0.001$). However, Lode PP and FI were significantly less than Monark (10.7 ± 1.0 vs. 12.4 ± 1.9 W·kg^{-1}, respectively; $F(1,64) = 21.1$, $p<0.001$) and 41.7 ± 1.6 vs. 62.1 ± 1.6 %, respectively; $F(1,64) = 85.1$, $p<0.001$). Lode MinP was significantly greater than Monark (6.2 ± 1.2 vs. 4.6 ± 0.8 W·kg^{-1}, respectively; $F(1,64) = 39.5$, $p<0.001$). There was no significant difference in MP between ergometers. **CONCLUSION:** The Lode Excalibur Sport cycle ergometer reliably provides common WAnT outcomes and correlates well to the Monark 894e Peak Bike. However, the difference in absolute values for PP, MinP, and FI between instruments prevent the use of the Lode ergometer for comparison of WAnT data to normative data generated by the Monark cycle.

Evaluation of Asymmetry in Power Production During Cycling

John W. Farrell III, Daniel Blackwood, Brian Pribble, Rebecca Larson. *University of Oklahoma, Norman, OK.*
(No relevant relationships reported)

Levels of asymmetry have been previously reported during cycling for both force and crank torque. However, these measurements are not currently being used as performance indicators in cycling, leading to a need for the evaluation of asymmetry in power production. **Purpose:** Therefore, the purpose of the current study was to evaluate the presence of asymmetry in power production during cycling. The effects of exercise intensity and cadence selection on asymmetry were also evaluated. **Methods:** 21 subjects, ages 18-45, participated in the study. Subjects were assigned to either a Cycling Experience (CE, n=9) or No Cycling Experience (NCE, n=12) group. All subjects performed three graded exercise test (GXT) using a cycle ergometer on three separate visits at three different cadence zones. Cadence zones consisted of: Self Selected (SS), High (100 to 115 rpm), and Low (55 to 70 rpm). Subjects performed the first GXT at the SS cadence while the cadence for the second and

third was randomly selected. Power output for each lower limb was assessed using a dual power meter. Power output asymmetry was calculated as the absolute difference between limbs at the initial stage (IS), the stage in which the onset of blood lactate accumulation (OBLA) occurred, and at the stage in which peak power output (PPO) occurred. Two way repeated measures ANOVA was used to determine if significant differences existed between groups and conditions. **Results:** Significant group by condition interactions were present. There were no significant differences between cadence selection at IS, OBLA, or PPO (P>0.05). However, significant differences were observed between groups at IS (CE 8.70±15.1 vs. NCE 2.87±2.62), OBLA (CE 9.73±14.3 vs NCE 4.31±3.20), and PPO (CE 12.21±14.4 vs. NCE 5.48±3.57). **Conclusion:** Cadence selection was not significantly related to the level of asymmetry for power output during cycling, but significant differences did exist between the groups for power asymmetry. Cycling performance is closely related to the ability to produce higher power outputs in an efficient manner, so levels of asymmetry in power production could lead to performance decrements. Further research is needed to understand this relationship as well as potential training interventions to reduce levels of asymmetry observed during cycling.

Posture Influence on Recovery Intervals in Sprint Cycling

Deanna Emnott, Lorrie Brilla, FACSM, Harsh Buddhadev, Wren McLaughlin. *Western Washington University, Bellingham, WA.* (Sponsor: Lorrie Brilla, FACSM)
(No relevant relationships reported)

There is a paucity of research on how trunk posture affects recovery during a race or practice immediately between cycling sprints, although there is speculation that posture may influence recovery. This study included 13 competitive male cyclists, with an average of nearly 10 competitions in the past year. Participants completed two 30-s maximal effort sprints on a cycle ergometer followed by two 4-min active recovery intervals at 75 W and the same cadence for each session. Participants assumed one of two trunk posture conditions during the recovery intervals on two separate days. They were randomly assigned to either a flexed thoracic spine position greater than 14° (FC) or a neutral thoracic spine position (NC) on the first testing day and completed the other no less than 48 hours later. Recorded variables included heart rate recovery (HRR), tidal volume (V_T), carbon dioxide output (VCO_2), change in sprint mean power (ΔMP), and change in sprint fatigue index (ΔFI). There were no significant differences between conditions in any of the variables ($p>0.05$). Results of FC versus NC for each variable were: HRR 23.5±0.4 vs. 21.3±5.0 bpm; V_T 3.00±0.51 vs. 3.19±0.54 L; VCO_2 3.28±0.25 vs. 3.26±3.60 L/min; ΔMP -29.7±17.0 vs. -28.8±19.0 W; ΔFI 0.59±0.25 vs. -0.43±1.90 W/s. Using the Cohen's d statistic, there was a small effect of thoracic spine position during recovery on HRR (d=0.33), V_T (d=0.34), and ΔFI (d=0.45) from one sprint to another. However, there was no effect of thoracic position on VCO_2 (d=0.062) or the ΔMP (d=0.051) from sprint to sprint and recovery intervals. There may be little to no benefit to recovery in assuming a more flexed thoracic position between cycling sprints.

Effects Of Cycling Cadence On Physiological Variables

Daniel J. Blackwood, John W. Farrell, III, Rebecca D. Larson. *University of Oklahoma, Norman, OK.* (Sponsor: Christopher Black, FACSM)
(No relevant relationships reported)

The rate of muscular contractions during cycling can be modified by increasing or decreasing pedaling revolutions. The manipulation of cadence (revolutions per minute, rpm) may lead to alterations in the physiological response at a given work rate and cadence selection may affect overall cycling performance. **PURPOSE:** Therefore, the purpose of this study was to assess the relationships between cadence selection and accumulated energy (AE), time to exhaustion (TTE), and VO_2peak. **METHODS:** 20 individuals age 18-45 participated in the current study. Participants were grouped into two groups, cycling experience (CE=8) and no cycling experience (NCE=12).Subjects in both groups each completed 3 graded exercise tests (GXT) at 3 different cadences over the course of 3 visits. The initial GXT (visit 1) was at a self-selected (SS) cadence and the subsequent 2 visits consisted of a GXT at either a Low (55-70 rpm) or High (100-115 rpm) cadence. The cadence for visits 2 and 3 were randomly selected. A two-way repeated measures ANOVA was used to determine if significant differences existed between groups as well as between cadences. **RESULTS:** A significant group by condition interaction was present. Significant group differences existed for AE (CE 196.17 ± 57.95 vs. NCE 100.67 ± 37.00), TTE (CE 1368.67 ± 207.37 vs. NCE 990.11 ± 174.64) and VO_2peak (CE 47.71 ± 8.21 vs. NCE 36.16 ± 4.87). Significant differences were observed between the High and Low cadences for AE (High 135.53 ± 66.14 vs Low 156.28 ± 66.97) and TTE (High 1123.42 ± 285.69 vs. Low 1218.167 ± 254.32). Significant differences were also observed between the High and SS cadences for AE (High 135.53 ± 66.14 vs SS 153.4 ± 66.68) and TTE (High 1123.42 ± 285.69 vs. SS 1196.58 ± 254.28). No significant differences were observed between the Low

and SS cadences for AE and TTE (p > 0.05). No significant differences were observed at the different cadences for VO_2peak. **CONCLUSION:** Cadence selection appears to have a significant effect on TTE and AE, but no effect on VO_2peak. These findings suggest that selecting a higher cadence will lead to earlier development of fatigue and volitional exhaustion compared to that of lower cadences. This indicates that improper cadence selection could have a detrimental effect on cycling performance and should be individualized.

Do High-Intensity Intervals 24hr Prior to a Simulated Cycling Race Enhance 40km Time Trial Performance?

G. Alan Garvick, Edward K. Merritt, R. Andrew Shanely. *Appalachian State University, Boone, NC.*
(No relevant relationships reported)

Previous endurance exercise studies suggest that a high-intensity low-volume taper period improves performance over a low-intensity taper period. However, few, if any, studies have examined different exercise intensities in the two days preceding a race, a period often manipulated during training. **PURPOSE:** To compare performance in a simulated 40km cycling time trial (TT) 24hr after a high-intensity interval - low volume cycling session (HII), commonly described as an "openers," or a low-intensity effort session (LIE). **METHODS:** Eight subjects (6 males/ 2 females, 29.6±4.5 yrs, VO_{2max} 62.3±2.21 ml kg^{-1} min^{-1}) completed two simulated 40km time trials following the familiarization 40km TT (FAM). The FAM trial was completed 5-10 d prior to the first performance trial. Performance trials, HII and LIE, were completed in a random crossover repeated measures design. Subjects rested the day before FAM, HII, and LIE trials to mimic normal pre-race structure. HII consisted of 1hr of cycling (15-min warm up at 63% of FAM power (FAMp)), three 1-min efforts at 150% FAMp separated by 5-min at 63% FAMp, three 30-sec efforts at maximum FAMp separated by 5-min at 63% FAMp, and 15.5-min cool down at 65% FAMp). LIE consisted of 1hr cycling at 35% FAMp. Time to complete the TT, average power, VO_2, respiratory exchange ratio (RER), and rating of perceived exertion (RPE) were measured. **RESULTS:** Neither time to completion nor average power differed between HII and LIE trials (63.2±3.51 min vs. 62.9±4.09 min, p=0.545; 219±36.3 watts vs. 222±38.6 watts, p=0.374). The time taken to reach each 5km interval over the 40km distance did not differ between trials (p=0.362). The pattern of change in VO_2, RER, and RPE did not differ between trials (p=0.775, p=0.281, p=0.508, respectively). **CONCLUSION:** Despite previous reports that high-intensity low-volume taper paradigms improve performance over a low-intensity taper, exercise performance, average power, VO_2, RER, and RPE did not differ in trained cyclists during 40km time trials completed 24hr after HII and LIE sessions.

Novice Cyclists Using Shorter Crank Lengths Produced Greater Power at Same VO_2

Boe M. Burrus[1], Jessie Armendariz[1], Brian M. Moscicki[2].
[1]*Humboldt State University, Arcata, CA.* [2]*Indiana University, Bloomington, IN.* (Sponsor: Vincent J Paolone, FACSM)
(No relevant relationships reported)

Compared to trained runners, novice runners employ lower stride frequencies and shorter stride lengths as they run at lower speeds vs trained runners. Novice cyclists may benefit from a similar paradigm, utilizing shorter crank lengths as an analog to the lower stride frequencies and shorter stride lengths used by novice runners. **PURPOSE:** To determine the impact of short crank arms on novice cyclist's performance and comfort during a bout of moderate intensity cycling. **METHODS:** A total of 14 male novice cyclists (25.9 ± 6.9 yrs.) were included in the current study. Subjects completed an incremental cycle test to determine VO_{2peak}. Experimental trials were performed in a randomized counterbalanced format. The experimental trials consisted of 30 min cycling bouts at 60% of VO_{2peak}, with one session using crank arms set to 175mm (normal length), and the other session the crank arms set to 145mm (short length). Bike fit was replicated for all trials. Repeated Measures ANOVAs were used to compare blood lactate, power output, RPM, HR, RER, V_E, and RPE across experimental trials and time. **RESULTS:** Power output was significantly greater during the short crank arm trial when compared to the normal crank arm trial at 10 min (136.8 ± 8.1 vs. 132.5 ± 7.9 W, $p = 0.012$), 15 min (138.9 ± 8.5 vs. 133.6 ± 7.9 W, $p = 0.002$), 20 min (139.3 ± 8.4 vs. 132.1 ± 8.0 W, $p = 0.002$), 25 min (136.1 ± 8.0 vs. 130.0 ± 8.0 W, $p = 0.002$), and 30 min (134.3 ± 8.1 vs. 128.6 ± 8.0 W, $p = 0.006$) at 60% of VO_{2peak}. All other variables did not differ between crank length trials. **CONCLUSION:** Novice cyclists were able to maintain a higher power output with no increase in physiological measures. The higher power output may be attributed to the slower pedal velocities and more extended hip and knee joints allowing for slower muscle contractions combined with an improved mechanical advantage.

---

The Influence of Exercise Intensity on Training Load in Professional Cycling.

Teun van Erp[1], Marco Hoozemans[1], Carl Foster, FACSM[2], Jos J. de Koning, FACSM[1]. [1]*Vrije Universiteit, Amsterdam, Netherlands.* [2]*University of Wisconsin, La crosse, WI.*
(No relevant relationships reported)

In elite cycling, a reliable estimation of training load (TL) is highly important for cyclists, trainers and sport scientists. In a recent study, we found that the TL - quantified as kJ spent, sRPE as well as luTRIMP - was proximately 50% higher in racing than in training. Surprisingly, when the difference in TL between racing and training was calculated by the widely used method of TSS, this difference appeared to be 117%.**PURPOSE: :** To investigate whether exercise intensity, expressed as 'intensity factor' (IF) quantified using categories of TSS, differently affects the associations between TL quantified by the kJ spent and TL quantified by sRPE or luTRIMP and TSS.
METHODS: Field data on power output, RPE and heart rate were collected from 21 professional cyclists during 4 consecutive years. 11716 training and racing sessions were categorized into low, middle and high IF based on the tertiles of the entire dataset. IF is defined as the ratio between normalized power during the session and maximal sustainable power for one hour. Regression analyses using generalized estimating equations (GEE) were used to estimate the associations between external TL (kJ spent measured with SRM or Pioneer power cranks) and the calculated internal TL (sRPE, luTRIMP and TSS). If these associations were differently affected by exercise intensity, the regression coefficients of the interaction between internal TL and IF would be different for the association between external TL (kJ spent) and internal TL by SRPE,luTRIMP and TSS.
RESULTS: The IF was statistically different ($p<0.05$) in training compared to racing (0.59±0.03 vs. 0.73±0.03). For sRPE and luTRIMP in association with external TL no significant interactions with IF level were observed ($p = 0.288$ and $p=0.905$, respectively). However, for TSS a significant ($p<0.001$) interaction with IF level was seen
CONCLUSIONS: The results show that exercise intensity has no effect on the association between external TL (kJ spent) and internal TL estimated by sRPE or luTRIMP. However, exercise intensity did significantly affect the association between external TL and internal TL estimated by TSS. External TL is underestimated during low intensity and overestimated during high intensity sessions by TSS, compared to the kJ spent, possibly due to the quadratic influence of IF in the calculation of TL by TSS.

The Physiological and Perceptual Response to Self-, Even- and Variable Paced Cycling Time Trials

Jos J. de Koning, FACSM[1], Tim Veneman[1], Wouter Schallig[1], Maaike Eken[2], Carl Foster, FACSM[3]. [1]*Vrije Universiteit, Amsterdam, Netherlands.* [2]*Stellenbosch University, Tygerberg, South Africa.* [3]*University of Wisconsin - La Crosse, La Crosse, WI.*
(No relevant relationships reported)

During self-paced time trials, cyclists show unconscious non-random fluctuations in power output (PO) up to 10% above and below average. It is unknown what the effect of fluctuations of this magnitude is on physiological variables and rating of perceived exertion (RPE). **PURPOSE:** The aim of this study was to describe the differences in physiological variables and RPE between time trials with a self-paced- and an enforced constant- and fluctuating PO. **METHODS:** Healthy male trained cyclists (N=10) completed three 10-km time trials. First, a self-paced time trial (SELF) was completed. Subsequently, in random order, time trials with an imposed constant (CON) and fluctuating (FLUC) PO were completed with both the same average PO as SELF. During FLUC, PO varied step-wise per kilometer with 10% deviations under and above the average PO. In all trials, RPE, muscle activation and metabolic variables were measured. **RESULTS:** A significant main effect on RPE was found between FLUC and CON (F=10.44, P=0.014). Analysis per kilometer showed that the RPE was significantly lower in FLUC compared to CON in kilometer 4, 5, 8, 9 and 10 (P<0.05). No main effect on RPE was present between SELF and FLUC or SELF and CON. No overall differences in muscle activation and metabolic variables were present between the trials, despite differences per kilometer. **CONCLUSION:** The differences in RPE with absence of overall differences in metabolic variables and muscle fatigue, suggest that the fluctuations in PO provide a psychological rather than a physiological advantage. The fluctuations might cause a shortening of in-race goal setting, since it divides the time trial into several segments. Shorter goal setting is known to be perceived as more feasible and increase motivation.

Comparison of Incremental Cycling Trial Protocols to Estimate Maximal Oxygen Consumption in Recreationally Trained Cyclists

Erica L. Salhus, James W. Smith, Anthony J. Bull. *Colorado College, Colorado Springs, CO.* (Sponsor: Joan M. Eckerson, FACSM)

(No relevant relationships reported)

Determining maximal oxygen consumption (VO_{2max}) in cyclists typically involves measuring expired respiratory gases during an incremental trial to exhaustion. These methods can be expensive and inaccessible to many recreational cyclists. Therefore, being able to estimate VO_{2max} from the peak power (W_{peak}) attained during an incremental cycling trial (ICT), may provide an easier and less expensive way for these cyclists to estimate their cardiorespiratory fitness. **Purpose:** The study had two aims: 1) to validate the regression equation of Hawley and Noakes (1992) (HNEQ) to predict VO_{2max} from W_{peak} attained during an ICT with a high initial power output (HIPO); and 2) to compare VO_{2max} measured during the ICT with a HIPO to an ICT using a lower initial power output (LIPO). **Methods:** Twelve recreationally trained cyclists (9 males and 3 females; cycling at least 4 d/wk or 6 hr/wk) completed both the HIPO and LIPO trials to measure VO_{2max} and W_{peak}. For the HIPO trial, initial power output (PO) was 2.5 or 3.5 W/kg body mass for females and males, respectively. PO increased by 50 W after 150 s, and 25 W every 150 s thereafter until volitional fatigue. For the LIPO trial, initial PO was 1.5 or 2.0 W/kg body mass for females and males, respectively, and PO increased by 25 W every 120 s until volitional fatigue. During each ICT, expired respiratory gases were measured with a calibrated metabolic measurement system and time to exhaustion was recorded to the nearest second to extrapolate W_{peak}, which was used to estimate VO_{2max} with the HNEQ. **Results:** There was a significant difference ($p<0.001$) between the mean VO_{2max} value measured during the HIPO trial (50.56 ± 7.28 mL/kg/min) and the predicted mean VO_{2max} value estimated from the W_{peak} using the HNEQ (57.46 ± 6.15 mL/kg/min). However, there was no significant difference ($p=0.165$) between the mean VO_{2max} values measured during the HIPO and LIPO trials (50.56 ± 7.28 mL/kg/min and 51.48 ± 6.94 mL/kg/min, respectively). **Conclusions:** This study found that the HNEQ overestimated VO_{2max} in recreationally trained participants. However, because the HIPO and LIPO protocols resulted in VO_{2max} values that were not statistically different, either protocol can be used to determine VO_{2max} in recreationally trained cyclists.

Feasibility and Effectiveness of using Electromyography to Track Physical Activity

Joel Ramirez, Stefan Keslacy, Deborah Won, Dominic Defiesta, Christine Dy. *California State University Los Angeles, Los Angeles, CA.*

(No relevant relationships reported)

Fitness tracking devices commonly use accelerometery (ACC) and heart rate (HR) data to quantify physical activity (PA). Inaccurate tracking of PA may occur using ACC during multimodal training (e.g. circuit training), and both HR and ACC may overestimate work performed during upper body exercise or in special populations. **PURPOSE:** Evaluate the effectiveness of using upper body muscle activity (EMG) to track PA during a bout circuit resistance training (CRT) performed by able bodied (AB) and those who have sustained a spinal cord injury (SCI). **METHODS:** N= 5 (3 AB and 2 SCI). First visit, participants performed a graded exercise test to volitional failure on an arm ergometer and analyzed via indirect calorimetry (IC). Second visit, participants performed a circuit resistance training (CRT) bout adapted from a previous protocol developed for persons with SCI. The protocol was three rounds of six resistance exercise (RE) interspersed with arm cycling (AC). A RE consisted of three blocks of 10 reps of arm exercises, performed with a resistance band at a consistent tempo (3,0,3). The first round was a warm-up, the second used a light resistance band (L), and the third a heavy resistance band (H). AC were 2 min blocks performed at 30% of peak power and ≥ 60 rpm. PA during the CRT was quantified via measurements of VO_2, HR, EMG, ACC, and upper body kinematics. **RESULTS:** Kinematics were not significantly different between conditions ($P< 0.05$). Both VO_2 and HR increased in the H condition for AB and SCI ($P< 0.000$). HR was much higher than VO_2. The increase in AB between RE conditions of 198% (L) and 206% (H). In SCI, the increase was 206% for L and 258% H conditions. Estimates of energy expenditure (EE) and METS derived by ACC and IC had similar trends during L in AB (AB by 33% kcal and 44% METS, Whereas SCI had 25% kcal and 140% METS). Switching to a H during RE resulted in an underestimation by ACC in both groups (AB by 74% kcal and 75% METS, SCI by 32% kcal 154% METS). Magnitude of EMG increased during RE with H compared to L. **CONCLUSION:** Early analyses indicate that HR measures tended to overestimate EE for upper body work whereas ACC tended to underestimate work performed with H resistance. EMG better related to cardio-metabolic changes. **SUPPORT:** 2017-18 *Sally Casanova Pre-Doctoral Scholarship.* The D.R.E.A.M Project NIDLRR Project Number: 90IFST0001

Electromyography Activity During Aerobic Exercise Using Swiss-ball Compared With Walking.

Toshihiro Wakimoto[1], Tatsuya Saito[1], Tomomi Monri[1], Yoshiyuki Yamanaka[2], Sohachi Fujimoto[2], Toshihiro Takao[2]. *[1]Kawasaki University of Medical Welfare, Kurashiki, Japan. [2]Kawasaki Medical School, Kurashiki, Japan.*

(No relevant relationships reported)

PURPOSE: To clarify the electromyography (EMG) activity of various movement on aerobic exercise using Swiss-ball (SB exercise), we compared the EMG activity between walking and SB exercise.
METHODS: Nine healthy men performed walking and SB exercise. EMG activity, respiratory metabolism and hart rate was measured during SB exercise and walking. During walking subjects walked at 6 km/h on treadmill ergometer. During SB exercise, subjects were sitting on the Swiss-ball and bouncing with upper and lower limb movements. The movements consisted of four patterns of upper and lower limb movements.
RESULTS: The exercise intensity during SB exercise (4.8 ± 0.6 Mets) was nearly identical with walking at 6 km/h (4.5 ± 0.4 Mets). Compared with walking, the EMG activity in biceps fomoris ($46\pm25\%$, $p<0.001$), gastrocnemius ($78\pm37\%$, $p<0.001$) and gluteus maximus ($70\pm29\%$, $p<0.001$) was significantly lower during SB exercise. On the other hand, the EMG activity in rectus abdominis during SB exercise ($198\pm68\%$, $p<0.001$) significantly higher compared with walking. The EMG activity in vastus laterais and latissimus dorsi during SB exercise were nearly identical with walking.
CONCLUSIONS: The exercise intensity was nearly identical during SB exercise and walking at 6km/h. However, the EMG activity during SB exercise was significantly lower in lower limb muscles and significantly higher in rectus abdominis muscle compared with walking.

Force and Electromyographic Responses during Sustained Isometric Muscle Actions anchored by RPE Values

Joshua L. Keller, Terry J. Housh, FACSM, Ethan C. Hill, Cory M. Smith, Richard J. Schmidt, Glen O. Johnson, FACSM. *University of Nebraska - Lincoln, Lincoln, NE.* (Sponsor: Terry Housh, FACSM)
(No relevant relationships reported)

PURPOSE: Anchoring exercise intensity with ratings of perceived exertion (RPE) can be used to examine the mechanisms underlying the perception of effort during fatiguing tasks. The purpose of the present study was to examine the fatigue-related patterns of responses for force and electromyographic amplitude (EMG AMP) during sustained isometric, leg extension muscle actions anchored by RPE. **METHODS**: Ten recreationally active men (mean ± SD: 22.9 ± 2.7 yr) performed 3 randomly ordered, sustained submaximal isometric leg extension muscle actions (knee joint = 120°) anchored at RPE values of 2, 5, and 8 (OMNI-RES 10-point scale) to volitional exhaustion or a maximal time limit of 5-min. Maximal voluntary isometric contractions (MVIC) were performed prior to and immediately following each sustained isometric muscle action and bipolar surface EMG signals were recorded from the vastus lateralis muscle during the sustained muscle actions. Linear regression analyses were used to examine the force and EMG AMP vs. time relationships during each sustained isometric muscle action. **RESULTS:** The pretest MVIC values (62.1 ± 14.4, 62.6 ± 14.7, and 63.5 ± 12.7 kg) were highly reliable (ICC= 0.90) and were not significantly (p=0.930) different. The posttest MVICs were significantly (p<0.001) less than pretest for each sustained isometric muscle action. There were significant (p<0.001) differences between all the mean times for the sustained muscle actions (RPE 2 = 300.0 ± 0.0 s; RPE 5 = 202.0 ± 95.5 s; RPE 8 = 72.7 ± 27.6 s). Furthermore, the percent decline in force decreased (p<0.001) with each increase in RPE (percent decline for RPE 2 = 61.0 ± 18.5%; RPE 5 = 47.4 ± 19.6%; RPE 8 = 24.9 ± 13.2%). For normalized EMG AMP, there were significant negative, linear relationships for RPE=2 (p=0.006) and RPE=5 (p=0.003) vs. time of the sustained isometric leg extension. **CONCLUSION:** For the RPE=2 and RPE=5 trials, EMG AMP and force decreased and, therefore, were dissociated from RPE. At RPE=8, however, EMG AMP was unchanged, but force decreased. Thus, EMG AMP tracked RPE, but was dissociated from force. Together, these findings suggested that the perception of effort during sustained, submaximal isometric leg extension muscle actions were not mediated by fatigue-related changes in force or EMG AMP.

A Comparison of Muscle Unit Activation during Biceps Curl Exercise at 40, 60, 80 and 100% of 1 Repetition Maximum

Alex Zykoff, Mike Aquino, Jacqueline Pellechia, John Petrizzo, John Wygand, FACSM, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.* (Sponsor: Robert M. Otto, FACSM)
(No relevant relationships reported)

The optimal intensity of resistance training exercise is subject to ongoing debate. There is universal agreement that electromyography (EMG) is an excellent index of motor unit (MU) activation or recruitment. The amount of EMG activity can infer the relative intensity of the exercise as compared to a maximal voluntary contraction (MVC) of a specific muscle, performing a specific exercise within one specific individual. **Purpose:** To determine the magnitude of muscle fiber recruitment (activation) of the Bicep Brachii during various loading of the muscle (40, 60, 80, and 100% of 1 RM) during bicep curl (BC) exercise performed to momentary muscular fatigue (MMF), 12 subjects (age 22.5±1.0 yr, ht. 169.4 cm±11.1 cm, body mass 75.3 kg±17.5 kg, 7♀) with resistance training experience, volunteered. **Methods:** A familiarization trial on a selectorized BC machine was performed and the 1 RM was titrated for each subject. In addition, a maximal voluntary contraction (MVC) was obtained for the BC exercise against an immovable load on the same selectorized machine. MU recruitment was estimated by EMG. All subjects adhered to a 3-1-3-1 sec repetition duration during all trials. All trials were randomly assigned and terminated at MMF. **Results:** Statistical analysis by ANOVA (p<.05) with repeated measures was applied to these data. Percent MVC for the concentric portion of the final repetition were 62.5±27.8, 71.7±24.0, 72.8±18.4, and 79.6 ±18.0 at 40, 60, 80, and 100% 1RM, respectively, with NSD among 60, 80 and 100%1RM. With the exception of the 40% trial, all trials revealed similar peak MU recruitment, despite different loading. The recruitment of ~70% of MVC at MMF may, in part, be attributed to the level of resistance training of the subject's and their ability to activate MU's. **Conclusion:** The size principle of MU recruitment is supported, in that peak recruitment of motor units can be accomplished at any workload greater than 60% 1 RM, provided MMF is achieved. Intensity is best defined by the final repetition, as opposed to the initial repetition (i.e. % of 1RM).

The Effect Of Using A Weightlifting Belt On Muscle Activation During A Conventional Deadlift

Jacqueline Pellechia, John Petrizzo, Robert M. Otto, FACSM, John Wygand, FACSM. *Adelphi University, Garden City, NY.* (Sponsor: John Wygand, FACSM)
(No relevant relationships reported)

The use of weightlifting belts for free weight training and competition is commonplace. Theoretically, the use of the belt in conjunction with a simultaneous valsalva maneuver provides additional support to the spine by facilitating increased stabilizing pressure inside the abdominal cavity. This is accomplished by isometric contraction of the core muscles in the abdominal wall and lower back with support from the belt. Generally lifts with 5-15% greater loading are reported when wearing a belt. **Purpose:** The purpose of this study was to determine the magnitude of motor unit activation in the biceps femoris (BF), gastrocnemius (G), and trapezius (T) during a conventional deadlift (DL) wearing a weightlifting belt (B) or without a belt (NB). **Methods:** 10 subjects with resistance training experience (age 22.2 ± 0.78, ht. 170.43 ± 11.19 cm, and body mass 81.72 ± 21.69 kg, 6♀) volunteered to perform a familiarization trial of the conventional DL technique of three repetitions at 70% of their self-reported one repetition maximum (1RM). A maximal voluntary contraction (MVC) was obtained while subjects exerted a maximal force against an immovable load at approximately 35% DL ROM. After safe lifting form was confirmed, a 1RM was titrated and randomized trials of B and NB were performed to momentary muscular fatigue (MMF) at 80% of subject's 1RM with a minimum of 30 minutes between trials. MU recruitment was estimated by EMG. All subjects adhered to a 3-1-3-1 sec repetition duration and terminated the lift at MMF on the concentric phase. **Results:** Statistical analysis by dependent t test was applied to these data and revealed no significant difference(p>.05) between trials with motor unit activation for BF of 98.0% and 93.7%, for G of 92.2% and 80.7%, and for T of 72.3% and 71.0%, for B and NB trials, respectively. **Conclusion:** The use of a properly aligned and fitted weight-lifting belt did not yield a significant difference in muscle activation between the (B) and (NB) trials for the tested muscle groups while performing the conventional DL. Thus, a weight lifting belt may augment the lifter's perception, but it does not enhance or detract from motor unit activation.

Comparison of EMG Muscle Activity and Turn Times Using Orthosis and Stock Insoles During Skiing

Heidi Nunnikhoven. *Montana State University, Bozeman, MT.*
(No relevant relationships reported)

New alpine ski boots are generally sold with generic, foam rubber stock insoles which may lead to over-pronation of the foot due to a lack of subtalar support. The use of stock insoles may result in inefficient movements of the foot and reduced transfer of force throughout the turn cycle. A flexible orthosis insole is designed to provide support of the foot and while still allowing for the rotation of subtalar joints which may improve the transfer of force from the foot to the boot to the ski edge. PURPOSE. The aim was to compare the EMG activity of the tibialis anterior (TA), peroneus longus (PL), and gastrocnemius (GA) muscles and turn times when skiing using heat molded, flexible orthosis insoles (OI) and stock insoles (SI). METHODS. Following IRB approval, five elite skiers (including 3 former national champions) skied two runs on a 13 brush-gate course with a 22° pitch. Each skier was asked to ski consistently for two trials, one trial with OI and one trial with SI. The SI were specific to the given boot company of the skier. Brush gates were set at a diagonal distance of 12 m. Surface EMG activity was processed by RMS. Turn times were assessed with a motion sensor attached to the ski boot. Data analysis utilized a 1-way ANOVA for comparison of EMG activity and time per turn. RESULTS. EMG activity for the TA and PL were significantly lower in the OI trial compared to the SI trial: 3.80 ± 1.28 mV vs. 4.26 ± 1.23 mV (p=.04) and 2.50 ± 0.59 mV vs. 2.80 ± 1.29 mV (p=.01), respectively. There was no statistical difference between insoles for GA activity: 1.81 ± 0.38 mV vs. 2.01 ± 0.7 mV (p=.09) for OI and SI. Average time per turn was significantly faster for OI than SI: 1.038 ± 0.012 sec vs. 1.058 ± 0.024 sec (p=.03). CONCLUSION. Although the thickness is similar to the SI, structure in the OI under the subtalar joints may provide more support of the foot allowing for greater transfer of force to the ski. EMG data from TA and PL activity would indicate more efficient force transfer with OI. These muscles are critical in stabilizing the ankle and allowing for foot eversion during the edge transfer and steering phases of the turn. Time per turn was significantly lower with the OI, up to 0.02 sec/turn. With 45-60 gates per run, the OI could have a significant impact on overall performance since placings in a ski race are often separated by fractions of a second.

Knee Joint-Specific Eccentric Utilization Ratio Determines Lower-Extremity Stretch-Shortening Cycle Function During Countermovement Jumps

Jordi Heeneman, John Krzyszkowski, Kristof Kipp. *Marquette University, Milwaukee, WI.* (Sponsor: Paula Papanek, FACSM)
(No relevant relationships reported)

The Eccentric Utilization Ratio (EUR) is an indicator of lower-extremity stretch-shortening cycle function in power athletes. Joint-specific EUR's have not been established, and their contributions to whole-body EUR are currently not known. Determining joint-specific EUR's and their contribution to whole-body EUR would help expand the understanding of the neuromuscular function and biomechanics of jumping exercises and provide insights for the program design process. **PURPOSE:** To determine joint-specific EURs and their associations with whole-body EUR. **METHODS:** Nine college track and field and soccer athletes (Height: 175 ± 15 cm, Weight: 71 ± 20 kg) participated in this study. All athletes performed three squat (SJ) and countermovement (CMJ) jumps. During all jumps, kinematic and kinetic data were obtained from 14 reflective markers (Plug-in-Gait marker set) and with two force plates, respectively. Hip, knee, and ankle joint powers of the right leg were calculated with inverse dynamics methods. In addition, jump heights were calculated from pelvis markers during each jump. EUR's (CMJ/SJ [unitless]) were calculated from the three-trial average peak joint powers of the hip, knee, and ankle joint (joint-specific EUR) and from jump heights (whole-body EUR) of the CMJ and SJ. Joint-specific EUR's were compared with a one-way ANOVA. Joint-specific EUR's were then correlated to whole-body EUR with simple linear regressions. **RESULTS:** Joint-specific EUR's were 1.04±0.18, 1.15±0.25, and 1.05±0.18 for the hip, knee, and ankle joint, respectively. Joint-specific EUR's did not differ across joints. Whole-body EUR was 1.11±0.70. The Pearson correlation coefficients (r) between joint-specific EUR's of the hip, knee, and ankle joint and whole-body EUR were 0.10 (p = 0.80), 0.70 (p = 0.01), and 0.50 (p = 0.17), respectively. **CONCLUSIONS:** The stretch-shortening cycle function of the knee joint appears to be the primary determinant of whole-body stretch-shortening cycle performance, while the ankle and hip joints do not appear to contribute much at all.

Neural And Muscular Alterations Of The Plantar Flexors In Middle-aged Women

Michelle Burge, Kevin Phillips, Byungjoo Noh, Matt Gage, Tejin Yoon. *Michigan Technological University, Houghton, MI.* (Sponsor: Sandra Hunter, FACSM)
(No relevant relationships reported)

It has been recently shown that while walking, old males produced significantly less power of the plantar flexors than young males. Additionally, old males have lower absolute and relative RTD of the plantar flexors, along with smaller pennation angle, but no differences in muscle size, when compared to young men. It is of interest if similar trends are seen from young to middle age in women. **PURPOSE**: Compare muscle structure and neuromuscular function of the plantar flexors in young and middle-aged women. **METHODS**: Twenty two middle-aged (years: 54 ± 6) and eight young women (years: 22 ± 2) volunteered to participate in this study. This study involved 2 sessions. During the 1st session, *In vivo* muscle architecture measurements were made using a B-mode real-time ultrasound scanner. Muscle thickness and pennation angle was examined in the gastrocnemius medialis (GM) and gastrocnemius lateralis (GL) muscles. During the 2nd session, participants completed maximal voluntary isometric contractions (MVIC) of the plantar flexor muscles on a dynamometer. Single electrical stimuli were applied over tibial nerve in the popliteal fossa to elicit twitch torque during the MVIC and upon relaxation (approximately 2 s) following the MVIC to assess voluntary activation [VA = (1-superimposed twitch/ resting twitch) x 100]. Maximal torque and rate of torque development were calculated and normalized by weight. Independent samples t-tests were used to examine any differences between the young and middle-aged women. Statistical significance was set at an alpha of p < 0.05. **RESULTS**: There were no differences in MVIC strength (128 ± 63 vs. 107 ± 30 Nm) or VA (96 ± 8.6 vs. 92 ± 10 %) between young and middle-aged women, however, rate of torque development trended towards being greater in the young women (626 ± 310 vs. 462 ± 150 Nm/s, p = 0.06). Additionally, no differences were noted between muscular size, however, pennation angle of the GM was significantly greater in the young women (25.8 ± 2.5 vs. 23.6 ± 2.4 degrees, p = 0.038). **CONCLUSION**: While maximal strength of the plantar flexors are maintained in middle-aged women, there were signs of a loss in the rate of torque development, and significant changes in pennation angle of the GM muscle.

Comparison Of Electromyographical Signal Analyses For Estimating Lactate Threshold

Ronald L. Snarr[1], Danilo V. Tolusso[2], Ashleigh V. Hallmark[3], Michael R. Esco, FACSM[2]. [1]*Georgia Southern University, Statesboro, GA.* [2]*The University of Alabama, Tuscaloosa, AL.* [3]*Cardiology Imaging Clinic, Birmingham, AL.* (Sponsor: Michael R. Esco, FACSM)
(No relevant relationships reported)

The relationship between the lactate and electromyographical (EMG) thresholds have previously been established via graded exercising testing during cycling. Currently, no published literature exists comparing the most appropriate and efficient filtering methods of EMG analyses to estimate the workload at which lactate threshold (LT) occurs. **PURPOSE**: The purpose of this investigation was to evaluate and compare EMG transformations and time windows to predict LT. **METHODS**: Participants (n=14) completed an incremental, maximal exercise test on a cycle ergometer until exhaustion. Blood lactate was measured every minute, while EMG was recorded continuously at the site of the vastus lateralis. EMG signaling was then transformed and filtered using two time-segment windows (i.e., 10 and 60 seconds), as well as three signal conversions (i.e., root mean square, smoothing, and peak amplitude averaging). **RESULTS**: Results indicated no mean differences between the EMG thresholds, for any of the filtering methods or time-segment windows, when compared to the LT criterion. Significant moderate correlations were seen when comparing the lactate and EMG time-curves ranging from 0.69 - 0.79. Root mean square and Smoothing filters accurately indicated LT in 10 out of 14 participants; whereas peak amplitude averaging indicated LT for 11 out of 14 participants. **CONCLUSIONS**: EMG may be a useful tool to estimate the work rate associated with LT. Averaging EMG over a minute of time and continual 10-second recordings demonstrate comparable readings and allow an easier application of EMG threshold in the field.

Are Upper Body Muscle Activations Different In Various Type Of Push-up Exercise?

Melanie Poudevigne, FACSM, Moroni Demoors, Thomas Andre, Hae Chung. *Clayton State University, Morrow, GA.*
(No relevant relationships reported)

Push-up exercises are widely used as a recommended home-based strengthening exercise for the upper body. Very little has been published on push-ups and the activation of upper limb major muscles in different hand positions using EMG. More research is needed to explain the workload done by Triceps Brachial (TB), Pectoral Major (PM) and Anterior Deltoid (AD). **PURPOSE**: The aim of this study is to measure the EMG signals of TB, PM and AD while performing push-ups in two different hand positions. **METHODS**: 50 African American subjects were recruited to perform push-ups on two separate occasions. The 2 different hand positions were dictated by the index or pinky alignment with the spine position. Hands were spread by shoulder length. The mean of peak EMG signals to exhaustion were analyzed. A non-parametric Kruskal-Wallis H test was applied and followed by Wilcoxon Signed-Rank test as the post hoc paired difference test. A Bonferroni correction of p=0.01 was applied which was derived from p=0.05/2. **RESULTS**: Significant differences were found in all muscles with a greater activation using the index finger position in the TB muscle. Males experienced a significantly greater activation in all muscles compared to females. **CONCLUSIONS**: Higher muscle activation of TB implies that the training effect of TB may be higher in the above-mentioned hand position. Future studies should address the increase in muscle strength in in-home setting especially in minorities.

Changes in Bilateral Hand Force After 30 Minutes of Climbing in Elite Level Rock Climbers

Philip F. Ferrara, James Becker, John G. Seifert. *Montana State University, Bozeman, MT.*
(No relevant relationships reported)

Rock climbing is a sport that requires finger flexor strength and endurance to maintain isometric contractions during an ascent. It has been shown that climbers have higher finger flexion strength and endurance than the general population at the proximal interphalangeal joint (PIP). What is unclear, however, is if years of training and conditioning have caused these adaptations to occur bilaterally in both the dominant (D) and non-dominant (ND) arms of elite level rock climbers. It is essential for climbers to have equal, bilateral finger flexor strength and endurance capacity as rock climbing stresses both sides of the body. Weakness on one side may result in a fall or failure to complete a route. **PURPOSE**: To analyze change in average force production in D and ND finger flexors of elite-level rock climbers over the course of 30 min of climbing. **METHODS:** 8 elite-level (age: 29.4 ± 4.7 y, climbing experience: 11.1 ±

5.2 y, mean project grade: 9.7 ± 0.3 UIAA) rock climber's D and ND finger flexor strength was tested using a mounted force transducer. A 20-sec isometric contraction was performed with the arm fixed at 90° elbow flexion and 120° of horizontal shoulder abduction. Subjects were given two warm up contractions on each hand before the 20-sec MVIC. Subjects then climbed on a treadwall for six 5-min intervals. Total climbing time was 30 min. The treadwall rotated at 6 m/min with a 6° overhang. The isometric force assessment was repeated at the end of each interval and kept to less than 3 min to prevent recovery. Force data were analyzed by removing the first and last 10% of the contraction and averaging the remaining 16 sec. Data were expressed both in absolute (N) and as a percentage of the initial MVIC trial (relative). A paired t-test was used to compare the pre-MVIC to the MVIC at 30 min. **RESULTS:** No statistical differences were found for change in absolute force between D (29.1 ± 26.1 N) and ND (41.5 ± 63.6 N) hands or in relative force between D (8.05 ± 7.5%) and ND (12.09 ± 11.7%) hand. Mean change in force relative to BW after 30 min of climbing: D (0.44 ± 0.39 N/kg BW), ND (0.62 ± 0.96 N/kg BW). **CONCLUSION:** Elite-level rock climbers do not show a bilateral deficit between their D and ND hands typically seen in other sports. This could be due to years of symmetrical training and the stresses that are applied to both limbs while rock climbing.

Effects Of Postactivation Potentiation On Subsequent 40-yard Sprint Performance In 16- To 23-year-old Male Athletes

Cody Yates[1], Peter J. Chomentowski[1], Mark Flury[1], Steven M. Howell[1], Anthony Deldin[2], Frank R. Wojan[1], Jamal Roper[1], Jeremy Armstrong[3]. [1]Northern Illinois University, DeKalb, IL. [2]Loyola University Chicago, Chicago, IL. [3]XCEL Sport Science & Fitness, Nicholasville, KY.
(No relevant relationships reported)

Postactivation potentiation (PAP) is a physiological adaptation which enables the muscles' contractile properties to optimally perform. PAP is engendered through pre-performance conditioning activities, such as parallel back squats performed prior to a vertical jump test. **PURPOSE:** The purpose of this study was to determine the effects of postactivation potentiation on subsequent 40-yard sprint performance in 16- to 23-year-old male athletes, specifically, the effects of hexagonal bar deadlifts (HBD) and weighted sled sprints (WSS) as PAP-loading protocols. **METHODS:** Thirty-one male subjects (age, 16.9 ± 1.4 years; height, 180.2 ± 6.2 cm; weight 83.4 ± 19.2 kg) participated in this study. Testing sessions included two different visits, a control trial and a PAP-loading protocol trial separated by ~48-hours, counterbalanced, allowing each subject to act as his own control. The HBD (n = 8) group performed four sets of HBD as the PAP-loading protocol, using body weight (BW) to calculate estimated one repetition max (1RM). The WSS (n = 23) group performed four sets of WSS for 15-yards, using WSS loads of 25%, and 50% BW. Both PAP-loading protocols were followed by a 6-minute rest period and concluded with two laser-timed 40-yard sprint performances. Control trials for both groups consisted of identical time intervals as the PAP trial, with active movement utilized instead of the PAP-loading protocol. **RESULTS:** The PAP trials had faster average 40-yard sprint times (5.35 ± 0.44 s) compared to the control trials (5.39 ± 0.39 s) for all subjects. The average difference for the PAP trials (-0.04 ± 0.10) was statistically significant (p = 0.029). However, there was statistical significance (p = 0.035) between PAP-loading groups, with WSS being the only group to improve in sprint time for the PAP trial. The WSS group improved in 40-yard sprint time for the PAP trial (5.33 ± 0.45 s) compared to the control trial (5.40 ± 0.41 s) with a PAP difference of -0.06 ± 0.10 s for 40-yard sprint time. **CONCLUSION:** The use of a PAP-loading protocol enhances 40-yard sprint performance, with the use of WSS proving to generate faster sprint times compared to the HBD.
Table 2: Average Control Trial (Trial A) vs Average PAP Trial (Trial X) (mean ± SD)
Figure 3: Average control trial (trial A) vs average PAP trial (trial X)

Altered Arginase Activity Following Ischemic Stroke: The Role Of Metabolic Syndrome

Shinichi Asano[1], Paul D. Chantler[2], Taura L. Barr[3]. [1]Fairmont State University, fairmont, WV. [2]West Virginia University, Morgantown, WV. [3]Valtari Bio Incorporated, Morgantown, WV.
(No relevant relationships reported)

Animal models of human pathology are important to elucidate the underlying pathophysiological mechanisms and examine novel interventions with stroke. However, there is on-going controversy surrounding the validity of rodent models in inflammation mediated diseases. A number of successful rodent models have failed to translate the findings into clinical research. Epidemiological studies suggest the metabolic syndrome (MetS) is strongly associated with poor stroke outcomes. Our laboratory has demonstrated altered plasma arginase 1 (*ARG1*) expression in stroke patients. A*RG1 has an important role* in immune system regulation and is correlated with stroke outcome. However, how ARG activity is regulated after the stroke in a rodent model of stroke and if metabolic syndrome affects these processes are not well understood. **PURPOSE**: The purpose of this study was to determine plasma ARG activity pre, and at 4hrs and 24 hrs post-stroke in lean (LZR) and obese (OZR, a model of metabolic syndrome) zucker rats. We hypothesized that OZR have altered ARG1 activity compared to LZR after the stroke. **METHODS**:
Stroke was induced by middle cerebral artery occlusion (MCAO) for 60 min in LZR and OZR. Laser Doppler flowmetry was used to detect regional cerebral blood flow during occlusion and reperfusion. Venous blood samples were drawn from rat rail vein before MCAO, 4 and 24 hrs post-MCAO. Plasma was isolated, and ARG activity was measured by enzyme linked immunosorbent assay.
RESULTS:In the OZR, ARG activity (Unit/L: ± SD) decreased (p<0.05) from pre (31.4±6.9 unit/L) - to 24hrs (20.6±4.9 unit/L) post-stroke in the OZR. No differences were noted at 4hrs post-stroke (24.3±5.1 unit/L). In contrast, no significant differences were noted in ARG activity pre and up to 24hrs post-stroke in the LZR. However, LZR generally presented with lower ARG activity levels than OZR.
CONCLUSIONS:These data suggest that ARG response in OZR appears to be different compared to LZR after experimental ischemic stroke insults. Further studies, a more stratified time course and biomarkers analysis of specific "inflammatory phase" of stroke in specific populations, are urgently required.

Exercise Intensity Reduces Circulating Annexin V-CD105 Microparticles in Adults With Prediabetes

Natalie ZM Eichner, Nicole M. Gilbertson, Emily M. Heiston, Julian M. Gaitan, Luca Musante, Sabrina LaSalvia, Eugene J. Barrett, Arthur L. Weltman, FACSM, Uta Erdbrügger, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.*
(Sponsor: Steven Malin, FACSM)
(No relevant relationships reported)

PURPOSE: Microparticles (MPs) derived from platelets, leukocytes and endothelial cells are important players in cardiovascular disease (CVD) risk. Exercise is established to reduce CVD risk, but no study has tested the effect of exercise intensity on various subtypes of MP in people with prediabetes. We tested the hypothesis that short-term interval (INT) training would reduce MP subtypes vs. continuous (CONT) exercise. **METHODS**: Eighteen obese adults (age: 63.8±1.5yrs BMI: 31.0±1.3 kg/m²) were screened for prediabetes using ADA criteria (75g OGTT and/or HbA_{1c}). Subjects were randomized to INT (n=10, 3 min intervals at 90% and 50% HR_{peak}) or CONT (n=8, 70% HR_{peak}) training for 12 supervised sessions over 2 wks for 60 min/d. Fitness (VO_2peak) and weight (kg) were assessed and arterial stiffness (augmentation index; AI) calculated using total AUC during a 75g OGTT. Total MPs, platelet MPs (CD31[+]/CD41[+]), endothelial MPs (CD105, CD31[-]/ CD41[+]) and leukocyte MPs (CD45[+]/CD41[-]) were analyzed from fresh plasma via imaging flow cytometry pre-/post- intervention. **RESULTS**: Our interventions had no effect on weight loss but INT exercise increased VO_2peak (*P*=0.04) and reduced fasted AI (trend: *P*=0.08) compared with CONT training. While our intervention had no effect on platelet or leukocyte MPs, INT exercise decreased Annexin V- endothelial MP CD105 (1.6±0.2 vs. 1.4±0.2 count) compared with CONT training (1.2±0.2 vs. 1.8±0.1 count; *P*=0.04). Increased VO_2peak correlated with decreased Annexin V+ CD105 endothelial MPs (r=-0.60, *P*=0.01). **CONCLUSION**: Exercise intensity decreases endothelial derived MPs through possibly a cardiovascular fitness related mechanism, independent of weight loss.

Differential Cardiac Protein Expression of Mice Exposed to Postnatal Undernutrition.

Joseph R. Visker[1], Larry J. Dangott[2], David P. Ferguson[1]. [1]Michigan State University, East Lansing, MI. [2]Texas A&M University, College Station, TX.
(No relevant relationships reported)

PURPOSE: Evidence shows humans who suffered poor nutrition during early postnatal life have altered cardiovascular development and increased likelihood for chronic disease during adulthood. Several studies have shown using an animal model that inadequate nutrient intake during early life causes changes in cardiomyocyte nucleation, maturation, and function. Protein expression differences as a result of early life undernutrition has yet to be studied and protein networks remain unidentified. **METHODS:** All experiments were conducted according to IACUC at Michigan State University. FVB mouse dams were fed either a semi-purified control (CON: 20% protein), or a low-protein (LP) isocaloric diet (PUN: 8% protein) beginning 1 week before mating. LP females produce 15-20% less milk thus; pups nursed by LP females experience a global nutrient deficit. Following birth, pups were reorganized to 8 pups/ female. After birth, day 1 (PN1) until day 21 (PN21) the PUN nursed and received milk from females fed the LP diet, the CON mice nursed from females being fed the 20% protein diet. At PN21 the hearts were collected from the CON and PUN mice and cardiac tissue was frozen in liquid nitrogen. Two-dimensional differential in-gel electrophoresis (2D DIGE), is a 2 step method of extracting proteins from the hearts of CON and PUN. Proteins are separated according to the electrochemical charge and weight. An ANOVA compared protein differences between diet (CON vs. PUN) and gender (male vs. female) using Decyder Protein identification software(standardized log abundance). **RESULTS:** 37 statistically significant proteins were identified from 2D DIGE. Over-expressed PUN proteins (134% greater abundance than CON) included polymerase I transcript release factor, Fetuin, and $Ca2^+$activated K^+ channels. CON over-expressed proteins included cyclin-dependent kinase inhibitor (114% greater abundance), and Alpha-1 type IV collagen (90% greater abundance). **CONCLUSION:** Identified proteins allow for a proposed mechanism that may explain the cellular change in the heart following undernutrition in early life and the associated increase for cardiovascular disease (CVD) in adulthood. Physical activity may serve as a positive countermeasure to contest the increased likelihood for CVD in adulthood.

The Effects of Calcitonin Gene-Related Peptide on Heart Function

Gabriel Almeida Alves, John Spitsbergen, Cindy Linn. *Western Michigan University, Kalamazoo, MI.* (Sponsor: Dr. Timothy J. Michael, PhD, FACSM, ACSM-CEP, FACSM)
(No relevant relationships reported)

Calcitonin Gene-Related Peptide (CGRP) is a 37-amino acid peptide produced by peripheral and central neurons. It is found in a variety of organs and systems, regulating important functions in the target tissues. The αCGRP isoform is present in sensory neurons and it has been suggested to play a role in preventing hypertension, pulmonary hypertension, and ultimately acting as a potent vasodilator, improving blood flow distribution and wound healing. Studies have shown that exercise increases the levels of CGRP in skeletal and cardiac muscle cells. Studies in our laboratory suggest that CGRP may increase neurotrophic factor production by cultured cardiac cells (HL-1) in a dose depend manner, especially Glial Cell Line-Derived Neurotrophic Factor (GDNF). Finally, additional studies in our laboratory suggest that CGRP may reduce contraction rate of cultured Hl-1 cells. **PURPOSE:** To determine the effect of CGRP on heart contractility in frogs. **METHODS:** 12 frogs were divided into 4 groups. Three treatment groups received different concentrations of CGRP (40nMol, 100nMol, and 400nMol) in frog ringer's solution. A control group was treated with only frog ringer's solution. All frogs underwent autopsies to expose their hearts and each heart was connected to a PowerLab data acquisition system, which for collection of electrocardiogram, force of contraction, and heart rate using LabChart software. One-way ANOVA with Tukey post hoc were performed to determine statistical significance. **RESULTS:** Our results show that CGRP decreases force of contraction in all treatment groups when compared to the control group (Control: +9.20%; 40nM of GGRP: -38.35%; 100nM of CGRP: -34.29%; 400nM of CGRP: -33.10%; P<0.05). In addition, only 400nM of CGRP could, significantly, reduce the heart rate (Control: +3.32%; 400nM of CGRP: -24.01%; P<0.05). Finally, treatment with CGRP did not alter ECG (PQRST) curves in any of the treatment groups. **CONCLUSIONS:** Treatment with CGRP reduces force of contraction (in all treated groups) and reduces heart rate (400nM) without altering the ECG in frogs.

Quantitative Analysis of Mitochondrial Morphology Under Different Fluid Shear Stress Conditions

Soon-Gook Hong, Malik Sylla, Junchul Shin, Jamie Seo, Jacqueline Sayoc, Soo-Young Choi, Joon-Young Park. *Temple University, Philadelphia, PA.*
(No relevant relationships reported)

Exercise-mediated changes in the pattern of fluid shear stress affect the activation or quiescent status of vascular endothelial cells. Mitochondria are dynamic organelles constantly changing their shapes in response to intracellular metabolic demand and environmental cues. Recent studies suggest that mitochondrial morphology is closely related to their metabolic function with respect to cellular stress response. **PURPOSE** The purpose of this study was to investigate effects of different patterns of fluid shear stress on intracellular mitochondrial distribution and mitochondrial morphology. **METHODS** Primary human umbilical vein endothelial cells were grown and seeded to 0.2 μ-slides and stained for mitochondria using MitoTracker Red FM™ (200 nM). When a monolayer was formed, cells in each slide were exposed to either Static (STT), unidirectional laminar (LSS), and oscillatory (OSS) shear stress using parallel chamber flow apparatus. Temperature was maintained at 37°C, and pH and oxygen levels were maintained in a 95% air / 5% CO_2 humidified incubation chamber. Live-cell imaging was performed using a 63x oil lens with an epifluorescence inverted microscope. The number of cells in each mitochondrial morphological category (fragmented, short tubes, tubular, fused, or elongated) was counted based on aspect ratio (AR) and form factor (FF) scores. **RESULTS** At baseline, mitochondria represented evenly distributed tubular shape. Following a 15-minute exposure to either LSS (20 dynes/ cm^2) or OSS (±4 dynes/cm^2), mitochondrial morphology was not significantly altered. However, when exposed to prolonged LSS (up to 90 min), the mitochondria gradually changed their shape to short and fragmented structures and translocated to the cell periphery. Furthermore, 1-hour post-LSS, we observed more cells containing elongated mitochondrial networks. Conversely, at 1-hour post-OSS, mitochondria tend to be more fragmented and localized in the perinuclear region. Potential underlying mitochondrial fusion/fission event mechanisms will be discussed. **CONCLUSION** Data suggest that different types of fluid shear stress lead to a distinct mitochondrial morphological response, which may reflect different metabolic demands depending on the flow pattern.

Does High Human Serum MG53 Level Associate with Better Cardiorespiratory Function?

Qi Han, Jinde Fu, Naixi Liu, Jing Shao, Lili Zhou, Baohua Xu, Muqing Yi. *National Research Institute of Sports Medicince, BEIJING, China.*
(No relevant relationships reported)

Ischemia reperfusion (IR) induces increased serum MG53 level, and intravenous injection of rh-MG53 protein can ameliorate the damage from cardiac stress. However, the association between human serum MG53 level and cardiorespiratory function haven't been studied yet. **PURPOSE**: To investigate the association between the endogenous human serum MG53 level and cardiorespiratory function. **METHODS**: Sixteen healthy male volunteers (23.1±2.9 yrs, 169.5±6.0 cm in height, 63.2±5.9 kg in weight, 12.2±3.1% in %FAT, 53.2±5.4 ml/min/kg in VO_{2max}) signed informed consent and participated in this study. Each individual performed two VO_{2max} tests on cycle ergometer, and they had 7 wks of regular camp training between the two tests. Fasting blood samples were drawn before each VO_{2max} test, and serum MG53 was measured by ELISA. **RESULTS**: Serum MG53 levels showed big difference among individuals, therefore, three levels of MG53 were divided, they are Low serum MG53 group (0.60±0.45 ng/ml) (L), Medium serum MG53 group (2.08±0.75 ng/ml) (M) and High serum MG53 group (4.23±1.80 ng/ml) (H). We found red blood cell count (RBC) (4.98±0.22 vs 4.65±0.31 *10^{12}/L, p<0.01), hemoglobin (Hb) (155.3±7.6 vs 141. 5±8.1 g/L, p<0.01), and hematocrit (HCT) (46.6±2.1 vs 43.1±2.6%, p<0.01) were higher in M than in L. Moreover, we found that ventilation threshold (VT) was higher in H than in L (47.5±6.5 vs 38.6±3.9 ml/min/kg, p<0.01) and higher than in M (47.5±6.5 vs 42.5±2.8 ml/min/kg, p<0.05). Similarly, we found H had higher VO_{2max} than L (59.6±4.7 vs 51.6±6.7 ml/min/kg, p<0.05) and higher workload at VT than L (13.2±3.7 vs 11.1±1.7 Watts, p<0.05). The RBC (5.20±0.18 vs 4.65±0.31 *10^{12}/L, p<0.01), Hb (158.8±4.2 vs 141. 5±8.1 g/L, p<0.01), and HCT (47.4±1.5 vs 43.1±2.6%, p<0.01) were also higher in H than in L. Correlation analysis demonstrated that VO_{2max} (r=0.43, p<0.05), workload at VT (r=0.41, p<0.05), RBC (r=0.53, p<0.01), Hb (r=0.57, p<0.01) and HCT (r=0.47, p<0.01) are positively correlated with Serum MG53. **CONCLUSIONS**: It predicted that human serum MG53 level might be positively correlated with cardiorespiratory fitness.

The Effects Of Prohibitin1 On The Content And Synthesis Activity Of F0f1-atpase And Mitochondrial Function In C2c12 Cells

Wen Fang[1], Hong Fong[2], Li Li Ji, FACSM[3]. [1]Tsinghua University, Beijing, China. [2]Tianjin University of Sport, Tianjin, China. [3]University of Minnesota, Minnesota, MN.
(No relevant relationships reported)

In the eukaryotic cells ATP synthesis is closely related to the structural and functional integrity of mitochondria. F0F1-ATP synthase participates in oxidative phosphorylation and ATP production.The effect of Prohibitin1(PHB1) on mitochondrial function and F0F1-ATP synthase expression and activity is largely unclear.**PURPOSE:**To investigate the effect of PHB1 on the Oxygen Consumption Rate(OCR),oxidative stress(ROS) and ATP production in C2C12 cells.The influence of PHB1 on the content and activity of F0F1-ATPase was also examined.**METHODS:**The PHB1 overexpression and the RNA-interfered vector are inserted into the adenoviral vector by the phb1 overexpression sequence and the interfering sequence.Intracellular fluorescence distribution was detected by fluorescence inverse phase microscope.The efficiency of PHB1 transfection was determined by flow cytometry. The content of PHB1 was determined by Western blot.The expression of F0F1-ATPase was measured by qPCR.F0F1-ATPase activity was detected using a mitochondrial respiratory chain complex V activity kit.ATP content was detected by a kit.The changes of OCR was assessed by a XF cell mitochondrial stress detection kit.**RESULTS:**The complex V activity and the mRNA level of FOF1-ATPase were significantly increased in the PHB1 over-expression C2C12 cells.Compared with the control group, the activity of complex V in PHB1 overexpression group increased by 226%(p<0.01),whereas it was significantly decreased in PHB1 RNA-interfered cells. Cells with low PHB1 activity showed lower complex V activity(-193%, p<0.01),whereas ATP content,OCR were significantly increased in PHB1 over-expression cells.Compared with the control group,the ATP content of PHB1 over-expression group was increased by 80%(p<0.01),but it was decreased in the low-PHB1 RNA group(-21%, p<0.01).ROS production was lowered in PHB1 over-expression cells(-74%, p<0.01) compared with control,but it was increased in the low-pHB1 RNA cells(104%, p<0.01). **CONCLUSION:**The over-expression of PHB1 can increase the content and activity of F0F1-ATP synthase,ATP production and improve energy metabolism in C2C12 cells. Over-expression of PHB1 can also reduce ROS production,suggesting that PHB1 may be involved in stabilizing mitochondrial structure.

Identifying the Onset of Frailty

Dongmin Kwak[1], Cory W. Baumann[2], LaDora V. Thompson[1]. [1]Boston University, Boston, MA. [2]University of Minnesota, Minneapolis, MN.
(No relevant relationships reported)

PURPOSE: Frailty is a clinical syndrome associated with adverse health outcomes in older adults. Currently, there is a great need to identify interventions to prevent or delay the onset as well as decrease the burden of frailty symptoms. Identifying the onset of frailty is one of the first steps in developing effective interventions. Therefore, the purpose of this study was to determine the onset of frailty using the mouse frailty index.
METHODS: Male C57BL/6J (n=32) were purchased at 12 months of age. At 14 months of age, the mice were subjected to a frailty assessment that included 5 criteria: loss of body weight, weakness (grip strength), slow walking speed (Rota-rod), low activity level (voluntary wheel running) and poor endurance (treadmill test). Mice repeated these tests every 3 months throughout their lifespan. The designated cutoff point for each frailty criterion was determined from data collected at 14 months of age and was set at 1.5 SD below the mean. If a mouse had three of the criteria scores below the cutoff points, the mouse was identified as frail, while a mouse with two criteria scores was identified as mildly frail.
RESULTS: Prevalence of frailty increased across the lifespan of the mice, with 75% of the 35 month old mice identified as frail. The survival rate at 35 months of age was 25% of the original cohort. The onset of frailty occurred at 23 months of age (88% survival) while mice 17 months of age (94% survival) were considered mildly frail. Mildly frail mice fell below the cutoff points for endurance and walking speed, whereas the frail mice fell below the cutoff points for endurance, walking speed, and activity levels. Although endurance, walking speed, and activity levels were the

criterion identified in the frail mice, all criteria included in the frailty assessment decreased across the lifespan of mice. Reductions were observed in body weight (5.3%), strength (18.9%) endurance (51.1%), walking speed (31.4%), and activity levels (89.9%). A progression from mildly frail to frail to mortality was observed; in that, mildly frail mice at 17 months of age were frail by 23 months and died at 26 months.
CONCLUSIONS: Taken together, the onset of frailty occurs early in the lifespan and is associated with negative outcomes in mice. It provides the framework to develop interventions for preventing or delaying the frailty.

Dynapenia And Low Skeletal Muscle Mass In Older-aged Women

Roberto Gabriel Gonzalez-Mendoza, Francisco Torres-Naranjo, Alejandro Gaytan-Gonzalez, Juan R. Lopez-Taylor, Noe Gonzalez-Gallegos, Isabel Valadez. Universidad de Guadalajara, Guadalajara, Mexico.
(No relevant relationships reported)

Low skeletal muscle mass (LSMM) is associated with strength loss and disability. Epidemiological findings suggest that LSMM and dynapenia are associated with both mortality and physical disability. The association of muscle mass loss and dynapenia is still controversial.
PURPOSE: This study aimed to examine the association between dynapenia and LSMM defined by several operational definitions in older-aged women
METHODS: We evaluated 107 women aged 65 o more years from the western of México. A whole body DXA scanning (Hologic QDR 4500) was performed to evaluate the body composition. The indicators and cut points used to diagnose LSMM were: 1) appendicular lean soft tissue absolute kilograms (ALSTKG) ≤15.02; 2) appendicular lean soft tissue corrected by body mass index (ALST/BMI) <0.512, both according to The Foundation for National Institutes of Health Sarcopenia Project (FNHISP); and 3) appendicular lean soft tissue corrected by squared height (ALST/HT[2]) ≤5.45 as stablished by The European Working Group on Sarcopenia in Older People (EWGSPOP). The criteria of dynapenia was a maximum isometric strength (MIS) of the hand and forearm muscles equal or lower the 20 kg evaluated by handgrip dynamometry (Jamar Handgrip Dynamometer).
RESULTS: Overall prevalence of dynapenia was 71.3%. The prevalences of LSMM and their respective prevalence of dynapenia are showed in Table 1. The probability for dynapenia was significant for women with LSMM defined by ALSTKG and ALST/BMI. No statistical probability was observed with ALST/HT[2]
CONCLUSIONS: We observed a high prevalence in both loss of muscle mass and dynapenia in our sample. Prevalence of dynapenia is higher in women with LSMM defined by FNHISP criteria. Our findings suggest that several indicators should be taken in consideration in order to properly assess the impact of LSMM

Table 1. Dynapenia in older-aged female adults with LSMM.				
LSMM criteria	Prevalence of LSMM	Prevalence of dynapenia	Odds ratio	95% CI
ALSTKG	60.75	84.62	5.5*	2.2 to 13.6
ALST/BMI	38.32	90.24	6.4*	2.0 to 20.1
ALST/HT[2]	42.06	77.78	1.8	0.8 to 4.3
* p<0.05

Comparison of Growth in Children Undergoing Three Different ACL Reconstructions

Dustin J. Richter, Roger Lyon, Scott Van Valin, Xue-Cheng Liu. Medical College of Wisconsin, Milwaukee, WI.
(No relevant relationships reported)

Three surgical procedures aim to minimize the risk of physeal damage in children undergoing ACL reconstruction. They include: transphyseal (TP), physeal sparing (PS), and a partial physeal sparing procedure with an all epiphyseal tibial tunnel and graft placement in the 'over-the-top' position (OT). **PURPOSE:** The purpose of this study was to address the lack of understanding concerning tunnel migration due to growth in skeletally immature patients following ACL reconstructions. Sequential, post-surgical radiographs were used to quantify changes in tunnel positioning and to assess the rate of migration between these surgical techniques. **METHODS:** Anterior-posterior and lateral follow-up radiographs were retrospectively obtained for 31 skeletally immature patients (average age = 13.1 yrs) placed in three groups: TP (n=17, average age=13.8 yrs), PS (n=6, average age=11.9 ys), or OT (n=8, average age=12.7 yrs). Along with measuring tunnel angle, length, and width, a two-dimensional grid system was superimposed over the films to assess changes in tunnel position and

location over time. ANOVA analysis compared mean values of all measurements at six and twelve months as interpolated time points. **RESULTS:** The rates of migration of several variables of tunnel position were measured at up to two mm per month. Among 53 variables, only one variable, the vertical rate of change of the femoral tunnel aperture, showed significant difference in both PS and OT groups in comparison to the TP group (0.22 and 0.33 vs. 0.85mm, p<0.0497). The mean values of the measured variables demonstrated few differences to a level of statistical significance as well. Both PS and OT groups demonstrated significant reduction of tibial tunnel width (7.88 and 6.93 vs. 10.58, p=0.0001) and medial condyle radius (13.86 and 14.73 vs. 16.35mm, p<0.0499) compared to the TP group. **CONCLUSION:** Given only several significant differences in rates of migration, despite 53 variables being measured, this implies ACL reconstruction technique did not significantly affect the migration of tunnel positioning. Overall, this suggests uniform post-operative growth, which supports the notion that TP, PS, and OT procedures are similarly successful in allowing growth around the knee following ACL reconstruction in skeletally immature patients.

Age Associated Muscle Strength Loss During A Single Bout of Eccentric Contractions in Mice

Christopher Rawdon, Christopher Ingalls. *Georgia State University, Atlanta, GA.*
(No relevant relationships reported)

The magnitude of strength deficits during recovery from eccentric contraction-induced muscle injury is generally greater in old compared with adult mice. However, less is known about age-related differences in the progression of developed eccentric force deficits during the eccentric contraction bout. **Purpose:** To determine if there are age-related differences in the 1) peak isometric torque deficits immediately after 150 eccentric contractions and 2) developed eccentric torque during the course of 150 contractions in female mice. **Methods:** Isometric tetanic torque output from anterior crural muscles [tibialis anterior (TA) and extensor digitorum longus (EDL)] was measured before and immediately after a single bout of 150 eccentric contractions (from -19° ankle dorsiflexion to 19° plantarflexion at 2000°/s) in anesthetized female adult (6 months of age; n=10) and old (21 months of age; n=7) mice. Developed eccentric torque was measured during the 1st, 50th, 100th, and 150th contractions, and is determined by the difference in the initial eccentric and peak eccentric torques. **Results:** Although older female mice weighed more than adults (30.7 ± 1.4g vs 24.1 ± 0.4g), there were no age-related differences in the weights of the TA (old= 41.2 ± 1.1g; adult= 40.1 ± 0.7g) and EDL (old= 10.0 ± 0.6g; adult= 9.6 ± 0.4g) muscles, or isometric tetanic torque before injury (old= 2.5 ± 0.1 NŸmm; adult= 2.4 ± 0.1 NŸmm) and peak eccentric torque of the 1st contraction (old= 4.1 ± 0.2 NŸmm; adult= 4.4 ± 0.2 NŸmm). However, older female mice experienced less isometric torque deficits after the injury than adult mice (old=-40.7 ± 1.1%; adult=-46.6 ± 1.1%), but had similar developed eccentric contraction deficits after 50 (old=-25.3 ± 2.7%; adult=-21.4 ± 3.0%), 100 (old=-26.6 ± 4.4%; adult=-26.2 ± 2.8%) and 150 (old=-30.2 ± 4.6%; adult=-30.8 ± 2.9%) contractions. The deficit in developed torque for the 150th eccentric contraction was significantly less than the isometric torque deficits after the injury for adults and old mice. **Conclusion:** Compared with adults, older female mice experienced less isometric and similar eccentric torque deficits associated with a single bout of eccentric contractions.

Fatigue Resistance To Eccentric Contractions In Older Adults

Caitlin Skousen, Jacob R. Sorensen, Kyle Williams, Robert D. Hyldahl. *Brigham Young University, Provo, UT.*
(No relevant relationships reported)

PURPOSE: Aging is associated with a loss in skeletal muscle force producing capacity. However, there is evidence that old muscle is more resistant to fatiguing isometric muscle contractions than young muscle. It is unknown if age-related fatigue resistance occurs with eccentric (lengthening) contractions (EC). The purpose of this study was to test the hypothesis that skeletal muscle of older adults is more resistant to fatigue induced by EC relative to muscle of young individuals. **METHODS**: 10 young (22.7 ± 2.25 yrs) and 8 physically active old (70.9 ± 7.5 yrs) subjects completed 30 sets of 10 repetitions on a Biodex dynamometer, and torque, power, and work were measured. Between each set of 10 reps, there was a one minute rest period. **RESULTS**: There were no significant differences between young and old for anthropometric measures. Likewise, the total amount of functional work (young: 44.2 ± 13.1 vs old: 47.6 ± 10.6 kJ), average torque (young: 50148±13011 vs old: 54450±11507 N*m) and average power output (28105±6985 vs old: 30825±5405 watts) that was completed during the bout of ECs was similar between groups. However, as hypothesized, the rate of functional decline (fatigue) was greater in the young relative to the old throughout the 30 sets of ECs for average work (p=0.038) and power output (p=0.024), but not average torque (p=0.63) as indicated by a group x time interaction. **CONCLUSIONS**: Consistent with other studies, we show that, contrary to isometric force production, eccentric force production is preserved in old muscle. Furthermore, older subjects

demonstrated significantly greater fatigue resistance through the eccentric exercise session than did the young subjects. High-force EC may be an ideal exercise for maintaining muscle mass in older individuals given the higher force production, and preservation of functional capacity when compared to shortening contractions.

Loss of Lean Mass Increases Risk for Postural Hypotension in Older Men and Women

Jefferson M. Spicher, Amy L. Silva-Smith, Melissa J. Benton, FACSM. *University of Colorado, Colorado Springs, CO.*
(No relevant relationships reported)

At the cellular level, muscle provides a reservoir for body fluids to maintain fluid volume and blood pressure, so older adults may be at risk for hypotension due to loss of muscle with age. **PURPOSE:** To evaluate lean mass, hydration, and postural blood pressure in adults ≥ 65 years of age. **METHODS:** Older men (n=17) and women (n=30) completed two measurements of lean mass and hydration using multi-frequency bioelectrical impedance, and postural blood pressure lying, sitting, and standing. Day 1 was mid-day in a euhydrated state. Day 2 was the next morning, within 30 minutes of waking, in a fasted state. All were grouped for analysis by lean mass relative to height, using Lean Mass Index cut points of **Low** (women <14.9 kg/m²; men <18.7 kg/m²) and **Normal** (women ≥14.9 kg/m²; men ≥18.7 kg/m²). **RESULTS:** On Day 1, the **Low** group had lower *relative lean mass* (men 17.1 ± 0.4 vs. 20.2 ± 0.3 kg/m²; women 13.5 ± 0.2 vs. 16.5 ± 0.3 kg/m²; $p < 0.001$), *absolute lean mass* (men 55.7 ± 2.1 vs. 66.7 ± 1.8 kg; women 34.8 ± 0.9 vs. 44.3 ± 0.9 kg; $p < 0.01$), *hydration* (total body water: men 44.9 ± 1.0 vs. 51.1 ± 1.0 L; women 30.3 ± 0.5 vs. 36.1 ± 0.6 L; $p < 0.001$), and *fluid volume* (extracellular water: men 19.0 ± 0.4 vs. 22.2 ± 0.5L; women 14.4 ± 0.2 vs.17.2 ± 0.3 L; $p < 0.001$) compared to the **Normal** group. Overnight (Day 2), both groups lost similar amounts of total body water (-0.83 ± 0.13 L; $p < 0.001$), extracellular water remained stable (0.01 ± 0.4 L), and the **Low** group preferentially lost more intramuscular water (-1.0 ± 0.8 vs. -0.4 ± 0.07 L). During postural changes from *lying to standing* the **Low** group had greater drops in systolic blood pressure (Day 1: -8.43 ± 2.8 vs. +2.29 ± 2.3 mmHg; $p < 0.01$; Day 2: -16.83 ± 2.7 vs. -2.83 ± 3.1 mmHg, $p < 0.01$). By comparison, diastolic blood pressure was more stable and compensated for postural changes from *lying to standing* in the **Normal** group, but not in the **Low** group (Day 1: **Low** +0.52 ± 1.7 vs. **Normal** +6.75 ± 1.4 mmHg, $p < 0.01$; Day 2: **Low** +0.35 ± 1.9 vs. **Normal** +5.58 ± 1.6 mmHg, $p < 0.01$). **CONCLUSION:** Loss of muscle with age is accompanied by loss of hydration and fluid volume that manifests as lower and less stable blood pressure. In fact, the severe drop in systolic blood pressure observed on Day 2 in the **Low** group approximates the criteria for diagnosis of orthostatic hypotension. Based on these data, loss of muscle increases risk for postural hypotension in older men and women.

Impact of Nitrite Therapy on Change in Steady State Submaximal Exercise in Older

Kelly Allsup[1], Rachel Eleazu[2], Nancy W. Glynn[3], Jessica M. Shultz[2], James Kostra, Jr.[2], Ross Arena, FACSM[4], Daniel E. Forman[2]. *[1]VA Pittsburgh Healthcare System, Pittsburgh, PA. [2]University of Pittsburgh/ VA Pittsburgh Healthcare System, Pittsburgh, PA. [3]University of Pittsburgh, Pittsburgh, PA. [4]University of Illinois at Chicago, Chicago, IL.* (Sponsor: Ross Arena, FACSM)
(No relevant relationships reported)

Purpose: The population of older adults is growing, with increasing prevalence of detrimental geriatric risks, particularly sedentariness and downstream risks of cardiovascular disease, disability, and frailty. Nitrate therapy may enable physiological efficiency such that oxygen demands for submaximal workloads are reduced, and daily activity more easily tolerated. We explored the impact of chronic oral nitrite therapy in a cohort of older healthy adults. Nitrites (40 mg) were administered as capsules 3 times daily over one month. Changes in oxygen uptake (VO_2) during steady state walking in association with rate of perceived exertion (RPE [10-20 scale]) were analyzed. **Methods:** 9 adults (5 male, 4 female) aged ≥70 (mean 77.7±6.3 years, range 70-88) were studied. Functional capacity was assessed at baseline and 4 weeks based on steady state VO_2 and RPE during a 5 minute treadmill walk (1.5 mph). **Results:** Steady state VO_2 decreased significantly in the older adults using nitrite therapy (**Table 1**). RPE also trended downward.

	Pre	Post	Change	P-Value
Steady state VO2 (mlO2•kg-1•min-1)	13.29±4.14	11.27±2.75	2.02±2.75	0.029
Peak RPE	7.66±1.32	7±1.8	1±0	0.23

Conclusion: This promising pilot work in older adults showed that chronic nitrite was well-tolerated and was associated with increased walking efficiency. Further study is needed to better understand the impact on physical activity and health in this large and growing patient demographic.

Abstracts were prepared by the authors and printed as submitted.

Circulating Irisin Levels And Bone Strength In Korean Adults

Jong Whan Choi, Jae Seung Chang, Jung Soo Lim, In Deok Kong. *Yonsei Univ. Wonju College of Medicine, Wonju, Korea, Republic of.*

(No relevant relationships reported)

PURPOSE: The aim of the study was to investigate the association of serum irisin concentrations with bone strength in Korean adults.
METHODS: We evaluated the osteoporotic and sarcopenic risk factors and circulating irisin levels of 472 adults (307 women) aged 19-89 years. Bone status was assessed using a calcaneal quantitative ultrasound method. Appendicular lean mass (ALM) was measured by bioelectrical impedance analysis and muscle function was evaluated by handgrip strength (HS) test. Serum irisin level was measured with ELISA methods. Sarcopenia and pre-sarcopenia were determined by the presence of muscle atrophy (ALM/height^2 < 7.0 kg/m^2 in men, and < 5.7 kg/m^2 in women) and/or weakness (HS < 26 kg in men and < 18 kg in women), respectively. Subjects were classified into four groups according to sex and quartiles of irisin levels.
RESULTS: As expected, the prevalence of those with sarcopenia tended to increase in the lowest quartile of irisin, whereas bone stiffness index (BSI) was significantly higher in the highest quartile of circulating irisin compared to the lowest one (93.6 ± 16.9 vs 81.7 ± 13.9 in men and 79.7 ± 18.1 vs. 71.6 ± 13.3, all for $p < 0.05$). Moreover, serum irisin levels had positive linear correlation with BSI in both sexes ($r = 0.1441$ in men and $r = 0.1438$ in women, all for $p < 0.05$).
CONCLUSIONS: Our results suggest that circulating irisin is associated with bone strength as well as sarcopenia in Korean subjects. Further investigations are needed to clarify the role of irisin as a mediator of bone-muscle unit.

Bone HealthAmongFemale Collegiate Athletes Participating in Loading and Active Loading Sports

Alexandra Sirois, Jessica A. Insogna, Ryan ER Reid, Nathan Chiarliti, Meghan McGillivray, Ross E. Andersen, FACSM. *McGill University, Montreal, QC, Canada.* (Sponsor: Ross Andersen, FACSM)

(No relevant relationships reported)

PURPOSE: Collegiate athletics are known to affect body composition, strength, and bone characteristics. However, it is unknown which sport is most beneficial for increased bone mineral density (BMD). To compare the BMD of female collegiate athletes (n=102) who compete in impact loading sports; ice hockey players (HP; n=24), cheerleading (CH; n=22), and ballet dancers (BD; N=10) to female athletes in active loading sports; synchronized swimmers (SS; n=20), and sedentary controls (SC; N = 26).
METHODS: Participants underwent a total body, lumbar spine and femoral neck iDXA scan to evaluate BMD. Participants aged 20.5 ±1.8 years and weighed 61.3 ±9.8kg. ANCOVA compared BMD of the femoral neck, greater trochanter, total femoral, and lumbar spine (L1-L4) by sport while controlling for age.
RESULTS: HP had the most regular menstrual cycles (83%), followed by SS (75%), SC (65%), CH (64%). BD had the least regular cycles (50%) and many were oligomenorrheic. BD and HP had a significantly higher BMD in the femoral neck and greater trochanter as compared to all other groups ($p \leq 0.05$; $p \leq 0.001$). However, HP had significantly higher total femoral BMD than CH, SS and SC. BD demonstrated higher femoral BMD compared to CH, SS and SC ($p \leq 0.01$). Analysis of the BMD in the lumbar spine revealed that HP and BD had significantly higher BMD as compared to the SS and SC (1.14±0.12g/cm^2). Furthermore, there was no statistical difference between BD and the CH. However, CH had higher lumbar spine BMD than the SS and the SC ($p \leq 0.00$) (Table 1).
CONCLUSION: Although, ballet is an aesthetic sport as compared to hockey, both offer superior benefits to bone health than cheerleading, synchronized swimming, and being sedentary. The high prevalence of menstrual irregularity in the ballet dancers did not appear to negatively influence BMD. These results suggest that monitoring bone health in female athletes participating in low impact sports should be a priority.
Table 1: BMD by Sport Type

	Weight (kg)	Femoral Neck (g/cm2)	Greater Trochanter (g/cm2)	Total Femur (g/cm2)	Lumbar Spine (g/cm2)
Hockey	68.3 (±7.8)	1.21 (±0.14)	1.0 (±0.11)	1.21 (±0.11)	1.31 (±0.13)
Ballet	55.7 (±5.5)	1.17 (±0.15)	0.9 (±0.94)	1.1 (±0.11)	1.22 (±0.16)
Cheerleading	60 (±9.7)	1.06 (±0.17)	0.83 (±0.11)	1.04 (±0.14)	1.25 (±0.12)
Synchronized Swimming	61.7 (±8.3)	1.06 (± 0.13)	0.80 (±0.12)	1.04 (±0.13)	1.16 (±0.12)
Sedentary Controls	57 (±10.7)	1.0 (±0.13)	0.78 (±0.10)	1.01 (±0.11)	1.14 (±0.12)

Weight Gain, not Simple Resumption of Menses, Improves Bone Metabolism in Amenorrheic Exercising Women

Emily A. Southmayd, Rebecca J. Mallinson, Nancy I. Williams, FACSM, Mary Jane De Souza, FACSM. *Penn State University, University Park, PA.* (Sponsor: Mary Jane De Souza, FACSM)

(No relevant relationships reported)

PURPOSE: To assess if menstrual resumption or weight gain contributed to improved bone metabolism during a nutrition intervention in amenorrheic exercising women.
METHODS: Amenorrheic exercising women (n=27, 18-25 yr) were recruited for a 12mo intervention to assess the impact of increased caloric intake on menstrual and bone health. Body weight and serum markers of bone formation (P1NP) and resorption (CTX) were measured at baseline (BL) and the time of menstrual resumption (n=15) or study completion if participants did not resume menses (n=12, range 5-49 wks) (post). Bone balance (BB) at BL and post was calculated as the multiple of median of formation (MoMf=[P1NP]/median[P1NP]$_{OV}$) divided by resorption (MoMr=[CTX]/ median[CTX]$_{OV}$) with an ovulatory control group serving as the reference (OV). Two-way ANOVA determined if change in MoMf, MoMr, and BB were related to menstrual resumption or weight gain. Women were classified as gaining ≥1 kg (Wt+) or not (Wt-). Menstrual resumption was defined simply as the occurrence of a single menses. **RESULTS**: 12/15 women resumed menses and 16/27 women gained ≥1 kg during the study. Average weight change was +2.6 kg in Wt+ and -0.1 kg in Wt-. There was a main effect of weight on BB change (p=0.007), indicating that women in Wt+ experienced increased BB (1.03 to 1.23) whereas women in Wt- experienced decreased BB (1.16 to 0.97). There was an interaction effect of resumption and weight on MoMf (p=0.027), such that the largest decrease in MoMf (1.4 to 1.1) occurred in women who neither resumed nor gained weight. There were no main or interactive effects of resumption and weight on MoMr, though MoMr decreased in Wt+ (1.25 to 1.15) and increased in Wt- (1.34 to 1.43). There were no differences in the proportion of women who resumed menses in Wt+ (10/16) vs. Wt- (5/11) (χ2=0.767, p=0.381).
CONCLUSIONS: Weight gain of ≥1 kg improved bone balance to favor bone formation. The occurrence of a single menses did improve bone metabolism. The change in bone formation depended on both menstrual resumption and weight gain. Our findings suggest that a single occurrence of menses is unlikely to coincide with enhanced estrogenic status necessary to improve bone health; weight gain, indicative of improved energy, may be a more robust predictor of bone health in amenorrheic exercising women. Supported by US DoD (PR054531)

The Effects Of A Single Bout Exercise On Rankl Pathway, Cytokines And Bone Turnover Markers In College Women

JIYEON KIM[1], HYOJIN KIM[2], GIWON KIM[2], SUKHO LEE[1], DONGHO PARK[3], SEOKKI MIN[4], Changsun KIM[2]. *[1]TEXAS A&M- San Antonio, San Antonio, TX. [2]Dongduk Women's University, Seoul, Korea, Republic of. [3]Inha University, Incheon, Korea, Republic of. [4]Korea Institute of Sport Science, Seoul, Korea, Republic of.*

(No relevant relationships reported)

PURPOSE: Exercise is well known to play a positive role in bone metabolism, but few studies have examined changes in exercise intensity relative to receptor activator of nuclear factor-kappaB ligand (RANKL)/ Osteoprotegerin (OPG) factors that regulate osteoclastogenesis. The objective of this study was to investigate the changes of RANKL pathway factors, cytokines, and bone turnover markers by applying moderate intensity and high intensity exercise.**METHODS**: Ten female collegiate students (21.8±2.4yrs) completed two exercise sessions 1) moderate intensity exercise (60% VO2max) and 2) high intensity exercise (80% VO2max) with seven days interval. Calorie outputs of two exercise sessions were matched (250 kcal). Blood

WEDNESDAY, MAY 30, 2018

samples were collected before, immediately after, and 90 min after exercise and were analyzed for serum levels of RANKL pathway (RANKL, OPG), cytokines (IL-6; Interleukin 6 and TNF-α; Tumor necrosis factor-alpha), and bone turnover markers (osteocalcin, CTx; collagen type 1 cross-linked C-telopeptide, Vitamin D). **RESULTS**: As a result, there was no significant time x group interaction effect for RANKL pathway, cytokines, and bone turnover markers (N.S.). A significant time effect was observed for TNF-α (F=26.185, p=.001) but, post-hoc analysis showed no significant effects. A significant group effect was observed for CTx (F=11.386, p=.006) but, post-hoc analysis showed no significant effects. However, significant correlation was found among RANKL pathway, cytokines, and bone turnover markers. It was found that TNF-α had a positive correlations with RANKL (r=.685, p=.000) and OPG (r=.244, p=.021). In addition, study shows that Vitamin D had a negative correlation with RANKL(r=-.323, p=.004) and OPG(r=-.278, p=.008), and had a positive correlation with OPG / RANKL ratio(r=.252, p=.026). **CONCLUSIONS**: This results suggest that a single bout of exercise used in current study may not enough to induce changes in RANKL pathway, cytokines, and bone turnover markers in 20s women with maximal bone mass. We also found that TNF-α and vitamin D have positive and negative relationship with RANKL and OPG respectively. Supported by NRF Grant 2015S1A5A2A01011501.

Influences Of Alcohol Consumption, Physical Activity, And Body Composition On Areal Bone Mineral Density In Korean College-aged Female Students

SoJung Kim[1], DongJun Sung[2], JaeWoong Gu[2], SeungBum Oh[2]. [1]University of Massachusetts, Lowell, MA. [2]Konkuk University, Chung-Ju, Korea, Republic of.
(No relevant relationships reported)

PURPOSE: The purpose of this study was to investigate the most important factor among alcohol consumption, physical activity, and body composition that affect aBMD in healthy college-aged female students. **MOTHODS:** One hundred thirteen college females (21.9 ± 1.8 years; 161.8 ± 5.2 cm; 53.2 ± 6.0 kg) were recruited from the Universities in Seoul and Gyeonggi areas, South Korea. The aBMD of L1-L4 and non-dominant side of proximal femur (TH; total hip, FN; femoral neck) were measured using Dual Energy X-ray Absorptiometry. The alcohol consumption was determined by the frequency and amount of alcohol intake during the past 12 months using self-reported questionnaires (less than once per month, n=45; 2-4 times per month, n=53; 2-3 times per week, n=15). The total bone-specific physical activity (tBPAQ, average of past and current BPAQ) score was used to obtain a comprehensive account of lifetime physical activity related to bone health. A qualified research analyzed all values using an online BPAQ calculator (www.fithdysign.com/BPAQ/). The X-scan plus II (Hospital body Composition Analyzer, Jawon Medical Korea) was used to measure height (cm), weight (kg), fat free mass (FFM, kg), and % body fat. **RESULTS:** Spearman's correlation showed no significant relationships between the frequency of alcohol intake and aBMD of L1-L4 and TH and FN at non-dominant side of femur (p>0.05). But there were positive correlations between FFM and aBMD of L1-L4 (r=0.410, p<0.001), TH (r=0.415, p<0.001) and FN (r=0.395, p<0.001). Also, positive relationships were found between %body fat and aBMD of L1-L4 (r=0.205, p<0.05), TH (r=0.302, p<0.01) and FN (r=0.282, p<0.01). The tBPAQ scores were positively related to aBMD of TH (r=0.299, p<0.01) and FN (0.292, p<0.01), but not found in L1-L4 (p>0.05). **CONCLUSION:** The most positive influential factor affecting healthy aBMD was FFM in college-aged female students, compared to %body fat and tBPAQ. Our study found that alcohol consumption did not affect aBMD variables and further studies are needed to determine its relations to aBMD in this population. Our findings suggest that maintaining healthy body composition would be the key for healthy bones in young college-aged females.

Sex-specific Mediation Of Physical Activity's Effects On The Muscle-bone Unit In Active Young Adults.

Simon Higgins[1], Chester M. Sokolowski[2], Megha Vishwanathan[2], Jessica G. Anderson[2], Michael D. Schmidt[2], Ellen M. Evans, FACSM[2], Richard D. Lewis, FACSM[2]. [1]Elon University, Elon, NC. [2]University of Georgia, Athens, GA.
(No relevant relationships reported)

Moderate-to-vigorous intensity physical activity (MVPA) promotes bone mineral accrual on periosteal surfaces. These adaptations are thought to largely result from mechanical forces applied to bones by contracting muscles. **PURPOSE:** To understand the pathway through which mechanical forces optimize cortical bone, we sought to identify the serial multiple mediation pathway through which measures of muscle mass and force interact with cortical bone during MVPA, in sex-specific models. **METHODS:** Time performing MVPA was assessed over 7 days in young adults (n=147, 19.7 ± 0.7 yo, 52.4% female) using an Actigraph GT3X+ accelerometer. Cortical diaphyseal bone was assessed via peripheral quantitative computed tomography at the mid-tibia. Muscular strength of the knee extensors via

Biodex isokinetic dynamometry was used to represent the mechanical forces applied to the tibia and thigh lean mass was assessed via dual-energy x-ray absorptiometry. **RESULTS:** Participants exceeded recommended levels of MVPA (89.14 ± 27.29 minutes/day), with males performing 40.9% more vigorous intensity activity relative to females (p<.05). Males absolute knee extension force, force relative to lean mass, and thigh lean mass were greater than females (59.9%, 16.1%, and 37.0%, respectively, all p<.05). In combined-sex models, controlling for tibia length and age, the effect of MVPA on strength strain index (pSSI) was completely mediated through two discrete pathways: 1) thigh lean mass (Coeff. = 1.11, LLCI .48, ULCI 1.96), and 2) thigh lean mass and knee extensor force in sequence (Coeff. = .26, LLCI .08, ULCI .65). However, in sex-specific models the effect of MVPA on pSSI was mediated through thigh lean mass in females (Coeff. = .95, LLCI .18, ULCI 2.18) and knee extensor force in males (Coeff. = .78, LLCI .04, ULCI 2.02). Bootstrapped confidence intervals confirmed these mediation pathways for measures of cortical structure but not density. **CONCLUSION:** The effect of MVPA on cortical structure in young adults appears to be mediated through a muscle mass, potentially paracrine, pathway, as well as through mechanical forces. Sex-specific pathways suggest that muscle force is influential in males but not females. These findings highlight potentially novel avenues for the sex-specific promotion of bone accrual.

Bone Mineral Content/Density And Muscle Strength In Young Women From Different Racial/Ethnic Backgrounds - A Pilot Study

JAPNEET KAUR, EDUARDO D.S. FREITAS, RYAN M. MILLER, AARON D. HEISHMAN, DEBRA A. BEMBEN, FACSM, MICHAEL G. BEMBEN, FACSM. UNIVERSITY OF OKLAHOMA, NORMAN, OK. (Sponsor: MICHAEL G. BEMBEN, FACSM)
(No relevant relationships reported)

Race/ethnicity is a major factor influencing both bone mass and muscle mass (bone free lean mass - BFLM) since muscular forces can enhance bone strength by applying mechanical stress to the skeleton. **Purpose:** To examine group mean differences and the relationships between bone mineral content (BMC) and density (BMD) to BFLM and muscle strength in young women from different racial/ethnic backgrounds. **Methods:** Twenty-seven young women aged 18-30 years self-identified themselves as Caucasian (Cau; n=6), South-Asian (SA; n=6), East-Asian (EA; n=4), Hispanic (His; n=6), and African-American (AA; n=5). Body composition (fat, BFLM, and BMC) and total and regional BMD were measured using Dual Energy X-Ray Absorptiometry, while jump test, leg press, and bilateral isokinetic strength testing of knee flexors/ extensors were used to quantify lower limb muscle strength and power. International Physical Activity Questionnaire (IPAQ) classified women into low, moderate or high levels of physical activity. Ethnic differences in each outcome variable were determined using one-way ANOVA, while Pearson correlation coefficients quantified relationships between variables. Statistical significance was set at p < 0.05. **Results:** Based on the entire sample (n=27), both total body BMD and BMC had significant positive relationships with total BFLM (r=0.78 and 0.87 respectively). Based on ethnicity, AA women had significantly higher total body and hip (left and right) BMC than His. Although non-significant, total BFLM values were highest for AA and lowest for EA and SA (47.7±9.6 kg vs. 37.9±5.5 kg and 37.8±5.5 kg respectively; p=0.08). Analysis of the entire sample revealed a significant positive relationship between MET minutes/week and total BFLM (r=0.45). As per IPAQ scores, highly active women had significantly lower percent body fat compared to moderately active women (26% ± 6% vs. 38% ± 7%; p=0.001). Finally, average muscular power (watts; W) during flexion at 60 deg/sec was significantly higher for Cau compared to EA and SA (54.98±18.74 W vs. 30.76±7.6 W and 27.7±9.0 W respectively; p=0.01). **Conclusion:** These findings suggest that BMC and BMD are significantly related to total BFLM, and that BMC varies across the ethnic groups, however, further data collection and analyses will validate the current findings.

Gender Differences in Mechanical Properties of the Achilles Tendon: Longitudinal Response to Heavy Loading Exercise

Jessica E. Digiacomo, Emily Rock, Nathan R. Daigle, Samuel B. Rosier, Parth B. Sureja, Adam S. Lepley. University of Connecticut, Storrs, CT.
(No relevant relationships reported)

Gender differences have been observed in the mechanical properties of the Achilles tendon, helping to explain the increased risk of injury in males. However, the response and recovery of tendon mechanics to heavy loading exercise, as well as gender dependent responses, are not well understood. **PURPOSE:** Compare Achilles tendon mechanical properties between males and females prior to, immediately after, and 60-minutes following a heavy loading exercise. **METHODS:** 17 female (age: 24.0 ± 3.9yrs; height: 167.4 ± 6.9cm; mass: 64.9 ± 8.5kg) and 18 male (age: 23.9 ±

2.4yrs; height: 179.2 ± 5.09cm; mass: 78.4 ± 8.7kg), recreationally active individuals volunteered. Isokinetic dynamometry and diagnostic ultrasound were used to assess levels of Achilles tendon stiffness (N/mm), stress (MPa), and Young's modulus (MPa) prior to 100 successive calf raises using a Smith machine at 20% body mass. Outcomes were reassessed immediately, and 60-minutes post-exercise. Separate 2x3 (gender x time) repeated measures analyses of variances and Bonferroni post-hoc comparisons were used to assess differences in males and females on each outcome across the three time points. **RESULTS:** Females exhibited less Achilles tendon stiffness (baseline: 146.8 ± 76.0; immediate: 127.8 ± 52.6; 60min: 137.7 ± 56.6), stress (baseline: 25.4 ± 14.3; immediate: 22.0 ± 12.9; 60min: 23.0 ± 12.8), and modulus (baseline: 211.9 ± 138.7; immediate: 182.8 ± 99.6; 60min: 194.4 ± 99.3) compared to males (stiffness - baseline: 206.5 ± 113.5; immediate: 164.1 ± 69.8; 60min: 180.8 ± 73.7; stress - baseline: 36.2 ± 14.8; immediate: 32.3 ± 12.1; 60min: 34.4 ± 13.5; modulus - baseline: 257.7 ± 112.1; immediate: 233.3 ± 125.0; 60min: 246.7 ± 91.9; P ≤ 0.05). Both genders responded to high loading exercise similarly, with immediate decreases in outcomes from baseline to immediately post-exercise, and restoration of outcomes by 60min (P ≤ 0.05). **CONCLUSION:** Females demonstrate less Achilles tendon stiffness, stress and modulus compared to males, however both genders respond to heavy loading exercise similarly. This indicates that baseline differences in tendon properties, and not distinctive responses to loading, may help to explain the disparity in injury risk. Future research should examine tendon properties in response to loading in patients with Achilles tendinopathy.

A-45   Free Communication/Poster - **Anterior Cruciate Ligament Injury**

Wednesday, May 30, 2018, 7:30 AM - 12:30 PM

Neuromuscular Changes During Return To Play After ACL Surgery In Elite Soccer Players

Frantisek Zahalka[1], Tomas Maly[1], Dai Sugimoto[2], Lucia Mala[1], Lee Cabell[3], Arnold Baca[4]. [1]Charles University, FPES, Prague, Czech Republic. [2]Boston Children's Hospital, Boston, MA. [3]Arkansas Tech University, Russellville, AR. [4]University of Vienna, Vienna, Austria.
(No relevant relationships reported)

Anterior Cruciate Ligament (ACL) tear is major concern.in soccer. Although ACL reconstruction and its postoperative rehabilitation are successfully performed, knee instability and neuromuscular control deficits are often prevalent at the time of return to play process.
PURPOSE: To investigate effect of postoperative rehabilitation protocol on postural control (PC) changes in three time points following ACL reconstruction in male soccer players.
METHODS: National level male soccer players (n = 16, age 24.7±3.9 years) volunteered in the study. Players performed postoperative rehabilitation protocol that had emphasis on enhancing postural stability (PS), muscular strength, and limb symmetry 6 times per week for 23 weeks. Static pressure measurements were obtained on a platform Footscan (RSscan International, Belgium). The following tests of PS were taken: bilateral narrow standing position (BS) with 2 levels of vision (eyes open and closed) for 30 seconds and single leg standing (SS) position test on injured and non-injured leg for 60 seconds. The tests were performed: (a) postoperatively, before rehabilitative intervention, five months (b), and 10 months (c) following ACL reconstruction. Mixed-design RM ANOVA, Bonferroni's *post hoc* tests and partial eta square (η_p^2) were used for statistical assessment. **RESULTS:** The main factor (Time) revealed significant effect on PC both for BS ($F_{2,60}$ = 56.39; $p<.01$, η_p^2 = .65) and SS ($F_{2,60}$ = 40.37; $p<.01$, η_p^2 = .57). Post-hoc test revealed significant improvement of PC improvement after intervention (BSa = 151.34±8.41 mm, BSb =127.00±6.56 mm, $p<.01$) as well as follow-up effect (BSb =127.00±6.56 mm, BSc =109.63±6.18 mm, $p<.01$). We found a significant interaction effect between observed factors (Time*Leg) within observed time ($F_{2,60}$ = 24.81; $p<.01$, η_p^2 = .45). Participants significantly improved PC on injured leg (SSa = 1748.63±78.81 mm, SSb = 1281.75±62.70 mm, p<.01); however, postural control SSb was non-significant compared to SSc (p>.05).
CONCLUSION: The postoperative rehabilitation protocol demonstrated favorable PC improvements following ACL reconstruction in elite male soccer players. Also, our findings indicated importance of continuous rehabilitation after 5 months following ACL reconstruction in order to eliminate asymmetry in PC.

Quadriceps Function Does Not Differ Between Subjects With ACL Reconstruction With Impulsive Vs. Normal Loading

Jonathan Goodwin, Chris Johnston, Brian Pietrosimone, FACSM, Troy Blackburn. University of North Carolina at Chapel Hill, Chapel Hill, NC.
(No relevant relationships reported)

Individuals with anterior cruciate ligament reconstruction (ACLR) are at a significant greater risk of knee osteoarthritis (OA). The heelstrike transient (HST) during gait is indicative of impulsive/high-rate loading, which has been implicated in cartilage degradation and knee OA development. The quadriceps attenuates loading during gait, and quadriceps dysfunction following ACLR may contribute to impulsive loading and knee OA risk. **Purpose:** To determine the differences in quadriceps function between impulsive loaders and non-impulsive loaders during walking gait.
Methods: Forty-five volunteers with unilateral ACLR participated in this study (32F, 20±3 years old, 71±19 kg, 1.7±0.1 m, 23±15 [range 7-58] months post-ACLR). Quadriceps function in the ACLR limb was quantified during maximal isometric contraction at 90° of knee flexion via the peak torque, rate of torque development (RTD) from 20% to 80% of the interval from onset to peak torque, RTD from onset to 100 ms, and RTD from 100ms to 200ms. All values were normalized to body mass. Gait biomechanics were assessed during overground walking at a self-selected pace. A trial was classified as possessing a HST if the ratio of the vertical ground reaction force peak immediately following heelstrike to the impending local minimum exceeded 1.2. Subjects were classified as "Impulsive" loaders if a HST was identified in at least 3 of 5 of trials. Independent t-tests and correlations were utilized for the analysis.
Results: 31% of the subjects were identified as Impulsive loaders. However, there were no significant differences between Impulsive and Normal loaders for $RTD_{20-80\%}$ (0.41±0.46 vs. 0.42±0.44, p=0.96), $RTD_{0-100ms}$ (2.9±1.9 vs. 3.5±2.6, p=0.41), $RTD_{100-200ms}$ (2.5±1.4 vs. 2.3±1.5, p=0.62), or peak torque (2.2±0.7vs. 2.3±0.7, p=0.45). There were no significant correlations between the %trials with HST and the quadriceps function indices (r=-0.043-0.172, p=0.258-0.952).
Conclusion: Roughly 1/3 of our subjects were identified as Impulsive loaders. This statistic mirrors the risk of knee OA development (~30%) in the first decade following ACLR. Our data suggest that this relationship is not associated with quadriceps function. Future research is necessary to determine the role of the HST in knee OA development and the factors that contribute to its presence.

Interlimb Asymmetries Post ACL Reconstruction During Sprints

Jamie Kronenberg[1], Nicole Veltri[1], Danielle Pasquale[1], Joshua M. Tome[1], Patrick McKeon[1], Kathy J. Simpson[2], Rumit S. Kakar[1]. [1]Ithaca College, Ithaca, NY. [2]Universiy of Georgia, Athens, GA.
(No relevant relationships reported)

Purpose: ACL reconstruction (ACLR) after a complete ACL tear is aimed at restoration of the mechanics of the limb. After reconstruction, neuromuscular mechanics of the lower extremities (LE) may change asymmetrically. Since the ACL is comprised of inert tissue, it has lower adaptability under stress. Abnormal force distribution between the LE joints of ACLR can increase the risk for a secondary tear while running. The purpose of this study is to use 2-Dimesional (2D) motion analysis to assess limb asymmetries in individuals with ACLR during sprints. **Methods**: 6 ACLR (4 females, 2 males, age 19-24, 1-5 yrs post-surgery)& 6 BMI-matched controls (MC) participated. Participants ran at a maximum (MAX) self-selected speed/sprint for 30s on a treadmill. 2D data were recorded via Apple iPads and analyzed via Kinovea© for max joint angular displacements (AngDisp: max flexion to extension) at the hip, knee and ankle in the sagittal plane. AngDisp were compared between groups using Kruskal-Wallis H Test. Limb symmetry indices (LSI) were calculated (Involved/Healthy *100) for participants and compared between ACLR and MC. **Results**: No statistically significant differences in AngDisp between the groups were observed (p=.281,.676,.895;χ²=2.538,.784,.222) for the hip, knee and ankle respectively. LSI values (85>X>115%) are clinical indicators of asymmetry between limbs. LSI values showed clinically significant differences at the ankle in ACLR group (84%) but not in MC (87%). There were no clinically significant differences in LSI at the hip or knee (92-94%). **Conclusions**: Neuromuscular deficits have been reported up to 2 years post-op. These deficits are usually not visible without use of 3D motion analysis. In the absence of advanced technology, common neuromuscular deficits can be missed, leading to earlier termination of rehabilitation and possibly leading to a secondary tear (reinjury rate: 23%). Although there were minimal asymmetries reported on LSI, detailed 3D analysis might be essential to understand the quality of the running mechanics or any possible neuromechanical deficits to help prevent any secondary ACL tear.

Quadriceps Strength and Landing Symmetry Following ACL Reconstruction

Skylar Holmes[1], Steven Garcia[1], Tyler Moffit[1], Mike Vakula[2], Melissa Montgomery[1], Derek Pamukoff[1]. *[1]California State University Fullerton, Fullerton, CA. [2]Utah State University, Logan, UT.* (Sponsor: Daniela Rubin, FACSM)
(No relevant relationships reported)

PURPOSE: Quadriceps strength asymmetry is common following anterior cruciate ligament reconstruction (ACLR). However, quadriceps strength symmetry may not reflect symmetry in other tasks such as a landing. The purpose of this study was to 1) examine the relationship between quadriceps strength symmetry and landing symmetry and 2) to compare landing mechanics between limbs of individuals with ACLR. **METHODS: :** Quadriceps strength and landing biomechanics were assessed in 46 individuals with primary unilateral ACL reconstruction (34 females, age=22.0±2.8 years, height=1.70±.09m, mass=71.9±16.1kg, IKDC=86.1±9.3). Participants completed 3 drop jump landings from a 30cm height located at a distance of 50% of their height onto 2 force plates. Quadriceps strength was assessed via isometric (peak and rate of torque development (RTD)) and isokinetic knee extension at 60°, 180°, and 240°/second. Limb symmetry index (LSI) was calculated as the ratio of the involved divided by the uninvolved limb for strength and landing biomechanics (knee flexion angle (KFA) (at ground contact, peak, and excursion), peak external knee flexion moment (KFM), and vertical ground reaction force (GRF)). Pearson correlation was used to assess the relationship between quadriceps LSIs and KFM and GRF LSIs. Spearman rho was used to examine the relationship between quadriceps LSIs and KFA LSIs. Paired samples t-tests were used to compare dependent variables between limbs (α=0.05). **RESULTS**: Isometric strength LSI (r=0.30, p=0.05) and RTD LSI (r=0.37, p=0.01) were associated with KFM LSI. Isometric strength LSI (rho=0.34, p=0.02) and isokinetic strength LSI at 60° (rho=0.40, p=0.01) and 180° (rho=0.31, p=0.05) were associated with knee flexion excursion LSI. Isokinetic strength at 180° (r=0.39, p=0.01) was associated with GRF LSI. Uninvolved limbs had greater GRF (2.48±0.77 vs. 2.23±0.69 BW, p=0.034) and KFM (0.17±0.04 vs. 0.14±0.04 %BW*height, p<0.001) compared to involved limbs. **CONCLUSIONS**: ACLR limbs had smaller GRF and KFM compared to uninvolved limbs. This may indicate a compensatory strategy to underload the involved limb during landing. The weak correlations between quadriceps strength LSI and landing LSI may indicate that other factors such as impaired neuromuscular control or fear of re-injury influence landing symmetry.

Quality Of Semitendinosus Tendon Regeneration As A Function Of Time Post-ACL Reconstruction

Clara Amat Fernandez, Anthony S. Kulas, Zachary J. Domire. *East Carolina University, Greenville, NC.*
(No relevant relationships reported)

Evidence exists of the semitendinosus tendon (ST) physically regenerating following harvest for ACL reconstruction. However, the quality of regenerated tissue, indicated by elastic modulus, is not well understood. The time-dependency of this regeneration is also important post-ACL reconstruction as the hamstring muscle group is inherently protective of the ACL. **PURPOSE**: Assess the quality of ST regeneration, as measured with shear modulus, as a function of time post-ACL reconstruction with comparisons to healthy controls. **METHODS**: Ultrasound Shear Wave Elastography determined shear modulus of the ST tendon on 10 ACL reconstructed individuals (age: 21.6±1.6 years, height: 171.6±8.5cm, mass: 71.4±7.1kg, Tegner scale: 5.9±1.0) and 10 healthy individuals (age: 20.6±2.0 years old, height: 173.4±9.3cm, mass: 71.6±13.0kg, Tegner scale: 5.6±1.1). Time since ST harvest averaged 4.3 years (range: 0.75-12.6 years) and all individuals were since cleared to return to play by their physician. While prone with the knee at full extension and relaxed, three ultrasound images (AIXPLORER, Supersonic Imagine S.A., France) were acquired of the distal ST tendon. Linear regression analysis determined the relationship between ST tendon shear modulus vs. time since tendon harvest. 99% confidence interval (CI) determined the range of tendon compliance in healthy subjects and served as comparison to ACL reconstructed subjects. **RESULTS**: The relationship between the shear modulus vs. time since ST harvest was R²=0.57 (p=0.012). 3 subjects under 2 years post-reconstruction had low shear modulus of ~100kPa or less. The 99% CI of the healthy tendons was 374-590kPa, and only 1 of the 10 reconstructed subjects reached this range. **CONCLUSIONS**: Despite these preliminary data supporting long-term time-dependent regeneration, ST quality is highly variable indicating other factors influence this regeneration post-ACL reconstruction. Low shear modulus has an effect on muscle function, which may alter the knee load leading to the early development of knee OA. Future research is needed to assess the clinical importance of regeneration quality post-harvest in order to establish interventions facilitating early material property recovery.

Greater Loading Rates during Gait are Associated with Knee Symptoms 1.5 Years Following ACL Reconstruction

Brian Pietrosimone, FACSM[1], Christopher Johnston[2], Brittney Luc-Harkey[3], Matthew Harkey[4], Laura Stanley, FACSM[1], Jonathan Goodwin[1], Hope Davis[1], Jeffrey Spang[1], J Troy Blackburn[1]. *[1]University of North Carolina, Chapel Hill, NC. [2]University of North Carolina at Chapel Hill, Chapel Hill, NC. [3]Brigham and Women's Hospital, Boston, MA. [4]Tufts Medical Center, Boston, MA.*
(No relevant relationships reported)

Previous studies indicate that females with an anterior cruciate ligament reconstruction (ACLR) demonstrate higher vertical ground reaction force loading rates (vGRF-LR) on the ACLR limb compared to the contralateral limb, as well as matched limbs of uninjured controls. There is conflicting evidence concerning whether greater ACLR limb loading is linked to the onset of posttraumatic osteoarthritis and worse clinical outcomes. **PURPOSE**: Determine the association between instantaneous vGRF-LR in ACLR and contralateral limbs and clinically-relevant knee symptoms (CRKS) in females > 1.5 years post unilateral ACLR. **METHODS**: Twenty-eight females were included in this study (21.07±2.71 years old, 23.8±4.21kg/m² body mass index, 55.14±34.69 [range 20-161] months post-ACLR. vGRF-LR was collected as participants walked barefoot at a self-selected speed over two force plates embedded in a 6m walkway. Instantaneous vGRF-LR (i.e. peak of the 1st time derivative) was extracted from the first 50% of stance phase and normalized to bodyweight (BW/s) for the injured limb. CRKS were determined using previously defined Knee Injury and Osteoarthritis Outcomes Score (KOOS) criteria (Quality of Life ≤ 87.5 and 2 of the following: Pain ≤ 86.1; Symptoms ≤ 85.7; Activities of Daily Living≤ 86.8; Sports and Recreation ≤ 85.0). A Receiver Operator Characteristic (ROC) curve was constructed to establish the accuracy of vGRF-LR to identify individuals with CRKS. If a significant area under the ROC curve (AUC) was determined (i.e. AUC 95% confidence intervals [CI] did not cross 0.5), we identified the cutoff value that maximized sensitivity and specificity. Lastly, odds ratios were calculated to demonstrate the association between reaching the vGRF-LR cutoff score and reporting CRKS. **RESULTS**: ACLR limb vGRF-LR was highly accurate in identifying those with CRKS (AUC = 0.77; 0.57-0.97). Participants with a vGRF-LR ≥ 53.23 BW/s on the ACLR limb were 18.00x (1.83-177.15) more likely to report CRKS. **CONCLUSIONS**: Greater vGRF-LR is associated with worse clinical outcomes in females >1.5 years post ACLR, which is contrary to previous data collected at earlier time points post-ACLR. When considered in the context of previous work, the current findings suggest that time post-ACLR may influence the association between joint loading and CRKS.

Biomechanical Evaluation Of Landing Maneuvers In Soccer Players With An Anterior Cruciate Ligament Reconstruction

Ahmad Alanazi[1], Katy Mitchell[2], Toni Roddey[2], Alexis Ortiz, FACSM[2]. *[1]Majmaah University, Majmaah, Saudi Arabia. [2]Texas Woman's University, Houston, TX.*
(No relevant relationships reported)

Altered landing has been reported in individuals with an ACL reconstruction (ACLR). However, no study has evaluated landing biomechanics during soccer-specific landing tasks in soccer players with an ACLR. **PURPOSE:** To evaluate landing biomechanics in soccer players following ACLR during planned and unplanned landing tasks compared with healthy soccer players. **METHODS:** Eighteen soccer players with an ACLR (age, 26.11 ± 3.95 years; height, 1.70 ± 0.09 m; weight, 68.15 ± 9.64 kg, BMI, 23.52 ± 2.69 kg/m², time since surgery, 5 ± 3.30 years) and 18 healthy soccer players (age, 25.83 ± 3.51 years; height, 1.66 ± 0.05 m; weight, 66.88 ± 10.37 kg, BMI, 24.09 ± 3.73 kg/m²) participated in the study. Planned landing included jumping forward and landing on the force plates, whereas unplanned landing included jumping forward to head a soccer ball and landing on the force plates. Participants performed 4 trials of each landing task. The outcome measures were peak flexion angles and extension moments of the hip, knee, and ankle joints, peak pressure, and electromyography activity of gluteus maximus, quadriceps, hamstrings, and gastrocnemius muscles. A 2×2 ANOVA (landing × group) was performed for each measure. **RESULTS:** A significant landing × group interaction was found only for knee flexion angles ($F_{1,34} = 11.26$, p = 0.002). Follow-up comparisons showed that the ACL group landed with greater knee flexion during planned landing compared with unplanned landing (p < 0.001). Significant main effects of landing (regardless of group) were found. The unplanned landing showed decreased hip flexion ($F_{1,34} = 48.55$, p < 0.001), decreased knee flexion ($F_{1,34} = 40.58$, p < 0.001), decreased hip extension moments ($F_{1,34} = 6.82$, p < 0.013), decreased knee extension moments ($F_{1,34} = 27.18$, p < 0.001),

and decreased peak pressure ($F_{1,34}$ = 20.98, p < 0.001). Also, a significant main effect for group (regardless of landing) for gastrocnemius muscle was found showing that the ACL group landed with reduced gastrocnemius activity ($F_{1,34}$ = 11.27, p = 0.002).

CONCLUSION: Unplanned landing showed greater injury predisposing factors compared with planned landing. The ACL group showed nearly similar landing biomechanics to the control group during both landing tasks. However, the ACL group used a protective landing strategy by reducing gastrocnemius activity.

Lesser Mechanical Loading During Walking Gait Associates with Worse Proteoglycan Density 6 months Following Anterior Cruciate Ligament Reconstruction

Steven J. Pfeiffer[1], Jeffrey Spang[1], Daniel Nissman[1], David Lalush[1], Kyle Wallace[1], Matthew Harkey[2], Laura Stanley[1], Randy Schmitz[3], Troy Blackburn[1], Brian Pietrosimone, FACSM[1]. *[1]University of North Carolina, Chapel Hill, NC. [2]Tufts Medical Center, Boston, MA. [3]University of North Carolina at Greensboro, Greensboro, NC.*
(No relevant relationships reported)

Optimal mechanical loading is necessary to decrease the risk of posttraumatic osteoarthritis (PTOA) following anterior cruciate ligament reconstruction (ACLR) and lesser mechanical loading early following ACLR may increase the risk for PTOA onset. T1ρ magnetic resonance imaging (MRI) has been used to measure cartilage composition at early time points following ACLR.
PURPOSE: To determine the association between proteoglycan density of femoral cartilage derived from T1ρ MRI relaxation times and peak vertical ground reaction force (vGRF) and instantaneous vGRF loading rate (vGRF-LR) during walking gait 6 months following ACLR.
METHODS: Twenty-nine individuals (52% female, BMI = 24±3 kg/m²) with a unilateral patellar-tendon autograft ACLR participated in this study. Five trials of walking gait at self-selected speed were performed 6 months following ACLR. Peak vGRF and instantaneous vGRF-LR were extracted from the first 50% of the stance phase in both limbs. T1ρ relaxation times were calculated for articular cartilage in the medial and lateral condyles (MFC & LFC) by fitting a monoexponential model. The weight bearing MFC and LFC cartilage was manually segmented into posterior, central, and anterior regions of interest (ROI) based on the location of the meniscus in the sagittal plane. Affine and deformable registration techniques were used to register the ACLR limb to the uninjured limb. Inter-limb mean T1ρ relaxation time ratios (RTR = ACLR limb / uninjured limb) were calculated for each ROI. Separate, stepwise linear regressions were used to determine the unique associations between vGRF outcomes and T1ρ RTR in each ROI after accounting for walking speed and meniscal injury (ΔR²; P≤ 0.05).
RESULTS: In the ACLR limb, lesser vGRF during gait was associated with lesser proteoglycan density in the posterior (ΔR²=0.22, P=0.02) and central LFC (ΔR²=0.22, P=0.02), as well as the posterior (ΔR²=0.12, P=0.05) and central MFC (ΔR²=0.21, P=0.01). vGRF-LR in the ACLR limb and all vGRF outcomes in the contralateral limb did not significantly associate with T1ρ RTR for any ROI.
CONCLUSIONS: Individuals with lesser vGRF in the ACLR limb presented with T1ρ MRI findings consistent with deteriorating cartilage health. Understanding how loading affects joint health is critical to developing interventions to delay PTOA onset.

Assessment of Torsional Knee Stiffness in Individuals Following Anterior Cruciate Ligament Reconstruction During Running

Kylie Davis, Cale A. Jacobs, Mary L. Ireland, FACSM, Darren L. Johnson, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: Brian Noehren, FACSM)
(No relevant relationships reported)

Purpose: To determine torsional knee stiffness in individuals with anterior cruciate ligament reconstruction (ACLR) during running, which has previously been speculated upon but not yet assessed.
Methods: 17 individuals with ACLR (19 ± 5.2 years, 16 F, 22.6 ± 2.4 kg/m², 6.4 ± 0.5 months post-surgery) and 17 control subjects (23 ± 1.5 years, 16 F, 22.7 ± 2.1 kg/m²) participated. Instrumented gait analysis was used to obtain knee angles and moments during running. Stiffness was calculated as the ratio of change in knee extensor moment to knee flexion angle over the period of initial contact (IC) to peak knee flexion angle (P1) as well as the first 60 ms after IC (P2). Isometric knee extension strength was also tested. An independent two-sample t-test (α = 0.05) was used to compare stiffness between groups. The Pearson correlation coefficient (r) was used to quantify the relationship between stiffness and peak knee extensor torque (KET), and between stiffness and knee extensor rate of torque development (RTD).

Results: Torsional knee stiffness was significantly greater in the surgery limb compared to the control limb during P1 (p = 0.049) and P2 (p = 0.0057). No correlation was found between stiffness and peak KET (r = 0.04), or between stiffness and knee extensor RTD (r = 0.088).
Conclusion: Individuals with ACLR had greater knee stiffness in running compared to control subjects but it is unknown whether this difference was present before, or resulted after injury. Increased stiffness has been suggested as a risk factor for developing osteoarthritis, which is known to be prevalent in this population. Based on the lack of correlation between strength and stiffness, increased stiffness observed in the ACLR group is likely an issue of control but further scrutiny is needed.

	Surgery limb	Contralateral limb	Control limb	p-value

Quadriceps Force Steadiness following Anterior Cruciate Ligament Reconstruction during a Maximum Voluntary Isometric Contraction

Alex Spencer, Cale Jacobs, Kylie Davis, Darren Johnson, Mary L. Ireland, FACSM, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: Brian Noehren, FACSM)
(No relevant relationships reported)

One of the repercussions of an ACL tear and subsequent reconstruction (ACLR) is a period of protracted quadriceps muscle weakness. While total force output is an important measure, the quality of this force, represented by quadriceps force steadiness (QFS), has been rarely investigated. Steadier force production implies smaller and/ or less frequent force fluctuations, which may signal better control and efficiency. Additionally, QFS studies have centered on submaximal contractions. While this is valuable, athletes need to be able to safely and efficiently load the knee during maximal effort situations such as jumping and cutting.
Purpose: To quantify the degree of asymmetrical QFS and strength between healthy and ACLR limbs during maximum voluntary isometric contractions (MVIC).
Methods: Seventy-two subjects who had an ACLR (38F, 20.2 ± 5.9 years old) underwent isometric strength testing six months post-surgery. Each subject completed five quadriceps MVIC's for five seconds each on both legs. The torque-time curves were analyzed using MATLAB code. In order to quantify the steadiness, the plateau region of the torque-time curve was first extracted utilizing force derivative cutoffs to define the outer boundaries. A 2nd order polynomial was fit onto the extracted curve to represent an "ideal" force output response (uniform concavity) that was consistent but subject-specific. The outcome variable (error from the "ideal" curve) was normalized to the force magnitude at each point (discrete normalization) and expressed as a percentage. A paired two sample t-test was used to assess differences between limbs (p<0.05).
Results: There was a significant difference in both QFS and mean strength between the ACLR and non-reconstructed limb respectively at 0.91 ± 0.51% and 0.73 ± 0.31% (p<0.001), as well as mean torque of 114.4 ± 41.8 Nm and 194.4 ± 56.3 Nm (41% deficit), respectively (p<0.001).
Conclusion: The results show a significant disparity in an ACLR knee in both quadriceps strength and QFS in comparison to a healthy knee. The lack of steadiness is a result of more frequent and/or higher magnitude force fluctuations over the loading phase. We speculate that these fluctuations results in a hindered ability to control the quadriceps which may lead to an increased injury risk and decreased performance.

Differences In Electrocortical Activity Between ACL-reconstructed Patients And Healthy Controls During A Force-Reproduction Task

Moniek Roe of Rohe[1], Carmen van den Hoven[1], Roy Hoogeslag[1], Bart Koopman[2], Rianne Huis in 't Veld[1]. [1]OCON Centre for Orthopedic Surgery, Hengelo, Netherlands. [2]University of Twente, Enschede, Netherlands.
(No relevant relationships reported)

Changes in cortical activity are hypothesized to be related to the high incidence of ACL re-ruptures. Presumably, these differences are a result of the loss of somatosensory signals of the ligament and changes in nociceptor activity due to pain and swelling. **PURPOSE:** To investigate the differences in electrocortical activity between patients with an ACL-reconstruction and healthy controls. **METHODS**: 12 patients one year post ACL-reconstruction and 12 healthy controls were compared during the execution of functional hop tests and a force-reproduction task (without visual feedback and with visual disruption) at biomechanical function (force reproduction and EMG (Root-Mean-Square)) and electrocortical activity using a EEG power analysis (Alpha-1, Alpha-2, Beta-1 and Theta-activity frequency bands were determined). Between-group differences and differences between the study condition without visual feedback and the study condition with visual disruption were examined. **RESULTS**: No differences in functional outcomes and biomechanical function (p≥0.194) exist between ACL reconstructed patients and healthy controls. However, ACL reconstructed patients showed a significant higher Theta-power in the parietal cortex (p≤0.038) and pre-frontal cortex (F8, p=0.038) compared to healthy controls during force reproduction without visual feedback. Visual disruption leads to higher power values at Fz (Alpha-1: p=0.050, Beta-1: p=0.010, Theta: p=0.050), F8 (Beta-1: p=0.034), P3 (Alpha-1: p=0.023, Beta-1: p=0.002, Theta: p=0.034), P4 (Alpha-2: p=0.041, Beta-1: p=0.019) and P7 (Alpha-2: p=0.006) in the healthy control group, while in the ACL reconstructed group only Alpha-2 power at T4 was significantly higher (p=0.050). **CONCLUSIONS**: Differences in electrocortical activity seem to be present in patients one year after ACL-reconstruction, while patients in both groups tended to be equal in terms of biomechanical function. In line with previous research of Baumeister et al. (2011) ACL reconstructed patients probably more rely on their visual system for an adequate planning and control of motion. This could be a compensation mechanism for the loss of sensory input out of the affected ACL and could be a point of therapeutic entry in the prevention of re-ruptures in the future.

Examining the Relationships Between the Mode of Quadriceps Contraction and Clinical Outcomes After ACL Reconstruction

Steven M. Davi, Adam S. Lepley, Julie P. Burland, Lindsey K. Lepley. *University of Connecticut, Storrs, CT.*
(No relevant relationships reported)

Quadriceps strength is a useful clinical predictor of physical function and patient reported outcomes after anterior cruciate ligament reconstruction (ACLR). However, it remains unknown which mode of muscle contraction (isometric, concentric or eccentric) is most important for optimal physical and patient reported recovery, creating uncertainty amongst clinicians as to the most ideal strength assessment tool. **PURPOSE:** Examine the association between the mode of quadriceps muscle contraction (isometric, concentric and eccentric) and functional performance and patient reported outcomes. **METHODS:** Ten individuals with history of unilateral ACLR volunteered (22.4±1.95yrs; 1.66±0.08m; 65.62±12.10kg; years from surgery, 5.88±1.86yrs). Peak concentric and eccentric quadriceps force production at 60°/s and peak isometric force production with the knee positioned at 90° were assessed via an isokinetic dynamometer and normalized to body mass. Objective clinical hop tests were evaluated for maximal distance during the single leg hop for distance (SLHD), cross-over hop (CH) and triple hop (TrH). Patient reported outcomes were assessed using the International Knee Documentation Committee (IKDC) form. Association between quadriceps strength outcomes and all functional and patient reported outcomes were assessed using Pearson product moment correlations. **RESULTS:** Peak concentric strength was only associated with maximal TrH distance (mean±SD; 1.90±0.57Nm/kg, 4.61±0.67m; r=0.723, P=0.018). Peak eccentric strength was only associated with maximal SLHD (2.82±0.78Nm/kg, 1.41±0.19m; r=0.680, P=0.044). Peak isometric strength was associated with maximal CH distance (3.06±0.59Nm/kg, 4.35±0.70m; r=0.696, p=0.025) and IKDC (84.94±9.92; r=0.803, P=0.005). **CONCLUSION:** No single mode of quadriceps contraction was associated with all clinical outcome measures. Hence, a multimodal approach to strength re-training and evaluation may be important for the development of proper quadriceps function and progression of optimal clinical outcomes. Clinicians should consider adding a multimodal strength program during ACLR rehabilitation to promote positive outcomes across a variety of clinical measures.

Dynamic Knee Orthosis System for Females with Anterior Cruciate Ligament Injuries

Menglin Jia[1], Joshua M. Tome[2], Mengyun Shi[1], Huiju Park[1], Jintu Fan[1], Rumit Singh Kakar[2]. [1]Cornell University, Ithaca, NY. [2]Ithaca College, Ithaca, NY.
(No relevant relationships reported)

PURPOSE: Anterior Cruciate ligament (ACL) injuries are one of the most common athletic injuries with greater prevalence in females. Knee orthoses are often prescribed post-injury for conservative management or post-surgery knee stabilization. The goal was to design and evaluate a lightweight and aesthetically more acceptable Dynamic Knee Orthosis System (DKOS) as a pair of close-fitting leggings with hinges and a detachable dynamic belt on the waist for females with an ACL injury. **METHODS:** Ten healthy females (right dominant; age: 21.5 ± 1.8 yrs; height: 1.7 ± .05m; weight: 64.1 ± 6.9 kg, leggings size medium) participated. Four test tasks (running, single hop, triple hop, drop landing) commonly used as return to sport clinical tests post ACL injury were performed with new design (C1), commercially brace (C2) and no brace conditions (C3: sports shorts, C4: leggings only). Mixed model analysis and least-squares means were employed to estimate and predict the difference of joint positions and moments (Vicon, 120Hz) in sagittal plane for lower extremity. **RESULTS:** Decreased knee flexion angle during running (C1: 29.43 ± 4.22º, C2: 23.78 ± 4.22º, effect size ES: 0.74) and drop landing (C1: 61.60 ± 4.22º, C2: 50.87 ± 4.21º, ES: 1.41) with C1 compared to C2 was observed. Also, greater knee flexion moment was observed during running (C1: 75.48 ± 7.64 Nm/kg, C2: 59.98 ± 7.65 Nm/kg, ES: 1.94), triple hop (C1: 78.21 ± 7.77 Nm/kg, C2: 68.23 ± 7.72 Nm/kg, ES: 1.23) and drop landing (C1: 74.77 ± 7.64 Nm/kg, C2: 63.55 ± 7.63 Nm/kg, ES: 1.41). **CONCLUSION:** C1 increased peak knee flexion angles during test tasks, but did not decrease anterior-posterior tibial translation compared to C2. Increased knee flexion and knee moments with C1, could potentially help increase the shock absorption, thus reducing the risk of re-injury. A possible reason for improved knee joint range of motion with C1 is that flexible materials of the leggings (instead of non-stretchable neoprene materials of C2) had less restraints on quadriceps muscles. The proposed leggings, therefore, may be used for rehabilitation with a focus on increasing ROM and facilitating quadriceps:hamstring neuromuscular coordination. Future research aimed at ergonomical designs that can promote safe activity while attenuating A-P translations is warranted.

Relationship Between Knee Valgus Asymmetry During Running And Side-Step Cutting Mechanics in Female Lacrosse Players.

Bhushan Thakkar, Jenna Kostiuk, Kathryn Harrison, Jacqueline Morgan, Gregory Crosswell, D.S. BLAISE WILLIAMS, III, FACSM. *Virginia Commonwealth University, RICHMOND, VA.* (Sponsor: D.S. Blaise Williams III, FACSM)
(No relevant relationships reported)

PURPOSE: Female athletes have a greater incidence of Anterior Cruciate Ligament (ACL) injuries than their male counterparts. Noncontact injuries are primarily responsible for ACL injuries in female lacrosse players. Side-step cutting (SSC) maneuvers are a common injury mechanism and it involves sudden changes in direction with acceleration or deceleration of the body. Dynamic knee valgus (KV) is an important biomechanical risk factor for ACL injuries during running and SSC but the relationship between KV asymmetry during running and kinetics related to ACL injury during SSC has not been identified. The purpose of this study was to compare ACL loading kinetics during SSC in female lacrosse players with symmetrical and asymmetrical KV during running. **METHODS**: Twenty-seven healthy female lacrosse athletes were classified in two groups (asymmetric: n=13 and symmetric: n=14) based on dynamic KV Symmetry Angle during a 3D analysis of running on an instrumented treadmill. Peak vertical ground reaction force (VGRF) and knee abduction moment (KABM) of the right limb were measured during right SSC to 45 degrees. Comparisons were made between the two groups for VGRF and KABM using Student's t-test(α=0.05). **RESULTS**: The asymmetric group had significantly higher VGRF (2.42±0.73 vs. 2.18±0.36*BW, p=0.01) and KABM (-0.82±0.35 vs. -0.80±0.6 Nm/kg, p=0.003) during SSC.

CONCLUSIONS: There is a suggestive relationship between KVA asymmetry during running and the magnitude of VGRF, KABM during SSC. Imbalances in knee kinematics during running could potentially be used as a screening tool to detect abnormal ACL loading kinetics during dynamic tasks like SSC.

Sex and Speed Influence Joint Moment Impulses During Running

Herman J. Feller, Christa M. Wille, Bryan C. Heiderscheit, Mikel R. Stiffler-Joachim. *University of Wisconsin-Madison, Madison, WI.*

(No relevant relationships reported)

Following lower extremity surgery, athletes demonstrate altered running mechanics particularly with regard to lower extremity joint moment impulses. The effect of speed and sex on joint impulses, even among healthy individuals, has not been investigated and describing these effects may facilitate more appropriate comparisons between injured and healthy athletes. **PURPOSE**: To determine the influence of sex and speed on hip extensor (H_{EXT}), knee extensor (K_{EXT}), and ankle plantarflexor (A_{PF}) moment impulses during running. **METHODS**: Whole body kinematics and ground reaction forces were collected for 99 NCAA Division I collegiate athletes (52 males) during treadmill running at 2.68, 3.35, and 4.47 m/s. Athletes were healthy at time of testing and had no history of lower extremity surgery. H_{EXT}, K_{EXT}, and A_{PF} were calculated during each stance phase and averaged across strides. Joint moment impulses for the right limb were compared between sex and speed using 2-way repeated measures ANOVAs. **RESULTS**: A significant sex by speed interaction (p < .01) for K_{EXT} was observed. Females exhibited greater K_{EXT} than males at all speeds (mean difference range, 6.8 to 15.2%). Among females, K_{EXT} decreased significantly at each speed (-.21 ± .05 Nms/kg, -.21 ± .04 Nms/kg, -.19 ± .03 Nms/kg at 2.68, 3.35, and 4.47m/s, respectively; p ≤ .04), while there were no significant speed effects among males (p ≥ .19). No significant interactions (p ≥ .08) were present for H_{EXT} or A_{PF}, though there were significant sex and speed main effects. Females demonstrated smaller H_{EXT} and A_{PF} than males (mean difference, 20.2% and 14.6% for H_{EXT} and A_{PF} respectively, p < .01). Across sexes, H_{EXT} increased significantly with speed (p < .01). A_{PF} at 4.47 m/s was significantly lower than all other speeds (-.39 ± .05 Nms/kg, -.39 ± .05 Nms/kg, -.38 ± .05 Nms/kg at 2.68, 3.35, and 4.47m/s, respectively; p < .01). **CONCLUSIONS**: Both sex and speed must be considered when evaluating the relative contribution of the hip, knee, and ankle during running. Females demonstrate greater KEXT than men at the same running speed but smaller HEXT and APF, indicating an increased reliance on the knee joint. As running speed increases, males increase demand at the hip while maintaining a constant demand at the knee, while females shift demands away from the knee and primarily toward the hip.

Do Selective Pressures on Pelvic Dimensions Influence Risk of Running Injury Development?

Naomi E. Frankston, Kevin Hunt, Jacob E. Vollmar, Ashley B. Nguyen, John J. Davis, IV, Andrea K. Chomistek, Allison H. Gruber. *Indiana University, Bloomington, IN.* (Sponsor: Joseph Hamill, FACSM)

(No relevant relationships reported)

Sex differences in endurance running may be attributed to selective pressures on pelvic dimensions imposed by birth requirements. However, Warrener et al. (2015) found that pelvic width did not have a significant effect on locomotor economy. However, a wider pelvis in females may explain higher rates of running related overuse injury (RROI). Physical activity (PA) during development is a confounding factor rarely considered when assessing injury risk; however early engagement in PA may be protective for RROI. PURPOSE: To determine whether pelvic dimensions and age PA began are risk factors for RROI. METHODS: 28 female and 17 male recreational runners were analyzed (Age: 32.0 ± 10.3 yrs; BMI: 22.4 ± 2.6 kg/m^2). Pelvic width was measured as the distance between iliac crest markers during a 3D standing calibration trial. Femoral angle was measured as the inverse tangent of the vertical distance between the ASIS and lateral knee markers divided by the horizontal distance. Lifetime PA and running history were recorded by questionnaire. Univariate statistics assessed differences between genders and between those who had and had not sustained a RROI. Stepwise logistic regression was used to determine predictors of pelvic width, femoral angle, and incidence of RROI (α = 0.15). Variables included in all models were age, BMI, years running, weekly mileage at enrollment, and age subject began meeting current ACSM PA guidelines, as well as pelvic width and femoral angle for RROI model only. RESULTS: No differences between genders were detected for any variable (P>0.05). Uninjured subjects began meeting PA guidelines at older ages vs. injured subjects (U: 10.3 ± 7.3 yrs; I: 8.2 ± 3.5 yrs, P<0.01). Pelvic width normalized by femur length was greater in injured vs. uninjured runners (U: 82.3 ± 11.6 mm; I: 82.6 ± 5.4 mm, P<0.01). Femoral angle was not different between injured vs. uninjured groups (P>0.05). The model identified femoral angle (P=0.147) and age PA began (P=0.115) as predictors for RROI development (P<0.15). Current mileage was a predictor for total number of

running injuries (P=0.018). CONCLUSION: Age PA began and femoral angle may be risk factors for RROI. Weekly running mileage may amplify anatomical risk factors for RROI.

The Effect of Real-Time Feedback on Vertical Oscillation and Running Economy

Richard Robinson, Teresa Rose, Hannah Jones. *University of Indianapolis, Indianapolis, IN.*

(No relevant relationships reported)

PURPOSE: Investigate whether real-time feedback could reduce vertical oscillation and improve running economy. **METHODS:** 6 male and 4 female collegiate cross country runners completed two 12 minute steady state, submaximal (mean RER = 0.87) treadmill trials one of which involved receiving real-time feedback on vertical oscillation with the instruction to reduce the displayed value. Breath-by-breath VO_2 data was averaged over the last minute of the trial and expressed as kcal·kg^{-1}·km^{-1}. Vertical oscillation data was averaged over the entire trial. Repeated-measures ANOVAs were applied to VO_2 and vertical oscillation data to test for significant effects of real-time feedback. **RESULTS:** Real-time feedback reduced vertical oscillation (10.04 ± 1.99 cm vs. 8.78 ± 2.03 cm, p = .008), but did not improve running economy (1.10 ± 0.09 kcal·kg^{-1}·km^{-1} vs. 1.07 ± 0.10 kcal·kg^{-1}·km^{-1}, p = .072). **CONCLUSION:** Reduction in vertical oscillation did not produce an improvement in the economy of trained runners.

Dynamic Hip Strength and Footfall Patterns in Competitive Distance Runners

Tyler J. Moffit, Brett K. Post, Melissa M. Montgomery, Robert G. Lockie, Derek N. Pamukoff. *California State University, Fullerton, Fullerton, CA.* (Sponsor: Daniela Rubin, FACSM)

(No relevant relationships reported)

PURPOSE: Foot strike pattern during running can contribute to lower extremity overuse injuries such as stress fracture, potentially due to high loading rates (LR). However, adopting a forefoot strike (FF) may require additional lower extremity strength due to the greater demand placed on the gluteal muscles compared to a rearfoot strike. The purpose of this study was to determine the association between hip extensor strength, foot strike pattern, and LR. It was hypothesized that greater hip extensor strength would be associated with a FF pattern, and a lower LR. **METHODS**: 23 uninjured, collegiate distance runners (91% male, age=21.9±2.5 years, height=1.77±0.06 m, mass=64.15±6.6 kg, running volume=82.55±17.45 km/week) who were resistance trained were recruited for this study. Hip extensor strength was assessed via maximal voluntary isometric contractions (MVIC) on an isokinetic dynamometer and 1-repetition maximum back squat (1RM BS). LR and foot strike index (FSI) were assessed during 5 overground running trials at the participant's preferred training pace. FSI was calculated as the distance (m) between the center of pressure and location of the calcaneal marker at initial contact relative to the participant's foot length (m). The highest MVIC peak torque (PT; N/kg) and 1RM BS, median FSI, and average LR (body weight/second) of the 5 trials were used for analysis. Spearman Rho and partial correlations were used to determine relationships between dependent variables. **RESULTS**: Greater 1RM BS was associated with a larger FSI (rho=0.499, p=0.018). Greater FSI was associated with lesser LR (rho=-0.494, p=0.017). Greater 1RM BS and lesser LR were not significantly associated (r=-0.394, p=0.077). PT was not associated with FSI or LR. **CONCLUSIONS**: Runners with greater 1RM BS land in a more FF position and with lower LR. These findings emphasize the contribution of hip extensor strength to running mechanics, and justify the selection of the back squat for runners.

The Effect of Fatigue on Impact Forces and Pressure Distribution During an Incremental Run

Dimitrios Katsavelis, Caroline Marnin, Matthew Maystrick. *Creighton University, Omaha, NE.* (Sponsor: Joan Eckerson, FACSM)

(No relevant relationships reported)

Background: Repetitive high impact forces are linked to increased bone-to-bone stresses that, over time, may exceed the repair and remodeling process of the bone structure. Running through fatigue is a condition that may exacerbate this phenomenon; however, research that has examined the effect of fatigue on impact forces during running is equivocal. **Purpose:** To investigate the effect of a high-intensity fatiguing run on impact forces and pressure distribution while running at various speeds. **Methods:** Four male college students (age = 20.8±1yr; weight =80.7±9kg; height = 175±4cm) were asked to complete an incremental run of five 30-second stages at speeds that ranged from 20% below to 40% above their self-

selected pace. Subsequently, they performed a graded exercise test to exhaustion followed by a second incremental run. Pressure insoles placed in the shoe of the subject's dominant leg recorded ground reaction forces and pressure distribution of the foot before and after the fatigue protocol. **Results:** A two-way repeated ANOVA (time x speed) showed that there was a main effect of speed for most independent variables, while there was a main effect of fatigue (p=0.04) only for pressure at the lateral part of the shoe. Post hoc analysis revealed that the peak impact force and pressure (total, forefoot, heel, medial and lateral side of the foot) were significantly greater at higher running speeds. In addition, there was a tendency for a shift in pressure distribution from the medial to the lateral side of the foot with increased speeds. **Conclusion:** These preliminary findings suggest that peak impact force was not affected by fatigue. However, running at faster speeds placed more stress on the foot, as shown by both the impact forces and pressure, which may predispose runners to injury.

Association Between Tibial Acceleration and Vertical Loadrates in Runners of All Footstrike Patterns

Todd Hayano[1], Adam Tenforde[2], Steve Jamison[3], Irene Davis, FACSM[2]. [1]*Spaulding Rehabilitation Hospital/Harvard Medical School, Charlestown, MA.* [2]*Spaulding Rehabilitation Hospital/ Harvard Medical School and Spaulding National Running Center/Spaulding Cambridge Hospital, Charlestown, MA.* [3]*Spaulding National Running Center/Spaulding Cambridge Hospital, Cambridge, MA.* (Sponsor: Irene Davis, FACSM)

(No relevant relationships reported)

Abstract
Running injuries have been associated with increased vertical loadrates, measured with forceplates. Tibial acceleration, which can be measured in the field with wearable technology, has been suggested as a surrogate for loadrates. However, the validity of this assumption is unknown.
Purpose: To determine the correlation between vertical and resultant loadrates to vertical and resultant tibial acceleration across footstrike patterns (FSP) in runners.
Methods: Participants: 169 runners (74 F, 95 M; age: 38.66±13.08 yrs) presenting at a running injury clinic. This included 25 forefoot strike (FFS), 17 midfoot strike (MFS) and 127 rearfoot strike (RFS). Participants ran on an instrumented treadmill (average speed 2.52±0.25 m/s), with a tri-axial accelerometer attached at the left distal medial tibia. Only subjects running with pain <3/10 on a VAS pain scale during the treadmill run were included. Vertical average, vertical instantaneous and resultant instantaneous loadrates (VALR, VILR and RILR) and peak vertical and resultant tibial accelerations (VTA, RTA) were averaged for 8 consecutive left steps. Correlation coefficients (r) were calculated between tibial accelerations and loadrates.
Results: All tibial accelerations were significantly correlated across all loadrates with the exception of RTA with VILR for FFS (Table 1). Specifically, VTA was strongly correlated with all loadrates ($r \geq 0.66$). RTA was also strongly correlated with both loadrates for RFS and MFS, but only moderately correlated with loadrates for FFS ($r \leq 0.47$).
Conclusion: The strong correlation between VTA and all loadrates (VALR, VILR, RILR) across all FSP, suggests that vertical tibial acceleration is a reliable surrogate for loadrates.

	FSP	VALR r	VALR p-value	VILR r	VILR p-value	RILR r	RILR p-value
VTA	FFS	0.82	<0.001	0.69	<0.001	0.70	<0.001
	MFS	0.74	<0.001	0.73	<0.001	0.73	<0.001
	RFS	0.66	<0.001	0.66	<0.001	0.67	<0.001
	All	0.72	<0.001	0.72	<0.001	0.72	<0.001
RTA	FFS	0.47	0.018	0.37	0.068	0.41	0.042
	MFS	0.63	0.007	0.66	0.004	0.68	0.002
	RFS	0.67	<0.001	0.67	<0.001	0.68	<0.001

Increased Foot And Tibial Angles at Footstrike Decrease Vertical Loadrates in Runners

Haylee E. Donaghe Borgstrom[1], Adam S. Tenforde[2], Robert Diaz[1], Steve T. Jamison[3], Irene S. Davis, FACSM[3]. [1]*Spaulding Rehabilitation Hospital, Harvard Medical School, Boston, MA.* [2]*Spaulding Rehabilitation Hospital, Spaulding National Running Center, Harvard Medical School, Boston, MA.* [3]*Spaulding National Running Center, Harvard Medical School, Cambridge, MA.* (Sponsor: Irene Davis, FACSM)

(No relevant relationships reported)

High vertical loadrates are a risk factor for running injuries. Overstriding is thought to increase loadrates, and is indicated by increased foot and tibial angles at footstrike. However, the relationship between landing alignment and loadrates has not been well established.
PURPOSE: To investigate the association between sagittal plane foot angle (FA) and tibial angle (TA) to vertical loadrates in both healthy and injured forefoot (FFS) and rearfoot strike (RFS) runners.
METHODS: This is an ongoing study with 52 healthy runners (35 RFS, 17 FFS) and 24 injured runners (14 RFS, 10 FFS) for a total of 76 runners (51 M, 25 F; age: 34.3±11.4 yrs). Vertical average loadrate (VALR) and vertical instantaneous loadrate (VILR) were obtained while running at 2.68 m/s on an instrumented treadmill. All runners reported 0/10 pain during the assessment. Sagittal plane FA and TA at footstrike were measured from video recording using an open-source program. Positive FA designated RFS. Positive TA defined as ankle anterior to knee. Correlation coefficients (r) were computed for FA and TA with VALR and VILR ($p \leq 0.05$; trend: $p \leq 0.10$).
RESULTS: <u>Healthy RFS</u> - FA and TA were negatively correlated with VALR and VILR. <u>Injured RFS</u> - Trend toward negative correlation between TA and both VALR and VILR. <u>Healthy FFS</u> - TA was negatively correlated with both loadrates. <u>Injured FFS</u> - No significant correlations.
CONCLUSION: In contrast to current thought, preliminary results suggest that increasing FA and TA at footstrike are associated with decreasing vertical loadrates. This relationship was strongest for the FA of healthy RFS runners and weakest for the FA of both healthy and injured FFS runners.

Increased Resisted Sprinting Load Decreases Bilateral Asymmetry in Sprinting Kinetics

Jacob A. McNabb, Trisha A. VanDusseldorp, Garret M. Hester, Yuri Feito, FACSM, Gerald T. Mangine. *Kennesaw State University, Kennesaw, GA.* (Sponsor: Yuri Feito, FACSM)

(No relevant relationships reported)

Sprinting performance is affected by technical and kinetic symmetry of the lower limbs. Sprint training against resistance may affect kinematics if the load is too great, and thus negatively impact performance. Although information exists regarding the effect of sprinting resistance on kinematics, little is known regarding its effect on bilateral sprinting kinetics or their symmetry. Further, because kinematic differences exist at various stages of a sprint (i.e., acceleration, peak velocity), it may also be more appropriate to assess the symmetry of sprinting kinetics separately in stages.
PURPOSE: To investigate the effect of resisted sprinting load on the bilateral kinetics across a 40-m sprint. **METHODS** Following a standardized warm-up, 16 male, collegiate rugby players (21.2±1.7 yrs; 89.5±16.4 kg; 178.4±6.7 cm) completed 3 maximal, 40-m resisted sprint trials while tethered to a robotic resistance device. The first two sprints (S1 and S2) were performed against minimal resistance (1-kg) with S1 being used as a familiarization trial. The final sprint (S3) used 15-kg of resistance. During S2 and S3, peak and average power (P_{PK} and P_{AVG}), velocity (V_{PK} and V_{AVG}), force (F_{PK} and F_{AVG}), and peak rate of force development (RFD) were recorded for each leg and used to calculate bilateral percent differences (%DIFF). Paired-samples t-tests were performed to compare S2 and S3 during the first 5 sprinting strides (SPR5), from start to peak velocity (SPR-V_{PK}), and the total sprint (SPR_{TOT}) for each sprinting kinetic variable. **RESULTS**: A greater (p<0.05) number of strides to reach V_{PK} (4.2±4.1 strides) and complete SPR_{TOT} (13.2±3.2 strides) were observed during S3. Additionally, S3 reduced %DIFF in F_{PK} and RFD during SPR5 (F_{PK}: -8.1±10.3%; RFD: -8.9±10.9%), SPR-V_{PK} (F_{PK}: -6.6±5.9%; RFD: -7.2±8.6%), and SPR_{TOT} (F_{PK}: -6.6±5.4%; RFD: -6.9±8.4%). Significant (p<0.05) reductions in %DIFF during S3 were not observed for

F_{AVG} until after SPR5 (SPR-V_{PK}: -2.7±3.7%; SPR_{TOT}: -3.4±4.9%) and not until SPR_{TOT} for P_{PK} (-13.1±19.1%). In contrast, S3 only produced a reduction in %DIFF for P_{AVG} at SPR5 (-7.0±9.2%, p=0.014). **CONCLUSION**: Applying resistance during a 40-m sprint reduces the acute bilateral asymmetries observed in sprinting kinetic measures. Resisted sprint training may reduce bilateral sprinting kinetic asymmetries.

Muscle Activation Characteristics of the Posterior Oblique Sling System in High and Low Economy Runners

Nicole K. Rendos[1], Moataz Eltoukhy[2], Wesley N. Smith[2], Christopher M. Kuenze[3], Joseph F. Signorile[2]. [1]Andrews Research & Education Foundation, Gulf Breeze, FL. [2]University of Miami, Coral Gables, FL. [3]Michigan State University, East Lansing, MI.
(No relevant relationships reported)

Sling systems are chains of global muscles and their innervating fascia that facilitate sequential muscle patterns and rotational lumbo-pelvic stability during movement. During running, sling systems promote a reciprocal gait pattern between the upper and lower extremities. The Posterior Oblique Sling (POS) connects the latissimus dorsi (LD) and contralateral gluteus maximus (GM) through the thoracolumbar fascia and provides a pathway for mechanical transmission between the pelvis and trunk during running. **PURPOSE:** To examine muscle activation patterns of the POS as they differ between high (HI) and low (LO) economy runners at different running speeds. **METHODS:** Recreational runners (11M, 14F, height 1.73 ± .07m, mass 70.3 ± 11.7 kg, age 28.6 ± 5.1 y) completed a running economy test and were classified as HI (n = 15) or LO (n = 10) based on published normative data. On a separate testing day, runners completed overground running trials at a 10K race pace (10K) and long slow distance training pace (LSD). There were no differences between groups in running paces. Muscle activation patterns of the POS were measured using electromyography. Mixed design ANOVAs were conducted to determine differences among paces and economy groups in muscle onset time (ON), muscle offset time (OFF), peak amplitude (AMP), time of peak AMP (PEAK), and root mean square (RMS). **RESULTS:** A significant interaction was seen in GM PEAK ($F_{(1,23)}$ = 6.8, p = .016) where PEAK occurs later in the gait cycle during LSD in LO (4.6% HI vs. 9.3% LO). A significant interaction was seen in LD OFF ($F_{(1,23)}$ = 4.7, p = .04) where LO displayed a significantly longer activation time of the LD during LSD compared to 10K. Higher AMP and RMS were seen in GM (AMP: $F_{(1,23)}$ = 4.8, p = .039; RMS: $F_{(1,23)}$ = 11.1, p = .003) and LD (AMP: $F_{(1,23)}$ = 21.0, p < .001 ; RMS: $F_{(1,23)}$ = 26.6, p < .001) during 10K compared to LSD. **CONCLUSION:** Muscles in the POS work in a defined sequential pattern throughout the gait cycle with significant variability at different speeds and between HI and LO runners.

Trunk Kinematics Comparison During Self-selected Treadmill Jogging Between Age Groups

Rumit S. Kakar[1], Zachary Finer[1], Natalie Knight[1], Joshua M. Tome[1], Yumeng Li[2], Kathy J. Simpson[3]. [1]Ithaca College, Ithaca, NY. [2]California State University, Chico, Chico, CA. [3]University of Georgia, Athens, Athens, GA.
(No relevant relationships reported)

PURPOSE: Differences in gait parameters during walking and running with advancing age have been reported, though little is understood of the effects of age on intra-trunk motions during running. Research has shown that spinal mobility, decreases with advancing age; however, the impact on running activities is less known. Knowledge of normative ROM of different trunk segments during running can be essential in prescribing safe physical activities and for rehabilitation. Purpose was to compare trunk ROM in the transverse plane during shod running at a self-selected speed. **METHODS**: Two adult groups, *young* (YA: n = 20; 21- 40yr; 33.2 ± 4.8yr) & *middle-age* (MA: n = 22; 41- 65yr; 54.7 ± 7.8yr), participated (mass = 68.9 ± 15.4, 69.5 ± 12.0 kg; height = 1.7 ± 0.1, 1.7 ± 0.3m; moderate to vigorous physical activity = 7.0 ± 3.4, 9.0 ± 1.0 hr/wk). 3D motion capture (8-cameras, Vicon, 120Hz) during participant running at self-selected speed (speed = 2.8 ± 0.3, 2.6 ± 0.4m/s) and maximal trunk rotation was performed. Relative angles between adjacent trunk segments (UP: C7-T8; MID: T9- T12; LOW: L1- L5) and pelvis (PEL) were calculated and averaged over 10 strides. ROM in running as a percentage of total available ROM (MANOVA) from the rotation trials were compared between groups using MANCOVA ($p<0.05$, running speed = covariate) **RESULTS**: No group differences were reported ROM in maximum rotation task (F (3,38) = 1.852, p = .15, Power = .44) or in running (F(3,37) = 2.182, p = .107, Power= .51). YA ran faster than MA (2.8 ± 0.3, 2.6 ± 0.4m/s, p = .04). **CONCLUSIONS**: Results depict no significant trunk movement differences for running or total ROM between age groups in the transverse plane. Literature claims decreasing spinal ROM with age, but this data shows advancing age to not be a significant factor affecting trunk rotational ROM necessary to run safely at self-selected speeds. A potential explanation is our participants being healthy, active

---

individuals and may not exhibit the structural spinal changes that we expect with advancing age as those expected in a sedentary population. Alternately, running trials at self-selected speeds may not be fast enough to elicit potential age-related changes. The overall lack of differences in trunk movement during running could support the safety and efficacy of running at self-selected paces with advancing age.

IMU Based Foot Strike Classification Algorithm For Real-time Feedback And Research Purposes In Running

Erik Maartens[1], Max Paquette[2], Clare E. Milner, FACSM[3], Jaap Buurke[1], Jasper Reenalda[1]. [1]Roessingh Research and Development, University of Twente, Enschede, Netherlands. [2]University of Memphis, Memphis, TN. [3]Drexel University, Philidelphia, PA.
(No relevant relationships reported)

Footstrike patterns (FSP) were studied to use for feedback purposes in gait retraining and in relation to the development of running injuries. Differentiation between both legs might provide insights in the unilateral nature of injury development. Inertial Measurement Units (IMUs) have proven useful to assess running mechanics in the field. Foot angular velocity at the instant foot strike occurs can be used to classify FSP. IMU based systems could serve as a tool in gait retraining to provide real-time feedback on FSP and are easily scalable to larger populations like RCTs. **PURPOSE:**To classify and investigate inter- and intra-individual differences in FSP between the left and right foot on a treadmill, using an angular velocity based algorithm. **METHODS:**Data was collected as part of a larger study. Data of 5 healthy experienced runners (5 M, age 27.3 +/- 5.9 yrs; height 181.8 +/- 5.7 cm; weight 71.3 +/- 4.8 kg) were used to confirm that runners had different strike patterns at 3.9 m/s on a treadmill. Sagittal plane foot angular velocity was measured using IMUs (240Hz). The maximum angular velocity (maxAV) prior to and the minimum (minAV) after initial contact were used to classify FSP as either a rear foot strike (RFS, maxAV<4, minAV<-8 rad/s), a mid foot strike (MFS, maxAV<4, minAV>-8 rad/s) or fore foot strike (FFS, maxRT>4, minRT>-8 rad/s). For each participant, 50 steps were used to calculate the 95% confidence regions for the left foot, right foot and the grouped data of both feet. **RESULTS:**Two runners showed a FFS, one runner a MFS and two runners a RFS.(Fig 1) The 95% confidence regions of the left and right leg show no overlap for S01, S04 and S05. **CONCLUSIONS:**The angular velocity based algorithm identified the FSP of two runners as RFS, one as MFS and two as FFS. Subtle intra-individual differences in angular velocity did not affect the overall classification, but could be of interest to tailor feedback in gait retraining and investigate the unilateral nature of injury development.

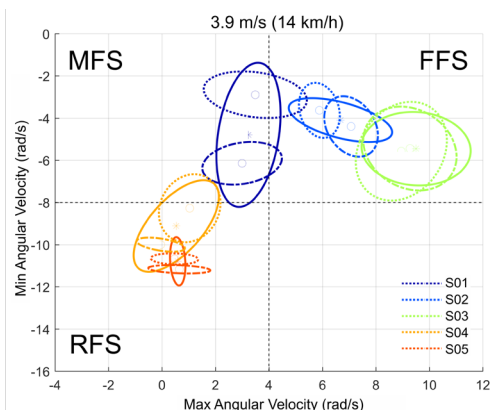

Figure 1 *The minimum and maximum sagittal angular velocity of the foot at initial contact for five runners with a rear foot (red), mid foot (blue) and fore foot (green) strike for their left (. . .) and right (---) foot and the grouped average of both feet (solid). Circles indicate the 95% confidence region.*

Influences Of Direction Of Locomotion And Body Weight Support On Metabolic Costs During Running

Kenji Masumoto[1], Kendell Galor[2], Andrew Craig-Jones[2], John A. Mercer, FACSM[2]. [1]Kyushu University, Kasuga, Japan. [2]University of Nevada, Las Vegas, NV.
(No relevant relationships reported)

Manipulations of direction of locomotion and body weight support (BWS) may influence running mechanics. However, the influences of direction of locomotion

---

and BWS on metabolic costs during running still await clarification. **PURPOSE**: To investigate metabolic costs during backward and forward running at different BWS conditions. **METHODS**: Nine subjects (40.9 ± 14.4 years) completed backward running and forward running on a lower body positive pressure treadmill at their mode-specific preferred running speed (PS) for 0%BWS, 20%BWS, and 50%BWS conditions. Oxygen uptake, heart rate (HR), rating of perceived exertion (RPE), and stride frequency (SF) were measured. Oxygen uptake, HR, RPE, PS, and SF were analyzed using a 2 (running directions) x 3 (BWS conditions) repeated measures analysis of variance (α = 0.05). **RESULTS**: HR, RPE, PS, and SF were not influenced by the interaction of direction and BWS (P>0.05). HR and RPE were not different between directions (P>0.05) but were different between BWS conditions (P<0.05). Specifically, HR and RPE during backward and forward running were lower with increasing BWS. Additionally, oxygen uptake was influenced by the interaction of direction and BWS (P<0.01). Oxygen uptake during running at 50%BWS was significantly lower than when running at 0%BWS, regardless of direction of locomotion (e.g., 36.9 ± 7.0 ml/kg/min and 27.5 ± 7.1 ml/kg/min for 0%BWS and 50%BWS during forward running, respectively, P<0.001). However, oxygen uptake was not significantly different between directions, regardless of BWS (P>0.05). Furthermore, PS and SF were different between directions (P<0.01) and between BWS conditions (P<0.05). Specifically, PS was higher and SF was lower during backward and forward running with increasing BWS. PS during backward running was 29%~42% lower than that of forward running. SF during backward running was 7%~12% higher than that of forward running. **CONCLUSIONS**: These observations demonstrate that a change in direction of locomotion may not influence metabolic costs and RPE during running at given BWS conditions, although PS and SF were different between backward and forward running. Furthermore, our observations indicate that a change in BWS influences metabolic costs, RPE, PS, and SF for both backward and forward running. Supported by JSPS Grant Number 16K01663.

The Influence of Activity Trackers on Physical Activity, Cardiorespiratory Endurance, Body Composition, and Exercise Motivation

Michael A. Smith[1], Melissa Powers[2], Larissa Boyd[2], Thomas Hancock[2]. [1]*University of Oklahoma, Norman, OK.* [2]*University of Central Oklahoma, Edmond, OK.*
(No relevant relationships reported)

PURPOSE: The purpose of this research was to examine the influence of activity trackers on physical activity (PA), cardiorespiratory endurance (CRE), body fat percentage (BF%), and exercise motivation. **METHODS:** Forty-eight healthy volunteer participants ages 18-72 who did not achieve more than 3000 metabolic equivalent of task minutes (METmin) per week of physical activity (PA) were recruited to participate in a 12-week walking intervention. Participants were given the International Physical Activity Questionnaire (IPAQ), exercise motivation inventory (EMI-2) survey, tested for anthropometric measures, and tested for CRE at baseline and final testing. Participants were divided into an activity tracker group and a control group. **RESULTS:** Thirty-four participants (female = 29, male = 5) completed the full 12-week study. Analyses revealed no significant differences between the treatment and control groups for PA, CRE, BF%, or motivation from baseline to final testing. There were significant improvements in PA measured by the IPAQ for both groups from baseline ($M = 1042.71$ METmin, $SD = 882.57$) to final testing ($M = 3499.35$ METmin, $SD = 2931.34$), $F_{(2, 64)} = 17.374$, $p = .000$; however, step counts did not improve for either group from baseline to final testing. Mean difference in step counts were 1,897 steps and 1,614 steps for the testing and control groups respectively. There were significant improvements in CRE for both groups from baseline to final testing (Mean difference = 2.24 ml 0_2/kg·min^{-1}), $F_{(1, 29)} = 13.016$, $p = .001$. **CONCLUSIONS:** Analyses revealed that the walking program may have been effective for improving PA and CRE, but that activity trackers did not provide any additional benefits. The conclusion is that activity trackers alone may not be an effective tool for the improvement of PA, CRE, BF%, or motivation.

Lifestyle Behaviors and Muscular Strength in Young Adults
Henry Piascik, Kristofer S. Wisniewski, Gabrielle M. Brennan Sara D. Dieterich, Patricia Fitzgerald, Maura L. Jegerski, Stephen LoRusso, Baruch Vainshelboim. Saint Francis University, Loretto, PA.
Sedentary lifestyle behaviors and poor muscular strength are associated with morbidity and mortality and are important determinants of general health. The association between those is less known in young population, given that assessing muscular strength is challenging in most clinical settings. **Purpose:** To assess the association between lifestyle behaviors and muscular strength in a pilot cohort of young adults. **Methods:** Ninety-four participants (20.2 ± 1.6 years, 46 men, 48 women) were assessed for self-reported physical activity and sitting time [Global Physical Activity Questionnaire (GPAQ)] and strength tests (isometric deadlift, 1RM bench press and 1RM leg press). Pearson's correlations were analyzed between the variables. **Results:** Means of the sample were as follows: sitting time (M: 5.7 ± 2.7 hours/day, W: 6.8 ± 2.8 hours/day), physical activity (M: 10,977.6 ± 11,068.3 MET-min/week, W: 7,181.9 ± 4,481 MET-min/week) isometric deadlift [M:229±106 (kg), W:96±26 (kg)], 1RM Bench Press [M:85±21(kg), W:39±9 (kg)] and 1RM Leg Press (M:210±106 (kg), W:153±43 (kg)]. Moderate correlations were found between physical activity and 1RM bench press (r=0.45, p=0.01) and 1RM leg press (r=0.39, p=0.027) in women subjects only. **Conclusions:** Self-reported physical activity is associated with upper and lower body strength in women, suggesting the GPAQ as relatively reliable tool for muscular strength evaluation in young female population. However, future studies are needed to confirm these results.

Increasing Physical Activity In Office Workers - An RCT Of Treadmill Workstations.

Frida Bergman, Viktoria Wahlström, Patrik Wennberg, Carl-Johan Boraxbekk, Ann Sörlin, Fredrik Öhberg, Tommy Olsson. *Umeå university, Umeå, Sweden.*
(No relevant relationships reported)

PURPOSE
Our primary hypothesis was that an intervention with treadmill workstations would increase time spent walking. Secondary hypotheses were a decrease in time spent sitting with a concomitant increase in time spent standing and in light intensity physical activity (LPA) leading to positive effects on body measurements and body composition.
METHODS
The intervention group received a treadmill workstation at their office desk during 13 months. Daily time spent sitting, standing and walking and number of steps was measured with activPAL®. Daily time in LPA and MVPA was measured with Actigraph®. Body weight, BMI and waist circumference were measured according to standardized protocols. Dual X-ray Absorptiometry was used to estimate body composition. Mixed models was used for the statistical analysis, with group, day of week (weekday/ weekend), time point and gender as fixed effects and age as a covariate. p<0.05 was considered significant.
RESULTS
Eighty participants were included. The intervention group significantly increased their time spent walking at all follow-ups, with a difference at 13 months of 22 minutes (p<0.01) and 1645 steps per day (p<0.05), respectively, versus controls. Concomitantly, they decreased their MVPA with 13 minutes per day (p<0.001) at weekdays at 13 months versus baseline. We also found a decrease in LPA with 19 minutes per day (p<0.05), and of 17 minutes per day for MVPA (p<0.001) at 13 months versus baseline at weekends.
The control group increased their time spent sitting with 25 minutes per day (p<0.05) and decreased the time spent standing with 35 minutes per day at weekdays (p<0.001) compared to baseline. There was also a decrease in LPA with 14 minutes per day (p<0.01) and in MVPA with 6 minutes per day (p<0.01) versus baseline during weekdays, with a decrease in sitting time with 36 minutes (p<0.05) at weekends. There were no significant changes in body measurements or body composition.
CONCLUSION
It is possible to increase daily walking time by introducing treadmill workstations at offices. A decreased MVPA within the intervention group may contribute to lack of effects on body measurements and body composition. It is therefore important that future interventions aim at both reducing sedentary time as well as increasing, or at least remaining, MVPA levels.

Effects Of Two Exercise Programs On The Values Of Cholesterol And Triglycerides In A Group Of Obese Adults In The Northern Center Of Mexico

Daniel Carranza-Bautista.[1], Marco A. Enriquez Martinez[2], Raúl Lomas Acosta[3], Julia Janeth Rosales Mares[4], Carlos Enríquez Martínez[5], Christopher Gonzalez Sandoval[4], Pedro Jimenez Alarcón[4], Valeria Vital Cruz[4], Carlos Menchaca Valdez.[6], Javier Martinez Pinedo[7]. [1]Universidad Autónoma de Nuevo León., San Nicolás de los Garza, Nuevo León, Mexico. [2]Benemerita Escuela Normal Manuel Avila Camacho., Zacatecas., Mexico. [3]Secretaria de Educación Coahuila., Saltillo, Coahuila, Mexico. [4]Secretaria de Educación Zacatecas, Zacatecas, Mexico. [5]En Forma Wellnes Lab., Guadalupe, Zacatecas, Mexico. [6]Benemerita Escuela Normal Manuel Avila Camacho., Zacatecas, Mexico. [7]Salud de Acero, Fresnillo, Zacatecas, Mexico.

(No relevant relationships reported)

BACKGROUND: According to the World Health Organization (2016) cardiovascular diseases are the main cause of death in the world population. In Mexico it represents 54% of the total deaths, considering an approximate of 100,000 annual deaths, in subjects with ages ranging from 45 years and older, with a higher prevalence in men than in women. Several studies showed the benefits of practicing physical activity reducing risk factors with a minimum of 60 minutes per day. **PURPOSE**: To assess the effects of an exercise program on the values of cholesterol and triglycerides in a group of adults with obesity in the northern center of Mexico. **METHODS**:This pre-post study was conducted in two fitness centers. 60 subjects (52 ± 2 years), 33 women and 27 men during 16 weeks. Subjects were randomly divided into three groups of twenty. Control group without intervention. Outdoor Group, a program with a frequency of 5 days per week and a duration of 60 minutes in outdoor cardio activities. Fitness Group a program of physical conditioning of strength and resistance with a frequency of 5 days per week and a duration of each session of 90 minutes. The lipid profile was measured in blood plasma. **RESULTS**: The main results showed after comparing both measurements that total cholesterol values decreased into OG (p=0.003) and a significant decrease in FG (p<0.001). The women of the FG showed a significant decrease in triglyceride values (p=0.008). **CONCLUSIONS**:Cardiovascular risk seems to be regulated by gender and by type of program. Both the outdoor exercise program and the fitness program show evidence of improvements in health. Into future research we recomend to increase the number of subjects and include other endocrine and metabolic variables.

Fitness Trackers and Motivational Interviewing: Effects on Body Composition in Chronic Low Back Pain

Kathryn J. Southard, Laura D. Ellingson, Jeni E. Lansing, Maria Perez, Greg J. Welk, FACSM. *Iowa State University, Ames, IA.* (Sponsor: Dr. Greg Welk, FACSM)

(No relevant relationships reported)

PURPOSE: Individuals with low back pain (LBP) are encouraged to stay active to manage symptoms and maintain function. However, promoting physical activity and sustained weight loss has proven to be challenging. This study demonstrated the effects of using a consumer fitness tracker (FT) alone or in combination with motivational interviewing (MI) on changes in body composition in patients with chronic LBP. **METHODS:** Participants (N=57; 51% female; mean age: 43.5 ± 10.1) were randomly assigned to receive a FT alone, (FT; N=16) or in combination with MI, (FTMI; N=17) or a waitlist control condition (WLC; N=19) for 12 weeks. FT and FTMI received monthly phone calls to discuss satisfaction with the tracker. Participants in FTMI also discussed motivation for change and self-selected goals during calls. WLC participants were advised to maintain current activity-related behaviors. Height was measured at baseline using a stadiometer, and body composition was assessed pre and post intervention via Inbody 720 Body Composition Analyzer (N=52). Group differences for weight, BMI, and body fat percent (BFP) were analyzed using ANOVA and effect size calculations (Cohen's d). **RESULTS:** There were no group differences in outcome measures at baseline. Following the intervention both treatment groups lost non-significant amounts of weight (p=0.33) while WLC maintained their weight (FTMI: 88.5 ± 24.3 vs 87.7 ± 23.5, FT: 86.9 ± 17.2 vs 85.6 ± 16.3, WLC: 78.9 ± 15.8 vs 78.8 ± 15.4 kg). Effect size calculations demonstrated a moderate difference between both treatment groups and WLC for weight loss post-intervention (d=0.45, 0.43). Following the intervention both treatment groups also showed non-significant decreases in BMI and BFP compared to WLC (BMI p=0.48; BFP: p=0.51). Effect size calculations demonstrated a small difference for BFP between treatment groups post-intervention (d=0.19, 0.23), as well as small and moderate differences for BMI between the FTMI, FT, and WLC (d=0.21, 0.46).

CONCLUSION: These preliminary data provide support for facilitated health coaching methods such as FTMI. Results show the independent use of a FT can also have small benefits. Additional work is needed to determine the optimal dose and intervention strategies for patients with LBP.

Changes in Body Composition Following a 6-Month Standing Workstation Intervention

Cara G. Daniels, Monisha Maharjan, Kyler Daugherty, Jacilyn Olson, Melissa Powers, Larissa Boyd. *The University of Central Oklahoma, Edmond, OK.*

(No relevant relationships reported)

Prolonged sedentary behavior may be associated with mortality and other health risks. Research shows a correlation between adiposity and uninterrupted sedentary time, supporting efforts for increasing workplace activity. **PURPOSE:** To determine if body composition changed following a 6-month intervention using sit-to-stand workstations (STS). **METHODS:** Participants included staff and faculty members of the University of Central Oklahoma. Participants (*N*=31) were randomly assigned to a treatment group (TG; *n*=16) and a control group (CG; *n*=15). IG participants given a STS and instructed to stand at least 2 hours in a day during work hours. Dual-energy X-ray Absorptiometry (DXA) was used to determine total mass (lbs.), fat mass (lbs.), lean mass (lbs.), body fat (%), and bone mineral density (g/cm^2) at baseline and 6 months of the intervention. A repeated-measures ANOVA was used to analyze data. **RESULTS:** No significant differences between or within groups were found (*p*>.05). Effect sizes were minimal. Small improvements occurred in all variables in the intervention group, but only for lean mass in the control group. **CONCLUSIONS:** Standing for at least 2 h/d may provide modest benefits to body composition. Future research should examine changes over a longer treatment time. This project was funded by the University of Central Oklahoma, Research and Sponsored Programs office

Effects of Exercise Referral Schemes on Physical Activity Levels

Nikita Price[1], T. Williams[2], Elizabeth Horton[1], Gary Liguori, FACSM[3], Steve Mann[2], Alfonso Jimenez[1]. [1]Coventry University, Coventry, United Kingdom. [2]ukactive Research Institute, London, United Kingdom. [3]University of Rhode Island, Kingston, RI.

(No relevant relationships reported)

Exercise referral schemes are clinical exercise interventions used in non-clinical settings throughout the UK, and are intended to improve physical activity (PA) levels and health conditions of medically referred individuals. At present, the literature reviewing the impact of exercise referral schemes on PA levels, well-being, and quality of life is inconsistent.
PURPOSE: To determine if exercise referral schemes positively influence PA levels in a large cohort of of individuals throughout England.
METHODS: Data were obtained from 7412 participants (Female N= 4965 [49.96, +/- 14.37y., Male N=2447 [53.15, +/- 14.75 y.) referred from hospitals (N=605), medical centres (N=406), outreach (N=353) and GP surgeries (N= 6048) to fourteen exercise referral schemes located across England. The participants' self-reported MET/minutes per week were calculated at the start and end of the scheme to determine whether the clinical exercise intervention had any impact on participants' PA levels. Scheme lengths were either 6 (N=1749) or 12 weeks (N= 5663) in duration and situated in leisure environments. PA programmes consisted of both aerobic and resistance training tailored to the individual. A paired samples t-test was conducted to determine if a statistically significant difference existed between pre- and post scheme PA levels.
RESULTS: METS/minutes per week were combined for both the 6- and 12-week groups. There was a statistically significant increase of 290.9 MET/mins per week from pre- to post-scheme for the participants (Pre= 856.1, +/- 1278 MET/min/week, 95% CI [827, 885) to Post= 1147 +/- 1801 MET/min/week; t(7411) = -34.18, p<0.001, 95% CI [1475, 1509), with a pairwise correlation of 0.367.
CONCLUSIONS: This is one of the larger samples to study PA levels in UK adults after completion of an exercise referral scheme. The results showed a significant pre-post increase in MET/min/week, although sustainability of this change is not known. Long-term follow up of participants, including a comparison group and deeper analysis of other health behaviors, is to be conducted to support the initial findings.

A Worksite Intervention Program for Obese Sedentary Women

Joan A. Cebrick-Grossman. *The University of Scranton, Scranton, PA.*

(No relevant relationships reported)

Workers spend a quarter of their lifetime, and up to half of their waking adult lives, at work or commuting. The sedentary aspects of work have been associated with increased health risks. Workplace health promotion programs are the ideal locations for impacting health behaviors. **PURPOSE:** To compare the effects of short duration, high intensity internal training (HIIT) and traditional walking or increased steps on anthropometric, body composition and body weight changes over a 12-week period. **METHODS:** Subjects (N=11) were obese, sedentary female volunteers, assigned into one of two exercise groups. Both groups increased their exercise and steps up to 5 days/week for 12 weeks monitored via an activity tracker, a Movband™. The resistance group (N=5) (42.9$\pm$8.1yr; 197.4$\pm$22.6lb body wt; BMI=33.8$\pm$2.2 kg/m^2; mean$\pm$ SD) exercised for (15.0$\pm$3.5 min) which consisted of eight different routines: upper and lower extremity, 2 cardio segments, 2 total body, yoga and abdominal exercises. The step group (N=7) (48.4$\pm$9.6yr; 192.7$\pm$22.6lb body wt; BMI=32.1$\pm$1.9 kg/m^2; mean$\pm$ SD) increased their steps up to 10,000 for 12 weeks. Relative (%) body fat was measured via DEXA scan, along with five anthropometric measurements prior to and after 12 weeks. Independent samples t tests probed for significant differences at the p<0.05 level. Values are expressed as mean$\pm$standard deviation. **RESULTS:** No significant changes were determined between the resistance and step groups for the pre-post anthropometric measurements: biceps, waist, abdomen, hips and thigh (13.5$\pm$1.3,13.1$\pm$1.3 vs. 12.5$\pm$0.8,12.2$\pm$0.9; 36.0$\pm$3.1,35.4$\pm$2.1 vs. 35.0$\pm$2.1, 34.6$\pm$2.2; 42.1$\pm$1.5,41.4$\pm$2.7 vs. 41.0$\pm$2.2,41.0$\pm$2.7; 45.6$\pm$1.9,44.9$\pm$2.0 vs. 44.6$\pm$2.7,44.0$\pm$3.0; 25.0$\pm$1.4,24.8$\pm$1.7 vs.24.4$\pm$1.5, 24.2$\pm$1.5 in, respectively). Pre-post relative fat measurements and body weight changes were not significantly different between the resistance and step groups (45.3$\pm$1.8, 44.2$\pm$1.2 vs. 45.8$\pm$4.4, 45.5$\pm$3.5 %fat; 197.4$\pm$22.7, 198.0$\pm$21.6 vs.192.7$\pm$22.6, 192.6$\pm$28.2 lb, respectively). **CONCLUSION:** This work is suggestive that there are no differences between the mode of exercise, short duration HIIT exercise compared to increased steps regarding anthropometric measures, relative percent fat and body weight over a 12-week period.

Dose Knowledge of Physical Activity Recommendations Change After a Physical Activity Intervention?

Katrina D. DuBose, FACSM, Deirdre Dlugonski. *East Carolina University, Greenville, NC.*

(No relevant relationships reported)

DOES KNOWLEDGE OF PHYSICAL ACTIVITY RECOMMENDATIONS CHANGE AFTER A PHYSICAL ACTIVITY INTERVENTION?
K.D. DuBose, FACSM, & D. Dlugonski. Dept. of Kinesiology, East Carolina University, Greenville, NC 27858
Purpose: To determine if a physical activity (PA) intervention improved parent's knowledge of adult and child PA recommendations. **Methods**: Twenty-six parents participated in an 8-week PA intervention with their 1 – 5 year old child. The parents were randomly placed into an intervention (n=19) or control (n=7) group. As part of the intervention, parents received information about adult and child PA recommendations. Knowledge of PA recommendations for adults and children was assessed through questionnaires pre- and post-intervention. **Results**: On average, the parents were 35$\pm$6.0 years of age and were overweight (29.2$\pm$7.7kg/m^2). The majority were Caucasian, women, had at least a college education, and worked outside of the house. Among all parents, 61% had not heard of the PA recommendations. Further, 54% and 96% did not know the moderate and vigorous PA recommendations for adults. Regarding children's PA recommendations, 62% and 81% of parents did not know the appropriate amount of PA for children <5 years old and $\geq$ 6 years, respectively. The knowledge of these PA recommendations did not differ by group status at baseline p>.05. There was a 15% - 18% increase in the percentage of intervention group participants who increased knowledge of adult PA recommendations and a 11 – 33% increase for knowledge of child PA recommendations. In contrast, there was no change in the control group. These findings were not statistically significant. **Conclusions**: Overall parents do not know either adult or children's PA recommendations. A short PA intervention can improve parent's knowledge of PA recommendations. Understanding the knowledge of parents before an intervention could be useful to deliver appropriate content during the intervention period.

Effects Of Two Consecutive 4 Month-a-year Training Program On Metabolic Syndrome And Vo$_2$Max Evolution

Felix Morales-Palomo, Miguel Ramirez-Jimenez, Juan Fernando Ortega, Ricardo Mora-Rodriguez. *UCLM, Toledo, Spain.*

(No relevant relationships reported)

Cross sectional data reveal that individuals with high cardiorespiratory fitness (i.e., CRF assessed by VO$_2$max) have lower prevalence of metabolic syndrome (i.e., MetS; Hassinen et al., 2010). However, there is a scarcity of exercise-training intervention trials with serial measures of CRF to confirm that exercise training reduces MetS through increases in CRF. We recently found that two consecutive years of 4-month aerobic interval training are required to chronically improve MetS (Morales-Palomo et al., 2017).
PURPOSE: To determine the chronic effects of two consecutive 4 months-a-year training program on the relationship between increased CRF and reduced MetS continuous z score-(Z-MetS). **METHODS:** Using a repeated-measures, randomized control design, MetS subjects were allocated to either a training group (TRAIN; n=20) or a control group (CONT; n=22) that remained sedentary. TRAIN extended for 4 months every year (November-mid-March) consisting in 3 sessions per week of aerobic interval training (Mora-Rodriguez et al., 2014). At baseline and after 7 months of the last training program, VO$_2$max, Z-MetS, 10 yrs atherosclerotic cardiovascular disease risk index (ASCVD) and medicine use were assessed. **RESULTS:** From a similar level at baseline, VO$_2$max increased by 1.31$\pm$0.96 mL$\cdot$kg$\cdot$min^{-1} after 2 yrs in TRAIN (9%; P=0.05) being 12% higher than CONT (P=0.05). Z-MetS decrease after 2 yrs in TRAIN (0.48$\pm$0.12 to 0.24$\pm$0.10; P=0.033) but remained unaltered in the CONT. ASCVD did not change in TRAIN but worsen in the CONT group after 2 yrs (7.8$\pm$1.3% to 10.4$\pm$1.9%; p=0.004). The correlation between the changes in VO$_2$max and Z-MetS was significant for the TRAIN group (r=-0.571; P=0.013; r^2=33%). After 2 yrs, a higher percentage of subjects in the CONT group in comparison to the TRAIN used cholesterol lowering medicine (45 vs 15%) and two medicines (45 vs 20%) in comparison to the TRAIN group. **CONCLUSION:** Two consecutive years of a 4-month intense aerobic exercise program raises CRF in association with a reduction in Z-MetS. The amount of variance in the reduction in Z-MetS that could be explained by the increase in VO$_2$max is 32% which suggest that exercise could be an important clinical non-pharmacological treatment to reduce the progression of MetS and the concomitant cardiovascular risk.

Exercise Intervention with Lifestyle Improves Mental Health and Decreases Morbid Thoughts

Francisco E. Ramirez[1], Neil Nedley[1], Daniel Peterson[2], Monica Fukuda[2], Johanna Emerson[2]. [1]*Nedley Clinic, Weimar, CA.* [2]*Weimar Institute, Weimar, CA.*

(No relevant relationships reported)

PURPOSE: Morbid thoughts can increase risk of self-harm or harm to others. We assessed the impact that exercise may have on mental health before and after an educational program.
METHODS: Trained facilitators ran an 8-week mental health educational program. Participants met once a week for 8 weeks for a 2-hour program. A mental health test was applied at baseline and at the end. It measured emotional intelligence (EQ), depression based on DSM-5 [The Diagnostic and Statistical Manual of Mental Disorders Volume 5] criteria, demographics, and patient history including the question "Are you thinking about death often or considering harming yourself or others." and exercise patterns. Minimum exercise was defined as 30 to 45 minutes of exercise at least 4 times a week. Patients were educated on healthy behaviors. **RESULTS**:N=5997 participants finished the program and were included in the study. Mean age 52.3 SD 15.1, n=4209 (71%) were females and n=5106 (85.1%) were Caucasian. At baseline those that meet the exercise minimum n=2121, had an EQ of 102.8, SD 15.4. n=851 (40%) of these participants had no depression, n=385 (18%) mild depression, n=634 (30%) moderate depression, and n=251 (12%) severe depression. At baseline those that did not meet the exercise minimum n=3876, had an EQ of 99, SD 14.8. n=899 (23%) had no depression, n=569 (15%) had mild depression, n=1407 (36%) had moderate depression, and n=1001 (26%) had severe depression. At baseline the n=2121 that had a regular exercise program, of that group, 27.6% had some degree of morbid thoughts and had a mean depression of 9.7 (mild), SD 7.1. N=3876 did not have a regular exercise program at baseline, of those, 34.5% had some degree of morbid thoughts and mean depression of 13.4 (moderate) SD 7.4.
By the end of the 8-weeks, n=3284 had a regular exercise program, from that group 11.3% had some degree of morbid thoughts and a mean depression of 5.4 (none), SD 5.3. N=2713 at the end did not established an exercise program, that group 16.3% had some degree of morbid thoughts and a mean depression of 7.8 (mild), SD 6.3.
CONCLUSIONS:

It seems that exercise decreases severity of depression and morbid thoughts, even at baseline. The educational program seems to benefit exercising and non-exercising participants but those that established the regular exercise improved the most.

The Effect of Early Life Undernutrition on Voluntary Physical Activity in Mice.
Eric C. Leszczynski, Ashley N. Triplett, David P. Ferguson
Michigan State University, East Lansing, MI
Regular physical activity reduces the risk of cardiovascular disease, Type II diabetes, and metabolic syndrome. Perinatal undernutrition has been shown to program the development of chronic disease. **PURPOSE:** To determine if early life undernutrition influenced frequency and duration of wheel running (measure of physical activity) in mice during adulthood. **METHODS:** Using a cross-fostering model, pups were undernourished during gestation (GUN, N= 8) or during lactation (PUN, N= 8) by feeding FVB mothers a low protein diet (8% protein) causing growth restriction. The control group (CON, N= 7) was fed a normal protein diet (20% protein) throughout gestation and lactation. At 21 days of age, all pups were weaned and fed a control diet. At PN45, mice were then individually housed in cages with free-moving running wheels which recorded number of spins per day (Columbus Instruments). Average spins per day were calculated on days 5 and 6 for three weeks, and a two-way ANOVA was run comparing the main effects of diet and gender on average wheel spins. **RESULTS**: There was a significant difference between GUN mice (29535.625 ± 296 spins·day^{-1}), CON (22988.7 ± 296 spins·day^{-1}) and PUN (19667.5 ± 274 spins·day^{-1}) (p<0.05). There were no significant differences between male and female groups. **CONCLUSIONS**: Based on the data, postnatal undernutrition elicits an impairment in physical activity engagement. Thus, the developmental processes that occur during this time period are suspected to program adult physical activity level.

Squatting With Elastic Bands Facilitates More Weight Used And Time Under Muscle Tension

Nicole L. Rogers[1], Javier Gene[2], Alvaro Juesas[2], Pedro Gargallo[2], Andres Gene[2], Rosario Salvador[2], Juan C. Colado[2], Michael E. Rogers, FACSM[1]. [1]*Wichita State University, Wichita, KS.* [2]*University of Valencia, Valencia, Spain.* (Sponsor: Michael E. Rogers, FACSM)
(No relevant relationships reported)

In has been shown that the variable resistance associated with elastic band training improves strength and several other outcomes. However, the efficacy of combining elastic bands (EB) with traditional resistance exercises is not well understood. **PURPOSE:** To evaluate performance (kg used and number of repetitions) during the squat exercise using free weights (FW) versus FW with EB applied with tension at the sticking point (50 degrees of knee flexion). **METHODS:** Twenty healthy, physically active men (25.5±4.7 yr) with resistance training experience performed four squat conditions on a Smith Machine in random order: (A) 10 maximum repetitions (RM) with FW; (B) 10RM with CLX EB added at the stand-up position (SUP) with the weight of 10RMFW; (C) number of repetitions with CLX EB added at the SUP using the weight of 10RMFW; (D) number of repetitions with CLX EB added at 50 degrees of knee flexion prior to the SUP using the weight of 10RMFW. Goniometer, tactile markers, and metronome were used to standardized range of motion and pace of movement. The eccentric phase was performed at a pace of 2 sec with a 1 sec pause before the concentric phase performed with maximum velocity. A validated bascule was used to measure kg. Friedman test identified differences between conditions and Wilcoxon signed-rank tests examined where differences occurred. **RESULTS:** Condition D employed more (p<0.05) weight than the other conditions (+24.70%). Conditions C and D performed more RM than the other conditions (8.4 and 3.45, respectively) with significant differences between conditions 3 and 4. **CONCLUSIONS:** Performing resistance exercises with EB increased the kg employed and time under muscle tension. This could be because EB provide an additional element of variable tension that changes through the range of motion. Combining EB with traditional weight training exercises may enhance the training effect.

Effect Of Kinesitherapy And Massage To Injury Skeletal Muscle Repair'S Histomorphology And C-reactive Protein

Pin Lu[1], qinlong liu[2]. [1]*Anhui Normal University, wuhu, China.* [2]*Tianjin Vocational College of Sports, tianjin, China.*
(No relevant relationships reported)

Abstract
Purpose: This project is based on mice acute blunt contusion model. And we use muscle histomorphology and C-reactive protein as observation targets. Hope our research result can help improving fitness enthusiasts' health knowledge level and offer choice to injury rehabilitation method.
Method: Project chooses 60 adult male healthy SD mice(360±22.7g) and use self-made tool to hit mice's right tibialis anterior muscle. After that we use randomization separate 60 mice into 4 groups, each group follow its own recovery plan. Collecting injury and health tibialis anterior muscle specimens after injury 2 day, 5 day, 8 day, 12 day, 16 day. Using HE staining method deal with muscle samples and observe its histomorphology. Using ELISA to measure the CRP level in serum. The result shows us inflammation level and span.
Result: (1) Regular Observation: These symptoms are vanishing in 6th day of massage group, 8th day of massage with kinesitherapy group, 10th day of kinesitherapy group, 16th day of spontaneous recovery group.
(2) Histological Observation: Mice acute blunt contusion model can cause all mice right tibialis anterior muscle construction destroy, muscle fiber break and increase interval. After each groups' therapy, tibialis anterior muscle's form repaired within several days.
(3) C-reactive protein: Massage Therapy Group, Kinesitherapy Group and Massage Therapy with Kinesitherapy Group C-reactive protein level back to normal time and degree compare with Spontaneous Recovery Group have showing significant different($p < 0.05$). Massage Therapy Group C-reactive protein level back to normal time and degree compare with Kinesitherapy Group and Massage Therapy with Kinesitherapy Group have show significant different($p < 0.05$).
Conclusion: Kinesitherapy and massage therapy can enhance muscle strength, correct injury skeletal muscle arrangement, tissue construction completion. Meanwhile, improve muscle microenvironment, reduce inflammatory cells infiltration and accelerate inflammatory cells elimination, decrease cellular stress response which come from muscle fibers degradation and shorten reaction span. In conclusion, kinesitherapy and massage therapy is the most efficiency rehabilitation therapy in skeletal muscle injury acute stage.

Changes In Cortisol Levels With An Aquatic Resistance Workout Versus A Weight Workout

Juan C. Colado[1], N. Travis Triplett[2], Jorge Flandez[3], Joaquin Madera[1], Victor Tella[1], Nicole L. Rogers[4], Michael E. Rogers, FACSM[4]. [1]*University of Valencia, Valencia, Spain.* [2]*Appalachian State University, Boone, NC.* [3]*Austral de Chile, Valdivia, Chile.* [4]*Wichita State University, Wichita, KS.* (Sponsor: Michael E. Rogers, FACSM)
(No relevant relationships reported)

Aquatic resistance training could be an effective type of strength training. However, the response of cortisol to aquatic exercise versus training with traditional weights has not been determined. **PURPOSE:** To compare the response of cortisol during similar resistance training protocols performed in an aquatic medium versus traditional weights. **METHODS:** 8 healthy, physically active males (24.8 ± 2.6 yr) with resistance training experience performed two conditions in random order: (a) 6 sets of horizontal shoulder ab/adduction and flexion/extension of both the shoulder and the elbow with a flat paddle-type device (782 cm^2 of projected frontal area) in each hand; and (b) 3 sets of exercises performed with dumbbells: (i) standing horizontal shoulder abduction, (ii) horizontal shoulder adduction, and (iii) shoulder flexion; and with pulley: (iv) standing pull-over, (v) biceps curl, and (vi) elbow extension. Rest between sets was 1-2 min. Aquatic exercises were performed at a pace that permitted the maximum number of repetitions in 15 sec. Weight exercises were performed with a load that permitted the same number of repetitions as the corresponding aquatic exercise pace. Cortisol blood samples were obtained from an antecubital vein in basal status, immediately after finishing each workout, and after 60 min of rest (60REST). **RESULTS:** Basal cortisol was 22.83±6.67 ng/ml. Post-workout and 60REST values were: (i) aquatic: 26.71±5.73 and 24.02±10.17 ng/ml, respectively; (ii) weights: 24.29±8.12 and 18.96 ± 6.45 ng/ml, respectively. There were significant (p<0.05) differences in cortisol levels following both workouts compared to basal values ($\chi2(4)=8.800$). There was also a significant increase in cortisol immediately after the aquatic workout compared to weights (Z=-1.820) and a significant decrease in cortisol between post- workout and 60REST with weights (Z=-2.240). **CONCLUSIONS:** Cortisol levels were higher immediately and 60 min after the aquatic workout compared to weights. The higher cortisol level

and the slower pace of recuperation could indicate that this type of aquatic training provokes a higher intensity. This could be due to the higher stabilization needed to maintain postural control in the water.

A Call for Physical Activity Guidelines to Be Established in Equatorial Africa

Brianna N. Tracy[1], Lonnae A. Hohman[1], William E. Herrin[1], Norah Madaya[2], Courtney D. Jensen[1]. [1]University of the Pacific, Stockton, CA. [2]Uganda Bureau of Statistics, Kampala, Uganda.
(No relevant relationships reported)

Current guidelines recommend adults perform a minimum of 30-60 minutes of moderate-intensity physical activity (PA) at least 5 days a week or vigorous PA on at least 3 days. Throughout Equatorial Africa, these recommendations are largely unmet and unknown. Among adults in rural areas, rates of sedentary behavior are reported to be 65-72%; in urban areas, where supplies are more accessible, 78-80% of men and women are sedentary. Geographic prevalence of metabolic syndrome reflects this with a 5-fold increase in urban populations. Currently, data are limited on how much PA should be prescribed to reduce the incidence of illness and physical suffering in Equatorial African populations. **PURPOSE:** To evaluate the effect of PA on health outcomes among Ugandan men and women. **METHODS:** The Uganda National Household Survey gathered data from a random sample of Ugandan homes between 2012 and 2013. Variables related to PA were limited; we used "hours spent gathering firewood" and "hours spent collecting water" as representations of daily activity. Dependent variables were whether subjects experienced an injury in the last 30 days, the number of days they reported "suffering" from illness or injury during that period, and the number of times they had to cease activity owing to illness or injury. Linear regressions tested the effect of PA on physical health outcomes. **RESULTS:** Across the total sample, more hours spent gathering firewood (p<0.001) and more hours spent collecting water (p<0.001) each individually associated with reduced frequency of suffering and the number of times subjects had to stop activity owing to illness or injury. Time spent gathering firewood (p=0.328), water (p=0.346), or both (p=0.982) had no relationship with the incidence of injury in the last 30 days; the implication is that illness associates more strongly with PA than does injury. As subjects performed more PA, they reported less suffering and less obstruction of daily tasks. **CONCLUSION:** These data offer a modest indication that PA and health are inextricable: increased engagement in activity corresponds to better health and less suffering. Owing to these preliminary associations and the lack of comprehensive data, there is a demonstrable need for governmental guidelines for PA and potentially the establishment of a Ugandan College of Sports Medicine.

Does Joint-angle Specificity After Short-term Isometric Strength Training Have A Neural Basis?

Marcel B. Lanza, Thomas G. Balshaw, Roxanas Panagiotis, Jonathan P. Folland, FACSM, FACSM. *Loughborough University, Loughborough, United Kingdom.* (Sponsor: Jonathan P Folland, FACSM)
(No relevant relationships reported)

The functional adaptations to isometric RT have been found to different between, and highly specific to, the type of contractions performed e.g. explosive vs sustained contractions. However, it is unknown if isometric resistance training combining sustained contractions and brief explosive contraction (EC) increases both explosive and maximum strength, and if the strength gains would be specific to the training angle (joint angle specificity) explained by neural drive specific to the training angle. PURPOSE: The primary aim of the present study was to investigate if a short-term intervention of isometric RT, with brief EC and sustained maximum voluntary contractions (MVC), increased both maximum and explosive strength. The second aim was to investigate the joint angle specificity of adaptations in strength and neural drive. METHOD: Twenty-two healthy males completed 4 weeks of either RT (RT group; n=13; 22 ± 3 years; 1.78 ± 0.07 m; 73 ± 7 kg) or habitual activity (CON group n=9; 23 ± 3 y; 1.79 ± 0.08 m; 75 ± 8 kg). All training sessions were performed isometrically (65° knee joint angle where 0° is full knee extension; 14 sessions) performing unilateral knee extension EC [3x10 repetitions (~1s)] followed by MVC [3×6 repetitions (3s)]. Isometric pre- and post-training measurements of torque were made at five different joint angles (35°, 50°, 65°, 80° and 95°) during: MVC; EC and evoked twitch contractions. Surface electromyography (EMG) amplitude measurements from the quadriceps femoris during voluntary contractions were normalised to maximum peak-to-peak compound muscle action potential.RESULTS: Changes in MVT were higher for RT than CON at the training angle (65°; P=0.001) and the two more extended angles (35° and 50°; P≤0.047). Normalized EMG at MVT increased more, or had a tendency to increase more, for RT vs CON at these same angles (50°, P=0.023; 35° and 65°, P≥0.073). Explosive torque, EMG during EC and twitch contractions did not show time x group interactions (P≥0.123).CONCLUSION: Resistance training with brief EC and sustained MVC increased MVT and associated neural drive, but

did not increase explosive strength or neural drive during the explosive phase of contraction. We also found angle specific changes in neural drive that appeared to underpin the joint angle specificity of MVT improvements after isometric RT.

Effects Of A Smartphone-based Intervention On Adults' Physical Activity, Self-efficacy, And Enjoyment

PENG ZHANG[1], You Fu[2], Ryan D. Burns[3], Pei LI[4], Steven Godin[3]. [1]EAST STROUDSBURG UNIVERSITY, EAST STROUDSBURG, PA. [2]University of NEVADA, Reno, Reno, NV. [3]University of Utah, Salt Lake City, UT. [4]Beijing University of Posts and Telecommunications, Beijing, China.
(No relevant relationships reported)

PURPOSE: Smartphone applications provide an opportunity for implementing physical activity (PA) interventions remotely. However, little research has been published to date on their effects. The purpose of the study was to test the effectiveness of *efitbuddy,* a theory-based PA smartphone application, on young adults' PA and motivational beliefs through a four-week intervention.
METHODS: A quasi-experimental design with control group was used to examine the effects of *efitbuddy* on participants' PA. 274 college students (167 females, mean age = 19.35±2.09 years) attended baseline and posttests and change scores were computed for each dependent variable (DV). After the baseline test, participants in the intervention group (n=187) downloaded *Efitbuddy* and used it daily for four weeks. *Efitbuddy was* a smartphone application developed to promote individual's PA and included four behavior change techniques such as self-monitoring, setting goals, and provision of general health information. PA participation, self-efficacy, and exercise enjoyment were selected as the DVs of the study. A Pearson's correlation analysis was employed on the raw data to examine if the data were suitable for multivariate analyses. The results displayed moderate linear relationships between the pretest and posttest scores on three DVs. Therefore a 2 (group) x 2 (time) x 2 (gender) Multivariate Analysis of Variance (MANOVA) was conducted to examine the differences in the dependent variables. Wilk's lambda was used to decide the statistical significance of the multivariate model.
RESULTS: There were no multivariate statistically significant interactions for Group x Time x Gender (Wilks's $\Lambda = 0.996$, $F_{(6, 269)} = 0.687$, P = 0.560), for Time x Gender (Wilks's $\Lambda = 0.003$, $F_{(6, 269)} = 0.508$, P = 0.677), and for Group x Time (Wilks's $\Lambda = 1$, $F_{(6, 269)} = 0.008$, P = 0.999). However, the results from the MANOVA yielded a significant interaction for Gender x Group (Wilks's $\Lambda = 0.985$ $F_{(6, 269)} = 2.720$, P = 0.044).
CONCLUSIONS: The results of the study demonstrate that *efitbuddy* has limited influence on young adults' PA through a four-week period of time usage. These results echo previous studies exploring the relationship between smartphone applications and PA behaviors and more research is warranted for longer intervention with more vigorous engagement of usage.

Cardiometabolic Effects of a Randomized Workplace Cycling Intervention

James E. Peterman, Kalee L. Morris, Rodger Kram, William C. Byrnes, FACSM. *University of Colorado Boulder, Boulder, CO.* (Sponsor: William C Byrnes, FACSM)
(No relevant relationships reported)

In laboratory settings, replacing sitting with cycling improves cardiometabolic risk factors. However, changes to risk factors following a cycling intervention in the workplace have yet to be examined. **PURPOSE:** To quantify how a compact, stationary cycling device used in a sedentary workplace affects cardiometabolic risk factors. **METHODS:** Twenty-one inactive to recreationally active office workers who sat at work ≥6 h·d⁻¹ visited the laboratory for baseline physiological measurements (resting blood pressure, blood lipid profile, VO2max, body composition, and 2-h oral glucose tolerance test). Participants were assigned to a 4-week intervention (n=12) or a 4-week control period (n=9). At the end of the control period, participants in the control group repeated the baseline physiological measurements and then began the workplace intervention. During the workplace intervention, participants were instructed to use the cycling device a minimum of 15 min·h⁻¹ which would result in a total use of ≥2 h·d⁻¹ during the workday. Following the 4-week intervention period, the physiological measurements were repeated. **RESULTS:** Participants averaged 1.73±0.47 h·d⁻¹ of cycling during the intervention with no changes in actigraphy monitored non-cycling physical activity. Four weeks of the workplace intervention increased VO2max (2.07±0.44 to 2.17±0.44 L·min⁻¹), end of VO2max test power output (166.3±42.2 to 176.6±46.1 W), and HDL cholesterol (1.09±0.17 to 1.17±0.24 mmol·L⁻¹). **CONCLUSIONS**: A compact stationary cycling device incorporated into a sedentary workplace improves some cardiometabolic risk factors in 4 weeks with no compensatory decrease in non-cycling physical activity. Therefore, compact cycling devices are a feasible intervention for a sedentary workplace.

This efficacy trial can inform the design of future randomized controlled trials aimed to modify lifestyle behaviors to decrease the proportion of women gaining excessive weight during pregnancy in a larger, more diverse pregnant population.

Effects Of A 12-month Community-based Exercise Program In Men And Women With Non-communicable Diseases.

Fiona Skelly, Brona Furlong, Lisa Loughney, Noel McCaffrey, Niall Moyna. *Dublin City University, Dublin, Ireland.*
(No relevant relationships reported)

INTRODUCTION: Non-communicable diseases represent a significant threat to human health and well-being, and carry significant implications including decreased quality of life and decreased physical functioning. The aim of this study was to evaluate the effects of attendance to a 12 month community-based chronic disease exercise rehabilitation program on measures of physical activity (PA) sedentary behaviour (SB) and physical function and to compare the results of those who attended regularly vs non-regular attenders.
METHODS: Participants (56.3% male; age (mean ± SD) 64.8 ± 0.5 yr) with coronary artery disease, (n=119); chronic obstructive pulmonary disease, (n=101); peripheral arterial disease, (n=53); or type 2 diabetes, (n=43) were referred by a physician to a community-based chronic disease exercise rehabilitation program. Standard anthropometrics, timed sit-to-stand (STS), hand-grip, sit-and-reach test (SAR) and performance during a 6-min time trial (6MTT), PA and SB were measured at induction to the community-based chronic disease exercise rehabilitation program and after 12 months. Results are presented as mean ± SD. Attenders were classified as those who attended at least one class per week for 12 months.
RESULTS: At baseline, attenders had significantly more favourable measures of BMI, hip circumference, STS and 6 MTT, significantly higher stepping hours, min of moderate/vigorous PA (MVPA) and step count, and spent significantly less time in SB > 90 min than non-attendees. Using baseline values as covariates, there was a significant difference in stepping hours, minutes of MVPA, step counts and BMI between attenders and non-attenders at 12 months. There was no significant difference at baseline for the number of sedentary bouts < 20 min, weight (kg), waist circumference and SAR. However, all values were significantly different between attenders and non-attenders at 12 months.
CONCLUSIONS: Participants who attended chronic disease exercise rehabilitation program a minimum of one day per week for 12 months had significantly greater improvements in MVPA, SB and physical functioning than non-attenders.

274   Board #115   May 30 9:30 AM - 11:00 AM

Efficacy Trial Of A Behavioral Lifestyle Intervention To Promote Appropriate Gestational Weight Gain

Lyndi M. Buckingham-Schutt, Laura D. Ellingson, Spyridoula Vazou, Greg J. Welk, FACSM, Christina G. Campbell. *Iowa State University, Ames, IA.* (Sponsor: Greg Welk, FACSM)
(No relevant relationships reported)

Appropriate gestational weight gain (GWG) is an important, modifiable risk factor in both maternal and fetal health; however, the majority of women in the United States exceed Institute of Medicine (IOM) weight gain recommendations. A need exists to identify effective strategies targeting lifestyle behaviors (e.g. diet and physical activity (PA)) to encourage healthy GWG. **Purpose**: The study examines the efficacy of a counseling-based lifestyle intervention designed to promote appropriate GWG and reduce post-partum weight retention. **Methods**: Participants were randomized to intervention (INT; n = 23) or to a usual care (UC; n = 24) group between 8-14 weeks gestation. To encourage appropriate weight gain during pregnancy, the INT group received at least six one-on-one counseling sessions over approximately 30 weeks. Counseling was based on principles of Motivational Interviewing (MI) and was delivered by a Registered Dietitian Nutritionist. INT participants were given a commercially available fitness tracker and an individualized meal plan. Stated goals for INT participants were to accumulate ≥10000 steps per day and eat 45% of total calories from carbohydrates. GWG, PA (steps/day and minutes of moderate and vigorous PA (MVPA), and diet quality (Healthy Eating Index-2010 (HEI)) were assessed at baseline, 26-28 weeks and 34-36 weeks gestation; weight retention was measured at two-months postpartum. **Results**: The proportion of INT women that met the 2009 IOM GWG guidelines was significantly greater than UC (60.8% vs. 25.0%, OR: 4.67 CI: 1.3-16.2; p = 0.019). INT PA increased from baseline to 26-28 weeks gestation (steps/day: 6661 ± 1737 vs. 8603 ± 3062; >30-min bouts: 41.4 ± 88.6 vs. 81.3 ± 73.7; both p<0.01) and was significantly greater at 26-28 weeks gestation compared to UC (steps/day: 6629 ± 2322; >30-min bouts of MVPA: 28.4 ± 55.8; both p<0.01). INT group HEI improved from baseline to 26-28 weeks gestation (61.2 ± 10.5 vs. 70.6 ± 12.8; p<0.01). In the INT group, 36.4% were at or below pre-pregnancy weight at two-months postpartum compared to 12.5% of UC (p = 0.05). **Conclusions**:

Baseline Body Composition Affects Exercise Training Outcomes: Results from Diabetic and Athletic Populations

Natalie M. Figueroa[1], Cynthia Villalobos[1], J. Mark VanNess[1], Paul D. Vosti[2], Courtney D. Jensen[1]. [1]*University of the Pacific, Stockton, CA.* [2]*St. Joseph's Hospital, Stockton, CA.*
(No relevant relationships reported)

When adults initiate an exercise prescription, approximately 51% do so with a declared goal of weight loss. Decreasing adiposity correlates with disease risk reduction and, in some sport contexts, improved performance. However, exercise adherence is typically poor; within 6 months of engagement, expected attrition exceeds 50%. Those who fail to sustain the practice commonly report being discouraged by a lack of progress. Thus, it is important to identify and understand the variables that influence the rate of fat loss at the onset of an exercise program. **PURPOSE**: To evaluate predictors of body composition improvement among diverse exercising populations. **METHODS:** We enrolled subjects from two distinct populations: older diabetic patients with no history of exercise (n=67) and college-aged rugby athletes (n=12). Each population underwent baseline testing to assess body fat percent (BF%) prior to and following a period of exercise. The diabetic population performed structured, supervised exercise for 10 weeks; the athletic population performed unsupervised, unstructured exercise for 4 weeks. Multiple linear regression analyses, holding other explanatory variables constant, tested predictors of BF% change. **RESULTS:** At baseline, the diabetic patients were 68.3 ± 10.7 years of age, had a body mass index (BMI) of 32.3 ± 6.7 kg/m², and 39.3 ± 6.9% body fat. The rugby athletes were 19.6 ± 2.0 years of age, had a BMI of 25.2 ± 2.8 kg/m², and 13.4 ± 4.3% body fat. Among diabetic patients, controlling for potential confounders, each additional point of baseline BF% predicted a 0.18-point reduction in BF% at post-test (p=0.010; 95% CI: -0.32 to -0.05); the overall model was significant (R²=0.395; p=0.002). Among rugby athletes, controlling for potential confounders, each additional point of baseline BF% predicted a 0.33-point reduction in post-test BF% (p=0.042; 95% CI: -0.65 to -0.02). **CONCLUSION:** Among exercising diabetic and athletic populations, higher baseline BF% corresponded to greater improvements in body composition throughout the exercise intervention. Among athletic populations, this may mean more rapid improvements in sport performance; for diabetic populations, this may lead to greater improvements in glycemic control.

Blood Flow RestrictionTraining and Functional Improvements in a Single Subject with Parkinson Disease

Peter C. Douris, Joanne Donoghue. *New York Institute of Technology, Old Westbury, NY.* (Sponsor: Gordon Schmidt, FACSM)
(No relevant relationships reported)

Blood flow restriction (BFR) applied with pressure cuffs to an active muscle, during low intensity exercise, produces muscle hypertrophy and strength gains equivalent to traditional high intensity resistance training. Previous research has shown the positive effects of BFR during gait training on younger and older adults. However, the effectiveness of BFR on subjects with Parkinson Disease (PD) and Restless Leg Syndrome (RLS) has not been investigated.**PURPOSE**:The purpose of this study was to determine the effects of BFR on a subject with PD in regards to functional improvements and safety.
METHODS: A single subject, B-A design was used. The subject was a 65 year old male diagnosed with PD and RLS for 7 years. Baseline data were measured on day one. The intervention (Phase B) consisted of 5, 2-minute bouts of exercise with lower extremity BFR cuffs interspersed with 1 minute rest, 3 times a week for 6 weeks, at 0 grade incline, and speed of 50 meters/min. The pressure increased from the initial 120 mmHg to 160 mmHg at the end of the phase B as per the subject's tolerance. A 4 week baseline phase (A) without the BFR intervention followed phase B. **RESULTS**: The outcome measures which were measured every 2 weeks over the 10 weeks included: Timed Up and Go Test (TUG), 6-Minute Walk Test (6MWT), 30-Second Chair Stand Test (30-sCST) and the Restless Leg Syndrome Questionnaire (RLS).The subject's TUG, 6MWT, 30-sCST scores steadily improved every 2 weeks during the 6 week intervention phase and steadily declined when the intervention was removed during the second 4 week baseline phase according to visual inspection of the graphed data points. The patient's RLS also improved during the intervention phase and steadily worsened again during the second baseline phase.

CONCLUSIONS: The subject enjoyed and tolerated the intervention well without any adverse effects. The results of this single subject design were that BFR training can produce significant functional improvements, reduce restless leg syndrome symptoms and can be safely utilized with a patient with PD.

A Knowledge Based Intervention on Health and Physical Activity Knowledge and Behavior in Hispanic College Students

Ulku S. Karabulut[1], Zasha Romero[2], Paloma Mendoza[1], Ricardo Parra[1], Murat Karabulut[1]. [1]UTRGV, Brownsville, TX. [2]UTRGV, Edinburg, TX.
(No relevant relationships reported)

PURPOSE: To investigate the effects of an intervention on Hispanic college students' basic health, healthy eating, and physical activity (PA) related knowledge and behaviors.
METHODS: Fifty-two (52) Hispanic college students (age= 24.16 ± 3.54) volunteered to participate in the study. Each subject read and signed the consent form prior to any measurements to take place. Demographic and anthropometric data including age, race, gender, major, height, weight, resting heart rate (RHR), blood pressure (BP), body composition (BC), waist (WC) and hip circumference (HC) were collected. Subjects completed The Food and Drug Administration's (FDA) Health and Diet Survey (modified). They were randomly assigned to a control (CG) or an intervention (IG) group. IG received a pamphlet containing general health knowledge and guidelines about healthy eating and physical activity behaviors. After 4-5 weeks, both CG and IG visited the lab second time for post measurements. Godin's (2011) Leisure-Time Exercise Questionnaire was used to quantify pre/post PA.
RESULTS: There was a trend for group*time interaction for DBP (p=0.09). The IG experienced a greater decrease in DBP. Both groups experienced similar changes in knowledge on BMI (p<0.01), amount of PA (p<0.04), and RHR (p<0.04) with time. A trend for group*time interaction was also reported on RHR (p=0.097). A significant interaction was found for students' knowledge on the effects of trans fatty acid on heart disease (p<0.02). The IG became significantly more knowledgeable compared to the CG. There was a time main effect (p<0.05) and group*time interaction (p<0.05) for the knowledge regarding the role of saturated fat on heart disease.
CONCLUSIONS: Findings of the study showed that many college students lack or have misconceptions about common health related knowledge. Findings also indicated that simple methods such as providing pamphlets may be effective enough to increase students' knowledge. Future studies should investigate the long-term effects of pamphlets and other simple educational strategies on retention of knowledge and behavioral change. In addition, since new technologies might be more appealing to young college students, the effectiveness of various new tech tools can also be used to increase the level of health related knowledge and behavioral changes.

The Moderating Effect of Baseline Depression and Age on the Efficacy of an Exercise Intervention on Preventing Postpartum Depression and Stress

Beth A. Lewis[1], Shira Dunsiger[2], Katie Schuver[1], Joe Ciccolo[3], Carrie Terrell[1], Melissa Avery[1]. [1]University of Minnesota, Minneapolis, MN. [2]Brown University & The Miriam Hospital, Providence, RI. [3]Columbia University, New York, NY.
(No relevant relationships reported)

PURPOSE: Support for the efficacy of exercise interventions on preventing postpartum depression is mixed. Therefore, it is important to examine potential moderating variables. The purpose of this study was to examine the moderating effect of age and baseline depressive symptoms on the effect of exercise on preventing postpartum depression and stress. **METHODS:** Participants were low active participants (n=450; average age = 30.7 years) who had a history of depression and participated in a trial examining the efficacy of exercise on preventing postpartum depression and stress (variables assessed at 6 and 9 months). Participants were randomly assigned to: 1) 6-month telephone-based exercise intervention (2) 6-month telephone-based wellness/support intervention or (3) usual care. **RESULTS:** Most participants were married (75%), had at least some college (93%), and were Caucasian (73%). There were between-group differences in baseline age (p=.01) and depressive symptoms (p=.03), so these variables were included as covariates in the models. Using generalized estimating equations (for binary depression outcome) and quantile regression (for depressive symptoms and perceived stress) we explored potential moderators of the association between exercise and outcomes (treatment assignment was controlled). Among older participants (based on a median of 30.5 years), greater exercise was associated with lower median stress at 9 months controlling for baseline (b=-4.74, SE=1.69, p=.005). Effects were not significant among younger participants. Among younger participants, lower exercise was associated with greater odds of depression at 6 months (OR=7.87, 95% CI:1.35-15.69). Finally, among those with higher depressive symptoms at baseline, exercise was significantly associated with

reductions in stress at 9 months (b=-4.00, SE=1.55, p=.01) and depression at 6 months (OR=3.41, 95% CI: 1.00-13.54). Among those with lower depressive symptoms at baseline, exercise was associated with greater reductions in depressive symptoms at 6 months (b=-1.13, SE=.57, p=.05). **CONCLUSIONS:** Low exercise levels appears to be a risk factor for depression among young postpartum women. Regarding stress, unlike older postpartum women, younger postpartum women may need strategies in addition to exercise for preventing stress.

The Acute Effect of a Single Yoga Lesson on Mood and Stress among College Students

Zhonghui HE[1], Xin Qi[1], Jiajin Tong[1], Senlin Chen[2], Shuchang He[1]. [1]Peking University, Beijing, China. [2]Louisiana State University, Baton Rouge, LA.
(No relevant relationships reported)

PURPOSE: Yoga is an exercise mode that has gained popularity across the world over the years due to its physical and mental benefits (e.g., flexibility, relaxation, calmness). This study examined the acute effect of one yoga lesson on college students' mood (both positive mood and negative mood) and cortisol level.**METHODS**:The study took place in a prestigious university in Beijing, China. The sample consisted of 192 students (Mean age = 19.76) enrolled in two types of physical activity courses offered at the university: yoga class (n = 98) or health-related fitness class (control group: n = 94). Both courses were 90 minutes long and taught by experienced physical education teachers following two separate lesson plans. The Chinese version of the Positive and Negative Affect Schedule Scale (PANAS; Watson, Clark, & Tellegen, 1988) was used to measure positive (e.g., mindfulness, resilience, self-esteem) and negative mood (e.g., self-criticism, self-correction). Saliva was collected to determine cortisol level which measures stress. The two measures were administered to students in both groups before and then after taking the physical activity classes. Multivariate analysis of variance was conducted to determine the time (pre- vs post-test), group (yoga vs fitness groups), and time x group interaction effects for mood and stress. **RESULTS**:The results demonstrated that students in both groups showed increase in positive mood (mindfulness, resilience, and self-esteem) and decrease in negative mood (self-criticism, self-correction) as a result of taking the respective physical activity lessons. However, compared to those in the fitness group, students in the yoga group showed significantly greater increase in mindfulness (yoga group: $\Delta M = .64$; fitness group: $\Delta M = .31$; $F_{1,190} = 4.08$, $p < .05$) and greater decrease in stress (yoga group: $\Delta M = -.70$; fitness group: $\Delta M = -.35$; $F_{1,190} = 5.96$, $p = .02$).**CONCLUSIONS**:This study confirmed the positive effect of physical activity classes on mood and stress. Furthermore, compared to the fitness lesson, the yoga lesson demonstrated greater effect on mindfulness and stress. This set of findings are meaningful to college students' mental health. Taking one single physical activity lesson, especially yoga, can help students be mindful of behaviors and manage stress.

Effects Of A 12-week Structured Exercise Intervention On Cholesterol

Brett Staniland[1], Jorge Lopez-Fernandez[1], Isabel Sanchez[2], Tamara Iturriaga[2], Maria Ayuso[2], Elizabeth Horton[1], Lou Atkinson[3], Steve Mann[4], Gary Liguori, FACSM[5], Alfonso Jimenez[1]. [1]Coventry University, Coventry, United Kingdom. [2]GOFit Lab, Madrid, Spain. [3]Aston University, Birmingham, United Kingdom. [4]ukactive Research Institute, London, United Kingdom. [5]University of Rhode Island, Kingston, RI.
(No relevant relationships reported)

Intro: The total cholesterol profile includes high and low-density lipoprotein, both of which contribute to cardiovascular disease (CVD) risk. This direct relationship between dyslipidaemia and CVD can be modified by increasing physical activity (PA), and a reduction in total cholesterol of 10.0 mg/dL has shown to reduce incidence of heart disease by up to 54% in adults. **PURPOSE:** Compare a structured exercise programme to usual exercise for the effects on total cholesterol in healthy, sedentary adults.
METHODS: Members (54 males, age 43.3±8.5 y. and 20 females, age 42.9±7.6 y.) of GOFit gym, Vallehermoso, Madrid, who had been absent for at least 60 days, were recruited and randomly grouped as control [CON=20], free gym use [FREE=20], and combined structured exercise [COMB=34], for a 12-week intervention. All participants were categorized as "at risk" according to ACSM Risk Stratification Screening Questionnaire. CON were instructed to continue usual at-home habits; FREE were given free roam of the gym and exercised 2-3 days/week; COMB completed a programme of aerobic exercise, resistance training and flexibility training 2-3 days/ week and also wore a physical activity tracking device. Cholesterol was obtained via the Accutrend Plus, and levels were compared pre and post intervention.
RESULTS: Twenty one participants (28%) completed the study, (CON=6, FREE=6, COMB=9). Paired t-tests showed a significant decrease in total cholesterol for all groups; CON: -8.5 mg/dL (pre=208.5±13.11, post=200±19.4, *p*=0.048), FREE:

-27.2 mg/dL (pre=207.5±32.86, post=180.3±23.29, p=0.027), COMB: -21.7 mg/dL (pre=219.8±33.84, post=198.1±25.85mg/dL, p=0.018). ANOVA showed no significant difference between exercise groups post intervention (p=0.680), although the COMB group showed the largest absolute improvement in cholesterol.

CONCLUSIONS: Programmes of aerobic exercise, resistance and flexibility training for 12-weeks are effective in improving cholesterol levels in healthy, sedentary adults. The exercise intervention used here was shown to be effective, but no better than other exercise options or controls. A larger sample should be used in future research to indicated if combined, structured exercise is more effective at lowering cholesterol levels.

281　Board #122　May 30 9:30 AM - 11:00 AM

The Influence Of Non-exercise Physical Activity During Aerobic Exercise On Cardiometabolic Risk Factors

Damon L. Swift[1], Joshua E. McGee[1], Savanna G. Barefoot[1], Patricia Brophy[1], Chesley A. Solar[1], Joseph A. Houmard, FACSM[1], Lesley D. Lutes[2]. [1]East Carolina University, Greenville, NC. [2]University of British Columbia, Kelowna, BC, Canada.

(No relevant relationships reported)

PURPOSE: To determine the impact of changes in non-exercise physical activity on changes in cardiometabolic risk factors in participants performing aerobic exercise training.

METHODS: Obese adults (N=25) were randomized to an aerobic training group or an aerobic training and increasing non-exercise physical activity group. Both groups performed supervised aerobic training (50%-75% VO$_2$ max) for 24 weeks at a dose of 12 kcals per kg per week. Non-exercise physical activity (total steps, minutes in low, moderate to vigorous [MVPA] physical activity) was quantified during the entire intervention using Fitbit One accelerometers (removed during supervised exercise sessions). Cardiometabolic assessments included lipids, glucose, insulin, 2-hour glucose/insulin from an oral glucose tolerance test, fitness, and body composition measures (% body fat, weight, and waist circumference). Linear regression models were run with change in the cardiometabolic variable as the dependent variable and baseline value, age, race, sex, supervised exercise time, adherence to exercise dose, change in non-exercise physical activity variables (change in total steps, minutes in light intensity and minutes in MVPA) as predictor variables.

RESULTS: Change in total steps was a significant predictor for change in weight (r^2= 0.17, p=0.04), percent weight loss (r^2= 0.18, p=0.03), waist circumference (r^2=0.31, p=0.004), triglycerides (r^2= 0.30, p=0.01) and relative fitness (r^2= 0.19, p=0.03). Change in total steps approached significance as a predictor for absolute fitness (p=0.052) and body fat (p=0.059). Change in minutes in low intensity was a significant predictor of the change in 2-hour glucose (r^2= 0.20, p=0.03). Change in MVPA was not associated with change in any cardiometabolic variables (all ps>0.05). Change in non-exercise physical activity did not predict changes in glucose, insulin, 2-hour insulin, low density lipoprotein, high density lipoprotein, total cholesterol, or lean mass levels (all ps>0.05).

CONCLUSIONS: Change in non-exercise physical activity outside of aerobic training was associated with changes in several cardiometabolic variables. Increasing total steps or minutes in low intensity may represent a clinical target to maximize the health benefits of aerobic exercise training in obese adults.

282　Board #123　May 30 9:30 AM - 11:00 AM

Video Conferencing Based Health Coaching is Effective for Inducing Weight Loss and Improving Metabolic Markers

Kelly E. Johnson[1], Michelle K. Alencar[2], Kathryn E. Coakley[3], Damon L. Swift[4], Christine M. Mermier[3], Len Kravitz[3], Fabiano T. Amorim[3], Ann L. Gibson, FACSM[3]. [1]University of Saint Mary, Leavenworth, KS. [2]California State University Long Beach, Long Beach, CA. [3]University of New Mexico, Albuquerque, NM. [4]East Carolina University, Greenville, NC. (Sponsor: Ann Gibson, FACSM)

(No relevant relationships reported)

Most health coaching (HC) interventions have been delivered through telephone, web-based chatting, or face-to-face instruction. Despite the potentially positive impact of group-based HC by video conferencing (VC) on weight loss and metabolic health, individualized VC sessions have not been studied. **PURPOSE:** To assess changes in physical activity, body mass, metabolic markers (fasting blood, insulin, glucose, hemoglobin A1c [HbA1c], and HOMA-IR), in obese adults. **METHODS:** Thirty adults (body mass index [BMI] ≥30 kg/m²) were randomly assigned to three groups video conferencing group (VC), in person (IP) group, or a control group (CG), n=10 per group). Participants received a wireless body weight scale and step-tracking accelerometer watch (Withings, Inc., Cambridge, MA, USA) to synch with their personal smartphones and apps. Participants assigned to VC and IP groups received weekly HC individualized based on data uploaded over the 12-week intervention.

Steps/day and body weight loss were analyzed via analyses of covariance (ANCOVA). Between-group ANOVAs analyzed pre-and post-intervention changes in weight (kg), blood glucose, insulin, HbA1c, and HOMA-IR. **RESULTS:** Mean weight loss and percent weight loss (%) was greater (*p*≤.05) for VC (8.23±4.5kg; 7.7%) than IP (3.4±2.6kg; 3.4%) and CG (2.9±3.9kg; 3.3%) respectively. Steps/day were significantly higher in VC than IP at week 4 only and VC was significantly higher than CG at weeks 6, 8, 9, and 11 (*p*≤.05). No within- or between-group differences were found for glucose, insulin, or HbA1C. HOMA-IR decreased for VC only (*p*≤.05).No between-group differences were found for any metabolic markers. However, there was a within-group decrease for HOMA-IR (p≤.05) for VC. **CONCLUSION**: Our innovative, multidisciplinary, telemedicine health coaching delivered through VC led to more favorable changes in weight loss, physical activity (steps/day), and HOMA-IR than in-person or no health coaching. VC may be an economical approach to improve health and promote behavior change in obese adults. Future studies using VC health coaching in group and individualized formats, and for other population subgroups, are needed to investigate impacts of weight loss on other health outcomes. Supported by NIH Grant 8UL1GM118979-02.

283　Board #124　May 30 9:30 AM - 11:00 AM

Effects Of Accumulated Short-bout Exercise On Obesity Index: A Meta-analysis

Heontae Kim[1], Joel Reece[2], Minsoo Kang, FACSM[3]. [1]Middle Tennessee State University, Murfreesboro, TN. [2]Brigham Young University–Hawaii, Laie, HI. [3]The University of Mississippi, University, MS.

(No relevant relationships reported)

Recent exercise guidelines allow individuals to perform accumulated short-bout exercise throughout the day rather than a continuous long-bout of activity. The guidelines may make it easier for individuals to comply with recommended amounts of physical activity. However, the effect of accumulated short-bout exercise on reducing the obesity index is uncertain. **PURPOSE:** To determine the effect of accumulated short-bout exercise on the obesity index. **METHODS:** A systematic literature search (key terms: short-bout, accumulated, exercise, obesity) was conducted of electronic databases (PubMed, PsycINFO, CINAHL, Cochran Library) to identify relevant studies. Studies were included if they met the following criteria: (1) at least one group had short-bout exercise intervention; and (2) obesity index [e.g., Body Mass Index (BMI), waist circumference (WC), body fat percentage, etc.] was measured at pre- and post-intervention. The mean and standard deviation of obesity index change scores (the difference between pre- and post-intervention) were extracted to calculate effect sizes (ESs). A random effects model was used to provide an overall ES and 95% confidence interval (CI). Moderator analyses were conducted to evaluate the effects of exercise days/week (e.g., < 5 times, ≥ 5 times), total exercise mins/week [e.g., < 150 mins/w, ≥ 150 mins/w, 100 to 200 mins/w (incremental increase)], and intervention length (e.g., ≤ 10 wks, 11 to 20 wks, > 20 wks) on overall ES. Heterogeneity was evaluated using Cochran's Q statistic. ES calculation and moderator analyses were conducted using Comprehensive Meta Analysis (Version 2.2).**RESULTS:** The searches yielded 2,535 articles. After initial screening of titles and abstracts, 159 potentially relevant studies were reviewed in full, 17 studies were included, and 51 ESs were calculated. Overall mean ES was significant [ES = 0.47 (near medium), CI = 0.34, 0.59]. Moderator analyses indicated that the mean ES was influenced by the three moderator variables: exercise days/week, $Q_{between}$ (Q_b) = 4.54, df = 1, *p* = .033; total exercise mins/week, Q_b = 9.61, df = 2, *p* = .008; intervention length, Q_b = 7.662, df = 2, *p* = .022. **CONCLUSION:** In this meta-analysis, there is sufficient evidence to conclude the accumulated short-bout exercise is effective in reducing obesity index among adults.

A Weekly Structured Physical Activity Program Enhances Short-term Retention Of Middle-aged Adult Fitness Centre Users

Jorge Lopez-Fernandez[1], Brett Staniland[1], Isabel Sanchez[2], Tamara Iturriaga[2], Maria Ayuso[2], Elizabeth Horton[1], Steven Mann[3], Gary Liguori, FACSM[4], Lou Atkinson[5], Alfonso Jimenez[1]. [1]Coventry University, Coventry, United Kingdom. [2]GO fit LAB, Madrid, Spain. [3]ukactive Research Institute, London, United Kingdom. [4]University of Rhode Island, Kingston, RI. [5]Aston University, Birmingham, United Kingdom.

(No relevant relationships reported)

A weekly structured physical activity program enhances short-term retention of middle-aged adult fitness centre users

Lopez-Fernandez, J., Staniland, B., Sanchez, I., Iturriaga, T., Ayuso, M., Horton, E., Mann, S., Liguori, G., Atkinson, L., Jimenez, A.

Fitness centres can play a key role in addressing physical inactivity, yet several studies reveal low retention rate in fitness centres. Few centres, however, use a structured approach by providing a weekly physical activity (PA) program meeting ACSM guidelines.

WEDNESDAY, MAY 30, 2018

Purpose: To assess attendance and retention rates in inactive middle-aged adults of a fitness centre between a traditional PA plan and a structured PA program meeting ACSM guidelines.

Methodology: Eighty inactive middle-aged adults (44.32 ± 6.99 years; 77.89 ± 19.22 kg; 158.75 ± 36.08 cm) from a Spanish fitness centre voluntarily enrolled in this study. Participants were randomly assigned to two groups (Free Exercise [FE = 40]; Structured Program [SP = 40]) and proved to be inactive through IPAQ short version. Participants completed baseline measures including body composition, VO2 max, cholesterol, triglycerides, blood glucose, flexibility, and muscular strength. During the ensuing 12 weeks, weekly attendance of both the FE and SP groups were tracked, with both groups initially agreeing to exercise 2-3 days per week for at least 20 sessions. FE group was introduced to trainers of the fitness centre and informed of group exercise sessions available. SP group received a structured program based on ACSM guidelines for PA.

Results:
No baseline differences (p>0.05) existed between groups for age, body composition, VO2 max, haematocrit, flexibility, and muscular strength. A total of 13 participants (16%) never attend the initial assessment, and only 20 members (25%) attended 20 days or more (FE=5 [12.5%]; SP=15 [37.5%]). Members of SP group attended more total days (15.73 ± 8.19) than FE group (7.79 ± 8.62) during the 12 weeks (+7.93 days; p<0.001; ES = 0.945; IC: 3.83 – 12.04).

Conclusion: Inactive adults receiving a structured PA program attended more days compared to those enjoying 'free' exercise, however, overall retention rate was still low for all participants. This pilot data shows the potential benefit of fitness centres providing structured daily programs to enhance retention.

Exercise Training in 'at Risk' Black and White Women: A Comparative Cohort Analysis

Megan Bowdon, Pamela Marcovitz, Susanna K. Jain, Judith Boura, Kaitlin Liroff, Barry Franklin, FACSM. *Beaumont Health, Royal Oak, MI.* (Sponsor: Barry Franklin, PhD, FACSM)
(No relevant relationships reported)

PURPOSE: Although African Americans are more likely to die of a myocardial infarction than any other racial group, few data are available regarding the impact of exercise interventions in 'at risk' black women as compared with their white counterparts. **METHODS**: Women ≥18 years without known cardiovascular disease with ≥1 coronary risk factor were enrolled in a community-based exercise program ≥3 days per/week for ≥30 min/session for 6 months. Exercise training intensity ~50–80% of functional capacity, using estimated heart rate (HR) and/or rating of perceived exertion (RPE) as the primary intensity modulators. Pre-versus post conditioning quality of life (QOL) assessments (depression [PHQ-9] and level of daytime sleepiness), dietary fat intake, Duke Activity Status Index (DASI score), changes in cardiovascular efficiency (systolic/diastolic blood pressure [SBP/DBP], HR, RPE during a standardized submaximal workload), and anthropometric measures, including body weight, body mass index (BMI), and waist circumference, were evaluated. **RESULTS**: Of 556 volunteers, 143 were excluded, leaving 413 women (222 white, 191 black; mean $\pm$ SD age = 61 ± 9) who met compliance criteria. Both groups demonstrated significant ($P <0.05$) post-conditioning decreases in BMI, waist circumference, resting SBP/DBP, total and low density lipoprotein cholesterol, reductions in HR, SBP/DBP, and RPE at a fixed submaximal workload, and in fat screener, depression, and sleep scores. DASI scores increased significantly ($P <0.0001$) for both groups, signifying increases in self-reported functional capacity. Women presenting with mild-to-moderate depression symptoms (n = 108) demonstrated the greatest decrease in PHQ-9 scores, averaging 8.9 and 3.5 at baseline and follow-up, respectively. Although 87 women (21%) experienced a musculoskeletal injury during the program, there were no exercise-related cardiovascular events. **CONCLUSION**: A progressive moderate-to-vigorous exercise intervention without preliminary exercise testing elicited comparable improvements in risk factors, anthropometric and QOL measures, and cardiovascular efficiency in 'at risk' black and white women. These adaptations were achieved at exercise levels *below* those recommended by contemporary Physical Activity Guidelines.

Association Between Stage Of Behavior Change With Cardiovascular Risk, Perception Of Health And Quality Of Life Among Professionals From Health Institutions

Amauri dos Santos, João Pedro da Silva Júnior, Victor Keihan Rodrigues Matsudo. *CELAFISCS, Sao Paulo, Brazil.*
(No relevant relationships reported)

Purpose: To analyze the factors associated to the stage of behavior change among professionals from health institutions. Methods: The sample consisted of 1036 professionals (241 male and 794 female). The dependent variable was the irregularly active group of the behavioral stage questionnaire (proposed by Prochaska, 1988). The independent variables were: gender, age, BMI, waist circumference, presence

of diseases, health perception and quality of life. Statistical analysis: Binary Logistic Regression (Odds Ratio (OR) and its respective 95% CI confidence intervals) were used to associate the study variables. Results: The factors associated with irregularly active behavior change were: gender, BMI, circumference of the abdomen, presence of disease, health perception and quality of life. On the other hand, age not associated with the stage of irregularly active behavior change, see table below. Conclusion: The irregularly active group presented a greater chance of being obese, having a cardiovascular risk, a negative health perception and a poorer quality of life.

Factors associated with irregularly active stages of behavior change (Pre-Contemplative, Contemplative, Preparation)			
Variable	Significant	OR	IC 95%
Sex			
Female		1	
Male	< .38	.73	(.51-.98)
Age (years)			
(15-24)		1	
(25-39)	.87	.87	(.50-1.79)
(40-59)	.66	.66	(.64-2.00)
(> 60)	.70	.72	(.58-.19)

Experimental Investigation of Exercise-Related, Perceived Hedonic Responses to Preferred Versus Imposed Media Content

Emily Frith, Paul D. Loprinzi, 38655. *University of Mississippi, Oxford, MS.*
(No relevant relationships reported)

PURPOSE: We evaluated the differential influence of preferred versus imposed media selections on distinct hedonic responses to an acute bout of treadmill walking, which has yet to be investigated in the literature. **METHODS**: Twenty university students were recruited for this [160 person-visit] laboratory experiment, which employed a within-subject, counter-balanced design. Participants were exposed to eight experimental conditions, including 1) Exercise Only, 2) Texting Only, 3) Preferred Phone Call, 4) Imposed Phone Call, 5) Preferred Music Playlist 6) Imposed Music Playlist, 7) Preferred Video and 8) Imposed Video. During each visit (except Texting Only), participants completed a 10-minute bout of walking on the treadmill at a self-selected pace. Walking speed was identical for all experimental conditions. Before, at the midpoint of exercise, and post-exercise, participants completed the Feeling Scale (FS) and the Felt Arousal Scale (FAS) to measure acute hedonic responses. The Affective Circumplex Scale was administered pre-exercise and post-exercise. **RESULTS**: Statistically significant pre-post enhanced valence scores were observed for happy (Imposed Call: P=0.05; Preferred Music: P=0.02; Imposed Video: P=0.03), excited (Exercise Only: P=0.001; Preferred Video: P=0.01; Imposed Video: P=0.03), sad (Preferred Music: P=0.05), anxious (Exercise Only: P=0.05; Preferred Video: P=0.01), and fatigue (Exercise Only: P=0.03; Imposed Video: P=0.002). For the FS all change scores statistically significantly increased from pre-to-mid and pre-to-post (p<.05). **CONCLUSIONS**: This experiment provides strong evidence that entertaining media platforms substantively influence acute hedonic responses to exercise. Future work should explore social media strategies to promote long-term exercise adherence.

The Glutathione Redox Status And Total Antioxidant Responses To Supervised Physical Exercises In Metabolic Syndrome

Roberto C. Burini, FACSM, Fernando Moreto, Hugo T. Kano, Okesley Teixeira, Camila R. Correa. *Sao Paulo State University (UNESP) - Botucatu Medical School, Botucatu, Brazil.*
(No relevant relationships reported)

PURPOSE: The major components of Metabolic Syndrome(MetS) are often associated with inflammation, decreased insulin sensitivity and impaired endothelial function, suggesting failure in the anti-oxidant defenses.
OBJECTIVE: To investigate the lipoperoxidation(MDA) , total antioxidant performance(TAP), and glutathione-redox state in MetS patients under a lifestyle-modification program(LiSM).
METHODS: From the 112 subjects participating in the ongoing longitudinal project "Move for Health" (2009-2012) 57 attended the 20wk LiSM with nutritional counseling and combined aerobic (3 times/wk) and resistance (2 times/wk) exercises. They all had anthropometric, clinical, dietary quality(HEI), cardiorespiratory fitness (CRF) and plasma-biochemistry data. Plasma hydrophilic TAP was measured by an antioxidant assay. Plasma malondialdehyde (MDA), total and oxidized (GSSG) glutathione were measured by HPLC. Reduced (GSH) glutathione was estimated. Statistical Analysis Software (SAS version 9.1.3, SAS Institute, USA) was used for $p<0.05$ significance.
RESULTS: The sample was predominantly composed by females (72%), under 65 yrs old (55±8 yrs), 65% obese, 59% taking medications and 33% smoking. Primary outcomes after LiSM were the decreasing of MetS by 33% (27% to 18%), BMI, WC and body fat and the increasing of HEI, CRF, HDL-C, GSH and plasma TAP. However, only subjects without MetS increased HDL-c, TAP and GSH and decreased GSSG/GSH ratio. After LiSM, subjects TAP–responsive (≥3%) differed from the non-responsive (≤3%) by presenting increased values of CRF, HDL-c and uric acid and decreased SBP. Additionally, The TAP-responsive group increased GSH and decreased GSSG as well as the GSSG/GSH ratio. In the presence of MetS the TAP responsiveness to LiSM was associated with decreasing WC, glucose and MDA whereas, in the absence of MetS, the TAP responsiveness to LiSM was positively influenced by the increased HDL-c and GSH. The multiple-adjusted regression analysis showed GSH as influencing factor for plasma TAP changes, in the presence and absence of MetS. However, only the decreased GSSG discriminated the non-MetS subjects.
CONCLUSION: LiSM decreased MetS and increased TAP and GSH however, only GSSG discriminated MetS in a 20-wk LiSM intervention.

The Wearable Technological Device as a Means of Physical Activity Monitoring

Alissa Underhill. *Olivet Nazarene University, Bourbonnais, IL.*
(No relevant relationships reported)

PURPOSE: To assess the use of a wearable technological device for the increase in attainment of physical activity (PA) with the goal of preventing Type II Diabetes Mellitus (T2DM) through weight loss. The Fitbit offers an advantage to other activity trackers when used for study purposes, in that it can provide continuous measurement of PA across the entire study period.
METHODS: Men and women over the age of 40, and at risk for prediabetes, were recruited. The study period was four months in length, with an initial four weeks of baseline PA testing, followed by 12 weeks of lifestyle intervention. Individualized PA goals were set. PA monitoring was very successful. Participants averaged 72 days of PA tracking with 46% of participants reaching the maximal number of days (77). The Fitbit Flex measures steps, minutes sedentary, minutes lightly active, minutes fairly active, minutes very active, and total active minutes.
RESULTS: Participants (N = 13) were aged 65.03 (SD = 8.3) years. At baseline, participants were performing 220.8 (SD = 249.0) minutes per week of moderate intensity PA. Participants increased moderate intensity PA to 243.3 (SD = 198.8) minutes per week. At baseline, participants were accumulating 7511.6 steps/day (SD = 3271.2) increasing to 8177.6 steps/day (SD = 3078.9) taken during the three month intervention. No statistical significance was found. A Pearson CC (0.598) showed there was a positive trend with minutes of moderate-to-vigorous activity and weight loss. 36% of the variants of weight loss was influenced by minutes of PA. Compliance to wearing the Fitbit was very good with 93.1% of the weeks having data tracked for at least ≥ 6 days/week. Wear time was corroborated by Fitbit data, which showed of the 1415 tracked days, only 9.3% days recorded were of less than 2000 steps. Barriers to technology were low and 100% of participants strongly agreed that continuous monitoring of weight and PA encouraged them to make healthy lifestyle changes.
CONCLUSIONS: Of particular importance was that 46% of participants initially self-reported that they were physically active for more than 150 minutes per week, which shows many people underestimate their actual PA. Continuous monitoring of PA through wearable technology can be a useful modality aiding in weight loss.

The Physiological Assessment and Analysis of the Physical Demand of Riding a Snowmobile

Tania J. Pereira. *University of Guelph, Guelph, ON, Canada.*
(Sponsor: Lawrence Spriet, FACSM)
(No relevant relationships reported)

Physical activity (PA) is widely regarded as an essential component for maintaining health, yet there are subsets of the population that remain insufficiently active. This issue can be exacerbated in the winter due to decreased daylight hours, high precipitation and low temperature, thus some individuals are less likely to engage in PA. In cold climates, snowmobiling is a popular recreational activity, and could offer a potential solution for increasing PA time to the recommended ACSM standards; predicated on the fact that it is an activity that is sufficiently intense to stimulate health benefit. PURPOSE: To measure the physical demands and activity patterns of a typical snowmobile ride in habitual snowmobile riders (n=44). METHODS: The physical demand of an average ride, and requisite tasks, were quantified using ambulatory oxygen consumption and pre/post strength and power assessments. Aerobic demand was compared to a graded exercise test (GXT) on a cycle ergometer to determine exercise intensity. RESULTS: A "representative" ride (30 ±17 min) involved a mean aerobic demand of 17.5 ± 6.6 ml/kg/min or 49 ± 20 % of VO₂max (5 METS), which compares to traditional forms of physical activity. During the ride, the VO₂ values ranged from a mean minimum of 7.1 ± 3.0 ml/kg/min to a mean maximum of 32.5 ± 12.4 ml/kg/min. Muscular strength decreased 6% for maximal hand grip (p<0.001) and a similar magnitude for vertical jump, but the latter change was not significant. This immediate decrement in strength demonstrates snowmobiling to be an activity that requires significant upper body work. The mean VO₂ while specifically freeing a stuck snowmobile was 27± 9.7 ml/kg/min (7-8 METS), indicating that riders were working at 77 ± 28% of their VO₂max. CONCLUSIONS: Snowmobiling is an activity which falls into the moderate to vigorous intensity activity range that is typically associated with health benefits. A typical ride involves both aerobically based and muscular strength components as shown by a moderately demanding riding VO₂ and strength decrements Based on the observed values, snowmobiling is of a sufficient PA intensity to stimulate changes in health and fitness. Funding support from Mitacs and The Canadian Council of Snowmobile Organizations.

Randomized Trial Of Amino Acid Mixture Combined With Physical Activity Promotion In Overweight Adults

Keisuke Ueda[1], Hiroyuki Sasai[2], Takehiko Tsujimoto[3], Chiaki Sanbongi[1], Shuji Ikegami[1], Hiroyuki Kobayashi[4], Yoshio Nakata[4]. *[1]Meiji Co., Ltd., Odawara, Japan. [2]The University of Tokyo, Meguro, Japan. [3]Shimane University, Matsue, Japan. [4]University of Tsukuba, Tsukuba, Japan.*
Reported Relationships: K. Ueda: Salary; Meiji Co., Ltd..

PURPOSE: The purpose of this study was to test the efficacy of arginine, alanine, and phenylalanine mixture (A-mix) ingestion at 1,500 mg/day in combination with the promotion of physical activity for abdominal fat reduction in overweight adults. METHODS: A placebo-controlled, double-blind, parallel-group, randomized trial for 12 weeks combined with a 4-week follow-up period was conducted at a single center in Minato-ku, Tokyo, Japan, between December 2016 and May 2017. The data were examined between June and August 2017. The study participants were 200 overweight adults within the age of 20-64 years old. The participants were randomly assigned to the A-mix or a placebo group, and were administered 500-mL test beverage containing 1,500 mg or 0 mg of A-mix, respectively, for 12 weeks. All participants endeavored to maintain a physically active lifestyle between week 0 and week 12 through monthly sessions of physical activity. The primary endpoints were the 12-week changes in the abdominal total, subcutaneous, and visceral fat areas, as assessed by computed tomography. RESULTS: Of the 200 enrolled participants, 199 (99%) accomplished the 12-week intervention and 4-week follow-up period. The per-protocol-based analysis for 194 participants demonstrated that the abdominal total fat area decreased significantly in the A-mix group compared with that of the placebo group (difference, 10.0 cm²; 95% confidence interval, 0.4-19.6 cm²; $P = 0.041$). Comparable outcomes were acquired for the abdominal subcutaneous fat area (difference, 7.4 cm²; 95% confidence interval, 0.1-14.7 cm²; $P = 0.047$). No study-related unfavorable events occurred. CONCLUSIONS: A-mix supplementation in combination with physical activity promotion facilitated abdominal fat reduction in overweight adults. This trial was based on a collaborative research agreement between the University of Tsukuba Faculty of Medicine and Meiji Co., Ltd. K.U., C.S., and S.I. are employees of Meiji Co., Ltd.

Validity Of Adhesive Worn Actigraph GT3X+ Accelerrometer

AnnaMagee Morris, Roxanna Lopez, Eleanor Stevenback, Ketherine H. Ingram, Ph.D.. *Kennesaw State University, Kennesaw, GA.*

(No relevant relationships reported)

PURPOSE: The ActiGraph GT3x+ activity monitor (ActiGraph, Pensacola, FL) is typically worn with a belt around the waist, ankle, or wrist. Due to low compliance and observations of discomfort with belt-worn accelerometers, this study examines the validity of wearing the ActiGraph directly on the hip using an adhesive patch.
METHODS: Eleven participants (Age: 22 ± 1, BMI: 24.2 ± 4.2) wore two ActiGraphs for four days; one on a waist belt and the other attached using a Tegaderm-Film adhesive (3M Medical, Maplewood, MN). Data gathered from accelerometers were uploaded to the ActiLife software. Wear-time of both devices was validated with participants' daily activity logs. Tri-axial motion data were then analyzed using a paired samples t-test.
RESULTS: Strong correlations were found on motion axes 1,2, and 3 (r= 0.946, 0.955, and 0.905, respectively, p <.001 for all).
CONCLUSIONS: When using ActiGraph GT3x+ accelerometer, adhesive worn devices may be a valid alternative to traditional belt-worn devices.

Changes in Perceived Importance of Physical Activity and Nutrition for Health Following (S)Partners Intervention

Breanne R. Carlson[1], Rachel Greco, 49855[2], Erich J. Petushek[3], Karin A. Pfeiffer, FACSM[3], Joseph J. Carlson[3]. *[1]Michigan State University Extension, East Lansing, MI. [2]Northern Michigan University, Marquette, MI. [3]Michigan State University, East Lansing, MI.* (Sponsor: Karin Pfeiffer, FACSM)

(No relevant relationships reported)

Physical activity (PA) and nutrition are important components to prevent or reduce risk of cardiovascular disease (CVD) in youth. School-based programs designed to promote nutrition and PA behaviors have shown some success in improving these health behaviors and overall health status. A factor related to adopting nutrition and PA behaviors is an individual's perceived importance of the behavior on health. PURPOSE: To determine whether perceived importance of PA and nutrition improves better in 5th grade students participating in a multi-level school and web-based Nutrition and PA intervention versus students receiving lessons alone (active comparison). METHODS: Pre- and post-data were collected from 1060 students from 14 schools in Michigan, from 2008 - 2015 who participated in the (S)Partners intervention (n=810; 8 lessons, web modules, and college mentors); or an active comparison (n=250; 8 lessons only). Participants completed a self-report survey on perceived importance of PA and nutrition in relation to health (4 Point Likert scale). RESULTS: Repeated measures ANOVA results revealed that there were no between-group differences or interaction in perception of importance of both PA (Mean(SD): Spartners pre = 2.32(0.74) and post = 2.48(0.66) vs Active pre = 2.19(0.72) and post = 2.38(0.72)), and nutrition (Mean(SD): Spartners pre = 2.26(0.78) and post = 2.37(0.73) vs Active pre = 2.10(0.80) and post = 2.31(0.71)) in relation to health, however both groups increased over time in both measures (p <.001 for time). CONCLUSION: Both groups improved their perception of the importance of health benefits regarding PA and nutrition. Future analysis will be conducted on this data to determine how improvements in perception of the benefit of nutrition and PA behaviors contribute to adopting or maintaining nutrition and PA behaviors throughout life.

Weight Status Differences In Light-intensity Physical Activity Increases From A Workplace Behavioral Intervention

Kara L. Gavin[1], Jennifer A. Linde[2], Nancy E. Sherwood[2], Julian Wolfson[2], Matthew P. Buman, FACSM[3], Mark A. Pereira[2]. *[1]Northwestern University, Chicago, IL. [2]University of Minnesota, Minneapolis, MN. [3]Arizona State University, Phoenix, AZ.* (Sponsor: Matthew Buman, FACSM)

(No relevant relationships reported)

Purpose: Workplace intervention targeting reductions in sedentary time and increases in light-intensity physical activity (LPA) may be effective at increasing LPA, especially among overweight and obese individuals, who may find it challenging to achieve recommended levels of moderate-vigorous physical activity. This study examined increases in LPA following 3 months participation in a workplace-based intervention targeting changes in sedentary and LPA time.

Methods: Data for this secondary analysis came from the Stand & Move at Work group-randomized worksite intervention trial conducted in 24 worksites throughout the Minneapolis-St. Paul, MN and Phoenix, AZ metropolitan areas. Recruitment began in January 2016. LPA was measured at baseline and 3 months (12 and 24 month data collections are ongoing) by activPAL accelerometers. Height and weight were measured at baseline by trained staff. Linear mixed models using an unstructured working correlation examined the association of BMI category with baseline work time LPA participation, all day LPA participation, and change in work time LPA participation from baseline to 3 months.

Results: **Light intensity physical activity associated with BMI category**

Baseline Total LPA:	β(SE)	p
BMI Category		
BMI <25	13.63 (2.80)	<0.01
25 ≥ BMI <30	7.77 (2.74)	<0.01
BMI ≥30	ref	ref
Baseline work time LPA:		
BMI Category		
BMI <25	3.05 (1.44)	0.04
25 ≥ BMI <30	2.39 (1.41)	0.09
BMI ≥30	ref	ref
Change in LPA from baseline to 3 months		
BMI Category		
BMI <25	1.06 (1.44)	0.46
25 ≥ BMI <30	2.62 (1.43)	0.07
BMI ≥30	ref	ref

All models adjusted for age, gender, race, marital status, and education level and study arm

Conclusion: These findings show that while LPA differed significantly by weight status at baseline, change in LPA was not significant. A worksite sedentary and LPA intervention may be effective for individuals across BMI category. Future worksite health interventions including those that target health behaviors such as diet and/or physical activity, weight management, and stress reduction should seek to examine potential differential effects by weight status.

Understanding Patient Experiences with Healthcare Providers and Exercise Promotion

Ann M. Sylvia. *Bridgewater State University, Bridgewater, MA.*

(No relevant relationships reported)

Purpose: Obesity-related diseases and disorders are the second leading cause of preventable death. The promotion of exercise from healthcare providers has been shown to significantly increase physical activity levels of patients. Prescribing exercise and referring patients to qualified exercise professionals has been identified as an opportunity to reduce the current rate of obesity. In order to use exercise as a form of medicine, it is recommended that physical activity counseling be a part of every wellness visit and that health care providers become active in counseling and referring patients to properly educated and certified professionals for exercise. The purpose of this study was to describe the type of information patients currently receive about regular exercise from primary healthcare providers (PHPs). Method: An exploratory descriptive study was conducted in an attempt to understand patient experiences with their healthcare providers regarding exercise promotion. Two dichotomous questions and one open-ended response were used to determine the nature of PHPs' recommendations regarding participation in regular exercise and the qualifications of fitness professionals to support those efforts. Results: The sample consisted of 459 adult females representing three calculated BMI categories. 63.4% of participants indicated their PHPs recommended they engage in regular exercise to support improved health. Through content analysis of open-ended responses of PHPs' exercise recommendations, six distinctive categories representing types of recommended exercise (e.g., endurance training, group exercise) were identified. Of the participants indicating that their PHP's recommendations included engaging in regular exercise, 100% received no information about qualified fitness professionals to guide their exercise efforts. Conclusions: While patients are being encouraged by PHPs to engage in exercise for improved health, the information being offered is limited to the type of exercise in which they should engage. No information is being provided to help patients identify a qualified exercise professionals to support and guide their efforts to use exercise as a means of improving their health.

296 Board #137 May 30 9:30 AM - 11:00 AM

Does Squat Depth and Width Influence Hip and Knee Joint Moments?

W Matt Denning[1], Brad Gardiner[2], Tyler Standifird[3], Lauren Williams[3]. *[1]Brigham Young University - Idaho, Rexburg, ID. [2]Weber State University, Ogden, UT. [3]Utah Valley University, Orem, UT.*
(No relevant relationships reported)

Squats are a popular closed-chain exercise that can benefit strength, power, balance, and range of motion. Proper squat technique includes varying depths and widths. **Purpose:** This study investigated sagittal plane knee and hip moments during 9 different squat variations. **Methods:** 10 healthy, college-aged adults (7 female, 3 male, mass = 67.4 ± 10.7 kg; height = 1.68 ± 0.08 m) performed body-weight squats at 3 widths (standard (shoulder width), wide (150% of shoulder width), and widest (200% of shoulder width)) and 3 squat depths (shallow (55 degree knee flexion), parallel (90 degree knee flexion), and deep (125 degree knee flexion)). Anthropometric, marker coordinate, and force data were combined to calculate peak hip and knee moments during the eccentric (downward) and concentric (upward) phases of the squat. 2x3 ANOVAs were used to evaluate the effect of squat depth and width on peak hip and knee eccentric and concentric moments. **Results:** Generally, concentric and eccentric hip and knee moments increased with greater squat depth and decreased with greater squat width. At the deep depth, the eccentric moments for the wide and widest stance widths were significantly less when compared to the standard width at the knee (standard = 1.23 ± 0.29 Nm/kg, wide = 1.09 ± 0.21 Nm/kg, widest = 0.98 ± 0.15 Nm/kg; $p < 0.01$) and at the hip (standard = 0.99 ± 0.21 Nm/kg, wide = 0.89 ± 0.19 Nm/kg, widest = 0.78 ± 0.17 Nm/kg; $p < 0.001$). At the parallel depth, the eccentric hip moment for the widest stance width (0.78 ± 0.13 Nm/kg) was significantly less than the eccentric hip moment for the standard (0.94 ± 0.18 Nm/kg) and wide stance widths (0.90 ± 0.14 Nm/kg; $p < 0.01$). The knee concentric moment for the deep depth was significantly less at the widest stance width (1.07 ± 0.20 Nm/kg) when compared to the wide (1.19 ± 0.21 Nm/kg) and standard stance widths (1.30 ± 0.28 Nm/kg; $p < 0.01$). **Conclusions:** Squat depth and stance width influence hip and knee joint moments, and both should be considered when performing a squat. If deep squats are used to increase lower-extremity muscle activation and overall work, increasing stance width will reduce sagittal plane hip and knee moments and possibly joint loads. Further research is needed to investigate other methods of reducing lower-extremity joint load while exercising.

297 Board #138 May 30 9:30 AM - 11:00 AM

Feasibility of Progressive Resistance Training in Retired Mexican Women with Ostearthritis

Oswaldo Ceballos-Gurrola, Erika M. Hernandez-Rojas, Maria C. Enriquez-Reyna. *Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico.*
(No relevant relationships reported)

Resistance training has been avoided in Osteoarthritis (OA) patients due to concern about exacerbation of pain, joint inflammation, rupture of tendons, popliteal cysts or joint capsules. Resistance exercise interventions have been shown to be beneficial in older adults, but there are few reports of the effect of this type of training in the Mexican context. **PURPOSE:** The feminization of aging is the background for the proposal to evaluate the feasibility of a progressive muscle strength training for retired women with OA. **METHODS:** Sedentary women from a private seniors club aged between 55 and 76 years old and under stable medication participated in the protocol study. The experimental group (n = 7) attended a 10-week progressive resistance program of low to moderate intensity (30-60% RM), with three weekly sessions of 60 minutes. The sequence of activities within each session was: warm-up, resistance training, flexibility exercises and cool down. The control group (n = 5) only received a report with the results of their physical tests after each evaluation. Pretest and post-test evaluation were applied.
RESULTS: Twelve retired women completed their participation in the study. The groups were homogeneous at baseline. Improvements were found in the experimental group with better results in gait speed ($t = 2.585$, $p < .05$) and Chair Stand Test ($t = 2.828$, $p < .05$). Handgrip strength and 8-Foot Up and Go Test remained without changes. The control group remained unchanged between measurements ($p > .05$).
CONCLUSIONS: Progressive resistance strength training is feasible and safe in well-controlled OA patients. This training could improve lower limb muscle strength without adverse effects as fatigue or joint pain.

298 Board #139 May 30 9:30 AM - 11:00 AM

Clinical Trial To Assess The Effect Of High-intensity Interval, Progressive Resistance Or Concurrent Exercise Protocol On Hormonal Responses In Latin-american Overweight Adults

Gina Paola Velasco-Orjuela[1], Andrea del Pilar Quintero[1], María A. Domínguez-Sanchéz[2], Jorge E. Correa-Bautista[1], Antonio García-Hermoso[3], Jhonatan C. Peña-Ibagon[1], Robinson Ramírez-Vélez[1]. *[1]Universidad del Rosario, Bogotá D.C, Colombia. [2]Universidad de la Sabana, Chía, Colombia. [3]Universidad de Santiago de Chile, USACH, Santiago de Chile, Chile.*
(No relevant relationships reported)

PURPOSE: We hypothesized that the concurrent training [high-intensity interval training (4×4 min intervals at 85-95% maximum heart rate [HRmax], interspersed with 4 min of recovery at 75-85% HRmax) + progressive resistance training (12-15 repetitions per set, at 50-70% of one repetition maximum with 60s of recovery)] induces the highest metabolic perturbations and therefore the highest hormonal responses compared to the progressive resistance training and the high-intensity interval training protocol in a cohort of Latin-American overweight adults (age 18-30 years old). **METHODS**: Randomized, parallel-group clinical trial among fifty-one men (23.6±3.5 yr; 83.5±7.8 kg; 28.0±1.9 kg/m2), physical inactivity (i.e. <150 min of moderate-intensity exercise per week for greater than 6 months), with abdominal obesity (waist circumference ≥ 90 cm) or body mass index ≥ 25 and ≤ 30 kg/m2 were randomized to the following 4 groups: high-intensity training (n=14), progressive resistance training (n=12), concurrent training [high-intensity and progressive resistance training (n=13)], or non-exercising control (n=12). Total- and free-testosterone and total-testosterone/cortisol-ratio assessments (all in serum) were determined before (pre) and 1-min post-exercise for each protocol session. **RESULTS**: Decreases in cortisol and total-testosterone/cortisol-ratio levels were observed; −57.08 (95%CI, −36.28 to −77.88; d=2.06) and −0.021 (95%CI, −0.012 to −0.032; d=1.49), respectively in the high-intensity training group. In per-protocol analyses, the combined training group had greater changes in cortisol levels (−54.49, 95%CI, −15.28 to −93.69; d=1.33) and total-testosterone/cortisol-ratio (−0.017, 95%CI, −0.004 to −0.030; d=0.90) vs the high-intensity training group, but not the other interventions. Analyses of covariance revealed no significant change in the total- and free-testosterone between groups over time. **CONCLUSIONS**: The present data indicate a concurrent, or high-intensity training reduced cortisol and total-testosterone/cortisol-ratio levels significantly in physical inactive adults. Further study is required to determine the biological importance of these changes in hormonal responses in overweight men. **TRIAL REGISTRATION:** ClinicalTrials.gov NCT02915913.

299 Board #140 May 30 9:30 AM - 11:00 AM

Volume Of Exercise For Prevention Of Weight Regain (MET POWeR)

Amanda N. Szabo-Reed, Joseph E. Donnelly, FACSM, Richard A. Washburn, FACSM, Debra K. Sullivan, Jeffery J. Honas, Matthew S. Mayo, Ron Krebill, Anna Gorzyca, Jeannine Goetz. *Kansas University Medical Center, Kansas City, KS.*
(No relevant relationships reported)

PURPOSE: There is limited evidence regarding the volume of exercise required to minimize weight regain. The purpose of this trial was to examine the impact of 3 levels of exercise on weight regain subsequent to weight loss in adult men and women. **METHODS:** Overweight/obese adults (n=175 (32 men, 143 women), age= 43 yrs., BMI~32 kg•m²) who lost ≥ 5% of their initial body weight in response to a 3-mo. weight loss intervention which included energy restriction and increased exercise (100 min•wk⁻¹) completed a 12 mo. maintenance intervention. Participants were prescribed a weight maintenance diet (RMR x 1.4), attended biweekly behavioral sessions, and were randomized to one of 3 levels of exercise (150, 225, 300 min•wk⁻¹), with a minimum of 3 sessions•wk⁻¹ under supervision. Exercise min across 12 mos. were obtained from direct observation or heart rate monitors for supervised and unsupervised sessions, respectively.
RESULTS (Table 1): There were no significant differences in the volume of exercise competed during weight loss (0-3 mos.) by randomized group ($p = .32$) or gender ($p = .85$). Average mins of completed exercise were significantly greater in those randomized to 300 min•wk⁻¹ (170 min•wk⁻¹) compared with both the 150 min•wk⁻¹ (147 min•wk⁻¹) or 225 min•wk⁻¹ (120 min•wk⁻¹, $p < .05$) groups. Weight regain across all 3 groups was minimal (<3%); however, there were no significant differences in the magnitude of weight regain by randomized group ($p=.21$) or gender ($p=.37$).
CONCLUSION: These findings suggest that exercise, irrespective of magnitude, is associated with weight loss maintenance.
Table 1.

Weight Loss	Exercise Min (SD)	% Weight Loss (SD)
150- Men (M)	91.3 (11.8)	-10.8 (4.1)
150- Women W)	84.4(15.5)	-9.4 (3.0)
150- Total	85.7 (15.1)	-9.7 (3.3)
225- M	83.5 (31.2)	-10.6 (4.3)
225- W	82.6 (17.2)	-9.1 (2.9)
225- Total	82.7 (20.1)	-9.4 (3.2)
300- M	83.5 (22.0)	-10.3 (3.3)
300- W	80.6 (20.9)	-8.9 (2.6)
300- Total	81.2	-9.2 (2.8)
Weight Maintenance	Mean Exercise Min (SD)	Mean % Regain (SD)
150- M	131.5 (40.2)	1.3 (5.0)
150- W	117(34.1)	1.6 (7.6)
150- Total	119.8 (35.5)	1.2 (7.1)
225- M	137.8 (61.6)	3.3 (8.2)
225- W	149.0 (51.1)	3.5 (6.0)
225- Total	147.0 (52.9)	3.4 (6.3)
300- M	171.7 (54.0)	0.6 (7.0)
300- W	169.0 (67.3)	3.6 (7.5)
300- Total	169.5 (64.8)	3.1 (7.4)

300   Board #141   May 30 9:30 AM - 11:00 AM

Preliminary Findings From A Stealth Physical Activity Intervention Targeting Inactive Dog Owners

Katie Becofsky, Brittany Mastellar, Erin Cawley, Rachel Mudway, Connor Saleeba, Alec Shostek. *University of Massachusetts Amherst, Amherst, MA.*

(No relevant relationships reported)

Given that 60 million American households own at least one dog, there is growing interest in promoting dog walking to increase physical activity at the population level. An estimated 40% of dog owners do not walk the dog regularly, providing a large target population for intervention. Dog obedience training could plausibly serve as a stealth physical activity intervention as it aims to strengthen the dog-owner bond, a construct strongly associated with dog walking behavior. **PURPOSE**: To examine changes in dog owners' self-reported dog walking behavior and device-measured moderate-to-vigorous physical activity (MVPA) after completing basic obedience training. **METHODS**: Forty-one healthy but inactive individuals (85% female; mean age=40) who reported walking their dog ≤3 d/wk were randomized to a 6-week basic obedience training class (INT; n=21) or wait list control group (CON; n=20). Participants recorded all dog walking bouts and wore an Actigraph GT3X+ on their right hip for 7d at baseline and 6-weeks. T-tests assessed group differences in self-reported dog walking and device-measured MVPA change scores. **RESULTS**: At baseline, participants reported 48.5±62.7 min/wk of dog walking and averaged 22.0±14.0 min/d of MVPA. Intervention participants that completed post-program assessments (n=17) attended an average 5.6 of 6 training classes. Preliminary analyses of n=31 participants (n=13 INT) with valid Actigraph data (≥4d with ≥8hrs weartime at both time points) found a differential change in self-reported dog walking behavior between groups (+36.1±58.4min/wk versus -26.7±90.3min/wk in INT and CON participants, respectively; p=0.04), but no differential change in MVPA (+7.4±22.2min/d versus +1.6±11.3min/d in INT and CON participants, respectively; p=0.35). **CONCLUSIONS**: In this small pilot study, dog obedience training led to increases in self-reported dog walking behavior but no change in device-measured MVPA as compared to a waitlist control group. There was large variability in both physical activity outcomes measures, so results should be interpreted with caution. This approach should be tested in a larger sample and should specifically target inactive dog owners that intend to or would like to walk the dog regularly but report barriers (rather than owners that do not intend to walk the dog).

The Effects of Physical Activity on Physical and Mental Health in Stroke Patients

City C. Hsieh[1], Yu-Chieh Liang[2], Yen-Ting Lai[2], Jung-Cheng Yang[2], Hsiao-Ling Huang[3]. *[1]Tsing Hua University, Hsinchu, Taiwan. [2]Taiwan University Hospital Hsinchu Branch, Hsinchu, Taiwan. [3]Yuanpei University, Hsinchu, Taiwan.* (Sponsor: Chia-Hua Kuo, FACSM)

(No relevant relationships reported)

Purpose: The purpose of this study was to investigate the effects of yoga exercise invention on physical and mental health in stroke patients. **Method:** Sixty-six stroke patients were randomly assigned to the following two groups. Thirty-three patients were in the experimental group (age: 58.30±11.04 yr), another thirty patients were in the control group (age: 60.23±9.59 yr). The experimental group had performed yoga exercise 3 times a week for twelve weeks with each session lasting 60 minutes per day, including warm-up (10 minutes), main exercise (35 minutes) and moderate stretching & meditation (15 minutes), additionally except rehabilitation courses held by the hospital. The control group had not carried out any exercise intervention except rehabilitation courses. The Borg balance scale, Beck depression inventory, quality of sleep, and quality of life were tested before and after yoga exercise intervention. Analysis of covariance (ANCOVA) was applied to examine the difference between experimental and control groups on balance, depression, quality of sleep and quality of life. **Result:** The score of Borg balance scale for stroke patients in the experimental group (↑9.62%) increased significantly compared to that in the control group (↑1.79%) (p<.05). The depression level in the experimental group (↓29.01%) decreased significantly compared to that in the control group (↓3.53%) (p<.05). The score of quality of sleep for stroke patients in the experimental group (↓29.37%) decreased significantly compared to that in the control group (↓4.67%) (p<.05). In addition, the score of quality of life in the experimental group (↑9.59%) increased significantly compared to that in the control group (↓2.18%) (p<.05). **Conclusion:** The result indicated that the yoga exercise intervention could improve the balance, depression levels, quality of sleep, and quality of life in stroke patients. As well as the yoga exercise intervention could be beneficial in physical and mental health for stroke patients.

Assessing Feasibility of Implementing Exercise is Medicine Referral Program at Tertiary Medical Center

Daniel Fosselman, Elisabeth Nogan. *The Ohio State University, Columbus, OH.*

(No relevant relationships reported)

The benefits of exercise on multiple health parameters has been well established, yet most individuals do not meet the recommended minimum standard of exercise, as defined by the American Heart Association (Garber et al., 2011; Thompson et al., 2003). Data suggests that supervision of exercise by an exercise professional improves exercise adherence, yet most studies and systematic reviews of referral based programs have failed to demonstrate their effectiveness (Garber et al., 2011; Orrow, Kinmonth, Sanderson, & Sutton, 2012; Williams, Hendry, France, Lewis, & Wilkinson, 2007). Exercise is Medicine at The Ohio State University (EIM@OSU) addresses many of the pitfalls of previously studied programs in order to increase patient participation and compliance with regards to exercise standards, and aims to encourage provider utilization of exercise in the prevention and treatment of chronic disease
PURPOSE: To evaluate patient participation and adherence, as well as provider utilization of a unique referral-based exercise program (EIM@OSU).
METHODS: Retrospective review of the EIM@OSU program from July 2015-May 2017 examining patient participation and completion of phase I and phase II of the program, determination of patient facilitators and barriers to participation, and review of provider utilization of the program including barriers and facilitators.
PRELIMINARY DATA: The majority of patients referred to the program (64%) participated in "Level I" of EIM@OSU whereas only 18% participated in "Level II". Only two-thirds of eligible primary care providers referred at least one patient to the program, and out of these providers, only 217 patients were referred to the EIM@OSU program.
CONCLUSION: To further increase patient and provider participation and adherence to the EIM@OSU referral program, facilitators and barriers to adherence need to be evaluated and improved upon.

Effects Of 4-week Crossfit Training On Weightlifters' Body Composition

Shui-Chang Hsu, Jyun-Ru Chen, Szu-Kai Fu, Wei-Chin Tseng, Kuo-Wei Tseng, Chang-Chi Lai. *Department of Exercise and Health Sciences, University of Taipei, Taipei, Taiwan., Taipei, Taiwan.*
(No relevant relationships reported)

Effects of 4-week Crossfit training on weightlifters' body composition

Shui-Chang Hsu, Jyun-Ru Chen, Szu-kai Fu, Wei-Chin Tseng, Kuo-Wei Tseng, Chang-Chi Lai Department of Exercise and Health Sciences, University of Taipei, Taipei, Taiwan **Abstract Background:** Crossfit training includes olympic weightlifting, gymnastics, and sprint. Previous studies revealed that crossfit training could increase cardiovascular fitness and decrease body fat, but it lacked crucial evidence for athletes, especially weightlifters. **Purpose:** The aim of this study was to determine the effects of 4-week crossfit training on weightlifters' body composition. **Method:** Eight college weightlifters participated in this study. All subjects were randomly assigned to two groups, which were resistance training group (RT, n = 4), and crossfit training group (CF, = 4). Both groups received training 3 days a week for 4 weeks. Snatch performance and body composition from both groups were measured at week 0 and week 5. **Result:** The result showed that there was no significant difference between two groups in all variables. CF significantly decreased in average rate of force development (RFD) of snatch, but significantly increased isokinetic strength and thigh muscle mass at week 5. RT significantly decreased on average RFD of snatch, but significantly increased body fat at week 5. **Conclusion:** The results showed that muscle mass increased after a 4-week crossfit training, but body fat level did not decrease. Thus, crossfit training is not suggested to be adopted to rapidly lose weight in pre-competitive phase. **Key words:** body composition, high intensity interval training, body fat

Maternal Aerobic Exercise and DHA Levels During Pregnancy Influences Infant Heart Outcomes

Cody J. Strom, Kim Kew, Blake Rushing, Christy Isler, Edward Newton, Linda E. May. *East Carolina University, Greenville, NC.*
(No relevant relationships reported)

Infant heart rate(HR) and heart rate variability(HRV) are used to estimate nervous system development and overall well-being of the fetus. Exercise during pregnancy is associated with improved infant HR and HRV. Similarly, DHA supplementation during pregnancy has also been shown to improve infant HR and HRV. However, there has not been any observation of the potential relationship between exercise intervention and maternal DHA levels on Infant HR and HRV. **PURPOSE:** To determine the relationship between maternal exercise and plasma levels of DHA on infant nervous system development, estimated by measures of HR and HRV. **METHODS:** Maternal plasma collected at 16 and 36 weeks of gestation were processed using solid phase extraction and analyzed using liquid chromatography/triple quadrupole mass spectrometry (LC/MS) to measure DHA levels. Samples were analyzed from 3 exercising (>50min aerobic exercise, 3x week) and 2 non-exercising pregnant women; average weekly METs were calculated based on standard MET values for each exercise activity. Infant HR and HRV were measured 1 month after birth. T-tests determined significance between groups; relationships between variables were tested with ANOVA and linear regression. Our p-value is set at 0.05. **RESULTS:** There were no significant differences between groups in infant HR (p=0.35, F=1.208) or 36 week plasma DHA levels (p=0.57, F=0.407). Linear regressions demonstrated negative relationships between Maternal average METs and Infant HR (r2=0.312) and 36 week maternal DHA levels and Infant HR (r2=0.156), as well as positive relationship between average METs and 36 week plasma DHA levels (r2=0.029). Multiple regression analysis of maternal average METs and maternal DHA levels to Infant HR was also determined (R2=0.404). Maternal average METs was the stronger of the predictors for Infant HR. **CONCLUSION:** The current data support the relationship between maternal exercise and DHA levels on infant HR. This is the first study to examine maternal exercise and DHA levels during pregnancy and infant heart outcomes. Further samples will be analyzed to confirm the relationship between maternal exercise, maternal DHA levels and infant outcomes.

Independent but Not Alone - A Physical Activity Intervention for Military Spouses

Rebecca Gasper, Emily Mailey, Brandon Irwin. *Kansas State University, Manhattan, KS.*
(No relevant relationships reported)

In comparison to the general population, military spouses face additional daily challenges to engaging in self-care behaviors like physical activity (PA). **PURPOSE:** To evaluate the impact of an online intervention specifically designed to address the unique challenges of being a military spouse on spousal PA and mental health. **METHODS:** A 10-week program entitled *Independent but not alone (IBNA)* was developed specifically for this population using information from focus groups and through partnerships with individuals in the health/fitness field that are also military spouses. The intervention consisted of weekly podcasts and team challenges designed to facilitate PA, stress management, and social connection among participants. A total of 119 participants (*M* age = 31.9) for *IBNA* were recruited from Fort Riley (Junction City, KS). Control group participants were recruited from other military bases around the United States. A total of 112 participants (*M* age = 33.1) in the control group received links to existing content on the Operation Live Well website. Data were analyzed using mixed design 2 (group) X 2 (time) repeated measures ANOVAs. **RESULTS:** Participants in both groups reported an increase in total overall PA levels [$F(1,152)$=12.29, p=.001)], including moderate PA [$F(1,152)$=14.98, p<.001)], household PA [$F(1,152)$=15.18, p<.001)], and PA for transport [$F(1,152)$=4.17, p=0.04)]. Participants also reported positive mental health impacts, including reduced feelings of stress [$F(1,149)$=52.38, p<.001)], anxiety [$F(1,150)$=58.29, p<.001)], and depression [$F(1,152)$=56.94, p<.001)]. The only significant difference between the two conditions was that those in the *IBNA* group reported a greater level of vigorous PA [$F(1,152)$=3.98, p=.048)] than those in the control condition. **CONCLUSION:** Despite few significant differences between groups, there were significant individual level improvements in multiple health outcome measures. These findings suggest that there can be a positive impact on the health of military spouses from tailoring a program to their unique challenges. Future interventions with this population should continue to emphasize the importance of prioritizing self-care and show an interest in meeting the needs of spouses that are often overlooked.

Post-operative Lifestyle Intervention And Markers Of Physical And Mental Health

Craig P. Flanagan, Wesley N. Smith, Kevin A. Jacobs, FACSM, Lee D. Kaplan. *University of Miami, Coral Gables, FL.*
(Sponsor: Arlette C. Perry, FACSM)
(No relevant relationships reported)

Physical inactivity is associated with increased cardiometabolic disease risk and reductions in emotional health. Patients recovering from orthopedic surgery of the lower limb often experience pain and functional limitations, that lead to reduced physical activity levels, and weight gain. The inclusion of a post-operative wellness consultation, with exercise and nutrition components, may motivate orthopedic patients to modify behaviors to mitigate the detrimental effects of inactivity following surgery and its associated adverse health effects. **PURPOSE:** The purpose of this study was to evaluate post-operative changes in physical activity, body composition, knee function, pain, and feeling scales as well as the efficacy of a nutrition and exercise consultation targeting the restoration of physical activity levels. **METHODS:** Twelve patients undergoing partial meniscectomy were evaluated by an exercise physiologist 1 week (1W) and 6 weeks (6W) after surgery, and were randomly assigned to a control (CON) or post-surgical consolation (PS) group. The PS received personalized exercise and nutrition recommendations and wore a fitness tracking device to promote adherence. The Lysholm Knee Score (LKS) was administered to assess pain, and the Short Form Health Survey (SF-12) was divided into a mental component summary (MCS) and a physical component summary (PCS). Body mass (BM), percent body fat (PBF), and skeletal muscle mass (SMM) were assessed using a multi-frequency bioelectrical impedance. Repeated measures ANOVAs assessed mean differences in outcome variables between intervention groups at 1W and 6W. **RESULTS:** A significant mean difference in MCS scores were observed ($F_{(1,10)}$ = 8.465, p=0.016, η^2_p =0.458) as MS subjects did not experience the reduction in MCS seen in CON. There were no significant between-group differences in BM (p=0.608), PBF (p=0.804), SMM (p=0.926), LKS (p=0.604), pain (p=0.604), or PCS (p=0.545). **CONCLUSIONS:** The addition of a wellness consultation helping patients pursue active lifestyle behaviors appears to eliminate the expected decline in patients' vitality and emotional well-being in a five-week period after surgery. This effect occurs independent of changes in body mass, body composition, pain, or functional outcomes related to knee surgery.

Maintenance Of Physical Activity Level And Dissemination Of "Plus Ten" Message In Community-based Group Exercise

Yoshinobu Saito[1], Yuko Oguma[1], Takayuki Tajima[1], Ayumi Tanaka[2], Yayoi Kibayashi[3], Chisato Shiba[3], Motohiko Miyachi[4], Toru Takebayashi[5]. *[1]Keio University, Fujisawa, Japan. [2]Fujisawa City Health and Medical Foundation, Fujisawa, Japan. [3]Keio University, Yokohama, Japan. [4]National Institute of Health and Nutrition, NIBIOHN, Shinjuku-ku, Japan. [5]Keio University, Shinjuku-ku, Japan.*
(No relevant relationships reported)

PURPOSE: We conducted a community-wide intervention to promote physical activity (PA) in Fujisawa, Kanagawa, Japan, since 2013. The intervention involves multilevel strategies, as part of which, community-dwelling elderly groups committed to exercising together were enrolled. This study aimed to assess the effects of community-based group exercises (CBGE) on increase and maintenance of PA level and dissemination of the PA message, as well as improvement of physical fitness. **METHODS**: This study included 148 older adults (mean age: 75.7 years, SD: 6.5 years; women: 66%) in 8 CBGE groups. The original 10-min exercise program (mean intensity: 2.7 METs, Osawa et al. 2015) was introduced to groups voluntarily exercising together at least once a week at a city center or a park in their community. Based on Japanese PA guidelines, we have recommended the individuals perform *"Plus Ten (+10-min of PA per day)"* and disseminate the message to surroundings. In addition, we held group discussions about maintenance and dissemination of CBGE at exchange meetings. Dissemination of *"Plus Ten"* message, total duration of PA (exercise and daily activities) by the questionnaire, and physical fitness tests were assessed at baseline, 6-month, and 1-year follow-up. Statistical analyses included Wilcoxon signed rank test, paired t test and chi-square test. **RESULTS**: We visited each group 5.6 times on average for assessment and follow-up in a year. The group exchange meeting was held 3 times. One year later, 137 (93%) continued CBGE and 11 (7%) dropped out due to health or relocation; 42 joined the group during the year. In neighborhoods, 79% of participants shared *"Plus Ten"* message. The median of total PA time at baseline and 1-year after was 780 and 840 minutes/week, respectively (P=0.118). Significant improvement was observed in the two-step test (1.33 to 1.39, P<0.001) and chair standing test (22.9 to 24.9 times/30 sec, P<0.001). **CONCLUSIONS**: CBGE had high persistence rates, maintenance of PA, and improvement of physical fitness. Dissemination of subjective the PA message from CBGE members can be effective in promoting community-level PA. Supported by the Japan Agency for Medical Research and Development (AMED), MEXT KAKENHI Grant Number JP41023054 and Keio Gijuku Academic Development Funds.

Body Composition Differences in Trained and Sedentary Individuals Matched for High BMI

Andrea Santi. *University of Minnesota, Minneapolis, MN.*
(No relevant relationships reported)

PURPOSE: This study determined whether aerobic training reduces body fat and insulin resistance. We compared body composition in obese insulin-resistant sedentary (OIR), obese insulin-sensitive sedentary (OS), and obese trained (OT) subjects matched for body mass index (BMI). We hypothesized that OT subjects would have less fat, especially visceral fat, and greater fat free mass than the OIR or OS subjects. **METHODS:** We measured body composition by Dual X-ray Absorptiometry (DXA) (n=33: N=11 in each group) in OIR, OS, and OT subjects matched for age, gender and BMI. The OT participants were selected by self-report, with preferential recruitment from running groups and marathon mailing lists. **RESULTS:** Each group was matched for age [Mean ± SE, overall age 31.7±0.9, overall sex distribution (64% female) and overall BMI (31.6 ±0.7)]. Insulin resistance (mean± SE), as measured by the homeostatic model assessment for insulin resistance (HOMA-IR), was higher in the OIR group (3.3 ± 0.2) than the OS (0.9 ± 0.2, p<0.01) or OT (1.6 ± 0.2, p<0.01) groups. Mean body fat percent was highest in the OIR group (43.5% ±1.7) than the OS (37.0 % 2.3, p=0.04) or OT group (34.0 % ± 3.1, p<0.01). The OIR group also had higher mean fat mass in the body (39 kg ± 18.3 vs 30.8 kg± 3.3 p<0.005), android (4.3 kg ± 0.4 vs 2.6 kg ± 0.3 p<0.05) and visceral region (1.3 kg ± 0.1 vs 0.6 kg± 0.08 p<0.005) than the OT group. In contrast, bone mineral content at the level of the total body (2.8 kg ± 0.1 vs 3.2 kg ± 0.1 p<0.05), arms (0.38 kg ± 0.03 vs 0.44 ± 0.02 p<.05), gynoid region (0.27kg ± 0.02 vs 0.33 kg ± 0.02 p<0.05), leg (1.0 kg ± 0.07 vs 1.2 kg ± 0.06 p<0.05) and pelvis (0.36 kg ± 0.02 vs 0.43 kg ±0.02 p<0.05) was lower in the OIR group than the OT group (p<0.05). Lean mass at the level of the arms (6.13 kg ± 0.38 vs 7.04 kg ± 0.64 p<0.01), trunk (23.6 kg ± 1.25 vs 27.5 kg ± 1.7 p<0.001), legs (18.1 kg ± 1.1 vs 21.6 kg ± 1.5 p<0.001) and total body (51.1 kg ± 2.7 vs 59.5 kg ± 3.8 p<0.005) was lower in the OIR group than the OT group. There was no significant difference in mean HOMA-IR or body composition between OS and OT groups. **CONCLUSION:** While matching for age, gender and BMI, obese trained subjects had higher lean mass, bone mineral content and lower fat mass than obese insulin resistant subjects. These findings support the limitations of using BMI to predict body composition, especially in trained subjects.

Opportunities and Frequency of Jumping Behaviors in Elementary Female Physical Education Students

Skip M. Williams, David Thomas, FACSM. *Illinois State University, Normal, IL.* (Sponsor: David Thomas, FACSM)
(No relevant relationships reported)

Physical activity, specifically jumping, is most effective in promoting bone health. Engaging adolescents in appropriate activity to achieve peak bone mass is critical. Although physical education (PE) programs offer content that would be deemed as bone-strengthening, no research has examined jumping opportunities in physical education. **PURPOSE:** to examine jumping behavior in 4th and 5th grade female PE students. **METHODS:** Thirty-eight 4th or 5th grade female students were randomly observed during PE lessons. The content of the lessons consisted of: tag games, mat ball/kickball, cardio activities and jump roping. Average lesson time was 24 minutes 30 seconds. Five researchers were trained to observe jumping behaviors of adolescents during PE. Jumping was defined as upward vertical movement during which both feet simultaneously and visibly left the ground. Prior to data collection inter-rater reliability was established at .80. Observers recorded all jumping behaviors that occurred during the warm-up, main lesson and cool down. Data were analyzed by lesson content (Jump Rope and Non Jump Roping). **RESULTS:** Descriptive statistics were used to analyze all data. Across all non-jump roping lessons (N = 26) students averaged 15.8 jumps at a rate per minute (rpm) of .6. Students averaged 3.3 jumps during warm-ups, 12 jumps during the main lesson and 0 jumps during the cooldown. Across all jump roping lessons (N = 12) results indicated that students averaged 91.2 jumps at rpm of 3.9. Additionally students averaged 3.9 jumps during warm-ups, 87.3 jumps during the main lesson and 0 jumps during the cool down. **CONCLUSIONS:** Jump roping in PE can provide frequent jumping opportunities. However, non-jump roping lessons provided fewer jumping opportunities. Additionally, PE teachers are not providing jumping opportunities during a warm-up which may be an opportunity if the main lesson does not emphasize jumping. Further research needs to explore the frequency of jumps for health benefits.

Cardiovascular Risk, Physical Fitness According To Socieconomic Level And Geographical In A National Sample

Guillermo Droppelmann[1], Felipe Feijoo[2], Josivaldo de Souza[1], Sandra Mahecha-Matsudo[1]. *[1]MEDS Clinics, Santiago, Chile. [2]Pontificia Univesedad Católica de Valparaíso, Valparaíso, Chile.*
(No relevant relationships reported)

9% of school students in Chile have the normal physical fitness standards. Chile presents important socioeconomic and geographical differences. **PURPOSE:** Compare the cardiovascular risk, and physical fitness, according to sex, socioeconomic level and geographical region in a national sample of Chilean school students. **METHODS:** Descriptive cross-sectional study. Sample was composed of 10,381 students, who completed the national physical condition tests (SIMCE-EF). Variables included sociodemographic (sex, socioeconomic level, region), anthropometric indicators (weight, height, waist circumference, BMI). Physical fitness was measured by lower limb strength (vertical jump test), abdominal strength (sit ups), upper limb strength (push ups), and trunk flexibility (sit and reach test), and effort heart rate (Cafra test). The BMI, heart rate (HR) and waist height ratio (WHR) were analyzed as predictors of cardiovascular risk. We use the T-Test, ANOVA Regression and Tukeys Test-Pairwise comparison with level of significance p < 0.01. **RESULTS:** The predictors of cardiovascular risk were (p < 0.01) when compared by region and socioeconomic level. Physical tests was (p < 0.01) in abdominal strength and lower limbs. Sex was (p < 0.01) in WHR and HR. There is an inverse relationship of statistical significance between WHR and HR in sit and reach and push ups. At regional levels, differences were also found to be statistically significant in averages and variances in extreme geographical zones. **CONCLUSION:** The differences found in the predictors of cardiovascular risk could apparently be explained due to the geographical and socioeconomic characteristics of each region. It is suggested that the physical fitness tests should consider the incorporation of variables that directly measure cardiovascular risk in Chilean school students.

Does Physical Activity Programming Influence Health and Wellness Attitudes in a Rural School District?

Madeline A. Lyon[1], Timothy K. Behrens, FACSM[1], Dick Carpenter[2], Elizabeth Tucker[2], Carmen Luna[3], Julaine Field[2], Cheryl Kelly[3]. [1]*Northern Arizona University, Flagstaff, AZ.* [2]*University of Colorado Colorado Springs, Colorado Springs, CO.* [3]*Kaiser Permanente Colorado, Denver, CO.*
(No relevant relationships reported)

PURPOSE: To investigate the impact of a district-wide wellness program on students, parents, and staff in a rural school district. **METHODS**: In this one-group, pretest-posttest design, a high need (45.1% free or reduced lunch) rural school district in southern Colorado (USA; N=13 schools) was awarded a grant to implement physical activity (PA) programming. The wellness team developed a survey consisting of 29 questions on a five-point Likert scale (SA-SD). These questions asked about PA and its importance to the participants (e.g., community support for health and PA, withholding PA as punishment, importance of health and PA for participants, etc.). The survey was provided via email link to parents and staff, and to students in classes, during fall and spring semesters. Intervention activities included various programming and challenges (e.g. Playworks™, Weigh and win™, bike/walk to school/work, Fitbit challenges, etc.). Descriptive statistics were calculated for all variables of interest, and non-parametric tests were used to examine significant differences between fall and spring semesters. **RESULTS**: Surveys of parents indicated no significant improvements in PA variables across semesters. Staff surveys indicated three areas in which the spring survey were significantly worse (healthy eating/active living are important p=.04, free play is important p<.0001, effective to withhold PA as punishment p=.0472), though these findings were not practically meaningful. Student surveys indicated significant positive change in seven areas (healthy eating & active living are important p<.0001, personal health & wellness are important to me p=.001, my school provides opportunities for healthy eating and PA p<.0001, it's acceptable to be withheld from PE/ recess as punishment p=.048, my community provides opportunities for healthy eating and active living p=.0091, how often do brain breaks occur? p=.005, what time of day to brain breaks occur? p=.0133), but the only "healthy eating/active living are important" and "community opportunities for healthy eating/active living" were practically meaningful. **CONCLUSIONS**: PA programming had a mixed influence. Future research should investigate similar phenomena in rural schools to better understand factors related to changes in PA awareness and behaviors.

The Influence Of Upper Extremity And Whole-body Movements On Energy Expenditure During Active Gaming Movements On Energy Expenditure During Active Gaming

Keith Naugle. *IUPUI, Indianapolis, IN.*
(No relevant relationships reported)

Active video gaming has recently become an entertaining tool used to exercise and increase energy expenditure. However, the evidence is mixed in regards to whether active gaming alone can facilitate energy expenditure similar to that of moderate intensity exercise, and likely depends on the type of movements elicited during game play. **PURPOSE**: To determine the influence of upper extremity and whole-body movements on energy expenditure during active gaming.
METHODS: Twenty-four healthy adults completed a training session and four experimental sessions. During each experimental session, participants played one of four active video games for two 15-minute periods, including two boxing-type games and two tennis games. During the first period, participants played the games at a self-selected intensity. During the second period, participants were given specific instructions designed to maximize movement during game play (standardized period). A portable pulmonary gas exchange measurement system measured energy expenditure during game play. Participants also wore an accelerometer on the hip to measure full body movement and one on the dominant wrist to measure arm movement. Accelerometry measures included percentage of time spent in whole body moderate to vigorous physical activity (MVPA), whole-body light physical activity, and whole-body sedentary time, as well as the same measures on the arm. Linear regression was used to determine the most important accelerometer variable in predicting energy expenditure (METS) during the self-selected intensity period and the standardized instructions period.
RESULTS: The regression on METS during the self-selected intensity period indicated that the accelerometer data predicted METS ($p<.001$), accounting for 47% of the variance. Whole body MVPA was the only significant variable ($p=.008$, *Beta*=.376), with percentage of time spent in whole body sedentary behavior approaching significance ($p=.052$, *Beta*=-.262). The regression on METS during the standardized period revealed similar results, with percentage of time spent in whole body MVPA the only significant predictor ($p=.021$, *Beta*=.498).

CONCLUSIONS: These results suggest that maximizing whole body MVPA, and not just arm movements, is integral to facilitating energy expenditure during active game play.

Promoting Physical Activity Via Cooperative Extension

Katherine B. Gunter, FACSM[1], Samantha Harden[2], Anne Lindsay[3]. [1]*Oregon State University, Corvallis, OR.* [2]*Virginia Tech, Blacksburg, VA.* [3]*University of Nevada, Reno, Reno, NV.*
(No relevant relationships reported)

Purpose: The aim of this study was to evaluate factors associated with physical activity (PA) promotion efforts via the cooperative extension (CE) system.
Methods: Cross-sectional survey distributed to Family and Consumer Science listservs across land grant institutions from all 50 states.
Results: Among responders (N=806), 625 (77.5%) completed ≥ 95% of survey questions and are included in this analysis. Respondents span the age categories of 18-29 (14.4%); 30-39 (18%); 40-49 (19.5%); 50-59 (27.9%); ≥ 60 (20.2%) and have been working with CE for 10.7 ± 9.5 years, and most (64.1%) spend ≥ 20% of their time working with government nutrition assistance education programs (SNAP-Ed and/or EFNEP). Most are county-based (73.2%) and work predominately in rural areas (60.1%). All agree or strongly agree that engaging in PA is important, however, only 40.5% and 50.6% personally meet or exceed the PA recommendations for muscle strengthening or aerobic activity, respectively. Forty-five percent implement PA as part of nutrition education lessons for youth or adult audiences, while 8.3% and 19.8% lead stand-alone youth or adult PA programs, respectively. Nearly 60% are engaged in PA promotion efforts in school and community settings. Only 50.6% have attended trainings related to PA promotion and (43.6%) agree or strongly agree that CE leaders provide support for PA training opportunities. While 63.7% agree or strongly agree that CE leaders endorse PA promotion as a role and responsibility of CE personnel, only 44% and 40% respectively, report PA promotion efforts are a component of outcome and impact reports, or a documented expectation in extension position descriptions.
Conclusions: A majority of CE personnel across the U.S. engage in a variety of PA promotion and programming efforts, but gaps exist in training and administrative support or documentation of these efforts. Trainings to address PA promotion efforts and impact/outcome assessment are needed.

Integrated Development of Health Promotion Cloud-based Mobile Platform and Application in New Taipei City

Chi-Hung Lin, Hui-Ping Lin, Hsiu-Heng Chung. *Department of Health, New Taipei City Government, New Taipei City, Taiwan.*
(No relevant relationships reported)

Frailty will increase the risk of disability, reduce the average life expectancy of health. In 2015, the pre-frailty prevalence rate and the frailty prevalence rate from the frailty screening survey of the elderly health check was 48.8% and 13.3% respectively in New Taipei City's 4 rural areas.
PURPOSE: As the result, the mayor declared the launch of the "Fit for Age APP" program in August 2015, which was designed to meet the needs of the pre-elderly and the elderly through the "Frailty and Muscle Strength Test", "Exercise Nutrition Intervention" and "Data Record" orientations to achieve the goal of prevention and reversal of frailty.
METHODS: We aim to develop an entertaining "Fit for Age APP" which includes "Health Assessment", "Sports, Diet and Nutritional Record" and "Health Communication". Furthermore, sports, nutrition, and medical professional teams will undergo the "Backstage Management System" to monitor and give personal feedback timely. We hope the establishment of this multi-functional module and new type health APP not only can improve the use of APP capacity and frequency by the participants.
RESULTS: From August 2015 to the end of December 2015, the promotion, use, and participation of the Fit for Age program were as follows: **(1)**Promotion effectiveness: Activity promotion screenings: 6,588 sessions, the number of propaganda: 303,480 people, the average daily publicity are 43.9 games with 2023.2 person-time. The number of service bases for Fit For Age: There are 1,559 spots, with average a spot per neighborhood. The situation of media exposure of Fit for Age: Facebook, Line and other community media platform: a total of 22, news media exposed (electronic and flat): a total of 148, an average of 1.1 per day. **(2)**The use condition of the "Fit for Age APP": The number of registration up to 31,566 people, the monthly population active utilization ratio: 40%, exercise recording utilization ratio: 23%, nutrition recording utilization ratio: 10%.
CONCLUSION: Through the APP and personal health feedback model, it can enhance personal health knowledge, change personal health attitude, and build self-manage healthy behavior, to achieve the goal of disease prevention and health for all.

Effect of anAutomatic Physical Activity Detection & Feedback System in PromotingExercise Compliance of a Virtual Trainer Project: A Randomized Control Trial

Stanley Sai-chuen Hui, FACSM[1], Ron Chi-wai Kwok[2], Eric Wai-cheung Tam[3], Winnie Wing-sze Mak[1], Phoenix Kit-han Mo[1]. [1]The Chinese University of Hong Kong, Shatin, Hong Kong. [2]City University of Hong Kong, Kowloon Tong, Hong Kong. [3]The Hong Kong Polytechnic University, Hung Hom, Hong Kong.
(No relevant relationships reported)

With advances in smartphone technology, automatic physical activity (PA) detection and feedback applications that integrate with movement measuring devices (such as smartphone apps and heart rate watches) have become widely available and popularized. However, it is not known whether such automatic systems provide any additional advantage in motivating exercise compliance compared to traditional self-report systems. **Purpose:** To investigate if the integration of an automatic PA detection and feedback system provides any additional advantage in motivating exercise compliance as compared to a traditional self-report PA system. **Method:** We developed a Virtual Trainer (VT) exercise promotion project that encourages exercise compliance via a website and a smartphone application. A total of 119 inactive adults entered a randomized control trial under one of the following three conditions: 1.) VT with a heart rate watch that allows automatic PA detection and feedback, or 2.) VT with self-reported PA record, or 3.) no VT (control) with self-reported PA participation. Exercise compliance data were retrieved from the VT PA record and a PA questionnaire (IPAQ) was collected at pre-, post-, and 3-months after intervention (maintenance). **Results:** All three groups improved PA compliance significantly (p< .01), although a slight drop at maintenance was observed. Two-way repeated measured ANCOVA (age & gender as covariates) found significant time effects (p< .01) but no interaction effect (p> .05). The IPAQ revealed that PA compliance in both VT conditions improved by more than double after intervention. Changes in exercise compliance between the three conditions were not different. **Conclusion:** In a web-based + smartphone app interactive exercise promotion program that promotes self-management of regular exercise training, the inclusion of an automatic physical activity detection and feedback system did not bring additional benefits compared to a traditional self-reported PA recording system.

316 Board #157 May 30 9:30 AM - 11:00 AM

Physical Education in the U.S.: Systematic Observations of Physical Activity, Lesson Length, and Class Size

Nicole J. Smith[1], Thomas L. McKenzie, FACSM[2]. [1]CSU Fresno, Fresno, CA. [2]San Diego State University, San Diego, CA.
(No relevant relationships reported)

Obtaining widespread information (i.e., surveillance) on physical education (PE) is important for educators and policy makers to understand programs and make valid judgments to improve policy and practices. Most of the information about PE in the U.S. is derived from self-reports—often from respondents distal to actual lessons. The System for Observing Fitness Instrument Time (SOFIT) has been validated, used since 1989, and recommended as a surveillance tool for PE.
PURPOSE: To locate and synthesize studies that used SOFIT to objectively assess class size, lesson length, and moderate-to-vigorous physical activity (MVPA) during PE in U.S. elementary and secondary schools from 1991-2016.
METHODS: Following PRISMA Guidelines, we searched 10 library databases and located 233 distinct SOFIT records. Of these, 137 full texts were reviewed, resulting in 20 studies eligible for the current analysis. Studies were included if they were (a) conducted in U.S. schools, (b) published in English in peer review journals, (d) assessed MVPA, lesson length, and class size, and if (d) data were not influenced by interventions. All observers were trained to use the SOFIT protocol.
RESULTS: Data were collected during 5,606 PE lessons (3,469 elementary; 2,137 secondary) in 1,239 schools located in 17 states. There was substantial variation for all variables, both within and among the 20 studies. Secondary school lessons were longer (M=40.5 vs. 30.3 min), had more students (M=40.5 vs. 28.2), and provided more MVPA (M=46.5% vs. 38.4% of lesson time). Overall, only 3 studies met the nationally recommended standard for lesson 50% MVPA. Factoring in lesson length, students in these elementary and secondary schools accumulated only 11.6 and 18.8 MVPA min/lesson, respectively. Even with PE daily, accrued weekly MVPA time would be only about half the recommended amount (IOM, 2013). Class size in secondary schools also exceeded recommendations.
CONCLUSIONS: Direct observations of 5,606 PE lessons show elementary and secondary schools are falling short of national recommendations for MVPA and class size. Schools were not selected at random; therefore, a larger on-campus surveillance study is recommended in order to establish an objective database for PE. SOFIT has been validated and widely used and could serve well as a surveillance tool.

317 Board #158 May 30 9:30 AM - 11:00 AM

Improving Functional Capacity And Physical Activity Through Education: Two-year Follow-up Of Parqve Study

José Messias Rodrigues da Silva[1], Márcia Uchoa de Rezende[2], Tânia Carvalho Spada[3], Lucila da Silva Francisco[4], Helenilson Pereira dos Santos[4], Júlia Maria D'Andréa Greve[2], Emmanuel Gomes Ciolac[5]. [1]São Paulo State University (UNESP), School of Sciences, Campus Bauru, Bauru, Brazil. [2]Traumatology,School of Medicine, University of São Paulo, Sao Paulo, Brazil, São Paulo, Brazil. [3]Traumatology,School of Medicine, University of São Paulo, Sao Paulo, Brazil., São Paulo, Brazil. [4]University of Guarulhos (UNG) – SP, Guarulhos, Brazil. [5]São Paulo State University (UNESP), School of Sciences, Campus Bauru, São Paulo, Brazil.
(No relevant relationships reported)

PURPOSE: The purpose of present study was to analyze the effects of an educational program emphasizing the regular practice of physical exercise on physical fitness, functional capacity and daily living physical activity levels in patients with knee osteoarthritis (OA).
METHODS: Two hundred and thirty-nine patients (X male and Y female) under treatment for primary or secondary knee OA (degree I to IV in the Kelgreen and Lawrence scale) at the public health system were randomly allocated to educational (EDU; n = 112) or control (CON; n = 127) groups. All subjects of EDU and CON have their physical fitness (six minute walking test (6MWT) and seat-and-reach test), functional capacity (stair climbing test) and daily living physical activity (IPAQ - short version) assessed at baseline (pre), and during 6,12 and 24 months of follow-up.
RESULTS: EDU improved ($P < 0,006$) 6MWT at 6 months (10%), which were maintained at 12 months, and slightly reduced (5%) at 24 months. 6MWT also improved ($P < 0,006$) in CON at 6 months, but it was of lower magnitude (4,5%) and returned to baseline at 12 and 24 months. EDU and CON showed similar improvements ($P < 0.05$) in stair climbing at 6 months (EDU = 13%; CON = 12.3%), which were maintained at 12 and 24 months.EDU also showed an increased prevalence of "actives" and "very actives" subjects, as well as a reduced prevalence of sedentary subjects during follow-up ($P < 0,05$). Although CON also showed an increased prevalence of "very actives" subjects during follow-up, it was lower than that observed in EDU. Flexibility did not change during follow-up in both groups.
CONCLUSIONS: The present results suggest that an educational program promoting the regular practice of physical exercise may be an effective tool for improving physical fitness, functional capacity and daily living physical activity in patients with knee OA.

318 Board #159 May 30 9:30 AM - 11:00 AM

Effect Of Exercise In A Desert Environment ("Brown Exercise") On Emotional And Physiological Measures

James W. Navalta, FACSM[1], Nathaniel G. Bodell[1], Elizabeth A. Tanner[2], Charli D. Aguilar[1]. [1]University of Nevada, Las Vegas, Las Vegas, NV. [2]University of North Texas, Denton, TX.
(No relevant relationships reported)

"Green exercise" (in a park or forest) is beneficial to emotional and physiological measures. The US has large desert areas (20% geography) and these regions are currently experiencing the greatest population growth. **PURPOSE:** to determine if exercise in a desert environment ("brown exercise") extends similar benefits as have been reported with green. **METHODS:** Participants (N=10) completed baseline measures (PRE), 30-min seated rest (SIT), and 30-min self-paced walking (WALK) in the following environments: indoor treadmill, outdoor urban environment (near Las Vegas Strip), green (Mt Charleston, NV), brown (Red Rock National Recreation Area, NV), and brown below sea level (Death Valley National Park, CA). Heart rate (HR), systolic blood pressure (SBP) and perceived stress, comfort, and calm were dependent variables. **RESULTS:** After SIT, HR was significantly elevated in urban vs green environments (66±11 vs 57±8 bpm, p=0.05) and significantly greater after WALK in below sea level brown (79±9 bpm) compared to all other conditions (p=0.011). SBP was lower after SIT (116±9) compared to PRE (119±9) and WALK (120±8 mmHg, p=0.05). No differences were reported for calm (p>0.05) but brown returned the highest comfort responses (p=0.02), and green the lowest (p=0.03). Regardless of condition, perceived stress was significantly lower following WALK (13.9±1) than PRE (15.5±1, p=0.002) and SIT (14.8±1, p=0.008). **CONCLUSIONS:** Cardiovascular responses to exercise in a brown below sea level environment (WALK HR higher than all others) can be attributed to significantly further distance walked (p=0.001). While not measured, it is hypothesized that enjoyment of the environment could explain this phenomenon. Comfort scores were the greatest in the environment to which subjects were habituated, and exercise served to significantly reduce perceived stress. Taken together, these data provide evidence that exercise in a brown environment is just as beneficial as that performed in a green environment.

Performance In Square Stepping Exercise Is Associated With Working Memory

Soichi Ando[1], Ryota Makino[1], Ryuji Takigawa[1], Koki Yasukawa[1], Masahiro Kokubu[2], Kazunori Sakamoto[3], Shinobu Tsurugano[1], Kazunori Ohkawara[1]. *[1]The University of Electro-Communications, Tokyo, Japan. [2]University of Tsukuba, Ibaraki, Japan. [3]National Institute of Informatics, Tokyo, Japan.*
(No relevant relationships reported)

Square-Stepping Exercise (SSE) program improves cognitive function as well as lower-extremity functional fitness in the elderly. However, it is unclear which aspects of cognitive function are closely associated with performance in SSE. Given that SSE comprises stepping exercise while remembering step pattern, we hypothesized that working memory plays a key role in performance in SSE.
PURPOSE: The purpose of the present study was to test the hypothesis that performance in SSE is associated with working memory. **METHODS:** Sixteen elderly people (10 males and 6 females, age: 72.9 ± 6.3 years, body mass index: 22.1 ± 3.2 kg/m^2) participated in the study. The participants performed a combination of spatial delayed response (SDR) and Go/No-Go (GNG) tasks and SSE. SDR task requires working memory. GNG task requires response inhibition and interference control. The SDR task was graded into three levels of difficulty. Cognitive performance was assessed by reaction time (RT) and accuracy. In SSE, the participants performed multiple directional step patterns on a thin mat partitioned into squares. SSE was graded into five levels of difficulty depending on step pattern. Time to complete SSE was used to assess performance. One-way repeated measures analysis of variance was used for each variable. Pearson correlation analysis was performed to determine the correlation. Data were expressed as mean ± standard deviation. The significance level was set at p < 0.05. **RESULTS:** RT in the SDR task increased with task difficulty (main effect: p < 0.001, level 1: 1.4 ± 0.2 sec, level 2: 1.8 ± 0.3 sec, level 3: 2.2 ± 0.4 sec), while accuracy was not altered. Time to complete SSE also increased with task difficulty (main effect: P < 0.001, level 1: 5.4 ± 0.7 sec, level 2: 8.6 ± 1.4 sec, level 3: 16.7 ± 1.7 sec, level 4: 18.0 ± 3.4 sec). Only eight participants completed SSE at level 5 (26.6 ± 3.4 sec). RT in the SDR task at level 2 was associated with time to complete SSE at level 2 (r = 0.54, p = 0.03). Performance in the GNG task was not associated with time to complete SSE. **CONCLUSION:** The moderate correlation suggests that performance in SSE is associated with working memory. Exercise intervention with square stepping may be particularly effective to improve working memory.

HealtheSteps Process Evaluation: Exploring Delivery of a Healthy Lifestyle Program from Coach and Participant Perspectives

Wendy Blunt, Dawn P. Gill, Brendan Riggin, Judith Belle Brown, Robert J. Petrella, FACSM. *Western University, London, ON, Canada.*
(No relevant relationships reported)

Health*e*Steps is a 6-month lifestyle program, whereby participants at risk for chronic disease meet bi-monthly with a trained Health*e*Steps coach to set prescriptions in the areas of physical activity, exercise, and healthy eating.
PURPOSE: A process evaluation was conducted alongside a pragmatic randomized controlled trial to explore the acceptability of delivering Health*e*Steps to participants at risk for chronic disease by members of the community working at primary care and health services organizations in Southwestern Ontario.
METHODS: Data for the process evaluation included interviews with trained Health*e*Steps coaches post-program (month 6) and interviews with participants, 6 months post-program (month 12). All coach interviews (n=12) and a purposeful sample of participant interviews (n=13) were analyzed separately. The sample of participant interviews were selected based on maximum variation in terms of site location, age, gender, ethnicity, marital status, education, occupation, body mass index, average daily step count, and self-rated health. Transcripts were read through by the research team; key themes and exemplar quotes to support these themes were then identified and summarized.
RESULTS: Coaches found Health*e*Steps was easy to deliver as the focus was only on three key risk factors for chronic disease. Coaches noted group sessions, ensuring participants had the same coach at every session, and evaluating participant readiness prior to beginning the program, could improve the program for future delivery. Participants spoke positively of their coaches and found the program promoted accountability over their healthy lifestyle changes through tracking progress and step counts on the pedometer, and meeting with their coach. Participant suggestions to improve the program included providing pedometers for participants to continue to monitor physical activity, and providing opportunities for the participants to be accountable to their lifestyle changes long-term, once the formal in-person coaching sessions are complete.

CONCLUSIONS: HealtheSteps is an acceptable program for improving the lifestyle habits of individuals at risk for chronic disease. Moving forward, the suggestions for improving the program delivery do not require significant changes to the program protocol.

The Relationship Between Usual Care Intervention And Expanded Intervention On Hospital Readmission And Cost Reduction

Lenard Angelo R. San Miguel. *CUNY-York College, Queens, NY.*
(No relevant relationships reported)

Purpose: This fixed meta-analysis examined the role of hospital interventions - both non-physical activity related and prescribed physical activity regimens - in the reduction of hospital readmission and costs in frail older adults with congestive heart failure after an index of stay.
Method: The data were drawn from the randomized control trials (RCT) of Linden & Butterworth (2014), Constantino et al. (2013), and Ekdahl et al. (2015), studies that sought to chronicle the effectiveness of non-physical activity related interventions compared to the usual care provided to Medicare beneficiaries in the United States. In addition, this paper utilizes the results of the Boa Sorte Silva et al. (2017) study, a two-arm RCT design. The Boa Sorte Silva et al. (2017) study utilized prescribed physical activity regimens with a view toward observing any physiological improvements of note in the study's intervention groups, the results of which will assist in furthering the study of the relationship between prescribed exercise regimens and any correlation with reduced risk for hospital readmission and hospital costs. The fixed effect of the meta-analytic comparison interventions provides considerable insight into potential revisions of continuous treatment plans in Medicare and Medicaid beneficiary programs with regard to risk reduction of hospital readmission and decreased costs.
Results: The results highlighted in Diagram 1, from Linden & Butterworth (2014), Constantino et al. (2013), and Ekdahl et al. (2015) demonstrate a correlational fixed effect on the reduction of the risk for hospital readmission within an index of stay in the intervention group compared to the control group receiving usual care and regardless of the type of intervention used. Constantino et al. reported that the treated intervention group had spent $42,317,329 on overall medical expenses compared to the untreated control group that spent $56,781,559 in total within 30-days post discharge of the first readmission (2013). **Conclusions:** If older adults with physical debilities due to congestive heart failure participate in a prescribed physical regimen, the resulting benefits would reduce the degenerative effects of physical debility as compared to non-participants, which would then lead to a reduction in hospital readmissions and costs.

The Role Healthcare Providers' Physical Activity Levels Have On Barriers To Physical Activity Counseling

Bhibha M. Das, Katrina D. DuBose, FACSM, Alexandra S. Peyton. *East Carolina University, Greenville, NC.* (Sponsor: Katrina D. DuBose, FACSM)
(No relevant relationships reported)

PURPOSE: Because of the link between physical activity and health outcomes, it is important to promote physical activity by prescribing physical activity to patients by healthcare providers. The purpose of this study was to assess healthcare providers' physical activity levels, examine healthcare providers' barriers to counseling physical activity to their patients, and determine if a relationship exists between healthcare providers' physical activity levels and their barriers to physical activity counseling.
METHODS: Providers (N=30; 70% female; 73% Caucasian) completed the International Physical Activity Questionnaire (IPAQ) and a physical activity counseling questionnaire while wearing a pedometer for 7 days
RESULTS: Based on objective measures, **h**ealthcare providers were very active (93%), yet very few knew the physical activity recommendations (7%). Overall the healthcare provider's physical activity level was not related to their physical activity promotion practices. This finding was found when steps per week (r=.12, p=.54), active minutes per week (r=.12, p=.52), and total physical activity minutes from the IPAQ (r=.01, p=.95) were used. The physical activity benefits, identified by the providers, of maintaining health, improving mental health, and attenuates physical declines were positively related with improving activities of daily living and coping with stress (p<.05). Healthcare providers' reported barrier of being unsure what to recommend was positively related with being unsure of the effectiveness of physical activity for patients (p<.05).
CONCLUSIONS: The most pertinent finding from this pilot, exploratory study is that despite only 7% of providers knowing physical activity recommendations, 87% of providers offered some form of physical activity counseling to their patients. Additionally, among this highly active sample of healthcare providers, personal activity habits did not influence physical activity promotion practices with patients. More research is needed to determine if this finding persists among providers who are not as physically active.

Public Health Impact of a Family-based Pediatric Obesity Treatment Program

Roderick T. Bartee, Paige Wuebben, Kate A. Heelan, FACSM. *University of Nebraska at Kearney, Kearney, NE.* (Sponsor: Kate A. Heelan, FACSM)
(No relevant relationships reported)

Family-based pediatric obesity treatment programs have been shown to be effective in reducing obesity among children (Epstein, 2007). A BMI z-score reduction of 0.10 has been shown to achieve clinically meaningful risk factor reduction (Ford et al., 2010), with a 0.25 reduction to maximize risk reduction. An important aspect of combatting childhood obesity is ensuring programs reach as many children as possible. Public health impact can be calculated by multiplying the reach of an intervention by its efficacy or effectiveness (Glasgow et al., 1999). **PURPOSE:** The purpose of this study was to determine the public health impact of Building Healthy Families (BHF): a 12-week family-based pediatric obesity treatment program in a mid-western community of 30,000. **METHODS:** BHF participants were ages 6-11 years (n=52, age: 9.28 ± 1.59 years) with a BMI ≥ 95th percentile. Participants were measured for mass and stature at baseline and post 12-week intervention for each of nine cohorts. BMI percentile and BMI z-score were calculated based on age and gender. Reach was defined as the number of children eligible for the program divided by those who initiated the program. Effectiveness was represented by change in BMI z-score between baselines and post 12-week intervention. Public health impact was calculated by multiplying the number of participants with a BMI z-score reduction of at least 0.10 divided by the number of children eligible for the program. Calculations were made for reach, effectiveness, and impact for all cohorts combined, and each individual cohort. **RESULTS:** The number of children meeting the eligibility requirements, and passively recruited, was 3,226. A total of 52 children initiated and completed the program for a reach of 1.61%. The overall BMI z-score change was -0.29 ± 0.21. Public health impact was 1.5% suggesting that BHF resulted in clinically meaningful risk reduction for body composition and cardiometabolic health for 1.5% of children ages 6-11 in Kearney, NE. **CONCLUSION:** The BHF program is effective and increasing its reach is an important consideration to maximize its public health impact.

Physician Characteristics and Hospital Contextual Factors Associated with Physicians' Intention to Provide Exercise Counseling

An-Min Lynn, Jiun-Hau Huang. *National Taiwan University College of Public Health, Taipei, Taiwan.*
(No relevant relationships reported)

PURPOSE: To identify the physician characteristics and hospital contextual factors associated with physicians' intention to provide exercise counseling (EC). **METHODS**: Self-administered anonymous surveys were conducted in 2016 among physicians attending medical conferences. Physician characteristics included gender, age, education level, specialty, seniority, number of patients per clinic, own exercise frequency, and educational training in sports and exercise. Hospital contextual factors included accreditation and access to health education materials and exercise referral measures. EC-related perceptions were also measured using the Theory of Planned Behavior. Physicians' EC intention was evaluated using a 7-point semantic differential scale, from 1 ("very unlikely") to 7 ("very likely"), which was dichotomized into high versus low EC intention using the median as the cutoff. The study protocol was reviewed and approved by the Research Ethics Committee of the National Taiwan University Hospital. Descriptive statistics were examined. Chi-square test, independent sample t-test, and multivariate regression were used to evaluate the relationships of physician characteristics and hospital contextual factors with physicians' intention to provide EC. **RESULTS**: A total of 1,006 responses were received (response rate = 89.1%) and analyzed. Significantly higher EC intention was found to be associated with the following physician characteristics: exercising "3 times or more/week", having "educational training in sports and exercise", having "30 or more patients per clinic", as well as having "positive attitudes", "supportive norms", and "high perceived control" about EC provision. Only one hospital contextual factor (i.e., working in "medical centers") was linked to higher EC intention. The final model passed the Omnibus and Hosmer-Lemeshow tests, showing satisfactory goodness-of-fit, and was able to accurately predict 79.8% of the results. **CONCLUSIONS**: Physicians' intention to provide EC to their patients was primarily influenced by physician characteristics. Despite the clear practical guideline for EC, physicians and medical students could benefit from educational training for EC and lifestyle medicine, leading to their own positive change toward a more active lifestyle.

Social Support is Associated with Change in Physical Activity Following Bariatric Surgery

Sara J. Kovacs[1], Anita P. Courcoulas[2], Renee J. Rogers[2], Kelliann K. Davis[2], John M. Jakicic, FACSM[2]. [1]*Temple University, Philadelphia, PA.* [2]*University of Pittsburgh, Pittsburgh, PA.*
(No relevant relationships reported)

PURPOSE: To examine the association between pre-surgical behavioral constructs and change in pre- to post-surgical physical activity. **METHODS:** Adults (N=83) who had undergone a Roux-en-Y Gastric Bypass (N=46) or Gastric Sleeve (N=37) procedure within the past 2 years (time since surgery = 0.7 ± 0.6 years) were examined. Leisure-time physical activity was assessed with the Paffenbarger Physical Activity Questionnaire at a post-surgery clinic visit, and participants reported on current physical activity and retrospectively reflected on pre-surgical physical activity. Behavioral constructs previously reported to be associated with physical activity in non-surgical populations were also assessed retrospectively. **RESULTS:** Pre- to post-surgery physical activity [median (25th, 75th percentile)] increased from 156.0 (56.0, 600.0) kcal/week to 976.0 (344.0, 1832.0) kcal/week. Bivariate analysis demonstrated that change in physical activity was correlated with pre-surgical behavioral constructs of health-related quality of life (physical function: r=-0.25, p=0.021, energy/fatigue: r=-0.34, p=0.001), perceived psychological benefits of physical activity (r=-0.22, p=0.046), physical activity self-efficacy (r=0.23, p=0.039), exercise enjoyment (r=-0.23, p=0.038), social support (r=0.26, p=0.016), body image (appearance evaluation: r=-0.22, p=0.043, fitness orientation: r=-0.31, p=0.005, health evaluation: r=-0.23, p=0.033, health orientation: r=-0.24, p=0.029) and perceived behavioral control (r=-0.27, p=0.014). These variables were included as independent variables in a step-wise regression analysis, with change in physical activity as the dependent variable, and controlling for pre-surgical physical activity, gender, surgical procedure and time since surgery. Pre-surgical social support from family was the only behavioral construct that was predictive of change in physical activity from pre- to post-surgery (β= -0.482, p<001). **CONCLUSION:** Social support for physical activity prior to bariatric surgery may be an important behavioral construct that influences the increase in post-surgery physical activity. Studies are needed that target this behavioral construct to confirm this influence on physical activity behavior in patients who undergo bariatric surgery.

Feasibility of Implementing a Healthy Vending Initiative on a Public University Campus

Alexis M. Malmkar, Roderick T. Bartee, Abbey A. Bryce, Kate A. Heelan, FACSM. *University of Nebraska at Kearney, Kearney, NE.*
(No relevant relationships reported)

Vending machines consisting of low-nutrient and high-energy-dense options have been identified as a contributor to weight gain at university campuses (Banna et al., 2017). A Healthy Vending Initiative (HVI) was implemented by a Nebraska Public Health District to encourage public institutions and worksites in rural Nebraska Counties to implement policy to increase access to healthier food options to at least 30% in vending machines. **PURPOSE**: The purpose of this study was to evaluate the feasibility of implementing a Healthy Vending Initiative on a public university campus (enrollment ~7000) in a mid-western community. **METHODS**: Twenty-one vending machines were evaluated using the Nutritional Environment Measures Survey-Vending (NEMS-V). Vending snack items were classified as HEALTHY based on Dietary Guidelines for Americans; ≤ 200 calories per package, $\leq 35\%$ total calories from fat, and $\leq 35\%$ weight from total sugars. Each vending machine was evaluated for percent of items that met guidelines at baseline and after implementing policy and meeting with local vendors, business managers, and administrators advocating to meet the policy guidelines. **RESULTS**: At baseline $20 \pm 3\%$ of vending contents met the guidelines for HEALTHY. Zero snack vending machines met the 30% of HEALTHY food options. After the policy was implemented and vendors and administrators met, only 3 vending machines (15%) met the 30% of HEALTHY food options, but $27 \pm 4\%$ of the food items were considered HEALTHY. **CONCLUSIONS**: Although there was a significant increase (p<0.05) in the percentage of HEALTHY options available in campus vending machines, we were unable to meet the policy of 30% of HEALTHY options in all vending machines. Only 15% of the vending machines on campus met the policy. Working with vendor companies was more challenging than anticipated. For example, the snack vendor communicated that reaching up to 30% of HEALTHY options would not affect revenue, yet an increase of HEALTHY snack items only reached 27%. All stakeholders continue to communicate on possible solutions moving forward. Future research should continue to measure policy implementation and longer-term outcomes including changes in vending purchasing behavior.

Does Music-Based Cadence Entrainment Alter Metabolic Intensity?

Colleen J. Sands, Scott W. Ducharme, Dylan C. Perry, Elroy J. Aguiar, Christopher C. Moore, Catrine Tudor-Locke, FACSM. *University of Massachusetts Amherst, Amherst, MA.* (Sponsor: Catrine Tudor-Locke, FACSM)

(No relevant relationships reported)

The relationship between cadence (steps/min) and intensity (metabolic equivalents; METs) has been primarily established with controlled treadmill-based studies. It may be possible to use music to shape performance of overground walking cadence and thus prescribe intensity. **PURPOSE:** To evaluate overground walking cadence entrainment to music at different tempos (beats per min; BPM) and its ability to evoke intensity in a predictable manner. **METHODS:** Ten participants (6 men, 4 women; age 22.6±1.9 years, height 172.5±11.8 cm, weight 79.3±18.8 kg) completed six 5-minute walking trials around an oval track (40 m). During three trials, participants listened to a single song and matched their foot strikes to the beat of the music. The song tempo was modulated to 80, 100, and 125 BPM (randomized) using a commercially available app. Participants were outfitted with a portable indirect calorimeter to measure intensity (METs). Cadence during all trials was measured via direct observation (hand tally). Mean absolute percent error (MAPE) was calculated to compare the accuracy of participants' entrainment (prescribed versus actual cadence). A simple linear regression model was used to evaluate the relationship between cadence and intensity. **RESULTS**: Participants successfully entrained to the cadences prescribed by the song tempo, especially at faster speeds (MAPE = 3.85±5.63, 3.12±2.88 and 2.63±2.31 for 80, 100 and 125 BPM, respectively). Increased music tempo was associated with a linear increase in intensity across all trials (y=0.16x - 2.14, r^2=0.63, p<0.001). MET values for 80, 100 and 125 BPM were 3.23±0.44, 3.84±0.59, and 5.27±0.78, respectively. **CONCLUSION**: Participants successfully entrained to the modulated tempo of a single song, and faster music tempos elicited increased intensity. Based on these findings, music entrainment appears to be an effective method for evoking desired cadences during walking. The findings further suggest that music may be selected according to its potential to evoke specific intensities of ambulation. Future studies should examine the relationship between music entrainment and intensity with various song styles.

Physical Activity and Cardiometabolic Risk in Young Adults: Baseline Results from the Healthy Body Healthy U Trial Young Adults

Melissa A. Napolitano[1], Jessica Whiteley[2], Meghan Mavredes[1], Laura Hayman[2], Jamie Faro[2], Loretta DiPietro, FACSM[1]. *[1]The George Washington University, Washington, DC. [2]University of Massachusetts Boston, Boston, MA.* (Sponsor: Loretta DiPietro, FACSM)

(No relevant relationships reported)

PURPOSE: Evidence supports the importance of physical activity (PA) in reducing cardiometabolic disease (CMD) risk in adulthood. Less information is available about age-related declines in PA in young adulthood and PA-CMD risk associations in this life course period. The purpose is to describe methods/ rationale for the Healthy Body Healthy U (HBHU) clinical trial, which uses digital intervention strategies to promote weight management among young adults. Recruitment strategies and messaging will be discussed, as will baseline data on objectively measured PA and CMD-risk factors (i.e., fasting glucose, HbA1c, blood pressure[BP]). **METHODS**: Young adults (18-35yo) enrolled in HBHU (n=334; % female=80.2%; % non-white=43.1%; M age=23.3±4.4; M BMI=31.2±4.2) completed laboratory assessments (i.e., fasting blood draws and objective PA monitoring analyzed using standard cutpoints). The sample was split into two age groups 18-24.9 yrs ("Younger") and 25-35 yrs ("Older") to examine differences in PA and CMD-risk during these life course periods. **RESULTS**: Accelerometry data revealed participants engaged in 225.0±148.6 min/wk of moderate-to-vigorous (MVPA), 19.2 ± 9.3 hrs/wk of light activity, and were sedentary 52.6±32.0 hrs/wk. Significant MVPA differences were found between Older vs Younger (204.7 vs 247.2 minutes; p<.01) and Obese vs. Overweight participants (196.2 vs 235.8 minutes p < .05); no differences by age nor weight status were found for light or sedentary activity. Older participants were 0.5 times less likely to meet PA Guidelines (95% CI [.31-.82] p < .01), p=ns by weight status. The relationship between type of activity and CMD-risk was examined by age. For the Older group, there were negative correlations between: light activity and blood glucose (r=-0.22) and diastolic BP (r=-0.20); MVPA and glucose (r=-0.21), all p's<.05. For the Younger group, MVPA was associated with systolic BP (r=0.18; p<.01).**CONCLUSIONS**: These preliminary findings indicate there may be particular risk periods within young adulthood associated with age-related declines in PA. PA may play an increasingly important role in cardiometabolic control as at-risk young adults transition throughout the life course. Future research could target age-related declines in PA and focus on increasing light activity to reduce CMD-risk.

Leg Extensor Power And Healthy Aging Are Associated In Older Adults: 10-year Follow-up Study

Mieko Shimada[1], Scott Going[2], Nobuko Hongu[2], Naofumi Yamamoto[3], Yasuo Kimura[4], Naoki Nakagawa[5], Yutaka Yoshitake[6], Hideo Miyazaki[7]. *[1]Chiba Prefectual University of Health Sciences, Chiba, Japan. [2]University of Arizona, Tucson, AZ. [3]Ehime University, Ehime, Japan. [4]Inst. of Fitness & Health Sciences, Tokyo, Japan. [5]Sanno University, Kanagawa, Japan. [6]National Institute of Fitness and Sports in Kanoya, Kagoshima, Japan. [7]Niigata University, Niigata, Japan.*

(No relevant relationships reported)

Aging is associated with a decline in functional fitness, which reduces mobility and impairs quality of life in older adults. **PURPOSE**: The aim of this study was to assess whether functional fitness tests (i.e., hand-grip strength, one-leg standing time with eyes open, step-test, leg extensor power, knee extensor strength) at age 70 years old (baseline) predict fitness at age 80 years old (10 years follow-up). **METHODS**: At baseline, 600 independent community-dwelling older adults (70 years old, 300 males and 300 females) performed functional fitness testing, with yearly testing for ten years thereafter. For this analysis, participants were divided into three groups: G1, performed testing each year for 10 years (n=180, 106 males, 74 females); G2, measured only at the 10-year follow up (n=343, 173 males, 170 females); and G3, deceased by 10-year follow-up (n=80, 60 males, 20 females). Differences in functional fitness at baseline among groups within males and females were determined using one-way univariate analysis of variance (*P*<0.05). **RESULTS**: Leg extensor power was significantly different between survivors and non-survivors (G1 vs. G3, G2 vs. G3) in males (G1: 14.8±3.5 watt/kg wt, G2: 14.6±3.6 watt/kg wt, G3:12.9±3.4 watt/kg wt) and females (G1: 9.1±2.6 watt/kg wt, G2: 9.0±2.6watt/kg wt, G3:7.3±3.3 watt/kg wt). Knee extensor strength was significantly different between survivors and non-survivors (G1 vs. G3, G2 vs. G3) in males (G1: 1.21±0.27kg/kg wt, G2: 1.12±0.34 kg/kg wt, G3:1.09±0.24 kg/kg wt), but not in females. Similarly, one-leg standing time and hand-grip strength at baseline was only significantly different between groups (G1 vs. G3, G2 vs. G3) in males (one-leg standing time, G1: 79.3±42.2 sec., G2: 75.5±43.2 sec., G3: 63.0±45.0 sec.; HG strength, G1: 40.7±5.6 kg, G2: 38.2±5.6 kg, G3: 38.0±5.5kg, respectively). Baseline stepping was significantly different between groups (G1 vs. G3) in females, but not males (G1: 71.1±11.0/10sec., G2: 70.1±13.0/10sec., G3: 64.4±12.7/10 sec.) **CONCLUSIONS**: Assessment of leg extensor power in older males and females may be an important addition to functional fitness assessment designed to predict healthy aging. Future intervention studies designed to improve leg power and its impact on daily activities could elucidate its role in healthy aging.

Physical Activity Moderates The Association Between Depression And Bone Mineral Density In Men: Korea National Health And Nutrition Examination Survey 2008-2011

Hyo Lee[1], Miyoung Lee[2], Eunhyung Cho[3], Jaegyun Jung[2], Jaemyung Kim[2], Muncheong Choi[2]. *[1]Sangmyung University, SEOUL, Korea, Republic of. [2]Kookmin University, SEOUL, Korea, Republic of. [3]Korea Institute of Sport Science, SEOUL, Korea, Republic of.*

(No relevant relationships reported)

PURPOSE: Research shows that depression is a risk factor for other chronic diseases including bone mineral loss in men. Also, there are strong evidences that weight-bearing physical activity may reduce risk for bone mineral loss. This study was purposed to examine whether MVPA and walking modify the association between depression and bone mineral density (BMD) in male adults. **METHODS:** This study analyzed KNHANES 2008-2011, a population-representative sample of noninstitutionalized Korean. Depression was a dichotomous variable regarding whether the individual have ever been diagnosed as depression by a psychiatrist. Physical activity was measured utilizing IPAQ. BMD was measured by DXA from femoral neck and lumbar spine. Age-group specific [19-34 yrs (*n*=408) vs. 35-49 yrs (*n*=607) vs. 50-64 yrs (*n*=580) vs. 65+ yrs (*n*=492)] linear regression analyses adjusting for sampling weight were conducted. Smoking, binge drinking, serum vitamin D level, calcium intake, age, BMI, and socioeconomic status were included as covariates. **RESULTS:** In 19-34 yrs old group, depression was significantly inversely

associated with femoral neck BMD(B=-.11, p=.015) and lumbar spine BMD (B=-.35, p<.001), but MVPA showed significant effect modifications on both femoral neck BMD loss (B=.09, p=.040) and lumbar spine BMD loss (B=.03, p=.007). Also, walking significantly moderated the association between depression and lumbar spine BMD loss in this age group (B=.05, p=.017). In 35-49 yrs old group, depression was significantly inversely associated with femoral neck BMD (B=-.07, p=003), but walking significantly moderated the association (B=.01, p=.029). In other age groups, depression was not significantly associated with BMD. **CONCLUSION:** This study suggests that practitioners should include MVPA and walking in the depression treatment program to prevent comorbidity for bone mineral loss in young adults. Cardiorespiratory Fitness, Different Adiposity Exposures, and Cardiovascular Disease Mortality Risk in Healthy Women

Stephen W. Farrell, FACSM, Carolyn E. Barlow, Benjamin L. Willis, David Leonard, Andjelka Pavlovic, Laura F. DeFina. *The Cooper Institute, Dallas, TX.*
(No relevant relationships reported)

PURPOSE: We examined the prospective associations among cardiorespiratory fitness (CRF), different adiposity exposures, and cardiovascular disease (CVD) mortality in women. **METHODS:** 19,838 apparently healthy women without history of CVD completed a comprehensive baseline health examination between 1970 and 2013. Clinical measures included body mass index (BMI), waist circumference (WC), waist-to-height ratio (W:HT), percent body fat (%Fat), and CRF quantified as duration of a maximal treadmill exercise test. Women were classified by CRF as low (quintile 1), moderate (quintiles 2-3), and high fit (quintiles 4-5) as well as by standard clinical cut points for adiposity exposures. Hazard ratios (HRs) were computed using Cox regression analysis. **RESULTS:** During a mean follow-up period of 19.2 ± 10.3 years, 391 CVD deaths occurred. Adjusted mortality rates for high, moderate, and low CRF groups were 0.55, 1.28, and 2.0 deaths/10,000 woman-years, respectively (p for trend <.001). Adjusted mortality rates of overweight women within each adiposity exposure were higher when compared with normal-weight women (p<.001). When grouped for joint analyses into CRF x adiposity categories, there was a significant positive trend in CVD mortality across decreasing categories of CRF within each category of W:HT and %Fat, as well as within the normal and overweight BMI categories and the normal WC category (p<.03). CRF was not significantly associated with CVD mortality within the obese BMI or high WC categories. **CONCLUSION:** Higher levels of CRF are associated with lower CVD mortality risk in women, and attenuate the risk of CVD mortality in overweight women. The use of various adiposity measures to estimate CVD mortality risk in women may be misleading unless CRF is also considered. These findings support the 2016 American Heart Association Scientific Statement recommending that CRF measurement or estimation be included in routine clinical practice.

A Strategy To Reduce The Dropout Rate In A Volunteer-led Community Weight-loss Program

Ryoko Mizushima, Yoshio Nakata, Xinyu Zuo, Seiji Maeda, Kiyoji Tanaka, FACSM. *Tsukuba University, Tsukuba, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)
(No relevant relationships reported)

We implemented a volunteer-led community weight-loss program within the Tsuchiura City (Japan) routine health promotion program in 2015. Although the participants successfully decreased their body weight, there was a relatively high dropout rate. We interviewed a focus group after the intervention, revealing a lack of understanding about the weight-loss program. To address this issue, we planned to increase communication among the participants in the subsequent 2016 trial. **PURPOSE:** The purpose of this study was to compare the degree of weight loss and the dropout rate between the 2 interventions (2015 vs. 2016). **METHODS:** Participants were Tsuchiura residents with a body mass index (BMI) >25 kg/m²: 27 in 2015 (4 men, age 60.7 ± 4.0 years, BMI 29.7 ± 4.0 kg/m²) and 39 in 2016 (9 men, age 57.3 ± 11.0 years, BMI 28.8 ± 3.8 kg/m²). The weight-loss program was led by community volunteers who attended 4 to 5 training sessions (3 hours per session). The program consisted of 8 sessions (2 hour per session) over 3 months. Participants were instructed to maintain a well-balanced low-calorie diet targeting 1680 and 1200 kcal/day for men and women, respectively. In 2016, we added exercises, group activities, and cooking demonstrations to increase communication and deepen participants' understanding of the weight-loss program. **RESULTS:** In 2015, 15 of 27 participants completed the 3-month program (dropout rate, 44.4%); their mean (95% confidence interval) weight loss was 6.7 (4.7–8.6) kg, corresponding to 8.7% of initial body weight. In 2016, 31 of 39 completed the program (dropout rate, 25.8%); their mean weight loss was 5.6 (4.5–6.6) kg, corresponding to 8.0% of initial body weight. A significant difference was found in the dropout rate (44.4% vs 25.8%, P < 0.05).

CONCLUSION: We reduced the dropout rate while obtaining equivalent weight loss by increasing communication among the participants during a volunteer-led community weight-loss program.

Physical Activity Guideline Attainment and Gender Influence Chronic Disease Risks Among African American College Students

Amanda A. Price, Georgia McCauley, Vanessa Duren-Winfield. *Winston-Salem State University, Winston Salem, NC.* (Sponsor: Melicia C. Whitt-Glover, FACSM)
(No relevant relationships reported)

Chronic disease risk and poor health behaviors, including physical inactivity, are increasing among college students. African American (AA) college students are a vulnerable population given the disproportionate manifestation of chronic disease in AA adults. AA women are particularly high risk given the higher prevalence of chronic diseases among women compared with men.**PURPOSE**: To examine differences in chronic disease risk among AA college students by attainment of physical activity (PA) guidelines and gender.
METHODS: AA college students (N=63; 43 female, 20 male; aged 18.2 ± 1.3 yrs) were recruited for a study examining and intervening on cardiovascular disease risk. Physical assessments and blood marker investigation were collected. Participants also completed self-report surveys: International PA Questionnaire (IPAQ), Perceived Stress Scale (PSS), and Pittsburgh Sleep Quality Index (PSQI). Students were categorized by meeting or not meeting PA guidelines ($\geq$ 150 min/wk). Descriptive statistics, frequencies, and independent samples t-tests were used to describe overall and stratified chronic disease risk profiles.
RESULTS: Overall, students were overweight/obese (54%), had optimal blood profiles, did not attain the PA guidelines for health (54%), were moderately stressed (PSS: 15.1 ± 6.5), had poor sleep quality (PSQI: 5.7 ± 3.1), and failed to meet sleep recommendations (6.5 ± 1.2 hrs/night). Females reported higher perceived stress than males (PSS score 16.7 ± 5.6 vs. 11.5 ± 7.2, p<.01); no other gender-specific differences in physical or blood biomarkers were detected. More males (85%) than females (28%) met PA guidelines. Females who met PA guidelines had significantly lower waist circumference (74.1 vs. 85.7 cm), BMI (23.1 vs. 28.6), and LDL cholesterol (65.1 vs. 74.3 mg/dL), and higher sleep quality (4.8 vs. 6.0) compared with females not meeting PA guidelines (all p <.05). There were no significant differences between males by PA guideline attainment.
CONCLUSIONS:We identified linkages between PA guideline attainment and chronic disease risk in AA college students, which was more meaningful among females. Given the low PA rates among females, additional work is needed to understand strategies for increasing PA among female AA college students.

The Prevalence of Hypertension in a Population of Former Professional Football Players

Jaime Kaplan, Genevieve E. Smith, Gregory W. Stewart, FACSM. *Tulane University School of Medicine, New Orleans, LA.* (Sponsor: Gregory Stewart, MD, FACSM)
(No relevant relationships reported)

OBJECTIVE: There is substantial data suggesting that former professional football players have considerable cardiovascular disease risk. The objective of this study was to better understand the prevalence of hypertension, a major risk factor for cardiovascular disease, in former professional football players. **DESIGN:** Data including blood pressure, height, and weight were collected from 981 former professional football players between April 2015 and May 2017 during cardiovascular screening events held throughout the U.S. Demographic information was collected from all subjects, including age, race, previous hypertension diagnosis, and treatment. Means were analyzed using one-way ANOVA, Chi square, or paired T-tests where appropriate. **RESULTS:** Pre-hypertension was greatest for former players aged 20-59, with almost 50% of those aged 20-39 pre-hypertensive at screening. Hypertension was greatest in former players aged 60+, with more than 50% of these individuals hypertensive at screening; over 20% of those 20-39 were hypertensive. White former players aged 60+ had the lowest prevalence of pre-hypertension. Hypertension prevalence was only significantly different between age-specific racial groups at age 40-59. The majority of former players had a BMI $\geq$ 30 kg/m², regardless of age; those with normal BMI were least likely to be hypertensive. Over 30% of former players reported previous hypertension diagnosis, with approximately 75% of those diagnosed reporting treatment. Of those former players that reported treatment, most had poorly controlled blood pressure at the time of screening. Of former players that reported no hypertension diagnosis, 41% had elevated blood pressure at screening. Former players aged 30-39 had the highest prevalence of previously undiagnosed elevated blood pressure at screening. **CONCLUSIONS:** Hypertension is a serious concern for former professional football players, even those considered to be younger and at decreased

---

risk. This may be related to the high BMI typically associated with these athletes. Blood pressure control in those reporting diagnosis is also a concern, as the majority of those men had high blood pressure at screening.

Waist Circumference Influences Associations Between Physical Activity And Metabolic Syndrome Risk In College-aged Females

G.M. Frederick[1], M.V. Fedewa[2], B.M. Das[3], W.J. McConnell[1], E.D. Hathaway[4], R.E. Salyer[1], S. Higgins[5], M.D. Schmidt[1], E.M. Evans, FACSM[1]. [1]University of Georgia, Athens, GA. [2]University of Alabama, Tuscaloosa, AL. [3]East Carolina University, Greenville, NC. [4]University of Tennessee Chattanooga, Chattanooga, TN. [5]Elon University, Elon, NC. (Sponsor: Ellen M. Evans, FACSM)

(No relevant relationships reported)

PURPOSE: Metabolic syndrome (MetS) increases risk for chronic disease with diagnostic criteria including elevated systolic and/or diastolic blood pressure (SBP and DBP, respectively), triglycerides (TRG), glucose (GLU), waist circumference (WC), and reduced HDL-cholesterol (HDL). Although the prevalence of MetS is low among college students, risk factors for this condition are emerging in this population, especially in females. Moderate-to-vigorous physical activity (MVPA) is known to aid in the prevention of MetS risk factors. While WC is a component of MetS, it may also influence the effect of MVPA on other MetS components. Thus, this study aimed to explore the impact of WC on the association between MVPA and MetS risk factors in college-aged females.
METHODS: College-aged females (n = 328; 18.7 ± 1.2 yo) were assessed for MetS risk factors using standard clinical methods with factor presence being defined by the Adult Treatment Panel III criteria. MVPA was measured using accelerometry (NL-1000; 4 valid, 10-h days of wear). Pearson's correlations were used to assess bivariate associations. Linear regression was used to examine whether here was a significant interaction between WC risk factor status and the associations between MVPA and MetS risk factors.
RESULTS: Among those with normal WC (NWC; n = 287), MVPA was significantly associated with SBP ($r = -.228$), DBP ($r = -.216$), TRG ($r = -.140$), GLU ($r = -.129$), WC ($r = -.250$.) and HDL ($r = .199$; all $p <0.05$). Among females with high WC (HWC; n = 41), associations between MVPA and MetS risk factors were similar in magnitude or stronger, and significant for SBP ($r = -.430$), DBP ($r = -.420$), and WC ($r = -.374$; all $p <0.05$). Only the association between MVPA and SBP was significantly different across WC strata, with a stronger association observed among the HWC group ($p < 0.05$).
CONCLUSIONS: As hypothesized, these results suggest that WC moderates the association between MVPA and some MetS risk factors. Future research should aim to explore these associations among a larger sample with more variation in WC.

The Prevalence of Obesity and Diabetes Mellitus in a Former Professional Football Player Population

Genevieve E. Smith, Gregory W. Stewart, FACSM. *Tulane University, New Orleans, LA.* (Sponsor: Gregory Stewart, MD, FACSM)

(No relevant relationships reported)

PURPOSE: To provide information on the prevalence of obesity and diabetes mellitus (DM) in former professional football players. **METHODS:** For this cross-sectional study, 1106 former NFL players were sampled between April 2015 and July 2017. Height and weight were used to calculate BMI; blood samples were obtained from fasted subjects for analysis of fasting blood glucose and hemoglobin A1c. Subjects also completed a questionnaire regarding DM diagnosis. Subjects were assessed for obesity and DM status based on BMI, FBG, HbA1c, and questionnaire results, and stratified by age (20-39, 40-59, 60+), primary career playing position (Big, Big Skill, Skill), and race (Black, White, Other). Statistical analyses included 1-way ANOVA and Tukey post hoc analysis when variances were equal, or Dunnett C statistic for heteroscedastic data. T-tests were used to evaluate differences between groups. **RESULTS:** The prevalence of obesity (BMI ≥ 30) for this population was 63.6%, while the overall prevalence of DM and pre-DM was 13.8% and 61.7%, respectively. Prevalence of both DM and self-reported DM diagnosis increased with each 20 year increase in age ($p<0.0001$). There was a significant effect of BMI on DM status, with obese men more than twice as likely to be diabetic (odds ratio 2.375, 95% CI 1.555-3.628). The "Big" position group were more likely to be obese as compared with "Big Skill" or "Skill" ($p<0.0001$). Curiously, there was no difference in the prevalence of DM between any of the 3 position groups. When examined further, "Skill" had the highest prevalence of non-obese diabetics, while "Big" had the lowest ($p=0.0002$), possibly explaining the lack of overall difference in the prevalence of DM between the 3 groups. Although White subjects were older than either Black or Other race subjects, Black subjects had higher BMI and prevalence of obesity than white subjects and, correspondingly, a

greater prevalence of DM. **CONCLUSION**: Although patterns and trends may reflect those commonly observed in the general population, the prevalence of obesity and DM may be higher in this population than typically reported in the general U.S. population. Furthermore, there may be special consideration that must be given to a former player's previous training with regards to his risk of developing diabetes, aside from current age, health, and BMI status.

Vigorous Intensity Volume, Not Total Volume Of Physical Activity, Predicts Adiposity In Young Adults

Minsuk Oh, Kathleen F. Janz, FACSM, Steven M. Levy. *University of Iowa, Iowa City, IA.* (Sponsor: Kathleen F. Janz, FACSM)

(No relevant relationships reported)

Vigorous intensity volume, not total volume of physical activity, predicts adiposity in young adults.
PURPOSE: To investigate which daily level of physical activity (PA) is the best predictor of adiposity in young adults.
METHODS: Young adults aged 19.8 years (n = 182 females and 147 males) in the Iowa Bone Development Study were examined. PA was objectively measured by the ActiGraph accelerometer and classified into categories of min/d (i.e., sedentary, light, moderate, vigorous, total metabolic equivalent task (MET)) using the Crouter 2-regression model equation. Lean body mass and total body fat (kg) including visceral adipose tissue (VAT, g) were measured by dual energy X-ray absorptiometry. Associations between PA categories and adiposity were analyzed by partial correlation analysis adjusted for height and lean body mass. Multiple linear regression analysis was used to examine the most influential PA exposure for adiposity. All analyses were conducted separately by gender. Significance level was set as $< 0.05*$ or $< 0.01**$.
RESULTS: Body fat was negatively associated with both vigorous PA ($r = -.29**$) and total PA MET time ($r = -.21**$) in males. In females, body fat was negatively related with vigorous PA time ($r = -.24**$), and VAT had significant associations with SED ($r = .18*$) and all PA variables (moderate $r = -.21**$, vigorous $r = -0.21*$, and total METs time $r = -0.22**$) except light PA time. Multiple linear regression analysis indicated that the best predictor for body fat mass (after adjustment for height and lean body mass) was vigorous PA time for females ($\beta = -.142*$, $R^2 = .70$, vigorous PA effect on R^2 for vigorous PA = .02) and males ($\beta = -.216*$, $R^2 = .50$, R^2 for vigorous PA = .04). Other PA exposures including total PA METs time were not significant after vigorous PA entered the model.
CONCLUSION: Vigorous intensity volume of PA, not total volume of PA, is the best predictor of body fat mass in young adults. This result suggests that interventions should focus on running, cycling and other intense physical activities to help young adults maintain a healthy level of adiposity.

Association Between Physical Activity Level, Body Composition And Muscular Strength Among Health Professional

João Henrique V. Pietri, Amauri dos Santos, João Pedro da Silva Junior, Diana Carolina Gonzalez, Victor Keihan Rodrigues Matsudo. *CELAFISCS, São Paulo, Brazil.*

(No relevant relationships reported)

PURPOSE: To examine the association between physical activity level (PAL), body composition and muscular strength health among health professionals.**METHODS**: Physical activity level (PAL) was determined by pedometer, and steps counting was taken according to Tudor-Locke C et al. 2004. Sample consisted of 68 women and 11 men, with mean age 48.7 ±9.3 years old. A pedometer (DIGI-WALKER/YAMAX) was used in the waist by the participants as soon as they wake up until they go to bed, removing the pedometer in cases involving water activities, during 7 days in a row, including a weekenday.**STATISTICAL ANALYSIS:** The regression linear analysis with 95% Confidence interval for β was determined using SPSS 20.0, and a level of $p<.05$ was taken as significant.**RESULTS:** 33% of participants could be considered sedentary, not reaching at least 5000 steps/day. They presented a mean BMI 31.3 ±6.6 kg/m², and they performed only 3,256 ±1,223 steps per day. The prediction values between physical activity level and the other variables are in the table below. **CONCLUSIONS**: Unfortunately, health professionals from Sao Paulo state are not active enough. Objectively measured of physical activity level was significantly associated with BMI health professionals.

Physical Activity (PAL) Steps/day

N= 79	β	95% Confidence Interval	p

The Influence of Physical Activity on Energy Balance and Resting Metabolic Rate in Adults

Robert Buresh, FACSM[1], Yuri Feito, FACSM[1], Cassie Williamson[1], Brian Kliszczewicz[1], Corrine Ellis[2], Leah Tsui[2], Anna Schlupp[2], Kelsey Shepard[2], Stella Volpe, FACSM[2]. [1]Kennesaw State University, Kennesaw, GA. [2]Drexel University, Philadelphia, PA.
(No relevant relationships reported)

Recent studies have suggested a constrained energy expenditure model, wherein the capacity of physical activity to increase total daily energy expenditure is limited in part by adaptations in resting metabolic rate. **PURPOSE:** To assess the influence of physical activity energy expenditure (PAEE) (quantified with an ActiGraph GT3X+ activity monitor) on energy balance (EBAL) in a cross-sectional study of free-living adults. **METHODS:** 36 women (39.7 ± 14.8 years of age) and 12 men (33.0 ± 13.7 years of age) participated in this study. Height, weight, waist circumference, body composition, and resting metabolic rate were assessed. Participants wore ActiGraph GT3X+ activity monitors and documented dietary intake via food logs and photographs for 5 to 6 consecutive days. **RESULTS:** PAEE was correlated with EBAL ($r = -0.42$, $p < 0.01$). PAEE explained more than 21% of the variance in EBAL when applied using a quadratic model - EBAL = $0.001(PAEE^2) - 3.105(PAEE) + 635.6$ ($p = 0.011$, $r^2 = 0.214$). Increases in PAEE were associated with decreases in EBAL up to approximately 1,100 kcal·day⁻¹, beyond which no further reductions in EBAL were observed. The capacity of PAEE to reduce energy balance may have been limited, in part, by the inverse relationship between PAEE and resting metabolic rate (RMR) ($r = -0.41$, $p < 0.01$). **CONCLUSIONS:** EBAL was reduced by increasing PAEE up to about 1,100 kcal·day⁻¹, beyond which adjustments in RMR may contribute to preventing further reductions in EBAL. These findings support a constrained model of energy expenditure.

Exercise and Anxiety in Adults with Arthritis and Other Rheumatic Diseases: Support for Evidential Value

George A. Kelley, FACSM, Kristi Sharpe Kelley. West Virginia University, Morgantown, WV.
(No relevant relationships reported)

PURPOSE: Determine whether evidential value exists that exercise reduces anxiety in adults with arthritis and other rheumatic diseases (AORD). **METHODS**: Utilizing data derived from a prior meta-analysis of 14 randomized controlled trials that included 926 participants (539 exercise, 387 control) with AORD, a recently developed approach, P-curve was used to determine evidential value by assessing for publication bias and p-hacking. Binomial tests with p values categorized as either low ($p < 0.025$) or high ($p > 0.025$ up to <0.05) were compared. In adults with AORD, evidential value of a true effect of exercise on anxiety was determined using the more robust Stouffer's test to combine results across studies with half p-curve results that were right-skewed (p value <0.05) or results in which both the half and full tests were right skewed (p value <0.10). Binomial and full p-curve tests based on Stouffer's method were also used to determine if evidential value was inadequate or absent when a 33% power test was <0.05 for the full p-curve or the half p-curve and the binomial test was <0.1. Statistical power was calculated by comparing the expected p-curve for each possible value ranging from 5% to 99% and then choosing the power level that results in an expected p-curve most similar to the actual p-curve. To examine the influence of selected studies on p-curve results, findings were also examined by dropping the highest and lowest p-values from the analysis. All analyses were conducted using P-curve, version 4.052. **RESULTS:** The binomial test trended towards evidential value of a true effect regarding the benefits of exercise in adults with AORD ($p = 0.11$) while the more robust Stouffer's test satisfied both conditions for evidential value ($p = 0.002$ for both full and half p-curves). Similarly, binomial ($p = 0.867$) and full p-curve ($p = 0.953$) results did not suggest that evidential value was inadequate or absent. Power analyses suggested a good fit for the observed p-curve. Results were generally robust when the most extreme values were either included or excluded. **CONCLUSIONS:** The lack of observed publication bias and p-hacking provide evidential support for the benefits of exercise on anxiety in adults with AORD.
Supported by NIH grant R01AR061346.

Activity Pacing, Fatigue, Physical Activity And Quality Of Life In Adults With Multiple Sclerosis

Ulric S. Abonie[1], Femke Hoekstra[2], Trynke Hoekstra[2], Cees P. van der Schans[2], Rienk Dekker[2], Lucas H. V. van der Woude[2], Florentina J. Hettinga[1]. [1]University of Essex, Colchester, United Kingdom. [2]University of Groningen, Groningen, Netherlands. (Sponsor: Carl Foster, FACSM)
(No relevant relationships reported)

In response to fatigue persons with multiple sclerosis (MS) make several behavioural adaptations, such as resting and limiting activity, sometimes resulting in an unevenly spread activity pattern throughout the day, consisting of short activity peaks followed by long rest periods. These patterns are inefficient and have been linked to increased disability. Activity pacing is a behavioural strategy that is thought to help alter such inefficient patterns, yet little is known about how persons with MS naturally use this strategy to manage fatigue and optimise their daily activities.
PURPOSE: To examine how actively engaged persons with MS are in pacing decisions in daily life and what their perceived difficulty in preventing overactivity is. Also explore relations of this naturalistic pacing behaviour with fatigue, physical activity (PA) and health-related quality of life (HRQoL).
METHODS: 53 persons with MS (median age= 45 ± 10 years) filled in questionnaires on their active engagement in pacing decisions and perceived difficulty in preventing overactivity (5-point Activity Pacing Questionnaire), fatigue (7-point Fatigue Severity Scale), PA (time spent on activities using an adapted SQUASH) and HRQoL (RAND-12) post rehabilitation, collected within the ReSpAct program, a nationwide multi-centre program aimed at stimulating and promoting an active lifestyle in rehabilitation. The relationships between the variables were examined using hierarchical regression models.
RESULTS: Active engagement in pacing decisions and perceived difficulty in preventing overactivity were high ($3.80 \pm .90$ and 4.00 ± 1.50 respectively). Fatigue was moderately severe (5.78 ± 1.44). HRQoL was fairly good (33.02 ± 10.50). Fatigue was related to low HRQoL ($\beta = -.340$; p= .019). No relations were found between active engagement in pacing decisions and fatigue, between active engagement in pacing decisions and PA and between active engagement in pacing decision and HRQoL.
CONCLUSIONS: The lack of associations between pacing and fatigue, PA and HRQoL despite the high engagement in pacing found in this study indicates the varied use of pacing. While some may be using pacing in response to high fatigue, others may be using pacing to optimise their daily activities. Guidance on pacing may lead to successful health outcomes in persons with MS.

Association Between Sedentary Behavior, Body Composition, Muscular Strength And Quality Of Life Among Health Professionals

Bianca Regina de Oliveira, Amauri dos Santos, João Pedro da Silva Júnior, Victor Keihan Rodrigues Matsudo. CELAFISCS, Sao Paulo, Brazil.
(No relevant relationships reported)

Bianca Regina de Oliveira, Amauri dos Santos, João Pedro da Silva Júnior, and Victor Keihan Rodrigues Matsudo.
Center of Studies of the Physical Fitness Research Laboratory from São Caetano do Sul (CELAFISCS)
aosseuspesagenda@gmail.com

Objective: to associate sitting time with body composition, muscle strength and quality of life in health professionals. Methods: The sample consisted of 1036 professionals (241 male and 794 female). Sedentary behavior was measured in minutes / day during the week (short IPAQ). Measures included BMI (kg / m2), abdominal circumference (cm), and handgrip (kg). Quality of life was divided into physical, psychological, social, environmental and general domains (WHOQOL-BREF). **Statistical analysis:** Multiple linear regression was used to associate the study variables. **Results:** Factors associated with sitting time comprised: age and the physical, psychological and social domains of quality of life. The percentage of fat, BMI, Abdomen circumference (cm), Muscular strength (kg) and the environmental and general domains were not associated with sitting time as it is shown in the table below. **Conclusion:** In the present sample sitting time during a weekday presented an inverse association with age and the physical, psychological and social domains of quality of life.

WEDNESDAY, MAY 30, 2018

Examining Relationships Between Pregnancy Symptoms and Gestational Weight Gain

Ashlyn A. Swafford, Rebecca A. Schlaff, Meghan Baruth, Samantha J. Deere. *Saginaw Valley State University, University Center, MI.*
(No relevant relationships reported)

Self-reported pregnancy symptoms may impact physical activity levels and dietary behaviors, thereby influencing gestational weight gain (GWG). However, little is known about the relationship between symptoms and GWG. **PURPOSE:** To examine the associations among various pregnancy symptoms (fatigue, back pain, pelvic pain, swelling, and nausea) and GWG. **METHODS:** Women who were 14-20 weeks gestation were recruited into a physical activity and nutrition behavioral intervention. At study enrollment, women completed an online survey that assessed various demographic variables, height and pre-pregnancy weight, and the presence (yes/no) of fatigue, back pain, pelvic pain, swelling, and nausea. GWG was calculated by subtracting pre-pregnancy weight from last recorded weight during pregnancy (range: 31-40 weeks gestation). Linear regression analyses were utilized to investigate relationships among individual symptoms and GWG, controlling for gestational age at last weight and pre-pregnancy body mass index (BMI). An alpha level of 0.05 was used to determine statistical significance. **RESULTS:** Participants (n=38) averaged 28.7±4.1 years of age and 18.1±2.5 weeks gestation at enrollment. A majority of women were married (76.3%), college graduates (65.8%), white (86.5%), and employed (84.2%). Pre-pregnancy BMI averaged 27.9±10.4 kg/m², and gestational age at the last recorded weight averaged 35.9±1.6 weeks, with total GWG averaging 30.9±13.3 pounds. Women reporting nausea had significantly greater GWG than those not reporting nausea (p=0.0015). There were no significant relationships between GWG and fatigue (p=0.97), back pain (p=0.19), pelvic pain (p=0.44), or swelling (p=0.98). **CONCLUSION:** Overall, the presence of nausea during early pregnancy was the only significant predictor of GWG. Specifically, women who reported nausea gained significantly more weight than those who did not. Future research should prospectively investigate the mechanisms by which nausea impacts health behaviors (thereby influencing GWG) within larger, more diverse samples. This information could prove to be valuable targets for behavioral interventions seeking to optimize GWG and maternal/child health outcomes.

Mean Combined Relative Grip Strength and Metabolic Syndrome: 2011-2014 NHANES

Mary Summerlin, Michael R. Richardson, James R. Churilla, FACSM. *University of North Florida, Jacksonville, FL.*
(Sponsor: James R. Churilla, FACSM)
(No relevant relationships reported)

PURPOSE: Examine mean combined relative grip strength (RGS), stratified by gender, according to individual metabolic syndrome (MetS) criterion and in those with MetS using a nationally representative sample of U.S. adults.
METHODS: Data from the 2011-2014 National Health and Nutrition Examination Survey (NHANES) was used to examine mean combined RGS (kg/BMI) in U.S. adults (≥ 18 years of age) according to individual MetS criterion and in those with MetS. Study sample (n=4307) included adults who participated in the muscle strength examination session in the mobile examination center. Cardiometabolic risk factors included elevated waist circumference (WC), elevated blood pressure (BP), elevated triglycerides (TG), impaired fasting glucose (IFG), and reduced high density lipoprotein cholesterol (HDL-C).
RESULTS: Compared to those with desirable values, mean combined RGS was significantly lower in men (p<0.05) with elevated WC (3.61 vs. 2.79 kg/BMI), elevated BP (3.36 vs. 2.83 kg/BMI), elevated TG (3.44 vs. 2.97 kg/BMI), IFG (3.48 vs. 3.05 kg/BMI), reduced HDL-C (3.31 vs. 3.06 kg/BMI), and in those with MetS (3.47 vs. 2.79 kg/BMI), respectively. Similarly, compared to those with desirable values, mean combined RGS was significantly lower in women (p<0.05) with elevated WC (2.47 vs.1.81 kg/BMI), elevated BP (2.14 vs. 1.72 kg/BMI), elevated TG (2.15 vs. 1.79 kg/BMI), IFG (2.18 vs.1.80 kg/BMI), reduced HDL-C (2.11 vs. 1.84 kg/BMI), and in those with MetS (2.19 vs. 1.72 kg/BMI), respectively.
CONCLUSIONS: Mean combined RGS was lower in men and women with increased cardiometabolic risk and in those with MetS.

Body Composition and Aerobic Capacity in Mexican Police officers

Maciste H. Macias Cervantes[1], Evelin Moreno-VArgas[1], Natalia Vilchis-Valadez[1], Arturo Figueroa, FACSM[2], Claudia Luevano-Contreras[1], Ma.Eugenia Garay-Sevilla[1], Ana L. Gonzalez-Yebra[3]. *[1]Departamento de Ciencias Medicas UG, Leon, Mexico. [2]Texas Tech University, Lubbock, TX. [3]UNIVERSIDAD DE GUANAJUATO, Leon, Mexico.*
(No relevant relationships reported)

In Mexico, there are scarce data on body composition and aerobic capacity (maximal oxygen consumption, VO$_2$max) in police officers. Purpose. To describe body composition and VO2max in Mexican police officers. Methods. This was a descriptive study evaluating body composition and VO2max in 494 police officers (426 men and 68 women). Weight, height and waist circumference were measured and body mass index (BMI) calculated. Body composition was evaluated by bioelectrical impedance analysis (BIA), and VO$_2$max was assessed using the modified Taguchi protocol in a cycle ergometer. VO$_2$max was calculated by the formula suggested by ASCM and classified as superior, excellent, good, fair, poor and very poor. Associations between body composition measures and VO$_2$max by BMI categories were evaluated. Results. The general characteristics of police officers are presented in table 1. By BMI, 19.6%, 49.4%, 24.5 and 6.5% were considered normal weight, overweight, obese class-1 and obese class-2, respectively. By BIA, 77.1% had elevated body fat percentage (BF%). By waist circumference, 57.7% are considered obese. In addition, 22.7% of normal weight, 53.3% of overweight, 81.9% of obese class-1 and 93.8% of obese class-2 had poor and very poor VO2max. By BMI categories, VO$_2$max was inversely correlated with waist circumference (r=-0.33, p=0.001), (r=-0.29, p< 0.001), (r=-0.34, p<0.001), and (r=-0.37, p=0.04), while by Body fat mass (r=-0.22, p=0.03), (r=-0.39; p<0.001), (r=-0.36; p< 0.001), and (r=-0.46; p=0.01) in normal weight, overweight, obese class-1, and obese class-2, respectively. Conclusions. A high percentage of police officers were obese or normal weight and elevated abdominal and/or total body adiposity was associated with low aerobic capacity.

Table 1. Subjects characteristics by BMI classification.			
	NORMAL WEIGHT n=97	OVERWEIGHT n=68	OBESITY CLASS 1 n=121	OBESITY CLASS 2 n=31
Age (years)	30.2 ± 7.3*	34.1 ±7.6	35.6 ±7.9	36.7 ±8.8
VO$_{2max}$ (ml/kg*min)	43.8 ± 6.5¨	39.6 ±6.3**	34.3 ± 5.1**	30.1 ± 4.2**
Waist circumference (cm)	82.7 ± 6.7 ¨	93.8 ± 7.3¨	104.7 ± 7.8**	114.7 ± 7.4 ¨
Body fat mass (kg)	13.5 ± 5.6 ¨	20.6 ± 4.2¨	29.4 ± 4.6 ¨	42.1 ± 5.8 ¨

VO$_{2max}$ = maximal oxygen consumption. Data are presented as mean±SD. ANOVA test was used for differences between BMI categories. Bonferroni post-hoc tests were used.
* p< 0.001 vs all groups. ** p< 0.001 all groups are different.

Trajectories of Stair Climbing Performance for Black and White Midlife Women

Brittney S. Lange-Maia[1], Imke Janssen[1], Carrie Karvonen-Gutierrez[2], Stephanie L. Fitzpatrick[3], Elsa S. Strotmeyer[4], Bradley M. Appelhans[1], Elizabeth F. Avery[1], Sheila A. Dugan, FACSM[1], Howard M. Kravitz[1]. [1]Rush University Medical Center, Chicago, IL. [2]University of Michigan, Ann Arbor, MI. [3]Kaiser Permanente, Portland, OR. [4]University of Pittsburgh, Pittsburgh, PA. (Sponsor: Sheila Dugan, FACSM)
(No relevant relationships reported)

PURPOSE: To identify longitudinal physical performance trajectories in midlife women and factors associated with each, with focus on physical activity and body mass index (BMI). METHODS: Participants were black (n=397) and white (N=416) women (age 42-57) from the Michigan and Chicago sites of the Study of Women's Health Across the Nation (SWAN). A stair climb test (ascend and descend 4 steps, 3 cycles) was performed at up to 10 visits (min 2; max follow-up about 9 years). Growth mixture modeling was used to identify longitudinal trajectories in stair climb completion time. Physical activity was assessed with the Kaiser Physical Activity Survey (KPAS) and BMI was derived from height and weight (all from baseline). Analyses were stratified by race due to racial disparities in physical performance in this cohort and the broader literature.
RESULTS: We identified two distinct trajectories—a group with relatively stable performance over time and one that substantially slowed—for each race. For black women, 92.9% were in the stable group (median baseline 19.0 sec) and had only a small increase in completion time over follow-up. The group who slowed (7.1%) had a median stair test completion time of 27.5 seconds and slowed about 10 sec over follow-up. For white women, 89.8% were in the stable group (median baseline 17.0 sec). The group who slowed (10.2%) was slightly larger compared to black women, though had a median baseline time of 24.0 sec and slowed about 5 sec over follow-up. Those who slowed had higher baseline BMI (black: 39.8 ± 8.6 vs 31.5 ± 7.3; white: 38.2 ± 7.5 vs 28.8 ± 6.6; $p<0.001$ each) and lower baseline KPAS scores (black: 6.2 ± 1.4 vs 7.4 ± 1.8; white 6.7 ± 1.7 vs 8.3 ± 1.7: $p<0.001$ each) compared to those with stable stair climb time.
CONCLUSIONS: The majority of women had stable stair climb times, but those with higher BMI and lower physical activity tended to substantially slow. Identifying physical performance patterns in midlife may be instrumental in the development of tailored, early interventions for those at risk for steep declines in physical function. SWAN has grant support from the National Institutes of Health Grants U01NR004061; U01AG012505, U01AG012535, U01AG012531, U01AG012539, U01AG012546, U01AG012553, U01AG012554, U01AG012495.

Relationship between Body Composition and Health Behaviors in High and Low Fit College Women

Chaise A. Murphy, Shinya Takahashi, Jim Bovaird, Jean Ann Fischer, Maruša Černjul, Desmond Cooney, Karsten Koehler. *University of Nebraska-Lincoln, Lincoln, NE.*
(No relevant relationships reported)

College-age women exhibit particular susceptibility to establishing health behaviors resulting in unwanted weight gain or chronic dieting. Understanding the relative contribution of health behaviors to body composition could inform targeted interventions to correct unhealthy weight gain or loss. **PURPOSE:** To create a model describing relationships among physical activity (PA), aerobic fitness (VO_{2max}), eating behavior traits and their association with body composition in female college students. **METHODS:** Female students (n = 98) were recruited from a freshmen-level university nutrition class. Percentage body fat (PBF) was assessed by bioimpedance following an overnight-fast. VO_{2max} was estimated from 1.5-mile time trial performance. Dietary energy intake (EI) was determined using 24-hour dietary recalls and PA was assessed by accelerometry. The eating behavior traits drive for thinness (DT), body dissatisfaction (BD) and cognitive dietary restraint (CRD) were assessed using online surveys. Participants were divided into high fitness (HF) and low fitness (LF) groups by median split and path analyses were conducted. **RESULTS:** HF and LF women differed significantly (p < .05) in EI [36.0 ± 11.7 vs 40.2 ± 9.7 kcal/kg FFM], PA [196.4 ± 42.1 vs 173.7 ± 31.6 axial counts], PBF [$23.2\pm5.7\%$ vs $29.3\pm6.2\%$], BMI [21.7 ± 2.1 vs 23.2 ± 3.0 kg/m^2] and VO_{2max} [41.9 ± 2.5 vs 32.8 ± 5.1 mL/kg/min]. Chi-Square [41.94 with 36 df, p value = 0.23] and CFI [0.85] indicate the models provide a reasonable representation of the data. In both groups, PBF positively correlated with BD [HF: 0.355; LF: 0.406] and negatively correlated with VO_{2max} [HF: -0.487; LF: -0.539]. PBF negatively correlated with DT [-0.252] and positively correlated with EI [0.236] in HF only. PA did not correlate significantly with any variables in the models. **CONCLUSION:** In college-age women, aerobic fitness appears to be the strongest predictor of body composition, even after adjusting for low and high fitness. HF individuals demonstrated expected relationships between DT, EI and PBF which were not seen in LF individuals. Although PA differed between HF and LF, it was not associated with other variables, particularly PBF. These results emphasize the importance of fitness and physical activity in producing favorable body composition among college-age women.

Association of Breakfast Frequency with Lean Body Mass in Healthy Young Subjects: A Cross-Sectional Study

Jun Yasuda[1], Mai Asako[2], Takuma Arimitsu[2], Satoshi Fujita[2]. [1]Graduate School of Sport and Health Science, Ritsumeikan University, Shiga, Japan. [2]College of Sport and Health Science, Ritsumeikan University, Shiga, Japan.
(No relevant relationships reported)

Skipping breakfast has been reported to decrease daily energy and nutrient intakes. Therefore, skipping breakfast and subsequent negative energy balance can be one of risk factors associated with reduced muscle mass.
PURPOSE: To investigate whether breakfast frequency is associated with lean body mass (LBM) in Japanese collegiate students.
METHODS: A total of 270 healthy young subjects (152 men, 118 women) participated in this study. We collected information on lifestyle (living condition, breakfast frequency, smoking and drinking habits), eating behavior with the Dutch Eating Behavior Questionnaire (DEBQ), sleep quality with the Pittsburgh Sleep Quality Index (PSQI), circadian rhythm type with the Morningness-Eveningness Questionnaire (MEQ), mental state with the Center for Epidemiologic Studies for Depression Scale (CES-D), and physical activity with the International Physical Activity Questionnaire (IPAQ). According to Dietary Reference Intakes for Japanese, the subjects were asked the breakfast frequency in the past one month (excluding consumption of tablets, energy drinks, confectionary, fruits, dairy products, or sweetened beverage alone). LBM in each part of body was assessed using dual-energy X-ray absorptiometry, and then calculated for appendicular LBM (ALBM). We classified the breakfast frequency into 2 categories (1: 0-6 times, 2: everyday) to clarify the importance of daily breakfast consumption for LBM.
RESULTS: Multiple regression analysis showed that having breakfast everyday was positively related to total LBM ($\beta = 0.065$, P = 0.028, $R^2_{adj} = 0.816$) and ALBM ($\beta = 0.075$, P = 0.012, $R^2_{adj} = 0.809$) after adjusting for age, sex, living condition, BMI, DEBQ, PSQI, MEQ, CES-D, and IPAQ scores as variables.
CONCLUSIONS: We demonstrated that breakfast frequency was associated with total LBM and ALBM regardless of possible confounders, such as sex, BMI, and physical activity. This result suggests that skipping breakfast is one of risk factors for lower muscle mass in healthy young population.

High Intensity Interval Training and Dietary Supplement Use in the Army

Jessica L. Kegel, Josh B. Kazman, Patricia A. Deuster, FACSM. *Uniformed Services University, Bethesda, MD.*
(No relevant relationships reported)

PURPOSE: To establish health and psychosocial profiles of US Army soldiers who engage in high intensity interval training (HIIT) and/or use risky dietary supplements (rDS).
METHODS: Data were from 2014 US Army Global Assessment Tool (n=252K) survey respondents to characterize Soldiers who engaged in HIIT and/or used rDS (i.e., performance-enhancing /weight-loss products) along with demographics, health behaviors (poor sleep, tobacco use, unhealthy eating, hazardous drinking, physical activity), and psychosocial profiles (emotional/social fitness). HIIT and rDS use were dichotomized and multiple logistic regressions were used to determine associated demographics and health behaviors. Continuous psychosocial scores were analyzed with independent t-tests.
RESULTS: 38% of Soldiers did HIIT and 14% took rDS at least once per year. Soldiers who participated in HIIT were 1.56 times more likely to use rDS than those who did not. Soldiers who engaged in HIIT had increased odds of being active duty (OR = 1.47), and were similar along other military/demographic characteristics. Interestingly, HIIT was associated with lower rates of unhealthy behaviors - including poor sleep (OR = 0.78), tobacco use (OR = 0.83), poor eating (OR = 0.62), hazardous drinking (OR = 0.91), and low activity (OR = 0.73) - and with higher emotional (Cohen's d = 0.22) and social (Cohen's d = 0.53) fitness. Soldiers who used rDS had particularly increased odds of being active duty (OR = 1.29) and male (OR = 1.43). In contrast to HIIT, rDS-use was associated with higher rates of poor health behaviors, including poor sleep (OR = 1.38), hazardous drinking (OR = 1.34), and low activity (OR = 1.15). Psychosocial differences by rDS-use were minimal. Next, Soldiers were classified into four groups based on both HIIT (y/n) and rDS-use (y/n). There were no

notable differences between the HIIT+rDS group and the other groups, although the group not participating in HIIT and used rDS had the poorest health behaviors among the groups.
CONCLUSIONS: HIIT is a popular form of exercise and is likely beneficial in moderation. However, Soldiers who engage in HIIT also have increased rates of rDS use, which could increase risk of adverse events. Even though HIIT and rDS are related to one another, they have distinct associations with health behaviors and psychosocial attributes.

The "Fit But Fat" Concept: A Re-evaluation Of National Health Data

Jennifer Bunn, Danielle Eustace, Taylor Miskech, Michael Jiroutek. *Campbell University, Buies Creek, NC.* (Sponsor: Michael J Webster, FACSM)

(No relevant relationships reported)

Data from the National Health and Nutrition Examination Survey (NHANES) have been used to estimate the proportion of US adults who have high, moderate, and low fitness levels by body mass index (BMI) category. These data have also been used to construct categories for fitness. However, these categories are often weighted unevenly to be more inclusive in the moderate and high-fitness categories. **PURPOSE**: To cross-classify adults in the US population by fitness level and BMI, as well as fitness level and body composition, and to calculate the percentage of the population that can be classified as "fit but fat" using tertiles.
METHODS: Three NHANES datasets covering six years (1999-2004) were included in this study, with a total of 6,648 records meeting the eligibility criteria. Fitness and body composition gender and age-specific percentile ranks were determined from norms published by the Cooper Clinic. A pair of matrices were created to report counts, means and standard errors by body composition level versus fitness level and BMI group versus fitness level.
RESULTS: The BMI matrix showed that $32.9 \pm 1.0\%$ of the population was classified as overweight, and $24.9 \pm 0.9\%$ was classified as obese. Further, $9.9 \pm 0.7\%$ and $6.7 \pm 0.5\%$ of the overweight and obese groups respectively, were classified in the top one-third for fitness. The body composition matrix (based on percent body fat) showed that $18.1 \pm 1.0\%$ were categorized in the middle third, and $68.4 \pm 1.3\%$ were categorized in the lowest tertile (high percent body fat). Additionally, $6.6 \pm 0.6\%$ and $21.0 \pm 0.9\%$ of the overweight and obese groups respectively, were classified in the fittest tertile.
CONCLUSIONS: These data support the notion that one can be "fit but fat," but most are not. Further, there is a large discrepancy in defining "fat". Two-thirds of the population was ranked below the 35th percentile in body composition (compared to 57.8% of the population qualifying as overweight or obese), and more of these individuals are of low fitness than in any other fitness category. These data further support the notion that BMI is a misleading classification and utilizing a more robust measure to qualify fatness may be necessary.

The Impact of Cardiovascular Disease Diagnosis on Physical Activity Behavior

Yuehan Wang, Martijn F.H. Maessen, André L.M. Verbeek, Maria T.E. Hopman, FACSM, Thijs M.H. Eijsvogels. *Radboud University Medical Centre, Nijmegen, Netherlands.*

(No relevant relationships reported)

Meeting physical activity (PA) guidelines ($\geq$675 MET-min/wk) is recommended by WHO in order to attenuate disease progression and incidence of events in patients with cardiovascular disease (CVD) and cardiovascular risk factors (CVRF).
PURPOSE: To investigate whether patients change their PA behavior after the first diagnosis of CVD/CVRF.
METHODS: This study used cross-sectional and prospective study data from the Nijmegen Exercise Study. Participants' PA and cardiovascular health information were collected from baseline and follow-up questionnaires. CVD was defined as myocardial infarction, stroke, heart failure, or angina. CVRF was defined as a diagnosis of hypertension, hypercholesterolemia, diabetes type 2, thrombosis, or atrial fibrillation. Average PA dose (MET-min/wk) was calculated before and after CVD/CVRF diagnosis. PA was categorized based on baseline PA levels; inactive (<675 MET-min/wk), moderately active (675-1350 MET-min/wk), or highly active (>1350 MET-min/wk) groups.
RESULTS: In the cross-sectional study, 432 CVD patients (86% males) and 1541 CVRF patients (68% males) were included. An increase in PA was observed after CVD/CVRF diagnosis for inactive (289 [93-510] to 540 [157-810] MET-min/wk, *P*<.01) and moderately active groups (975 [810-1155] to 1080 [795-1350] MET-min/wk, *P*<.01). In contrast, the highly active group decreased their PA from 2147 [1702-2939] to 1620 [1011-2273] MET-min/wk (*P*<.01). In the prospective study, 53 new cases (76% males) of CVD and 253 (61% males) of CVRF were observed during a 5-year follow-up. After CVD/CVRF diagnosis, the inactive group increased their PA (450 [270-540] to 1020 [405-1689] MET-min/wk, *P*<.01); the moderately active

group maintained their PA (1013 [810-1215] to 990 [731-1530] MET-min/wk, *P*=.09); whereas the highly active group decreased their PA (1978 [1620-2625] to 1650 [1080-2430] MET-min/wk, *P*<.01).
CONCLUSION: Changes in PA behavior appears to be dependent on initial PA dose. Inactive patients may be more motivated to increase their PA dose after CVD/CVRF diagnosis, whereas no changes were found for moderately active patients and a significant decrease in PA dose is observed in highly active patients. These findings demonstrate that personalized exercise prescription may be needed to optimize PA behavior in CVD/CVRF patients.

Weight Status, Physical Fitness & Health-related Quality Of Life Among Chinese Adolescents

Xiangren Yi[1], Meng Ding[2], Shuyuan Huang[1], Lei Zhang[1], Wenxin Chen[1], Nuo Yi[3], Peng Zhang, FACSM[3], Yong "Tai" Wang, FACSM[4]. *[1]Shandong University, Jinan, China. [2]Shandong Normal University, Jinan, China. [3]East Stroudsburg University, East Stroudsburg, PA. [4]the University of Texas at Tyler, Tyler, TX.* (Sponsor: Yong "Tai" Wang, FACSM)

(No relevant relationships reported)

PURPOSE: The physical fitness on adolescents' health–related quality of life (HRQOL) is an important health issue in China. The purpose of this study was to examine associations between body mass index (BMI), cardiorespiratory fitness (CRF), musculoskeletal fitness (MSF) and HRQOL among Chinese adolescents. **METHODS:** Participants were 10,007 students (boys: 14.14 years±1.79; girls: 14.22 years±1.81) selected from 30 secondary schools in Shandong, China. Weight, height, 1000 m/800 m runs and the standing-long jump were measured to present BMI, CRF and MSF, respectively. HRQOL was measured by the Quality of Life Scale for Children and Adolescents (QLSCA). ANCOVA and multiple regression were employed to analyze the relationships among BMI, CRF and MSF and HRQOL **RESULTS:** BMI and physical fitness variables were partially associated with HRQOL in Chinese adolescents. Only several dimensions in ANCOVA showed a significant difference by BMI in this test. For boys, significant differences were found in physical sense, living convenience, self-satisfaction. For girls, the significant differences were observed only in social activity opportunity. For both boys and girls, the results also showed the higher MSF scores, the higher student partnership scores; the higher CRF scores, the lower scores in teacher and student relationship , and parent and children relationship. The multiple regression analysis demonstrated that BMI was significantly associated with social activity opportunities. For boys, CRF was associated with teacher and student relationship, self-satisfaction . whereas MSF was only associated with physical sense. For girls, CRF was significantly linked with parent and children relationship, learning capacity and attitudes and self-perception, while MSF was associated with self-perception and other factors. **CONCLUSION:** physical activity and physical fitness will be a crucial pathway in enhancing adolescents' HRQOL in China.

Leisure-time Physical Activity Throughout Adulthood: Implications For All-cause, And Cause-specific Mortality

Pedro F. Saint-Maurice[1], Diarmuid Coughlan[1], Sarah K. Keadle[2], Richard P. Troiano[1], Charles E. Matthews, FACSM[1]. *[1]National Cancer Institute, Rockville, MD. [2]California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Charles E. Matthews, FACSM)

(No relevant relationships reported)

PURPOSE: Limited evidence documents the benefits of leisure-time physical activity (LTPA) throughout adulthood on mortality risk. This study modelled LTPA patterns from adolescence into middle-age and their associations with all-cause, CVD, and cancer mortality. **METHODS**: In 1994-96, 315,059 adults (58% males) aged 50-71 yrs enrolled in the NIH-AARP Diet and Health study retrospectively described their participation in LTPA (hours/week) for approximate ages 15, 25, 35 yrs, and 50 yrs. LTPA patterns over these age-periods were modelled using semi-parametric group-based mixture models and 10 LTPA patterns throughout adulthood were identified. Participants were followed for mortality through 2011. Associations between life-course LTPA patterns and mortality were modelled using Cox proportional hazard models [(Hazard Ratios (HR) and 95% CI)] adjusting for age, sex, race, education, smoking, body mass index, and diet. The least active LTPA pattern (0 hrs/wk throughout all age-periods) was used as the referent group.
RESULTS: Over 13.6 yrs of follow-up. a total of 71,377 deaths from all-causes, 22,219 deaths from CVD, and 16,388 deaths from cancer occurred. Compared to those who were consistently inactive throughout adulthood, participants who maintained LTPA participation over time were at lower risk for all-cause, CVD, and cancer mortality. For example, maintaining 7+ hrs/wk resulted in risk reduction of 29% for all-cause [HR: 0.71 (0.68, 0.73)], 24% for CVD [HR: 0.66 (0.62, 0.70)], and 10% for cancer mortality [HR: 0.90 (0.83, 0.97)]. Adults who were inactive at ages 15-35

(~1hr/week) but increased LTPA over time also had consistent reductions in risk for all-cause [HR: 0.65 (0.62, 0.68)], CVD [HR: 0.57 (0.53, 0.61)], and cancer mortality [HR: 0.84 (0.77, 0.92)]. In contrast, adults who reduced LTPA in adulthood had the lowest mortality benefits for all-cause and CVD mortality, and no benefits for cancer mortality.
CONCLUSIONS: Participants who maintained or increased LTPA by their ~50's had the lowest risk for mortality, independent of previous LTPA. LTPA during midlife (i.e., ~50yrs) rather than LTPA early in adulthood (i.e., 15's through 35's) seems to be most important for both all- and cause-specific mortality.

354   Board #195   May 30 9:30 AM - 11:00 AM

Physical Activity Declines At Significant Life Events In Young Adults

Jon Miller, Megan Winkler, Mary Christoph, Toben Nelson, Daheia Barr-Anderson, FACSM, Dianne Neumark-Sztainer. *University of Minnesota, Minneapolis, MN.* (Sponsor: Daheia Barr-Anderson, FACSM)
(No relevant relationships reported)

Purpose: Predictable life events like marriage, birth of a child or gaining employment may be opportunities to intervene on health behaviors like physical activity. The purpose of this study was to determine which life events during the transition from adolescence to adulthood are associated with the greatest changes in moderate to vigorous physical activity (MVPA). **Methods**: Adolescent participants in Project EAT (ages 11 to 18 at baseline and 25 to 36 at EAT-IV) were surveyed at four time points, roughly 5 years apart, on whether they had married or divorced, had children, begun or lost employment, begun or ended post-secondary education or left or returned to their parent's home between each wave. Linear regression was used to model the effect of each of these life events on change in self-reported MVPA. Post-hoc four-way decomposition mediation analysis was conducted to examine whether the effect of having a child mediated the effect of getting married on change in MVPA. **Results**: Average reported MVPA declined from 6.5 hours per week at baseline to 4.3 hours per week at EAT-IV. Having a child was associated with a significant decrease in MVPA between waves 2 and 3 (-0.84 hours per week, 95% CI: -1.39 to -0.30) and between waves 3 and 4 (-1.02 hours per week, 95% CI: -1.52 to -0.53). Getting married (-0.99 hours per week, 95% CI: -1.58 to -0.41), moving back in with parents (-1.06 hours per week, 95% CI: -2.06 to -0.07), and leaving parents' home (-1.07 hours per week, 95% CI: -1.97 to -0.17) were associated with significant decreases in MVPA between waves 3 and 4. The proportion of the total effect of getting married on physical activity that was mediated by having a child (proportion mediated: 0.42, 95% CI 0.16 to 0.69) was similar to the proportion of the total effect that was due to interaction with having a child (proportion attributable to interaction: 0.54, 95% CI -0.12 to 1.20). **Conclusion**: There is evidence in this study that physical activity declines both after getting married and after having a child. Interventions to maintain or increase physical activity should be targeted at couples planning to get married or have a child. Pre-marital counselling and pre-natal clinics would be efficient targets for interventions like financial incentives for gym or fitness group memberships.

Why Do Girls Play? Strength And Competitiveness But Not 2d:4d Ratio Are Predictive Of Retrospective Sport Participation In University Aged Women

Elizabeth Vandenborn, Cayla Wood, Kevin Milne. *The University of Windsor, Windsor, ON, Canada.*
(No relevant relationships reported)

Women continue to participate in sport at a lower rate than males at all ages. Girls who participate in sport gain many advantages (e.g. better bone health, greater cardio-respiratory fitness, better mental health). However, even with programs designed to emphasize participation, some women choose to continue sport participation, while others do not. Given the potential advantages and controversies currently surrounding testosterone and female sport participation, it is possible that this hormone may predispose women toward sport participation.
PURPOSE: To determine if the 2nd to 4th digit ratio (2DR) correlates with sport participation throughout adolescence and young adulthood in women. **METHODS:** A cross-sectional analysis of indirect prenatal androgen concentrations (i.e. 2DR) was obtained from 92 females (aged 18-30y). Participant demographic, anthropometric, behavioural, and retrospective sport participation information were collected on one occasion. **RESULTS:** 2DR was not significantly correlated with total sport participation (r = -0.650, p = 0.538). Secondary analysis revealed significant correlations between sport participation and max hand grip (r=.406, p = 0.000), sport competitiveness (Sport Orientation Questionnaire) (r = 0.475, p = 0.000) and Sport Aggression (Scale of Children's Action Tendencies in Sport) (r = 0.240, p = 0.021). **CONCLUSION:** While 2DR does not, strength and the sport specific behavioural traits of competitiveness and aggression are able to predict retrospective sport participation. However, causality of these relationships could not be determined because some traits are likely strengthened through sport participation and androgens

---

have been linked to strength, competitiveness, and aggression. Given that females participate in sport at lower rates than males, and that sport provides multiple social and health advantages, continuing to determine what factors influence female sport participation is necessary.

Demographic, Health Behavior, And Cardiometabolic Risk Factor Profiles In Yoga And Non-yoga Participants: Nhanes 1999-2006

Bethany M. Forseth[1], William R. Boyer[2], Eugene C. Fitzhugh[3], Amy Miller[2]. *[1]University of Wisconsin - Milwaukee, Milwaukee, WI. [2]California Baptist University, Riverside, CA. [3]University of Tennessee, Knoxville, TN.*
(No relevant relationships reported)

BACKGROUND: Previous studies have described the demographic and limited disease status characteristics of yoga participants using nationally representative data. However, there is a paucity of population-based data describing the cardiometabolic risk factors of yoga participants in the U.S. PURPOSE: To examine the demographic, health behavior, and cardiometabolic risk factor characteristics of participants who report participating in yoga verses not participating yoga using a nationally representative sample of U.S. adults. METHODS: Study participants were from the 1999-2006 National Health and Nutrition Examination Survey (NHANES) who self-reported participation in yoga (n=171) or no-yoga (n=8,817). Demographic variables included: age, gender, race/ethnicity, and education. Health behaviors included: smoking status, alcohol consumption, and the healthy eating index. Cardiometabolic risk factors included: HbA1c, blood pressures (BP), BMI, waist circumferences, cholesterol, homeostatic model assessment of insulin resistance (HOMA), glucose, and insulin. SAS survey procedures were used for all analyses. RESULTS: Yoga participants were primarily female (82.6%), were college educated (57.6%), were mostly non-smokers (61.7%), and reported moderate alcohol consumption (75.1%). Yoga participants, compared to their non-yoga counterparts, had a healthier cardiometabolic risk profile: HbA1c (5.2 vs 5.4%), BP (114/69 vs 121/72mmHg), BMI (24.7 vs 27.7 kg/m²), waist circumferences (85.9 vs 95.3 cm), HOMA (1.2 vs 2.0mIU/L), glucose (91.8 vs 100.0 mg/dl), and insulin (7.8 vs 10.8 uU/mL), respectively. CONCLUSION: These results are the first to examine the cardiometabolic risk factor profiles of yoga users using a nationally representative sample of U.S. adults. Given the emergence of yoga as a common form of physical activity, it is imperative to understand the characteristics of those who participate in yoga to further understand its relationship with cardiovascular risk.

Determination of Health Status Using SelfRated health and Physiological Markers of Fisherfolks in Ghana Central Region

Olufunmilola L. Dominic[1], Yayra, Kluboito[2], Nathaniel Atikumi[2], Edward W. Ansah[2]. *[1]University of Ilorin, Ilorin, Nigeria. [2]University of cape Coast, Cape Coast, Ghana.*
(No relevant relationships reported)

PURPOSE: Occupational lifestyle is ascertained to influence one's health. Studies have shown that 10 bpm increases in resting heart rate especially when compared with 45bpm is a significant risk cause for all mortality with increasing heart rate (HR) in linear relation. Self-rated health has been accepted as a predictor of health and mortality as well as HR and blood pressure. There is the need to ascertain the self-rated health through objective measures using physiological markers (systolic blood pressure (SBP), diastolic blood pressure (DBP), HR, Body mass index) in determining health status of fisherfolks in Central Region of Ghana. **METHODS**: The research designs were survey and quasi experimental. Purposive and convenient sampling methods were used to select the two urban fishing communities and 361 participants (64.3% (n=233males and 35.7% (n=129females) with ages ranging from 15-100 (M = 37.5, SD = 1.399) for the study. Institutional approval and informed consent were obtained. Deluxe auto Digital Blood Pressure Monitor (Model MS-752), stadiometre and body fat/hydration scale (Model 7032497) were used to collect the physiological data and a standardized self-rated health questionnaire. Descriptive statistics and multiple regression analyses were the statistical tools used.**RESULTS**: SRH of fair or poor was reported by 49% ($n = 177$) of the participants. However, 7.8% ($n = 28$) had low HR while 30% ($n = 108$) had high or very high HR; 36.3% ($n = 131$) had SBP stage one and two hypertension while 47.1% ($n = 170$) were pre-hypertensive; 44.6% ($n = 161$) had stage one or two DBP hypertension, with 23% ($n = 83$) being pre-diastolic hypertensive. Multiple regression analysis indicated that the general model was statistically significant in predicting the health status of the fisherfolks, $F (8,352) = 3.582$, $p = 0.001$, $adj.R^2 = 0.005$. However, gender ($p = 0.021$) and age ($p = 0.002$) were the only significant independent predictors of the health status of the fisherfolks. **CONCLUSIONS**: The fair and poor health of 49% SRH correlated with the objective measures of 30% high HR as well as 36.3% and 44.4% high SBP and DBP

Abstracts were prepared by the authors and printed as submitted.

predicting health status of the fisherfolks. This revealed high mortality and all-cause of cardiovascular disease risks among fisherfolks signaling the need for multilevel interventions considering age and gender.

The Association Between Muscle Strength and Hyperuricemia in the Healthy Adults

DooYong Park[1], On Lee[2], Yeonsoo Kim[2]. [1]GreenCross HealthCare, Gyeonggi-do, Korea, Republic of. [2]Seoul National University, SEOUL, Korea, Republic of.

(No relevant relationships reported)

PURPOSE: This study aimed to examine the prevalence of hyperuricemia in association with relative grip strength and leg strength in Korean Elderly.
METHODS: We studied cross-sectional analysis with 1,896 rural adults(40-88 year-old), who were surveyed for 7 years from 2007 to 2014. grip strength was measured by using Takei grip strength dynamometer. Leg strength was measured by using Takei leg strength dynamometer. hyperuricemia was defined by examining serum uric acid(SUA) concentration(Male=SUA$\geq$7mg/dL, Female=SUA$\geq$6mg/dL). Logistic regression was conducted to evaluate the association of grip strength and Leg strength with hyperuricemia (p<0.05)
RESULTS: When age, sex and other risk factor of the hyperuricemia are adjusted, subjects who reported high level of relative grip strength had a significantly lower odds ratio (OR) of hyperuricemia than subjects who reported low level of relative grip strength (OR: 0.36, 95% CI: 0.16-0.82). When it comes to gender, subjects both high relative muscle strength(are significantly lower Multivariate-adjusted OR of hyperuricemia than subjects both low relative muscle strength in man (OR: 0.56, 95%CI: 0.31-0.99) and women (OR: 0.50, 95%CI: 0.28-0.90). But, subjects who have high relative grip strength and low relative leg strength are significantly lower Multivariate-adjusted OR of hyperuricemia than subjects both low relative muscle strength only in women (OR: 0.38, 95%CI: 0.17-0.84)
CONCLUSIONS: The relationship between hyperuricemia and relative grip strength may be mediated through decreased estimated glomerular filtration ratio (eGFR). Therefore, muscle strength is important factor in prevention of renal vascular dysfunction which is a risk factor of hyperuricemia, and resistance exercise is needed to improve muscle strength.

Separate Associations of Intrinsic and Acquired Cardiorespiratory Fitness on All-Cause Mortality

Louise de Lannoy[1], Xuemei Sui[2], Steven N. Blair, FACSM[2], Robert Ross, FACSM[1]. [1]Queen's University, Kingston, ON, Canada. [2]University of South Carolina, Columbia, SC.

(No relevant relationships reported)

Cardiorespiratory fitness (CRF) is a strong and independent predictor of mortality risk, however, it is unclear whether the association between CRF and mortality is mediated by the adoption of physical activity (PA; acquired CRF) or by underlying intrinsic CRF. In response we examined the association of intrinsic and acquired CRF on risk of all-cause mortality in men and women using follow-up CRF data from the Aerobics Centre Longitudinal Study cohort.
PURPOSE: To determine whether all-cause mortality risk differs between individuals who achieve high CRF through the adoption of PA compared to those who have intrinsically high CRF.
METHODS: A prospective study with at least two clinical visits (mean follow-up time: 14.0 (8.6) years) between 1974 and 2002 to assess CRF mortality risk in individuals who became active vs those who remained inactive at follow-up. Participants were 2,337 inactive men and women at baseline. Acquired CRF was defined as CRF of individuals who became active and improved CRF at follow-up, intrinsic CRF was defined as CRF of individuals who remained inactive at follow-up. The range of follow-up CRF values for both groups was set to 8-12 METs to achieve high (~10 METs) follow-up CRF values.
RESULTS: Individuals who had intrinsically high CRF at follow-up had a 20% reduced mortality risk for every 1 MET increase in CRF after adjusting for age, sex, follow-up weight (p<0.05). Hazard ratios were not materially different after further adjusting for change in systolic blood pressure, smoking, alcohol intake, diabetes mellitus, total cholesterol, abnormal ECG, family history of CVD (HR: 0.82 (0.68, 0.98); p<0.05). Individuals who had acquired a high CRF at follow-up had a 32% reduced mortality risk for every 1 MET increase in CRF after adjusting for age, sex, follow-up weight (p<0.05). Hazard ratios were not materially different after further adjusting for common risk factors associated with premature mortality (HR: 0.72 (0.59, 0.87); p<0.05).
CONCLUSION: While both intrinsic and acquired CRF were associated with a reduction in all-cause mortality risk, individuals who became active and improved CRF had a lower risk of all-cause mortality than those with intrinsically high CRF. This is the first analysis to show that the way in which CRF is achieved influences its association with mortality.

Flourishing in Overweight and Obese Adolescents of Varying Physical Activity Levels

Stephanie M. McCoy[1], Kristie Rupp[2]. [1]University of Southern Mississippi, Hattiesburg, MS. [2]Brooklyn College of the City University of New York, Brooklyn, NY.

(No relevant relationships reported)

Adolescents, who are overweight or obese, are less likely to flourish, and more likely to bully others and experience emotional difficulties. However, it is unknown whether engagement in regular physical activity (PA) is associated with these measures among overweight and obese adolescents. **PURPOSE:** To examine associations between body mass index (BMI) and PA levels with measures of flourishing, bullying and emotional difficulties. **METHODS:** Analyses included 12,592 adolescents, ages 10-17 years, from the 2011-12 National Survey of Children's Health. Adolescents were grouped into categories based on BMI (overweight or obese) and PA (0-2, 3-4, or 5-7 d/wk). Outcomes included measures of flourishing (finishing tasks, staying calm when faced with a challenge, and showing interest in learning new things), emotional difficulties (excessive arguing and unhappiness) and bullying. Logistic regression models, adjusted for age, sex, gender, household income, and education assessed the odds of each outcome comparing BMI classification and PA groupings. **RESULTS:** Compared to overweight adolescents who engaged in 0-2 d/wk of PA, those who engaged in PA 3-4 d/wk were 44% more likely to finish tasks, 58% more likely to stay calm, 72% more likely to show interest in learning new things, 30% less likely to argue excessively, and 42% less likely to be unhappy (p's<0.01). Compared to obese adolescents who engaged in 0-2 d/wk of PA, those who engaged in PA 3-4 d/wk were 41% more likely to finish tasks, 37% more likely to stay calm, 73% more likely to show interest in learning new things, 27% less likely to argue excessively, 58% less likely to be unhappy, and 47% less likely to bully others (p's<0.001). Furthermore, for adolescents who engaged in PA 5-7 d/wk, the odds of flourishing were significantly higher, and the odds of emotional difficulties and bullying were significantly lower (p's<0.001). **CONCLUSIONS:** Overweight and obese adolescents that engaged in greater amounts of PA ($\geq$3 d/wk) were significantly more likely to flourish, and less likely to experience emotional difficulties and bully others compared to adolescents that engaged in >3 d/wk of PA. This suggests that increasing engagement in physical activity may increase flourishing and decrease emotional difficulties and bulling behaviors among overweight and obese adolescents.

Combined Association of Cardiorespiratory Fitness and Family History of Hypertension on the Incidence of Hypertension

Yuko Gando[1], Susumu S. Sawada, FACSM[1], Ryoko Kawakami[2], Haruki Momma[3], Kazunori Shimada[4], Yasushi Fukunaka[5], Takashi Okamoto[5], Koji Tsukamoto[5], Motohiko Miyachi[1], I-Min Lee, FACSM[6], Steven N. Blair, FACSM[7]. [1]National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan. [2]Waseda University, Saitama, Japan. [3]Tohoku University Graduate School of Biomedical Engineering, Sendai, Japan. [4]Juntendo University Graduate School of Medicine, Tokyo, Japan. [5]Tokyo Gas Co., Ltd., Tokyo, Japan. [6]Harvard Medical School, Boston, MA. [7]University of South Carolina, Columbia, SC.

(No relevant relationships reported)

Family history of hypertension (FH) is a non-modifiable risk factor of hypertension. However, cardiorespiratory fitness (CRF) is a modifiable risk factor and may be important for preventing hypertension for both people with and without FH.
PURPOSE: The purpose of this study was to investigate the combined association of CRF and FH on the incidence of hypertension in male Japanese workers. **METHODS**: A total of 6890 male workers, who were free from hypertension, were included in this study. CRF was determined using a submaximal exercise test, with a cycle ergometer. A self-reported questionnaire was used to determine FH. Six groups were established, combining the 2 groups with and without FH (Yes, No) and the 3 groups based on age-specific tertiles of CRF (Low, Moderate, High). The incidence of hypertension, defined as systolic blood pressure of $\geq$140 mmHg or diastolic blood pressure of $\geq$90 mmHg, or self-reported physician-diagnosed hypertension, was evaluated. Cox proportional hazards regression analysis was performed with incidence of hypertension as the dependent variable and the 6 groups as independent variables. Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated after adjustment for age and potential confounding factors (BMI, cigarette smoking, and alcohol intake). **RESULTS**: During the observation period of 101,212 man-years of observation (median 17 years, minimum 1 year, maximum 23 years), 2210 workers developed hypertension. There were 3860 participants who had a FH (56%). As compared with the Yes-Low group, the HRs for hypertension were 66% lower in No-High (HR 0.34 [95%CI, 0.28-0.40]),

---

47% lower in No-Low (HR 0.53 [95%CI, 0.46-0.61]), and 24% lower in Yes-High (HR 0.76 [95%CI, 0.67-0.86]). FH and CRF did not show a significant interaction (*p* for interaction = 0.181).
CONCLUSIONS: The combination of FH and CRF showed a clear association with the risk of hypertension, and even participants with FH showed a lower risk of hypertension when the level of CRF was high. FH and CRF did not show a significant interaction. Therefore, these findings suggest that CRF might be equally beneficial for preventing hypertension in both people with and without FH.

Impact of Air Pollution on Physical Activity: A Cohort Study of Beijing College Students

Hongjun Yu[1], Weimo Zhu, FACSM[2], Chunmei Cao[1]. [1]*Tsinghua University, Beijing, China.* [2]*University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
(No relevant relationships reported)

Purpose: Air pollution has become a substantial environmental issue affecting human health and health-related behavior worldwide, especially in Beijing, China. Physical activity (PA) has been well demonstrated as a means to promote people's health and well-being and is potentially being influenced by the air pollution. Yet, the effects of air pollution on PA behavior have not been well investigated. This study examined of the impacts of air pollution on moderate to vigorous PA(MVPA) among college students in Beijing, China. **Methods:** We conducted the follow-up health surveys on 9,095 freshmen from Tsinghua University in Beijing during 2013-2015, and their PA was measured by the "International Physical Activity Questionnaire" (IPAQ) questionnaire. Air pollution data included average hourly air quality index (AQI), $PM_{2.5}$, PM_{10}, SO_2 and NO_2 (μg/m³) were measured by Ministry of Environmental Protection of the People's Republic of China. The data were analyzed using the linear fixed-effect regressions. **Results:** An one standard deviation (SD) increase in air pollution concentration in AQI, $PM_{2.5}$, PM_{10}, SO_2 and NO_2 was associated with a reduction in weekly total minutes of vigorous PA by 61.18, 43.14, 71.37, 20.73 and 19.66, respectively; a reduction in weekly total minutes of moderate PA by 80.10, 56.62, 93.52, 27.47 and 25.88, respectively; a reduction in weekly total minutes of MVPA by 147.17, 104.15, 171.90, 50.57 and 47.64, respectively. **Conclusions:** Air pollution discouraged MVPA among college students. Future studies are warranted to replicate study findings in other subpopulations and China cities, and policy interventions are urgently called to reduce air pollution level in China.

Cardiorespiratory Fitness and Incidence of Dyslipidemia: A Cohort Study Among Japanese Women

Takahisa Ohta[1], Susumu S. Sawada, FACSM[2], Kana Takagi[3], Junzo Nagashima[3], Takeshi Yoshihisa[3], Yasunori Imagawa[3], Nobuyoshi Ono[3], Wataru Fukuda[3], Reno Koyanagi[3], Yuko Gando[2], Motohiko Miyachi[2], Hiroyuki Sasai[1], I-Min Lee, FACSM[4], Steven N. Blair, FACSM[5], Naokata Ishii[1]. [1]*The University of Tokyo, Tokyo, Japan.* [2]*National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan.* [3]*Yokohama City Sports Medical Center, Yokohama, Japan.* [4]*Harvard Medical School, Boston, MA.* [5]*University of South Carolina, Columbia, SC.*
(No relevant relationships reported)

Low cardiorespiratory fitness (CRF) and overweight/obesity are independent risk factors for dyslipidemia. However, the relationship between the combination of CRF and body mass index (BMI) on incidence of dyslipidemia is not clear among Asian women.**PURPOSE:** To investigate the joint effects of CRF and BMI on the incidence of dyslipidemia among Japanese women. **METHODS:** This cohort study was conducted in 927 normolipidemic Japanese (median [interquartile range] age 49 [37-63] years). Participants completed a submaximal exercise test, a medical examination, and questionnaires on their smoking and drinking habits. BMI was calculated from measured weight and height. CRF, physical work capacity at 75% of maximum heart rate, was measured using a cycle ergometer. We determined the incidence of dyslipidemia, defined as having at least one of the following criteria; fasting plasma high-density lipoprotein cholesterol <40 mg/dL, low-density lipoprotein cholesterol ≥140 mg/dL, fasting triglyceride ≥150 mg/dL, or self-reported physician-diagnosed dyslipidemia. Multivariable odds ratios and 95% confidence intervals for the incidence of dyslipidemia were obtained using logistic regression models after adjustment for age, systolic blood pressure, smoking, and drinking habit. **RESULTS:** During the mean follow-up period of 10.0 years, 196 (21.1%) women developed dyslipidemia. There was an interaction between CRF and BMI (p for interaction = 0.006). Using the 1st tertile of CRF and high BMI (≥25kg/m²) as reference, the multivariable odds ratios and 95% confidence intervals were 0.52 (0.31-0.86) for 1st tertile of CRF and low BMI (<25kg/m²), 1.92 (0.73-5.03) for 3rd tertile of CRF and high BMI, and 0.30 (0.17-0.52) for 3rd tertile of CRF and low BMI, respectively. **CONCLUSION:** This result

suggests that there is a strong interaction effect of CRF and BMI on the incidence of dyslipidemia among Japanese women, such that CRF was inversely related to lower incidence of dyslipidemia only among those with low, but not high, BMI.

---

364   Board #205   May 30 9:30 AM - 11:00 AM

Cardiorespiratory Fitness Measured from Cardiopulmonary Exercise Testing for Mortality Risk Prediction in Apparently Healthy Men and Women

Mary T. Imboden[1], Matthew P. Harber, FACSM[1], W H. Finch[1], Derron L. Bishop[2], Mitchell H. Whaley, FACSM[1], Leonard A. Kaminsky, FACSM[1]. [1]*Ball State University, Muncie, IN.* [2]*Indiana University School of Medicine, Muncie, IN.* (Sponsor: Leonard A. Kaminsky, FACSM)
(No relevant relationships reported)

Over the past three decades numerous studies have illustrated the inverse relationship between cardiorespiratory fitness (CRF) and mortality. However, this relationship has almost exclusively been studied using estimated CRF (CRF_e), with known error of ± 3 to 7 ml/kg/min, with no studies assessing this association using directly measured CRF in both men and women that were apparently healthy at baseline testing. **PURPOSE**: To assess the association of CRF, obtained using cardiopulmonary exercise testing (CPX) on all-cause mortality in a large cohort of apparently healthy men and women at baseline. **METHODS**:Participants included 4,137 participants (2,326 M, 1,811 W; mean age: 42.8 ± 12.2 y) free from cardiovascular disease and cancer at baseline, who underwent a maximal CPX to determine CRF. Participants were followed for 24.2 ± 11.7 years (1.1 to 49.3 y) for mortality outcomes using data from the National Death Index. Participants were categorized into CRF tertiles (low, moderate, and high) based on age and sex-specific percentiles, from the Fitness Registry and the Importance of Exercise National Database (FRIEND). Cox-proportional hazard models adjusted for age were performed to determine the relationship of CRF with all-cause mortality. **RESULTS**: After a mean follow-up of 24.2 years, 727 participants were deceased. CRF was inversely related to all-cause mortality, where low CRF was associated with a 31% increased risk for all-cause mortality compared to high CRF (Hazard ratio (HR) 1.31; p<0.01). The inverse relationship between CRF and all-cause mortality was also present for men and women when examined independently. Specifically, Low fit men and women had a 54% and 28% higher risk of dying from all-causes compared to high fit men and women (Men HR 1.54, p<0.01; Women HR 1.28, p<0.01), respectively. **CONCLUSIONS**: These data demonstrate that CPX measured CRF is a strong predictor of all-cause mortality. This coupled with the known diagnostic and prognostic value of CPX measures in clinical populations and the recent support for CRF as a vital sign suggest it should be considered in clinical practice, as it may help to improve the efficacy of the risk assessment and guide clinical decisions.

Obesity And Health-related Physical Activity Behavior In Selected European Countries: Needs Assessment for the Eubohealth-consortium

Lina Hermeling, Marion Flechtner-Mors, Romy Lauer, Jürgen M. Steinacker, FACSM, Susanne Kobel. *Ulm University, Ulm, Germany.* (Sponsor: Prof. Jürgen M. Steinacker, FACSM)
(No relevant relationships reported)

The global burden of overweight and obesity is constantly rising for several decades. Physical activity (PA) is an essential determinant for health, prevention and treatment of many chronic diseases that are related to overweight and obesity. **PURPOSE**: In 2017, he EUBOHEALTH-Consortium was founded with the intention to promote health and normal weight for citizens in Central, Eastern and South Eastern Europe. In order to prepare a large-scale scientific study proposal, a needs assessment in form of a meta-analysis of the initiating countries is being conducted. **METHODS**: A comparison of obesity prevalence and PA behavior between the countries of Croatia, Hungary, Estonia, Germany and the (estimated) European Union average is conduced based on the European Health Interview Survey (EHIS), wave 2 (Eurostat, 2014). Data on non-work-related PA and effort involved in performing work-related PA were used. In addition, the time spent in health-enhancing aerobic PA was assessed and subdivided into four categories: zero, one to 149, 150 to 200 and above 300 minutes per week. All subjects were aged 15 years or over. **RESULTS**: In all four observed countries, the obesity prevalence was higher than the European Union average of 15.4% (Croatia: 18.0%, Hungary: 20.6%, Estonia: 19.9%, Germany: 16.4%). On average, 48.8% of the population of the European Union are not engaged into health-enhancing aerobic PA (Croatia: 58.6%, Hungary: 43.4%, Estonia: 52.3%, Germany: 28.8%). The most severe heterogeneity can be observed in performing muscle strengthening activities (EU-average: 24.2%, Croatia: 9.6%, Hungary: 23.7%, Estonia: 15.4%, Germany: 44.1%). **CONCLUSIONS**: There is a substantial need for the promotion of health-enhancing PA to stop the rising burden of obesity associated disease in several (European) countries. No comparable data from the fifth member state (Serbia) were available. The EUBOHEALTH-Project is funded by the German Federal Ministry of Education and Research.

The Association of Physical Activity and Body Mass Index with Myocardial Infarction: The Tromsø Study

Marius Renninger[1], Maja-Lisa Løchen[1], Ulf Ekelund, FACSM[2], Laila A. Hopstock[1], Lone Jørgensen[1], Ellisiv B. Mathiesen[1], Inger Njølstad[1], Henrik Schirmer[1], Tom Wilsgaard[1], Bente Morseth[1]. [1]UiT - The Arctic University of Norway, Tromsø, Norway. [2]Norwegian School of Sport Sciences, Oslo, Norway. [3]University Hospital of North Norway, Tromsø, Norway.
(No relevant relationships reported)

PURPOSE: Physical activity and overweight are both associated with myocardial infarction (MI). However, their joint association with MI remains unclear. Our objective was to examine the independent and joint association between physical activity, body mass index (BMI) and MI.
METHODS: This prospective cohort study included 16572 men and women aged 20-54 years who took part in the second Tromsø Study survey. At baseline in 1979-80 physical activity was assessed by questionnaire. Data on MI was collected through hospital registries between 1979 and 2013. Cox proportional hazards models were used to examine the independent and joint associations between physical activity, BMI and MI.
RESULTS: After exclusions, the final sample used in the analysis included 16104 individuals. During a median follow up of 34 years, 1613 incident cases of MI were documented. Physical activity and BMI were both independently associated with MI. Hazard ratio (HR) (95% confidence interval) for moderately active compared to inactive individuals was 0.87 (0.77-0.98), for overweight compared to normal weight individuals HR was 1.54 (1.39-1.72), and HR for obese compared to normal weight individuals was 2.70 (2.24-3.26). In joint analysis, normal weight inactive individuals had a 20% higher risk of MI compared to their active counterparts (HR 1.20 (1.02-1.41)). The highest risk of MI was seen in obese inactive individuals with a 3-fold increased risk compared to active normal weight individuals (HR 3.20 (2.30-4.44)). The risk of MI increased with increasing BMI regardless of the activity level. Nevertheless, HRs were lower for active compared to inactive individuals within the same weight category.
CONCLUSIONS: The findings suggest that physical activity and BMI are independently associated with risk of MI in young and middle-aged men and women. Physical activity seems to attenuate but not eliminate the risk of being overweight or obese with MI.

Cardiorespiratory Fitness, Alcohol Consumption And The Incidence Of Hyper Non-hdl Cholesterolemia: A Cohort Study

Natsumi Watanabe[1], Kazunori Shimada[2], Susumu S. Sawada, FACSM[3], I-Min Lee, FACSM[4], Yuko Gando[3], Haruki Momma[5], Ryoko Kawakami[6], Motohiko Miyachi[3], Yumiko Hagi[7], Chihiro Kinugawa[8], Takashi Okamoto[8], Koji Tsukamoto[8], Steven N. Blair, FACSM[9]. [1]Juntendo University, Chiba, Japan. [2]Juntendo University Graduate School of Medicine, Tokyo, Japan. [3]National Institutes of Biomedical Innovation, Health and Nutrition, Tokyo, Japan. [4]Harvard Medical School, Boson, MA. [5]Tohoku University, Sendai, Japan. [6]Waseda University, Saitama, Japan. [7]Tokai University, Kanagawa, Japan. [8]Tokyo Gas Co., Ltd., Tokyo, Japan. [9]University of South Carolina, Columbia, SC.
(No relevant relationships reported)

Physical inactivity is a risk factor of non-high-density lipoprotein (HDL) cholesterolemia, and also high alcohol consumption increases HDL cholesterol. However, the interaction between cardiorespiratory fitness (CRF), an objective marker of physical activity, and alcohol consumption on the incidence of hyper non-HDL cholesterolemia is not clear.**PURPOSE**: To investigate the joint effect of CRF and alcohol consumption on the incidence of hyper non-HDL cholesterolemia among Japanese men. **METHODS**: We evaluated CRF and the incidence of hyper non-HDL cholesterolemia in 4,067 Japanese men [median (IQR) age 36 (30-44) years] who were free from hyper non-HDL cholesterolemia. Participants underwent a submaximal exercise test, a medical examination, and questionnaires on their health habits including alcohol consumption (less than 1g/day, 1-22g/day, ≥23 g/day) in 1986. CRF was measured using a cycle ergometer and maximal oxygen uptake was estimated. The incidence of high levels of non-HDL cholesterolemia (≥ 170 mg/dL) from 1986 to 2006 was ascertained based on fasting blood levels. Hazard ratios and 95% confidence intervals for the incidence of hyper non-HDL cholesterolemia were calculated using Cox proportional hazard models after adjustment for age, body mass index, systolic blood pressure, smoking, and family history of dyslipidemia. **RESULTS**: Hyper non-

HDL cholesterolemia was observed in 1,482 participants during the follow-up period. Using the Low CRF & less than 1g/day alcohol consumption group as reference, the hazard ratios and 95% confidence intervals were 0.88 (0.73 - 1.06) for Low CRF & ≥23 g/day alcohol consumption group, 0.77 (0.64 - 0.93) for the High CRF & less than 1g/day alcohol consumption group, and 0.70 (0.57 - 0.87) for the High CRF & ≥23 g/day alcohol consumption group, respectively. **CONCLUSIONS**: Japanese men with a high CRF and a high alcohol consumption have a lower the incidence of hyper non-HDL cholesterolemia.

Overturning the Hypothesis that Cigarettes Can Enhance Hematocrit and Improve Aerobic Capacity

Grace L. Naylor[1], Jennica Harrison[1], J. Mark VanNess[1], Michelle M. Amaral[1], Jonathan M. Saxe[2], Lewis E. Jacobson[2], Courtney D. Jensen[1]. [1]University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.
(No relevant relationships reported)

Some athletes are willing to try any supplement or drug to enhance performance. Recent reports suggest cigarette smoking may improve endurance performance by inducing oxidative stress which would, in turn, stimulate an increase in hemoglobin and thus increase oxygen-carrying capacity. It is important to validate these claims, given the hazardous side effects of cigarette smoking. **PURPOSE:** Examine the influence of cigarette smoking on blood hemoglobin levels to determine if smoking stimulates training-like conditions for aerobic enhancement. **METHODS:** Hemoglobin and oximetry levels were measured in 594 smokers and 1,626 non-smokers across a wide age-range (ages 15 to 98). Independent variables were age, sex, obesity, smoking status, and presence of diabetes, COPD, or other respiratory diseases. Dependent variables were hemoglobin and oximetry. Independent-samples t tests and chi-square tests were used to detect group differences between smokers and non-smokers. Multiple linear regressions were used to isolate the effect of smoking on hemoglobin and oximetry. **RESULTS:** Subjects were 52.5 ± 22.5 years of age, 55.7% were male, 16.5% were obese, average hemoglobin was 13.5 ± 1.9 g/dL, and oximetry was $97.0 \pm 2.9\%$. Independent-samples t tests revealed cigarette smokers' hemoglobin levels to be 4.6% higher ($p<0.001$) and oxygen saturation to be 0.3 percentage points higher ($p=0.042$). Cigarette smokers were also 13.5 years older ($p<0.001$) and more likely to be male ($p<0.001$). Age ($p<0.001$) and sex ($p<0.001$) were strongly correlated with hemoglobin. When controlling for all significant confounders, multiple linear regression did not demonstrate a significant effect of cigarette smoking on hemoglobin ($p=0.317$) but it found a reduction of 0.4 percentage points on oximetry ($p=0.005$). **CONCLUSIONS:** Simple t-tests indicated cigarettes might confer an ergogenic advantage via elevations in hemoglobin and oximetry. This, left alone, could suggest inadequate oxygen saturation of the blood (owing to smoking) may simulate training-like conditions. However, the predominant explanatory variables were age and sex. It is not the smoking, but other subject factors of the person who smokes that influences hemoglobin levels. Controlling for confounders, smoking has no effect on hemoglobin and reduced oxygen saturation.

The Association Between Physical Activity, Sleep, and Cardiovascular Risk Factors in College Students

Heather H. Betz, Julie M. Cousins. Albion College, Albion, MI. (Sponsor: Jonathan Myers, FACSM)
(No relevant relationships reported)

Physical activity can help improve traditional cardiovascular risk factors, including blood pressure and body composition (Archer and Blair, 2011). In addition to the traditional cardiovascular risk factors, sleep has started to emerge as an important component to overall and cardiovascular health (Grandner et al., 2014). Low levels of sleep have been shown to negatively impact a host of cardiovascular risk factors, including blood pressure, blood lipids, markers of inflammation, and body fatness. (Carnethon et al., 2016) **PURPOSE:** The purpose of this study was to examine the associations between physical activity and sleep with blood pressure and waist circumference in college-age adults. **METHODS:** A total of 57 Albion College students (23 males, 34 females) participated. Height, weight, waist circumference, and blood pressure were measured. Physical activity was self-reported and sleep was assessed with The Pittsburgh Sleep Quality Index. Multiple regression was used to assess the purpose. **RESULTS:** 47.4% of participants were physically active five or more days per week, while 38.5% of participants averaged eight or more hours of sleep per night. 8.8% had a waist circumference categorized as high and 5.2% of participants were pre-hypertensive. 52.6% of the total participants were athletes, with 48% of those currently in-season. There was a significant interaction between physical activity and total hours of sleep on systolic blood pressure (p=0.035, $R^2 = 0.117$) and waist circumference (p=0.023, $R^2=0.13$). Total hours of sleep had a significant unique contribution to the model ($\beta=-0.364$, p=0.007) when examining waist circumference, while physical activity had a significant unique contribution to the model ($\beta=-0.264$, p=0.050) when examining systolic blood pressure. **CONCLUSIONS:** The importance

of being physically active and getting the proper amount of sleep should to be stressed to college students as this can impact their cardiovascular health at a young age. Additionally, discussing the development of cardiovascular risk factors needs to start with this age group, as some participants were noted as being pre-hypertensive or having a high waist circumference. Since this was a very active sample, additional studies need to examine these relationships with a wider variety of college students.

The Association of Body Composition with Cardiometabolic Risk Factors in Apparently Healthy Young Adult Females

Samantha C. Orr, Mary A. Elsesser, Ryan T. Tyler, Timothy A. Rengers, Evan Eschker, Tamara Hew-Butler, FACSM, Charles RC Marks, Kristin R. Landis-Piwowar, Myung D. Choi, Elise C. Brown. *Oakland University, Rochester, MI.*
(No relevant relationships reported)

Although risk factors associated with cardiometabolic diseases (CMD) such as excess adiposity are oftentimes detected in young adults, most of the research examining these relationships has focused on middle-aged and older adults and those "at-risk" for chronic diseases. Given the U.S. trend of increased obesity prevalence with age and the high prevalence of metabolic abnormalities in normal-weight young adult females, understanding the link between body composition and CMD risk in healthy young females is important for developing intervention strategies for primary prevention of obesity and CMD diseases. **PURPOSE:** Therefore, the purpose of this study was to examine the associations of body composition with CMD risk factors in apparently healthy young adult females. **METHODS:** Twenty-five non-obese [body mass index (BMI) < 30 kg/m^2] apparently healthy females (22.6 ± 4.2 years) took part in this cross-sectional study. All participants had height, weight, waist circumference (WC), body composition using Dual-energy X-ray Absorptiometry, resting heart rate (HR), blood pressure, and fasting biomarkers assessed. Bivariate correlations using Spearman's rho were used to examine the relationships of CMD risk factors with anthropometric obesity indices and body composition. Significance was set a priori at P≤0.05. **RESULTS:** Significant associations were found between waist-to-height ratio (WHtR) and resting HR (Spearman's ρ = 0.436, P = 0.03), cholesterol (ρ = 0.404, P = 0.04), low-density lipoprotein cholesterol (LDL-C) (ρ = 0.475, P = 0.02), and glucose (ρ = 0.485, P = 0.01); BMI and resting HR (ρ = 0.41, P = 0.04), cholesterol (ρ = 0.437, P = 0.03), and LDL-C (ρ = 0.477, P = 0.02); total body fat percentage and resting HR (ρ = 0.636, P = 0.001); bone mineral content and glucose (ρ = -0.536, P = 0.007); and lean mass and glucose (ρ = -0.461, P = 0.02). WC was not significantly associated with any of the CMD risk factors. **CONCLUSION:** While WHtR was correlated with more CMD risk factors than other measures of body composition, the strongest correlation was found between total body fat percentage and resting heart rate. These data suggests that body composition may play an important role in cardiometabolic health in young adult females even when classified as apparently healthy and non-obese.

Lifelong Ketogenic Diet Feeding Increases Longevity, But Does Not Alter Oxidative Stress Markers in Rats

Hailey A. Parry, Wesley C. Kephart, Petey Mumford, Matthew Romero, Cody Hann, C. Brooks Mobley, Yufeng Zhang, Michael D. Roberts, Andreas N. Kavazis, FACSM. *Auburn University, Auburn, AL.* (Sponsor: Andreas N. Kavazis, FACSM)
(No relevant relationships reported)

Purpose: Ketogenic Diets (KD) consist of high fat, moderate protein and low carbohydrate. KD have been used as a weight loss tool and as a therapeutic tool for neurological disorders. It has been suggested that KD increase longevity, but to date only two studies in mice have been performed with equivocal results. Therefore, we determined the effects of KD on longevity and multi-organ oxidative stress markers in rats. **Methods:** Ten month-old male Sprague-Dawley rats (n=8 per group) were provided with one of two isocaloric diets: standard chow (SC; 24% (% kcal) protein, 58% CHO, 18% fat; 20 g/day) or KD (23% protein, 10% carbohydrate, 67% fat; 16 g/day). Rats were euthanized if: a) vitality scores (range = 4 (good health) to 20 (poor health)) exceeded a score of 16 per the recommendations of Phillips et al. (J Am Assoc Lab Anim Sci, 2010, 49(6): 792-799), b) rapid weight loss accompanied by changes in food and water consumption, or c) the rat suffered from a condition to which a university veterinarian deemed euthanasia necessary for humane purposes.

Upon euthanasia, the gastrocnemius muscle, liver, and brain were removed and stored at -80ºC and analyzed for markers of oxidative damage (4-hydroxynonenal (4HNE) and protein carbonyls (Oxyblot)) and protein levels of the antioxidants superoxide dismutase 1/2 (SOD1/2), catalase (CAT), and glutathione peroxidase (GPX). **Results:** The survivability log-rank test indicates that KD increased the lifespan of rats (p=0.009) when compared to SC. No significant difference in body mass was observed at the beginning (SC=425.7±13.2, KD=435.9±5.8) or end (SC=428.0±25.4, KD=417.1±22.6) of the experiment, and liver and gastrocnemius mass at sacrifice was not significantly different between groups (p>0.05). Liver CAT protein levels were about 30% higher in KD, albeit not significant (p=0.062). Additionally, liver SOD1 protein levels were about 20% higher in KD, but again, this was not significant (p=0.094). No other significant differences in protein levels of antioxidants, 4HNE, or Oxyblot were observed in either the gastrocnemius, liver, or brain. **Conclusions:** Lifelong KD improves longevity in rats without altering body mass and our data show that the longevity benefits of KD come without altering oxidative damage or antioxidant protein levels in the gastrocnemius, liver, or brain.

The Effects of Choline Intake and Resistance Exercise Training on Strength Gains in Older Adults

Chang Woock Lee[1], Elfego Galvan[2], Teak V. Lee[3], Vincent CW Chen[4], Steve Bui[5], Stephen F. Crouse, FACSM[6], James D. Fluckey[6], Stephen B. Smith[6], Steven E. Riechman, FACSM[6]. [1]*University of Houston-Victoria, Victoria, TX.* [2]*University of Texas Medical Branch, Galveston, TX.* [3]*Pierce College, Woodland Hills, CA.* [4]*Georgian Court University, Lakewood, NJ.* [5]*Dixie State University, St. George, UT.* [6]*Texas A&M University, College Station, TX.*
(No relevant relationships reported)

PURPOSE: The micronutrient choline plays a major role in neurotransmission and skeletal muscle contraction. We conducted a randomized controlled trial to examine the effects of choline intake on skeletal muscle responses to resistance exercise training (RET) in older adults.
METHODS: Three groups of 50 to 69-year-old generally healthy men and women (n=37, age=59.8 ± 6 y, height=168.4 ± 9 cm, weight=79.5 ± 16 kg, body fat=30.3 ± 10 kg, male/female=15/22) underwent 12 weeks of RET (3x/week, 3 sets, 8-12 reps, 70% of maximum strength [1RM]) and submitted >1,776 diet logs (>4x/week for 12 weeks, 37 subjects). Participants' diets (mean choline intake: 5.9 mg/kg lean/d) were supplemented with 0.7 mg/kg lean/d (Low, n=13), 2.8 mg/kg lean/d (Med, n=11), or 7.5 mg/kg lean/d (High, n=13) of choline in the form of egg yolk. Body composition, 1RM, and blood tests were performed before and after training.
RESULTS: ANCOVA tests showed Low choline intake, compared with Med or High choline intakes, resulted in significantly diminished gains in composite strength (leg press + chest press 1RM; Low: 19.4 ± 8.2%, Med: 46.8 ± 8.9%, High: 47.4 ± 8.1%, p=0.034) and thigh muscle quality (leg press 1RM / thigh lean mass; Low: 12.3 ± 9.6%, Med/High: 46.4 ± 7.0%, p=0.010) after controlling for lean mass, protein, betaine, and vitamin B$_{12}$. No differences were observed in lean mass gains, clinical markers of liver/muscle damage, or blood lipid profiles.
CONCLUSION: These data indicate that low supplemental choline intake negatively affects strength gains with RET in older adults.
This study was supported by U.S. Poultry and Egg Association.

Utilization And Efficacy Of The "Run Fueled" Smartphone Application Among Collegiate Endurance Runners

Michelle Barrack[1], Michael Fredericson, FACSM[2], Emily Kraus[2], Brian Kim[3], Sonal Singh[4], Kristen Gravani[2], Beth Miller[5], Aurelia Nativ, FACSM[4]. [1]*California State University, Long Beach, Long Beach, CA.* [2]*Stanford University, Stanford, CA.* [3]*University of California, Irvine, Irvine, CA.* [4]*University of California, Los Angeles, Los Angeles, CA.* [5]*Duke University, Durham, NC.* (Sponsor: Aurelia Nattiv, FACSM)
(No relevant relationships reported)

PURPOSE: We evaluated the use and efficacy of an interactive, goal-specific, nutrition education intervention aimed at optimizing energy availability and the intake of bone-building nutrients among collegiate endurance runners. **METHODS**: In Spring 2016, 77 male and female NCAA Division I runners were invited to complete the 8-week nutrition education curriculum, administered through "Run Fueled", a smart-phone application. The curriculum, delivered through two, 4-week modules, provided content through daily nutrition tips and electronic handouts, videos, recipes on a weekly topic. Athletes were assessed during a one-on-one meeting with a registered sports dietitian prior to completing Module 2, which provided tips and resources specific to their nutrition goals. Each week, runners were invited to complete assessments regarding the

WEDNESDAY, MAY 30, 2018

WEDNESDAY, MAY 30, 2018

weekly resources and/or dietary behavior change. **RESULTS**: Forty-eight (62.3%) of the 77 runners utilized one or more components of the 8-week curriculum. For Module 1, 39.6% (n= 19) of the 48 runners engaging with the curriculum exhibited use of ≥80% of components, i.e. "high-use". Twenty-three (47.9%) of the 48 application users completed one or more components of Module 2, four runners exhibited "high-use" of Module 2. Built-in assessments indicated that 75.8% (n= 25) of 33 runners reported the Module 1 daily tips as "engaging and effective", while 70.6% (n = 24) of 34 runners rated that the tips could assist with dietary change. Among 11 runners completing the Module 2 assessments, 54.5% (n= 6) reported making changes consistent with the nutrition goals. Runners indicating "Yes" the tips were "engaging and effective", compared to "No", "Unsure", or those not completing the assessment exhibited higher use of Module 1 (i.e. 54.8 ± 2.5 vs. 34.8 ± 4.3 vs. 7.3 ± 3.2, p<0.001) and Module 2 (6.8 ± 1.2 vs. 3.6 ± 2.2 vs. 0.0 ± 0.0) components. All runners (n= 4) exhibiting "high use" of Module 1 and Module 2 reported dietary change. **CONCLUSIONS**: A majority of runners (62.3%) engaged with one or more components of the "Run-Fueled" application, with over 70% of runners that completed the assessments rating the tips and resources as engaging, effective, and able to facilitate dietary change. Runners' reporting dietary change consistent with their nutrition goals exhibited higher application use.

Effect Of Pre-sleep Whole-food Or Protein Beverage On Morning Metabolism In Active Women

Samantha M. Leyh, Brandon D. Willingham, Daniel A. Baur, Lynn B. Panton, FACSM, Michael J. Ormsbee, FACSM. *Florida State University, Tallahassee, FL.*
(No relevant relationships reported)

Dietary protein consumed as a liquid supplement pre-sleep has been shown to increase next-morning resting metabolism without blunting fat oxidation. However, the influence of whole-food protein consumed pre-sleep on metabolism is unknown. **PURPOSE:** To determine the effect of a whole-food protein (cottage cheese, CC) consumed pre-sleep on next-morning resting energy expenditure (REE), respiratory exchange ratio (RER) and appetite compared to an isocaloric/isonitrogenous liquid casein protein (CP) supplement and a placebo (PL) in active women. **METHODS:** In a beverage-blinded, randomized, cross-over design, ten active (physical activity ≥4 days/ wk for at least 12 m) women (age, 23.1 ± 1.9 yrs; body fat, $22 \pm 4.6\%$; means ± SD) consumed pre-sleep CC (160 kcals, 30g protein, 10g carbohydrate, 0g fat), calorie and nitrogen matched liquid CP, or PL (0 kcals) 30-60 min pre-sleep. Participants arrived at 1800 h for an overnight stay in the lab. 30-60 min prior to participants' normal bed time and 2 h after a standardized meal, participants consumed CC, CP, or PL and then immediately underwent measurements of REE and RER for 30 min. Upon waking the next morning (0500-0800 h) measurements of REE and RER were repeated and subjective measures of appetite (visual analog scale) were recorded. Testing occurred during the follicular phase of menstrual cycle. Statistical analyses were conducted using repeated measures ANOVA. Significance was accepted at $p \le 0.05$. **RESULTS:** There were no significant differences in acute REE (CC, 1725 ± 327; CP, 1718 ± 214; PL, 1691 ± 265 kcal/d, p=0.95) or acute RER (p=0.56) or morning REE (CC,1396 ± 293; CP, 1361 ± 175; PL, 1432 ± 216, kcals/d, p=0.79) or morning RER (p=0.52). Subjective measures of appetite were not different between groups. **CONCLUSION:** In active women, pre-sleep consumption of CC does not alter REE or RER more than a CP or PL beverage. These data suggest the form of the nutrient does not alter the metabolic response.

The Acute Effects Of A 30-min Moderate Aerobic Exercise On Autonomic And Inhibitory Control

Yiu-Man LEE, Stanley Sai-chuen HUI, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.* (Sponsor: Prof. Stanley Sai-chuen HUI, FACSM)
(No relevant relationships reported)

High frequency component of heart rate variability (HF-HRV) is a promising biomarker of the autonomic nervous system to reflect the brain-heart integration and control of behavior that can inform research and clinical applications.
PURPOSE: The current study aims at exploring whether inhibitory control will be changed after a 20-min bout of moderate cycling exercise plus 5-min warm-up and

5-min cool-down. The study hypothesizes that subjects who demonstrate greater HF-HRV reactivity (i.e. larger HF-HRV decrease) under a mental stress evoked by a Stroop color-word test, will perform better on the Stroop tasks.
METHODS: Thirty-two healthy Chinese young male adults (mean age: 21.2 years old) participated in two separate testing sessions. The first session involved baseline VO2max test; and in the second session, participants were randomly assigned to either an exercise intervention or no exercise (control) condition. For the exercise intervention group of participants, computerized Stroop color-word test was conducted before and after the intervention to examine the acute effects of aerobic exercise on inhibitory control. HRV was measured during the Stroop tasks by using the Electrocardiogram (ECG), which was recorded via two bipolar electrodes that were placed on the left and right chest of the participants. ECG was sampled continuously with a rate of 1000 Hz.
RESULTS: Two-way repeated measures MANOVA showed significant Intervention X Time interaction on Response Time (RT) of the Stroop tasks ($p < 0.01$). Furthermore, significant Intervention X Time interaction on HF-HRV differences was revealed between the exercise intervention and control groups on the Stroop tasks ($p < 0.01$). Exercise group performed significantly faster RT on Stroop tasks at post-test than the Control group ($p < 0.05$). Larger decrease of HF-HRV during mental stress had a positive relationship with RT of the Stroop tasks.
CONCLUSION: A 30-min acute moderate aerobic exercise could elicit inhibitory control for young adults. The studies manifested the potential physiological mechanism between central nervous system and autonomic nervous system which were reflected by HRV index, likely being influenced by acute aerobic exercise in enhancing an individual's inhibitory control.

Physical Fitness and Cognitive Performance in Women

Julia R. Rebellon, Meir Magal, FACSM, Daniel Henderson, Christina Huber, Abigail Leonard, Lyndsay Wolfe, Andrea Tobar, Sierra Hayden, Shannon K. Crowley. *North Carolina Wesleyan College, Rocky Mount, NC.*
(No relevant relationships reported)

PURPOSE: Cognitive impairment (including dementia and Alzheimer's disease) affects approximately 1/3 of women over the age of 75. Studies suggest that increased levels of physical activity are associated with preserved cognitive function, however, the mechanisms by which physical activity may prevent or delay cognitive decline remain elusive. Chronic psychosocial stress has been proposed as a potential contributor to cognitive decline, and research suggests that exercise training may help to buffer the negative effects of stress. However, to date, there has been limited investigation of the stress-related mechanisms underlying the relationship between physical fitness and cognitive performance in women. This study aimed to investigate relationships among physical fitness, cognitive performance, and physiological responses to mental stress in women, while experimentally controlling for ovarian cycle phase effects on the stress response. **METHODS:** Following a two-tiered screening process, healthy women (18-45y) who were medication-free and had regular menstrual cycles completed: (1) an enrollment visit, (including assessment of cardiorespiratory fitness via maximal oxygen consumption during exercise), and (2) a mental arithmetic stressor [(the Paced Auditory Serial Addition Task (PASAT)], where hemodynamic stress responses were recorded. Mental stress testing sessions occurred during the follicular phase of the menstrual cycle to control for hormone fluctuations which can profoundly influence the physiological response to stress. **RESULTS:** Results from this study (n = 28) showed that higher levels of physical fitness were associated with greater cognitive performance on fast (r = 0.42, p = 0.02), and moderate (r = 0.33, p = 0.08; trend) stimulus presentation rates of the PASAT. Consequently, higher levels of physical fitness were also associated with lower HR during the PASAT (r = -0.41, p = 0.03). **CONCLUSIONS:** Our results suggest that physical fitness is associated with improved cognitive performance in women, which may be explained by improved sympathetic nervous system (e.g., HR) activity during mental stress. Whether exercise training may help to delay cognitive decline via its impact on physiological stress responding will require further investigation.

The Acute Effect Of Endurance Exercise On An Executive Function Task In Middle-age And Older Adults

Brandon A. Yates[1], Ariela R. Orkaby[2], Ekow Dadzie, Jr.[3], Elaine C. Lee[3], Lawrence E. Armstrong, FACSM[3]. *[1]Spaulding Rehabilitation Hospital, Cambridge, MA. [2]VA Boston Healthcare System, Boston, MA. [3]University of Connecticut, Storrs, CT.* (Sponsor: Lawrence Armstrong, PhD, FACSM, FACSM)
(No relevant relationships reported)

Middle-age and older adults are encouraged to participate in regular physical activity to counteract age-related declines of cognitive function. Acute aerobic exercise bouts of 10-60 minutes have been reported to improve key domains of cognition such

as executive function within this population. However, it is unknown if prolonged exercise bouts, which induce great cardiovascular stress and fatigue, elicit similar improvements in cognition. **PURPOSE:** To investigate the acute effects of prolonged endurance exercise on executive function in middle-age and older adult recreational cyclists. **METHODS:** This field study was conducted at the Hotter'N Hell Hundred cycling event (HHH) in Wichita Falls, Texas (ambient temperature, 26°C mean, 30°C maximum; relative humidity, 75% mean, 93% maximum). Sixty recreational cyclists (52±9 y) were enrolled following informed consent. All cyclists were screened for mild cognitive impairment via Mini-Cog assessment (4±1). Physical function was assessed utilizing a 3-meter usual gait speed measurement (1.08±0.16 m/s). At baseline (i.e., 1 day before HHH), participants were familiarized with the executive function pencil-paper test (Trail Making A and B Tests, TMT) and anthropometric measurements were recorded (14±5 % body fat, 28.4±5.1 kg body mass). Cyclists completed TMT prior to and immediately following the HHH event. Ratings of perceived exertion (RPE) were collected at 0, 98, and 164 km and total exercise time was determined at the finish line. Pre- and post TMT scores were compared via paired T-test and all data are presented as mean±SD. **RESULTS:** After the HHH 164-km endurance cycling event, there was a significant improvement (i.e., faster completion time; p<0.001) of executive function (pre vs post, 83±26 vs 75±21 s). The mean RPE at cessation of exercise was 16±2 and mean total event time was 6.15 ±1.25 h. **CONCLUSION:** An acute bout of prolonged, moderate intensity endurance exercise (> 6h) increased performance of an executive function task in a cohort of middle-age and older adults. This suggests that such exercise may provide chronic improvements in attention, working memory, and cognitive flexibility which counteract age-related declines of cognitive function.

Experimental Effects of Acute Exercise on Episodic Memory Acquisition: Decomposition of Multi-Trial Gains and Losses

Eveleen Sng, Emily Frith, Paul Loprinzi. *University of Mississippi, Oxford, MS.*
(No relevant relationships reported)

PURPOSE: Research demonstrates that acute exercise may enhance retention of multi-trial episodic memories. This work has examined the effects of exercise on the mean level of memory recall. However, no study has examined whether exercise can influence the acquisition of new items, which was the purpose of this experiment. **METHODS**: Using a randomized controlled trial design, participants completed either a high-intensity bout of treadmill exercise for 15-min (n=22) or sat for 15-min (n=22) prior to completing a multi-trial episodic memory task (RAVLT). This task involved recalling 15 words for 6 successive trials, as well as after a 20-min delay (Trial 7). The performance on the multiple trials was categorized into gains (items not recalled on Trial n that were recalled on Trial $n+1$) and losses (items recalled on Trial n that were not recalled on Trial $n+1$). **RESULTS**: The exercise group recalled more words on Trial 6 (11.4 vs. 9.7; P=.009) and after the 20-min delay (10.9 vs. 9.4; P=.01). The exercise group (vs. control) had a smaller proportion of losses from Trial 3-4 (10.4% vs. 20.3%; P=.04) and had a greater proportion of gains from Trial 5-6 (38.5% vs. 14.8%; P=.01). **CONCLUSIONS**: The exercise-induced multi-trial memory effect may be influenced by greater item gains and fewer item losses from exercise.

EMF Stimulation As Passive Exercise Improves Cognition And Psychomotor Activity In Senescent Rats

Timea Teglas[1], Gabriella Dörnyei[2], Karoly Bretz[1], Csaba Nyakas[1]. [1]*University of Physical Education, Budapest, Hungary.* [2]*Semmelweis University, Budapest, Hungary.*
(No relevant relationships reported)

PURPOSE: During advanced aging passive exercise (PE) is becoming a valuable therapeutic intervention to improve physical and mental performances. In the present study chronic PE (electromagnetic field stimulation, EMF-S) was introduced to rats reaching the senescent age of 32 months in order to develop a translational model for supporting healthy aging, attenuating cognitive decline and to clarify the mechanism of action of EMF-S on brain and muscle tissues during advanced aging. **METHODS:** Male Wistar rats were treated with EMF-S for six weeks, 3 times per week, 24 min per sessions prior to the age of 32 months. The doses of stimulation were: 45, 95 and 1250µT (Santerra MCR System, Pinding, Germany). Psychomotility (horizontal and vertical ambulation in novel environment) was estimated in open field (OF), the attention ability in novel object recognition (NOR) test, and spatial learning, reference and working memories, in Morris water maze (MWM) tests. **RESULTS:** OF: EMF stimulation enhanced novelty-induced motility, especially that of vertical type after both the middle and high doses (p<0.05 at both doses). NOR: EMF-S increased attention after middle and high doses (p<0.001 and p<0.01, respectively) reflecting an enhanced attentional capability based on memory enhancement. MWM: passive exercise facilitated the working memory type spatial learning in this test and the

highest dose of 1250µT was clearly effective (ANOVA, p=0.024). **CONCLUSION:** The results obtained on cognitive tasks showed that EMF stimulation as PE is effective in senescent age to improve cognitive and psychomotor function in rats. In the age of 32 months rodents showed rather deteriorated cognitive functions in our earlier studies. Furthermore, it may be added that the highest dose of 1250µT did not uncover undesirable side effects on the brain, which is promising for a wider therapeutic window. The results support the notion that PE may complete dementia prevention program in elderlies. These animal studies can provide options to study the cellular and molecular mechanisms behind this treatment helping human interventions. Supported by OTKA Grant K116511 in Hungary

Effects of Acute Exercise on Stress-Induced Memory Function

Pamela Ponce, Dylan Delancey, Emily Frith, Paul D. Loprinzi. *University of Mississippi, University, MS.*
(No relevant relationships reported)

PURPOSE: Acute exercise during the memory consolidation stage can enhance memory, whereas acute psychological stress post-memory encoding has been shown to impair episodic memory function. However, no study has evaluated whether acute exercise during memory consolidation can attenuate the detrimental effects of psychological stress-induction on memory retrieval, which was the purpose of this experiment. We also evaluate potential gender-specific effects, which has yet to be explored in this context. **METHODS:** Forty-four university students completed a between-group randomized control trial. Participants completed the WMS-III Logical Memory sub-test prior to moderate-intensity walking for 15 minutes, or sitting for 15 minutes. After walking or sitting, participants completed an oral presentation per the Trier Social Stress Test (TSST) method, and then re-completed the memory assessment. **RESULTS:** There was no group x time x gender interaction effect (F=1.52; P=0.22), but there was evidence of a group x gender interaction (F=4.11; P=0.04). In both groups, men had a greater decline in memory function from the TSST. From pre- to post-assessment, respectively, male participants' Logical Memory scores decreased from 16.31 (3.4) to 14.54 (3.7), whereas female participants' scores remained more stable 17.89 (2.9) to 17.28 (3.1). **CONCLUSIONS:** These findings suggest gender effects extend to paragraph and logic-based memory performance, as men experienced a larger decline in memory function following a social stressor, irrespective of an acute exercise response.

The Effects of Acute Exercise on Working Memory and Delay Discounting

Julie A. Cantelon[1], Grace E. Giles[2], Robin B. Kanarek[1], Caroline R. Mahoney[2], Holly A. Taylor[1]. [1]*Tufts University, Medford, MA.* [2]*U.S. Army NSRDEC, Natick, MA.*
(No relevant relationships reported)

Given the choice, people tend to prefer immediate rewards over delayed rewards. This tendency to devalue rewards with increasing delays to their receipt is referred to as delay discounting. Previous research has demonstrated an inverse relationship between working memory capacity and delay discounting. Furthermore, an acute bout of moderate intensity exercise has been shown to improve working memory and thus could potentially alter discounting. Increased delay discounting has been associated with a variety of unhealthy behaviors, such as smoking, drug abuse and obesity. Therefore, intervention strategies aimed at reducing such impulsive decision-making would be advantageous across a variety of domains. To date, research has focused on the effects of prolonged exercise interventions on reducing discounting, but the effects of acute bouts of exercise remain unexplored. **PURPOSE:** To examine whether an acute bout of moderate intensity exercise improves working memory and subsequently decreases delay discounting. **METHODS:** Twenty-four healthy young adults (13 men, 11 women, age 18-35) participated. A repeated measures design was utilized in which participants first completed questionnaires assessing physical activity and impulsiveness. They then completed a 30-minute treadmill run at 65% Heart Rate Reserve or rest period. Following exercise, participants completed an intertemporal choice task, measures of working memory (*n*-back) and mood (PANAS). **RESULTS:** Preliminary results revealed exercise related changes in mood, specifically increases is positive affect and decreases in negative affect following exercise compared to rest. However, no differences in working memory performance or delay discount rates were observed between conditions. Future directions examining the influences of individual differences and acute vs. prolonged exercise interventions are discussed. **CONCLUSION:** These preliminary data suggest that although prolonged exercise interventions may effectively reduce delay discounting, an acute bout of moderate intensity exercise does not. These findings inform strategies for eliciting exercise-induced changes in decision-making and highlight the importance of intervention duration.

Abstracts were prepared by the authors and printed as submitted.

The Effects Of Pilates On Cognitive Functions In Middle-aged Women

Yuya Fujii[1], Keisuke Fujii[2], Kayoko Isono[3], Naomi Otsuki[4], Kaya Joho[1], Tomohiro Okura[1]. *[1]University of Tsukuba, Ibaraki, Japan. [2]Ibaraki Prefectural University of Health Sciences, Ibaraki, Japan. [3]Pilates Alliance association, Tokyo, Japan. [4]THF Inc., Ibaraki, Japan.*
(No relevant relationships reported)

Pilates is a popular form of exercise for women, and previous studies have shown its effectiveness for improving physical and psychological health. Pilates is a mindful approach to exercise, stimulating awareness of body structure, muscle recruitment, and body alignment during movement. Thus, Pilates requires concentration on the body. However, the effects of Pilates on cognitive functions remain unknown. **PURPOSE**: This study aimed to investigate the effects of Pilates on cognitive functions in middle-aged women through a randomized clinical trial. **METHODS**: Forty-four middle-aged women (average age: 56.4 ± 7.3 yrs) were randomly divided into Pilates (n = 22) and control groups (n = 22). Pilates classes were performed for 60 minutes twice per week for 10 consecutive weeks. The control group underwent health education sessions three times during the intervention. Prior to the intervention and 10 weeks afterwards, cognitive functions were assessed by the Trail Making Test A/B and Stroop Color-word test. Repeated-measures analysis of variance was performed to compare between-group changes. **RESULTS**: There were no significant differences between the Pilates and control groups for any measured variables (P > 0.05) despite Trail-Making Test B significantly improving from pre- to post-Pilates classes (61.5 ± 22.0 to 52.2 ± 9.6 sec; P = 0.02; Cohen's d = 0.55) without significant changes during the control phase (64.9 ± 16.3 to 62.4 ± 12.3 sec; P = 0.53). There were no changes in Trail-Making Test A. Stroop interference time significantly weakened in both groups (Pilates: 154.6 ± 124.6 to 216.7 ± 95.6 msec; P < 0.01, control: 166.0 ± 133.0 to 258.0 ± 88.3 msec; P < 0.01) because only the neutral task significantly improved (Pilates: 1016.5 ± 159.2 to 918.0 ± 134.7 msec; P < 0.01, control: 1014.8 ± 163.2 to 887.5 ± 168.1 msec; P < 0.01). **CONCLUSIONS**: Although there were no significant between-group differences, the Pilates group showed improvement in Trail-Making Test B. Further large clinical trials are warranted to determine the effectiveness of Pilates for improving cognitive functions.

Trade-off Between 30-minute Physical Activity And 1-hour Revision Time

Jacky Ka-wai Chan, Stanley Sai-chuen Hui, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*
(No relevant relationships reported)

One of the major barriers for promoting physical activity (PA) in children is the general belief about the negative impact of PA on academic achievement. PA was then being scarified for extra study time and/or replaced by sedentary activity.**PURPOSE**: To explore the relationship between PA, revision time, and mathematics achievement among Chinese adolescents. **METHODS**: A total of 16 secondary schools were randomly invited in Hong Kong. Within an academic year, 781 grade 9th Chinese students' PA level, revision time afterschool, and mathematics achievement were measured twice with 9 months apart (start: T0; end: T1). Comparing the responses from a self-reported questionnaire (PAQ-A) between the two time-points, participants were categorized into Increasing-PA (IPA), Decreasing-PA (DPA), and Unchanged-PA groups. The longitudinal changes of mathematics test scores were examined between IPA and DPA groups using two-way repeated measures ANCOVA, adjusted for gender, family income, and revision time. PA-group and revision time were put into the regression analysis to investigate the explained variance of academic performance change. **RESULTS**: Significant Time x PA-group interaction effect on mathematics score (F=4.36, p=0.04) was observed. Significant improvement was found in IPA participants. In the multiple linear stepwise regression model, mathematics score change was significantly regressed on revision time (B=0.05, t=2.64, p=0.01) and PA-group (B=3.35, t=2.27, p=0.03) with *R-square* at 5.09%. **CONCLUSIONS**: Both revision time and PA level statistically predicted the change in mathematics achievement. Spending more time on PA did not necessarily deteriorate academic performance. More importantly, compared to the positive impact of increasing revision time (about 1 hour per day) on mathematics, an increment of relatively little time in PA (about 30 minutes daily) may bring similar effect in addition to physical fitness enhancement. However, other learning areas have not yet been examined.

Does False Feedback Alter Performance in an Anaerobic Maximal Test Among Healthy Young Adults?

Nathaniel G. Bodell, Andrew Craig-Jones, Jeffrey Montes, James W. Navalta, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: James Navalta, FACSM)
(No relevant relationships reported)

It has been observed that extrinsic factors, such as music or verbal encouragement, can influence performance while exercising. It has yet to be determined if this effect is present in supra-maximal efforts. **PURPOSE**: to determine whether positive feedback (PF) or negative feedback (NF) prior to a maximal anaerobic exercise test improves or degrades performance. **METHODS**: 23 college aged adults were recruited for a two-day exercise protocol and were randomly divided into a PF or NF group. Day one: participants were oriented with the Wattbike Pro cycle ergometer and underwent a 30-second anaerobic test of power (in line with a Wingate test of power). Day two: Participants had a 24 hour-2 week window in which they could perform the second trial. Prior to the second trial participants were informed they performed better (PF) or worse (NF) than a hypothetical average prior to their second 30-second anaerobic test of power. **RESULTS**: Both PF and NF groups observed a significant improvement in peak power (p=0.03, p=0.02 respectively), and average power (p=0.042, p=0.035 respectively). Additionally, there was a significant improvement in power/mass ratio among the NF group (p=0.026). There was no difference in peak or average power between groups among the day 2 trial (p=0.95, p=0.18, respectively). **CONCLUSIONS**: PF or NF prior to a maximal anaerobic test of power improved peak and average power. It is theorized that the improvement among the PF group corresponded to an increase in self-efficacy; while the improvement among the NF group was related to a desire to perform at or above the fabricated average.

Increased Exercise Activity In An Enriched Environment Improves Anxiety-like Behavior And Cognition.

Mizuki Sudo[1], Soichi Ando[2], Yutaka Kano[2], Toshiya Nagamatsu[1]. *[1]Physical Fitness Research Institute, Meiji Yasuda Life Foundation of Health and Welfare, Hachioji, Tokyo, Japan. [2]University of Electro-Communications, Chofu, Tokyo, Japan.*
(No relevant relationships reported)

An enriched environment consists of complex housing with increased space and a variety of toys, which results in enhanced exercise activity and social interactions. Housing rodents in the enriched environment are known to improve both anxiety-like behavior and cognition. However, the contribution of increased exercise activity to such a functional plasticity are less clear. **[Aim]** The aim of the present study was to examine effects of increased exercise activity in the enrich environment on anxiety-like behavior and cognition. **[Methods]** Wistar rats were housed in the two different housing groups [standard environment (SE) group (N = 22); enriched environment (EE) group (N = 22)]. EE contained a slope, a small hut, three tunnels, and a running wheel such that exercise activity was increased. Exercise activity was continuously recorded using three-axis accelerometers for 6 weeks. The accelerometers were embedded in the back. The animals were submitted to the elevated plus maze (EPM) and Morris Water Maze (MWM) tests to assess anxiety-like behavior and spatial learning and memory. The muscle hypertrophy was evaluated from immunostained (MHC IIa) cross-section area (CSA). All experimental data were expressed as mean $\pm$ standard deviation. Comparisons were performed using a t-test. The level of significance was set at p < 0.05. **[Results]** Exercise activity was higher in the EE group compared with the SE group in light period. All hindlimb muscle wet weights per BW were greater in the EE group compared with the SE group. Moreover, the CSA of MHC IIa in the soleus muscle increased in the EE group (EE: 1729 ± 224 μm², SE: 1589 ± 144 μm², p < 0.05). In the EPM test, time spent in open/closed arms was significantly increased in the EE group (39.4 ± 15.8%, p < 0.05) than the SE group (24.0 ± 15.1%). This result suggests that anxiety-like behavior was reduced in the EE groups. On the third day of the MWM test, escape latency was reduced in the EE group (11.50 ± 1.87 sec) than the SE group (17.93 ± 3.40 sec, p < 0.05), which indicates that spatial learning and memory was improved in the EE group. **[Conclusions]** Increased exercise activity in the enriched environment improves anxiety-like behavior and spatial learning and memory.

The Role of Low Frequency Power in the Relationship Between Exercise and Memory

Alexis B. Slutsky, Jennifer L. Etnier, FACSM, Sudharania Arunachalam, Laurie Wideman, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Laurie Wideman, FACSM)

(No relevant relationships reported)

PURPOSE: Acute exercise (AE) has been shown to have a positive effect on memory performance, however these results are not always observed. Although some studies control for factors such as age and gender, there may be physiological factors that affect memory and the relationship between AE and memory and that may help explain inconsistent results. Low-frequency power (LF) has been suggested as a marker of baroreflex sensitivity (BRS), which is associated with memory performance. We aimed to investigate the influence of LF in the relationship between AE and memory. METHODS: 68 active adults (M=21.9, SD=3.9 yrs) were randomly assigned to 4 groups in relation to a memory task: 20-min AE prior (n=17), 20-min AE after (n=15), 10-min AE prior and 10-min AE after (n=19), and no exercise control (n=17). Baseline heart rate (HR) was collected for 5-min in the seated position, and R-R intervals were reduced to LF. AE consisted of cycling at 55-65% HR reserve and the memory measure was the Rey Auditory Verbal Learning Test 24-hr recall. RESULTS: A significant group x LF interaction was found ($F(3,60)=2.79$, $p=.048$); LF was associated with 24-hr recall for the control group ($r(15)=.637$, $p=.006$), but not for the exercising groups (p>.05). Post-hoc tests revealed benefits to 24-hr recall only for the groups that exercised before (M=10.295, SE=0.59) or both before and after (M=10.10, SE=0.57) memory tasks compared to control (M=7.72, SE=0.60, $p=.002$, $p=.004$, respectively). CONCLUSION: Evidence supports that baseline LF, as a marker of BRS, is associated with memory. Importantly, activating the sympathetic nervous system, through AE, prior to encoding appears to disrupt this relationship and improved memory performance.

The Effect of Acute Aerobic Exercise on Attention and Affect in Middle-Aged Women

Jonathan Little, Kara T. McNeill, Cara Poole, Eric E. Hall, FACSM, Theresa Ramos, Elizabeth S. Evans. *Elon University, Elon, NC.* (Sponsor: Eric E. Hall, PhD, FACSM)

(No relevant relationships reported)

PURPOSE: To explore the effect of one bout of moderate intensity aerobic exercise on attention and affect in healthy middle-aged women. **METHODS**: Five healthy women, age 55.2 ± 8.9 years, BMI 30.2 ± 4.4 kg/m2, and percent body fat 35.5 ± 5.7% completed a 30-minute session of aerobic exercise on the cycle ergometer at a workload corresponding to 60% of VO2peak. Subjects also completed a 30-minute control session on the cycle ergometer at 0 Watts. Before and after both 30-minute sessions, participants completed two computerized tests of attention: The Digit Span Test and the Flanker Task. Performance on the Digit Span was assessed by examining the mean forward digit span and mean backward digit span achieved. Performance on the Flanker Task was assessed by examining the error proportion and mean reaction times for incongruent and congruent trials. Participants also completed the Activation Deactivation Adjective Checklist (AD-ACL) to assess affect (i.e. energy, tiredness, calmness, and tension) before and after both 30-minute sessions. **RESULTS**: Repeated-measures ANOVAs indicated that participants achieved a significantly higher forward vs. backward mean digit span (mean difference: 0.7 ± 0.2, p = 0.046) and that mean digit span performance significantly improved from pre- to post-session (mean difference: 0.5 ± 0.2, p = 0.033). Participants displayed a larger decrease in error proportion from pre- to post-session for the incongruent vs. the congruent trials of the Flanker Task (p = 0.058), as well as a significant decrease in mean reaction time pre- to post-session (mean difference: -23.0 ± 6.8 ms, p = 0.028) that was more pronounced for the congruent vs. the incongruent trials (p = 0.08). Participants also reported feeling significantly more energetic and less tired from pre- to post-session on AD-ACL subscale scores (mean differences: 3.5 ± 0.9, p = 0.013 and -4.7 ± 1.8, p = 0.052, respectively). **CONCLUSIONS**: Exploratory results suggest that 30 minutes of aerobic exercise may positively impact some aspects of attention in middle aged women. Participants reported feeling more energized and less tired after 30 minutes of activity. Additional ongoing investigation is needed to more clearly understand the impact of acute aerobic exercise on cognitive function in this population.

Exercise Training Related Changes in Verbal Fluency in Healthy Older Adults and Mild Cognitive Impairment

Allison P. Williams[1], Zuleyha Ozturk[1], Tina Mirzazadeh[1], Yasmeen Faroqi-Shah[1], Kristy A. Nielson[2], J. Carson Smith, FACSM[1]. [1]*University of Maryland, College Park, MD.* [2]*Marquette University, Milwaukee, WI.* (Sponsor: J. Carson Smith, PhD, FACSM)

(No relevant relationships reported)

We have previously reported that exercise training (ET) in older adults diagnosed with mild cognitive impairment (MCI) is associated with increased functional connectivity of the default mode network (Chirles et al., 2017), increased cortical thickness (Reiter et al., 2015), decreased cortical activation during semantic memory retrieval and increased episodic memory performance, but no change in verbal fluency (Smith et al., 2013). Verbal fluency, which refers to producing words from a specific category (e.g., starts with F), involves selecting words by inhibiting competing alternatives (e.g., phone). It is not known if the ET influences the total score or the complexity of the words produced. **PURPOSE**: The purpose of this study was to examine the effects of a 12-week walking ET intervention on the frequency and complexity of words produced during a phonemic fluency task. **METHODS**: Seventeen MCI participants and 18 cognitively intact controls completed a 12-week ET intervention consisting of supervised treadmill walking at a moderate intensity. Before and after ET, participants completed a phonemic verbal fluency task as part of a larger neuropsychological battery. Total word count and complexity of responses, measured by word frequencies and syllable length, were examined. **RESULTS**: There was no change in total word count. However, both groups produced words with greater frequency after ET (p = .016, partial eta-squared = .163). In addition, participants diagnosed with MCI produced words with fewer syllables after ET, an effect not observed in healthy controls (interaction p = .034, partial eta-squared = .129). **CONCLUSIONS**: These findings suggest 12-weeks of walking exercise training may modify lexical retrieval strategies, with a greater reliance on more frequently appearing words, and in the case of MCI, words that have fewer syllables. Our past finding of reduced semantic memory activation after ET suggests improved neural efficiency. These results could be interpreted similarly if producing more frequent and shorter words is adaptive and more efficient in the face of demands to quickly produce words under a time constraint. It is plausible ET is related to enhanced cognitive control by inhibiting competing words and facilitating a search for easier words to speak.

Effects Of An Acute Bout Of Resistance Exercise On Cognitive Performance In Young Adults

Jarod Vance, Randal Claytor. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)

(No relevant relationships reported)

There is overwhelming support for enhanced cognitive performance (CP) as a result of an acute bout of aerobic exercise. However, there is less research, and the research is less clear regarding the effects of an acute bout of resistance exercise (RE) on cognitive performance. **PURPOSE:** To investigate the effect of an acute bout of high-intensity RE on reaction time (RT), working memory (WM) & inhibition (IC) - parameters of CP. To determine if there were sex differences for RE & CP, & to examine the relationship between CP & RE-Total Load (TL). **METHODS:** 23 healthy males (9) & females (Age = 21.7±1.8 yrs) volunteered. Day 1: body composition (Bodpod) and VO$_2$ max were assessed (HRmax = 189.6 +/-5.4 b/min, VO$_2$max = 49.0+/-7.3 ml/kg/min, BF% = 18.1+/-6.5). Day 2: Ss completed an initial battery of CP tests (imPACT) & then completed 1-repitition maximums (1-RM) for 7 Res that made-up the RE routine. Days 3&4: Ss underwent either 30 minutes of semi-reclined Rest (R) or the RE routine. The RE routine consisted of 2 consecutive sets (12 reps) of each RE at 75% 1-RM, followed by 1min of R. R & RE routine order was counter-balanced. Days 2, 3&4 were separated by 1wk. Prior to (PreR & PreEx) & following R & RE routine (PostR & PostEx) Ss performed the imPACT assessment for CP. 4(Conditions) X 2(Sex) ANOVAs with Repeated Measures & *a priori* contrasts were used to test for significant main effects & interactions for the CP variables. **RESULTS:** T-Tests confirmed Males (M) exhibited higher VO$_2$max, TL, RE-VO$_2$ & lower BF%. PreEx-PostEx RT (526+/-60ms - 510+/-58ms) was significantly reduced (p<0.02), whereas PreR-PostR RT (525+/-53ms - 532+/-67ms) & PreR-PreEx RT (525+/-53ms - 526+/-60ms) did not differ significantly. None of the CP variables differed by Sex. RT-change (PreEx-PostEx) & TL & RE-VO$_2$ were not significantly correlated. **CONCLUSION:** Following a single-bout of a high-intensity RE routine, RT was significantly reduced for M & F. However, WM & IC did not differ significantly following RE or R for M or F. M exhibited greater VO$_2$ & VCO$_2$ in response to greater TL, however the change in RT (PreEx-PostEx) was not related to TL the entire group or for M or F.

The Impact of Music and Attentional Focus on Muscular Activation

Andrew Moore[1], Jasmin Hutchinson[2], Christa Winter[2], Paul Dalton[2], Brendan O'Neil[2], Vincent Paolone, FACSM[2]. *[1]Augusta University, Augusta, GA. [2]Springfield College, Springfield, MA.*
(No relevant relationships reported)

Neuromuscular efficiency is improved during exercise when attention is focused externally on the effects of movement, rather than internally on the generation of movement. Music is a form of external attentional focus which may yield additional psychological benefits during exercise. The impact of music on neuromuscular efficiency remains to be fully investigated. **PURPOSE**: To determine the effects of music and other attentional focus conditions on muscular activation and psychological response to single-joint isometric exercise.
METHODS: Apparently healthy subjects (N = 23; 12 men) completed an isometric elbow flexion task (40% of predetermined 3RM) for 1 min in three randomized, counterbalanced conditions: internal focus (INT), external focus with a simple distraction task (EXT), and external focus listening to music (MUS). Muscle activation of the biceps (BI) and triceps (TRI) brachii were recorded at 15 s intervals using a 4 channel Delsys EMG system, and were used to compute cocontraction ratio (CCN). Heart rate (HR) was measured throughout the exercise tasks and recorded at 15 s intervals. Psychological characteristics of perceived exertion (RPE), affective valence, task-motivation, and attentional focus were measured at the end of each trial using single-item scales. Repeated measures 3 (condition) x 4 (time) ANOVAs were used to analyze the physiological variables (BI, TRI, CCN, and HR). Psychological variables were compared across conditions using a series of one-way repeated measures ANOVAs.
RESULTS: No significant interaction effect or main effect for condition was found for any of the physiological variables (p > .05), though there was a trend (p = .071, $\eta2$ = .12) for decreased HR with MUS (91.41 bpm) compared to INT (93.87 bpm). There was a significant main effect of condition on RPE (p = .002, $\eta2$ = .25), with a greater RPE in INT (13.87) compared to EXT (12.39) and MUS (12.61).
CONCLUSIONS: The primary finding from the current study was that external focus, through both music and a distraction task, reduced the perception of effort during brief single-joint isometric exercise, despite the fact that muscle activation and physiological demand were unchanged.

391　　Board #232　　　　May 30 11:00 AM - 12:30 PM

The Influence Of Self-generated Emotions On Aerobic Physical Performance: An Investigation Of Happiness, Anger, And Sadness

Brianda Cortez, Manuel Guillen, Roberto Baca, Teresa Loya, Alberto Garcia, Michelle Kowalski, Murat Karabulut. *University of Texas Rio Grande Valley, Brownsville, TX.*
(No relevant relationships reported)

PURPOSE: The purpose of this study was to test the influence of self-generated emotions on exercise performance during an aerobic workout on a cycle ergometer.
METHODS: Sixteen males (Mean ± STDEV age = 23.1 ± 2.7 years; height = 162.7 ± 26.2 cm; weight = 82.6 ± 16.1 kg) performed 4 sessions of aerobic exercise on a cycle ergometer. A randomized within-subjects experimental design was used to test the hypotheses. The four randomized testing sessions included: the control (No-Emotion), sadness (SAD), happiness (HAPPY), and anger (ANGRY). Cycle ergometer seat heights for subjects were measured and used for each session. Subjects performed a 3-min warm-up, a 15-min workout on the cycle ergometer at a 2.5 kg resistance, and a 3-min cool-down. Subjects were instructed to stop pedaling on the cycle after the warm-up and take 1-2 min to begin self-generating the emotion being tested. Subjects alerted testers when ready to begin workout. Flexibility was measured and recorded before and after testing. Heart rate (HR) was observed and recorded before testing, every 3 min during exercise, and immediately after exercise. Blood pressure (BP) measurements were taken before and immediately after each testing session, and at the 5 min, 10 min, and 15 min mark following cycling exercise.
RESULTS: No significant condition main effect for systolic and diastolic BP was observed, but there was a significant time main effect (p < .05). HR values were significantly higher during the ANGRY session compared to the values recorded during the No-Emotion and SAD sessions (p < .05). Participants covered significantly longer distance during the ANGRY condition compared to all other conditions (p < .05).
CONCLUSIONS: Self-generation of angry emotion during aerobic exercise resulted in significant increases in heart rate and distance traveled compared to all other emotions tested. Increased performance during the ANGRY session could be due to increased sympathetic nervous system activity and/or hormonal changes such as epinephrine, norepinephrine, and cortisol leading to a temporarily altered state of consciousness similar to a situation that is perceived as a threat or danger. Further studies should investigate the effects of emotion on hormonal changes, performance, and hemodynamic responses during long-distance events such as a 10K and marathon.

Assessment Of Knee And Ankle Proprioception In Young And Old Adults Using The AMEDA

Nicholas P. Cherup, Savannah V. Wooten, Shayaan Qazi, Brian Zalma, Joseph F. Signorile. *University of Miami, Miami, FL.*
(No relevant relationships reported)

Proprioception is often associated with neuromuscular abilities and injury prevention in older persons. While several methods exist for testing proprioception, most instruments are impractical and assess joint position sense (JPS) in an artificial environment. The Active Movement Extent Discrimination Apparatus (AMEDA) offers a low-cost alternative to evaluate JPS in a natural standing environment. **Purpose:** To compare the active proprioception of the lower limbs and ankles in healthy young (YG) and older individuals (OG) using the AMEDA. **Methods:** Forty-four persons (YG: n=22, OG: n=22) participated in the study. During lower limb (hip, knee) testing, participants were asked to touch a rear bar before kicking forward to strike a stop board placed at one of three positions (11cm, 16cm, 22cm). For the ankle, the foot was inverted to one of three angles (1=12o; 2=14o; 3=16o). Our testing included 3 conditions: condition 1 (C1=no difference between sequential positions), condition 2 (C2=minimal differences between sequential positions), and condition 3 (C3=maximal difference between sequential conditions). Participants were asked to identify all positions while blindfolded over the course of 50 trials. Two two-way ANOVA (condition) x (group) were used to examine the number of errors within each group at each joint position. **Results:** The YG made significantly more errors than the OG for the left lower limb during C1 and C3 (p < .05). Furthermore, for the YG, the number of errors decreased from C1 through C3 (p<.05). The YG also produced significantly more errors than the OG in C1 for the left and right ankles (p<.05). The OG made more errors during C2 then any other condition for both ankles (p<.05). **Conclusion:** The YG made more JPS errors then the OG. These findings are contrary to the proposition that proprioception decreases with age. Based on these findings, older individuals appeared to be more aware of their knee and ankle joint positions. These differences may be attributed to the OG paying greater attention to their movement patterns during day to day activities as a precaution to reduce fall risk.

393　　Board #234　　　　May 30 11:00 AM - 12:30 PM

During- Versus Post-Exercise Affective Forecasts: Some Affective Forecasts Are More Important than Others

Rachel M. Kahn, Zachary Zenko, Julia D. O'Brien, Dan Ariely. *Duke University, Durham, NC.* (Sponsor: Panteleimon Ekkekakis, FACSM)
(No relevant relationships reported)

An affective forecast is the prediction of how positive or negative one will feel in response to a future event. Researchers have identified a positive relation between affective forecasts and exercise behavior. **PURPOSE:** The purpose of this study was to determine whether forecasts about pleasure experienced during an exercise bout are more strongly related to behavior and intentions than forecasts about pleasure experienced after an exercise bout. **METHODS:** A four-item scale was generated to assess forecasted affect, both during and after a future exercise bout (Cronbach's α = .97 and .98, respectively). These items consisted of bipolar visual analog scales (e.g., "I will feel terrible" to "I will feel wonderful"). Participants (N = 250, 51% men, 48% women, 1% non-binary, age: 36 ± 12 years) were randomly assigned to either (1) forecast their affect during their next exercise bout (i.e., "How will you feel during your next exercise session?"), or (2) forecast their affect 10 minutes after their next exercise bout ends (i.e., "How will you feel 10 minutes after your next exercise session?"). Participants also indicated the number of minutes of aerobic exercise they completed in the previous week and how many minutes they intend to complete in the next week. **RESULTS:** Forecasts about during-exercise affect were more strongly related to exercise intentions than forecasts about post-exercise affect (r = .49 vs. r = .22, Z = 2.34 p = .01). Likewise, forecasts about during-exercise affect were more strongly related to past exercise behavior than forecasts about post-exercise affect (r = .46 vs. r = .22, Z = 1.99, p = .02). **CONCLUSIONS:** Forecasts about post-exercise affective states explained 4.75% and 5.01% of the variance in exercise intentions and past behavior, respectively. However, forecasts about during-exercise affective states explained 23.52% and 20.70% of the variance in exercise intentions and past behavior, respectively. Researchers should consider more specific measures of affective forecasts; these data indicate that predictions about how one will feel at different times (e.g., during and after an exercise experience) are differently related to exercise behavior and intentions. Further, specifying a time point may help reduce participant confusion and measurement error.

Effects Of Mental Fatigue Induced By A Continuous Cognitive Task On Attention Abilities Of Athletes

Jianxiu Liu, Ruidong Liu, Chunmei Cao, Xindong Ma. *Tsinghua University, Beijing, China.* (Sponsor: LiLi, FACSM)

(No relevant relationships reported)

Athletes need to maintain high concentration of attention in training and competition, while mental fatigue could damage their concentration, response and motor control abilities. However, there is a lack of research exploring the effect of mental fatigue on specific attention abilities of athletes.
Purpose: The present study is aimed to explore the effect of mental fatigue on athletes' selective attention and involuntary attention from the evidence of behavioral and ERPs.
Methods: Thirty elite tennis players (16 male, 14 female) were randomly selected and separated into Experiment Group (EG, n=15, age 21.08±1.5) and Control Group (CG, n=15, age 20.92±1.04). The athletes in EG were in mental fatigue after 1 hour of Flanker task, while the athletes in CG relaxed and kept themselves clear-headed for 1 hour. Heart rate variability (HRV), behavioral index and Rating of Perceive Exertion (RPE) were measured to detect players' mental fatigue during Flanker task which was divided into 4 periods (each stage 15 min). Selective attention (P3b) and involuntary attention (P3a) were evoked by novel auditory oddball task before and after the Flanker task.
Results: The accuracy of behavioral data was significantly different in 4 periods (F=35.83, $p<0.001$). The RPE score was higher in EG than CG (F=47.62, $p<0.001$). The time domain (rMSSD) and frequency domain (LF, HF and LF/ HF) in HRV data showed significant difference between the EG and the CG in all periods. Such, the mental fatigue was induced after the Flanker task. In the auditory oddball task, the reaction time was prolonged after the fatigue was induced (371.13±100.21ms vs. 388.07±93.64ms, $t = 4.878$, $p<0.01$). ERPs data showed that, after the fatigue-inducing task, P3a (19.290μV vs. 14.836μV, F=6.749,$p<0.05$) significantly decreased, indicating the impaired involuntary attention. Meanwhile, the P3b amplitude decreased and the latencies (15.373μV vs.12.036μV, F=10.451,$p<0.05$) at Fz, Cz and Pz sites increased significantly, indicating that the selective attention was impaired.
Conclusion: One hour of continuous cognitive task could induce psychological fatigue. Athletes' involuntary attention and selective attention were damaged after mental fatigue.

Effects of Sedentary Behavior and Physical Activity on Cognitive Function are Conferred by Cortical Thickness

Evan Pasha, Takashi Tarumi, Tsubasa Tomoto, Marcel Turner, Justin Repshas, Rong Zhang. *University of Texas Southwestern Medical Center, Dallas, TX.*

(No relevant relationships reported)

Effects of Sedentary Behavior and Physical Activity on Cognitive Function are Conferred by Cortical Thickness
Evan P. Pasha[1,2], Takashi Tarumi[1,2], Tsubasa Tomoto[1,2], Marcel Turner[1], Justin Repshas[1], and Rong Zhang[1,2]
[1]Texas Health Presbyterian Hospital Dallas, [2]University of Texas Southwestern Medical Center
Physical activity and aerobic fitness may have positive impacts on brain structure and function in older adults. Conversely, sedentary behavior may have negative effects.
PURPOSE: To determine associations of sedentary behavior with cerebral cortical thickness and neurocognitive function in older adults in cognitively normal older adults (NC) and patients with mild cognitive impairment (MCI).
METHODS: We tested 28 NC and 50 MCI participants matched for age, sex, and education. Participants wore a 3D accelerometer for 1 week to measure daily physical activity levels. Minutes spent in sedentary behavior (<4.0METs) and moderate-to-vigorous physical activity (MVPA) (>5.0METs) were recorded.
RESULTS: Sedentary behavior and MVPA were associated with cortical thickness in multiple brain regions within the default mode network. The effects of sedentary behavior on Trails B performance were mediated through left middle temporal gyrus (B=0.0017, SE=0.0010, 0.0002 to 0.0046 95% CI) and right frontal pole (B=0.0027, SE=0.0013, 0.0006 to 0.0058 95%CI) cortical thickness. MVPA (B=-0.011, SE=0.0070, -0.0304 to -0.0006 95%CI) positively impacted Trails B through left middle temporal gyrus thickness. California Verbal Learning Test cued recall was negatively affected by sedentary behavior (B=-0.00026, SE=0.0013, 0.0006 to 0.0058 95%CI), but positively affected by MVPA (B=0.0012, SE=0.0008, 0.0001 to 0.0033 95%CI) through right superior parietal cortical thickness. Cognitive status moderated the association of sedentary behavior with left posterior cingulate thickness (interaction, p=0.02) and MVPA to right supramarginal gyrus thickness (interaction, p=0.04) with greater effects occurring in NC.

CONCLUSION: Sedentary behavior is associated with reductions in cerebral cortical thickness which lead to impairment in memory and executive function in older adults. Sedentary behavior may be more detrimental to individuals with normal cognitive function.

Don'T Forget To Exercise: The Effects Of Different Forms Of Exercise On Memory

Emma K. Wilsie, Carrie Cuttler, Emily M. LaFrance, Christopher P. Connolly. *Washington State University, Pullman, WA.*

(No relevant relationships reported)

Acute bouts of exercise have been shown to positively affect memory. Although the majority of previous research has focused on the effects of exercise on retrospective memory, recent findings suggest resistance exercise may enhance prospective memory. The impact of yoga on prospective memory has not been previously examined.
PURPOSE: This study examined the effects of different forms of exercise on prospective memory (i.e., the ability to remember to execute tasks in the future) and retrospective memory (i.e., the ability to remember previously learned information).
METHODS: 145 students were randomly assigned to one of four groups: 1) treadmill running (R) (n=37), 2) kettlebell resistance exercise (K) (n=32), 3) yoga (Y) (n=35), or 4) sitting (S) (control group) (n=41). After exercising or sitting, participants completed a one-hour battery of neuropsychological tests that included two prospective memory tests: 1) an episodic prospective memory test (the reminder test) and 2) a habitual prospective memory test (the difficulty ratings test). To assess retrospective memory participants completed 1) a verbal memory test (CVLT-II) and 2) a visuospatial memory test (BVMT-R). Participants in the R, K, and Y groups performed video-guided exercise at a moderate level of intensity (50-70% of HHR) for 20 minutes, with a 5-minute warmup and a 5-minute cooldown. Participants in the S group watched an exercise video while sitting for 30 minutes. **RESULTS:** There was no significant effect of exercise on the habitual prospective memory test [$F(1,140)$=.64, p=.59], but there was a significant effect of exercise on the episodic prospective memory test [$\chi(3)$=8.30, p=.04]. Follow-up tests indicate that aerobic exercise led to fewer episodic prospective memory failures (11%) than resistance exercise (41%), yoga (31%), or sitting (27%). No significant effects were detected on either retrospective memory test [CVLLT-II, $F(3,141)$=.71, p=.55; BVMT-R, $F(3, 141)$=.48, p=.70]. **CONCLUSION:** Prospective memory is positively affected by exercise among college students. In contrast to previous findings, aerobic exercise specifically (but not resistance) appears to enhance prospective memory. This discrepancy may be due to differences in the time at which the prospective memory instructions were administered in the two studies.

Relationship between Affective State and Enjoyment of Acute Exercise

Battogtokh Zagdsuren, Colleen L. Geary, Hayley V. MacDonald, Mark T. Richardson, Jonathan E. Wingo, FACSM, Phillip A. Bishop, FACSM, James D. Leeper, Frances A. Conners. *The University of Alabama, Tuscaloosa, AL.* (Sponsor: Jonathan E. Wingo, FACSM)

(No relevant relationships reported)

Increasing exercise adherence is one of the main challenges in lifestyle interventions. Although the affective response to exercise has been investigated extensively, it is unclear whether one's enjoyment of exercise is influenced by pre-exercise affective state. **PURPOSE:** To evaluate the relationship between pre-exercise affective state and enjoyment of acute bouts of walking of varying durations. **METHODS:** Regularly active college-aged participants (n=29; mean ± SD age=21±2 y) completed 3 counterbalanced exercise sessions involving moderate-intensity (3–5 METs) walking for 5, 10, and 30 minutes, respectively. Participants completed the Positive and Negative Affect Scale pre-exercise and Physical Activity Enjoyment Scale (PAES) immediately post-exercise. **RESULTS:** Positive affect (PA) was similar across walking bouts (28.9±6.9). Pre-exercise PA was not associated with PAES after 5 min of walking (r=0.35, p=0.07). In contrast, there was a significant association between PA and physical activity enjoyment following both the 10- (r=0.45, p=0.02) and 30-min (r=0.73, p<0.001) walking bouts. **CONCLUSION:** Pre-exercise PA appears to influence physical activity enjoyment experienced following acute walking bouts lasting 10 min or more, an effect that was strongest following the longest walking duration.

Cognitive Function And Quality Of Life: Relationships In Individuals With And Without Spinal Cord Injury

Shauna Dudley-Javoroski, Jinhyun Lee, Richard K. Shields.
University of Iowa, Iowa City, IA.
(No relevant relationships reported)

Cognitive decline is a problematic secondary complication of spinal cord injury (SCI), arising from chronic hypotension, undiagnosed brain injury, medications, or other systemic causes. In many other patient populations (the elderly, multiple sclerosis, Alzheimer's disease), mild cognitive decline exerts a negative effect on quality of life (QOL). People with chronic SCI often report lower QOL than the general population, but the potential influence of cognitive function is unknown. **PURPOSE:** The purpose of this study is to examine relationships between cognitive function and QOL in individuals with and without SCI. **METHODS**: Individuals (n = 25) with and without SCI rated QOL with two global scales (EQ-5D, PROMIS physical/mental health), and two SCI-validated scales (Secondary Health Conditions Scale (SCS-M), SCI-QOL). Cognitive function was assessed using NIH Toolbox (Dimensional Change Card Sort, Flanker Inhibitory Control & Attention, List Sorting Working Memory, Picture Sequence). **RESULTS**: Subjects with SCI rated physical function QOL dimensions (EQ-5D, PROMIS physical health, SCS-M) lower than non-SCI subjects (all $p < 0.0002$). QOL dimensions relating to mental/emotional function (PROMIS mental health, SCI-QOL Positive Affect & Well-Being (PAWB), Anxiety, Depression, Resilience) did not differ between groups (all $p > 0.14$). Subjects with SCI reported greater Pain Interference and lower Ability to Participate than non-SCI subjects (both $p < 0.011$). In non-SCI subjects, correlations existed between cognitive test scores and certain QOL domains (Resilience R^2 = 0.46 to 0.72; PAWB R^2 = 0.29 to 0.51). No correlations between QOL and cognition emerged for participants with SCI. **CONCLUSIONS**: Individuals with SCI may report high mental/emotional QOL despite reporting low QOL on domains related to physical function and participation. Relationships between cognitive function and QOL were not observed in participants with SCI, despite robust associations in those without SCI. The relationship between the QOL domain Resilience and the cognitive trait "executive function" warrants further investigation. Supported by R01HD084645 and R01HD082109. REDCap access (Institute for Clinical and Translational Science) provided via the National Center for Advancing Translational Sciences (U54TR001356).

Both Combined And Aerobic Training Improve Cognitive Function In Hypertensive Elderly

Wellington Martins Santos, Amanda Sardeli, Victor Gadelha, Daisa Moraes, Claudia Cavaglieri, Mara Chacon-Mikahill.
University of Campinas, Campinas, Brazil.
(No relevant relationships reported)

Aging process and diseases such as hypertension contributes to cognitive impairment. Exercise training has been extensively recommended due to its benefits to the cognitive function in elderly. Inconsistent findings in the literature related to the better exercise training program for learning, executive functions and memory. **PURPOUSE:** Compare the effects of two different exercise program (combined vs. aerobic) on cognitive function of hypertensive elderly. **METHODS:** Hypertensive medicated elderly (age 65.5±4, mini-mental state examination 25.4±3, geriatric depression scale 3.5±2.2, PAS 133.8±20, PAD 84±11) were allocated to combined training (CT, n=17), composed by resistance exercises to the main muscle groups (15 rep) twice/week and the aerobic exercises at 50min walking on a treadmill at 60% VO_2 reserve, three times/week, or to Aerobic Training (AT, n=13) composed by the same aerobic protocol, or to the control group (CG, n=19) which received no treatment. Cognitive function of the three groups were performed before and after 16 weeks of interventions or control period. Groton Maze Learning Test (GML) was used to assess spatial memory executive function (Working memory, attention and inhibitory control), along with Shopping list (ISL) for auditory learning and latter memory recall. We compared delta of groups by ANOVA One-way followed by Hochberg post hoc test and by Kruskal-Wallis following by Mann-Whitney for parametric and non-parametric data, respectively. Data is presented in mean ± standard deviation. **RESULTS:** There was larger GML rule-break error reduction (P<0.05) for CT (-2.7±6) and AT (-2.7±4) compared to CG (2.3±4). There was a tendency (p<0.07) to improve recording short auditory memory (ISL) after CT (1.5 ± 2) when compare to CG (0.0±0). No differences were found for latter recall. Furthermore, CT (-2.6±2) reduced more depression scores (P<0.05) compared to AT (-0.7±0) and CG (0.16±1). **CONCLUSIONS:** The reduction in rule-break errors suggest CT and AT improve attention, inhibitory control and

working memory and only CT improve short term auditive memory in hypertensive elderly individuals. The improvement in short-term memory could be associated with the improved attention which could be also dependent of lower depression score in this group.

Mismatch Between Perception of Disability and Functional Outcomes in Individuals with Large Burn Injuries

Mu Huang[1], Manall F. Jaffery[1], Gilbert Moralez[1], Matthew N. Cramer[1], Steven A. Romero[2], Craig G. Crandall, FACSM[1].
[1]*Institute for Exercise and Environmental Medicine, Dallas, TX.*
[2]*University of North Texas Health Science Center, Fort Worth, TX.* (Sponsor: Craig Crandall, FACSM)
(No relevant relationships reported)

Functional limitation can be a serious problem in burn survivors. Such individuals report physical limitations following a burn injury which leads to a perceived reduction in health-related quality of life that persists years after the initial injury. **Purpose:** We tested the hypothesis that well-healed burn survivors having prior burn injuries covering a large body surface area will have greater subjective and objective functional limitations compared to those with prior injuries covering a small body surface area. **Methods:** Subjective information was collected through the SF-36 questionnaire, with a focus on the physical function domain. Objective measurements of functional ability included a maximal aerobic capacity test, timed-up-and-go, five times sit-to-stand, and timed stairs test. These variables were collected in three experimental groups: 8 individuals (2 female) with burn injuries greater than 50% (high burn, HB) of their total body surface area (TBSA); 9 individuals (5 female) with burn injuries covering less than 50% (low burn, LB) of their TBSA; and 7 (3 female) non-injured control subjects (CON). **Results:** Analysis of the perception of limitations in Physical Function from the SF-36 revealed a statistically significant difference between groups (P=0.0014). Further post hoc pairwise testing revealed that SF-36 Physical Function scores were higher in the CON group (99±2, p=0.002) and LB group (93±9, p=0.02) when compared to the HB group (71±19). No difference was found in the SF-36 Physical Function scores between the LB and control groups (p>0.99). Of note, this pattern of differences in the perception of physical limitations between the experimental groups was not reflected in the functional measurements. Specifically, no significant differences were identified in maximum aerobic capacity (CON:32±10, LB:27±5, HB:29±5 ml/kg/min, p=0.65), five times sit-to-stand (CON:9±2, LB10±2, HB:10±1 s, p=0.26), timed up-and-go (CON:13±3, LB:13±2, HB:14±2 s, p=0.51), and timed stairs test (CON:11±2, LB:11±1, HB:11±2 s, p=0.85). **Conclusion:** Collectively, these data suggest that in burn survivors with injuries covering greater than 50% of their TBSA, perceived physical limitations do not reflect objective measures of functional ability. Supported by NIH Grant GM068865

Effects of Acute Aerobic Exercise on Cognitive Function in Individuals with Down Syndrome

Sang Ouk Wee[1], Elizabeth Schroeder[2], Georgios Grigoriadis[2], Alexander J. Rosenberg[2], Kanokwan Bunsawat[3], Garett Griffith[2], Tracy Baynard, FACSM[2], Bo Fernhall, FACSM[2]. [1]*California State University San Bernardino, San Bernardino, CA.* [2]*University of Illinois at Chicago, Chicago, IL.* [3]*University of Utah, Salt lake city, UT.* (Sponsor: Bo Fernhall, FACSM)
(No relevant relationships reported)

Individuals with Down syndrome (DS) commonly exhibit a mild to moderate level of cognitive impairment, which further affects quality of life in this population. Regular aerobic exercise has been shown to improve cognitive function among individuals with and without DS. However, if an acute bout of moderate intensity aerobic exercise has cognitive benefit in individuals with DS has yet to be explored. **PURPOSE**: To investigate the effect of an acute bout of aerobic exercise on cognitive function in individuals with and without DS.
METHODS: Forty volunteers with and without DS (DS=20, 25 yrs; Control=20, 25 yrs) participated in this study. VO2peak was obtained via indirect calorimetry by an individualized maximal exercise treadmill protocol. Participants exercised at 60% of maximal capacity for 20 min on a separate day. Cognitive function tests (task completion time and accuracy of task completion, A Quick Test for Cognitive Speed, AQT) were measured before, immediately after, and 30 min after the submaximal walking bout. Individuals without DS performed an additional cognitive function test, the Flanker test, to avoid the known ceiling effect of the AQT.
RESULTS: Individuals with DS exhibited impaired cognitive function compared to individuals without DS with slower task completion time and higher error rate. (p < 0.05 for both). AQT components, task completion time and error rate, were not altered after 20 min of treadmill exercise in either group. However, improved reaction time and error rate on the Flanker test (immediate; 30 min post), suggest exercise positively benefited cognitive function among those without DS. (p < 0.05).

CONCLUSIONS: Our results indicate that individuals with DS may need a higher intensity or longer exercise time for cognitive improvement. In addition, in-depth cognitive function testing may be more sensitive in detecting changes with exercise in individuals with DS.

The Effects of Cardiovascular Health on Cognitive Function in Older Adults

Justin Mason[1], Salvador Jaime[2], Arun Maharaj[3], Roque Nelson[1], Gershon Tenenbaum[1], Arturo Figueroa, FACSM[3]. *[1]Florida State University, Tallahassee, FL. [2]University of Wisconsin - La Crosse, La Crosse, WI. [3]Texas Tech University, Lubbock, TX.* (Sponsor: Arturo Figueroa, FACSM)
(No relevant relationships reported)

Aging is associated with a decline in cognitive and psychomotor functions, resulting in difficulties with daily activities such as driving. Cognitive function has been found to be associated with carotid intima-media thickness (IMT) and aortic stiffness (carotid-femoral PWV, cfPWV). These age-related decrements can be mitigated through routine aerobic exercise.
PURPOSE: To determine the effects of life-long aerobic exercise on cognitive function, driving performance, and cardiovascular health among older adults (65 – 84 years old). **METHODS:** A cross-sectional design was utilized to compare 27 endurance-trained (ET) with 35 sedentary (S) older adults (70±5yrs). Older adults were excluded from the study if they were classified as having stage II hypertension, diabetes mellitus, cardiovascular diseases, or currently taking more than 1 medication for blood pressure or cholesterol. Driving performance and cognitive function were measured via driving simulator and a cognitive battery, respectively. Cardiovascular health consisted of assessing estimated VO_2max, carotid IMT, and cfPWV. Fitness comparisons were made using an independent sample t-test. Cognitive function and driving performance scores were transformed to Z-scores. **RESULTS:** VO_2max was higher among ET than S (41±9 vs 25±3 ml/kg/min, p<.01). BMI was higher among S than ET (26±4 vs 24±4, p<.01) There were no differences in brachial systolic blood pressure (131±13 vs 132±19 mmHg), cfPWV (12±2 vs 12±2 m/s), carotid-IMT (.74±.15 vs .76±.13 mm), and cognitive function scores (-.01±.57 vs -.09±.97) between the groups. However, ET performed better on the driving simulator (.18±.58 vs -.28±.92, p<.05). Carotid IMT and cfpwv were moderately associated (r = .38, p < .01). VO_2max was no associated with age, carotid IMT, or cfpwv. **CONCLUSION:** Enhanced cardiorespiratory fitness may mitigate age-related decrements in driving performance independently of central artery structure and function.

Longitudinal Investigation of Daily Physical Education on Fitness Levels and Processing Speed among Minority Youth

Brooke E. Huhn, Julian A. Reed, Caroline E. Stanton. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
(No relevant relationships reported)

PURPOSE: To examine the impact of 45 minutes of daily physical education on the fitness levels and Processing Speed among minority elementary school youth. **METHODS**: An analysis of variance (ANOVA) univariate linear model was used to evaluate the effectiveness of 45 minutes of daily physical education on physical fitness and Perceptual Speed among youth in grades 2 through 5 attending Legacy Early College, a Title I school in the southeastern United States. Gain scores (post-test assessment in May 2017 -- pre-test assessment in September 2015) were calculated, stratified by ethnicity and gender, and analyzed for significance. The interaction between school and time was estimated for each outcome. Each analysis was stratified by gender and adjusted by age to control for baseline differences by school. Control school students received physical education only once per week. **Summary of RESULTS**: Legacy students demonstrated significant gain increases on 3 of 3 (p<0.05) FITNESSGRAM[R] assessments. Legacy females improved on the number of laps during the Progressive Aerobic Cardiovascular Endurance Run (PACER) (Gain Score=10.58; F=7.766; df =1; p=0.007), number of push-ups (Gain Score=4.09; F=15.030; df =1; p=0.000), and number of curl-ups (Gain Score=13.69; F=19.619; df =1; p=0.000). Legacy males improved on PACER laps (Gain Score=15.97; F=10.355; df=1; p=0.002), number of push-ups (Gain Score=4.16; F=19.030; df=1; p=0.000), number of curl-ups (Gain Score=14.79; F=24.138; df=1; p=0.000), and 3 of 4 Perceptual Speed sections. Most notably, significant increases were observed in the Total section (Gain Score=15.43; F=8.294; df=1; p=0.005). **CONCLUSION**: 45 minutes of daily physical education led to an increase in physical fitness levels and Processing Speed among minority elementary school youth attending Legacy Early College.

Investigation Between Daily PE, Fluid Intelligence, Fitness and BMI among Middle School Youth Over Time

Caroline E. Stanton, Julian A. Reed, Brooke E. Huhn. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
(No relevant relationships reported)

Developmental research has demonstrated that higher cognitive abilities are often linked to physical activity participation. **PURPOSE**: The purpose of the study was to examine the impact of 45 minutes of daily physical education on Fluid Intelligence, fitness levels and BMI among middle school youth. **METHODS**: An analysis of variance (ANOVA) mixed effect linear model was used to evaluate the effectiveness of 45 minutes of daily physical education on Fluid Intelligence, Progressive Aerobic Cardiovascular Endurance Run (PACER), push-ups, curl-ups and BMI among youth in grades 6th-8th attending Legacy Early College, a Title I school in the southeastern US. Gain scores (final post-test assessment in May 2017 - original pre-test assessment in September 2014) were calculated and analyzed for significance. The interaction between school and time was estimated for each outcome. Each analysis was stratified by gender and adjusted by age to control for baseline differences by school. A Title I control school that provided physical education for only one semester was identified and utilized as a comparison. **Summary of RESULTS**: Legacy Early College students observed gain increases on Fluid Intelligence sections, significantly the Total Section, (Gain Score=10.31; F=5.920; df=140; p=.016) over time. Legacy students observed gain increases in PACER laps, push-ups and curl ups, over time compared to controls. Legacy students also observed decreases in BMI over time, compared to gain increases in controls. **CONCLUSIONS**: 45 minutes of daily physical education led to increases in Fluid Intelligence, PACER laps, push-ups and curl-ups, as well as decreases in BMI among Legacy middle school students from 2014 to 2017.

405   Board #246   May 30 11:00 AM - 12:30 PM

Lasting Effects of Acute Exercise on Working Memory Performance in Older Adults with Long and Short Sleep

Junyeon Won[1], Alfonso Alfini[2], Lauren Weiss[1], Corey Michelson[1], J. Carson Smith, FACSM[1]. *[1]University of Maryland at College Park, College Park, MD. [2]John's Hopkins University, Baltimore, MD.* (Sponsor: J. Carson Smith, FACSM)
(No relevant relationships reported)

BACKGROUND: A growing body of research indicates that acute exercise in older adults is associated with enhanced executive function, including inhibitory control and working memory. However, most studies have measured cognition shortly after the exercise session, and whether or not acute exercise has longer lasting cognitive benefits in older adults has not been established.
PURPOSE: To investigate executive function performance 1.5 hours after a single session of exercise, compared to rest, in healthy older adults; and to secondarily determine if sleep moderates these effects.
METHODS: 24 healthy older adults (65.8±8.1 years) completed two experimental sessions on different days that entailed 30-min of seated rest or moderate intensity exercise on a Monark cycle ergometer. Ninety minutes after exercise and rest, participants performed the Stoop Color and Word Task (Stroop) to measure inhibitory control and the Symbol Digit Modalities Test (SDMT) to for working memory. To examine sleep, participants wore an actigraphy watch for at least three days prior to the first experimental session.
RESULTS: SDMT performance following acute exercise (60.0±9.6) was significantly better compared to rest (57.7±8.9) [p = .049, η^2 = 0.146]. Moreover, oral SDMT performance was significantly better after exercise compared to rest in short sleepers (< 7.5 hr/night) [p < .001, η^2 = 0.885], but did not differ between exercise and rest in long sleepers (> 7.5 hr/night) [Condition*Sleep interaction, p = .047, η^2 = 0.174]. Short sleepers also significantly performed better in written SDMT after exercise relative to rest [p = .004, η^2 = 0.583]. Stroop interference score (incongruent minus congruent) was not significantly different between exercise and rest conditions.
CONCLUSION: These findings suggest that working memory performance is enhanced up to 1.5 hours after acute exercise in older adults who sleep less. Future studies should explore whether these effects of acute exercise confer a long-term protection against cognitive decline in older adults with poor sleep.

Cognitive Performance Changes After 12 Weeks Of Strength Training In Elderly Overweight Women

Andre C. Smolarek[1], Steven R. McAnulty[2], Brad J. Schoenfeld[3], Karla D. Varela[1], Monica Dangui[1], Luis H. Ferreira[4], Luis P. Mascarenhas[1], Cleyton S. Oliveira[4], Alan C. Utter, FACSM[5], Tacito P. Souza-Junior[4]. *[1]UNICENTRO, Irati, Brazil. [2]Appalachian State University, Boone, NC. [3]University of New York City - Lehman College, New York, NY. [4]Universidade Federal do Parana, Curitiba, Brazil. [5]Texas Woman's University, Denton, TX.* (Sponsor: Alan C Utter, FACSM)
(No relevant relationships reported)

Healthy aging is a challenge to the world population, not only due to age related cognitive impairment but also dinapenia and sarcopenia which can affect strength dependent activities. Therefore, it is of interest to evaluate the effects of strength training concurrent with cognitive performance. The purpose of the study was to determine the effect of 12 weeks of strength training on cognitive performance changes in overweight older women. Twenty-one elderly overweight women were recruited and divided into a Control group (n = 5) and Intervention Group (n = 16). Participants had body mass, height, body mass index (BMI), waist circumference, waist to height ratio, Upper Lean Limbs (ULL) Lower Lean Limbs, (LLL) and cognitive performance measured. To evaluate differences between the control group and intervention group, a 2-way ANOVA with Tukey's post hoc comparison was used. The results indicate that after the intervention period with strength training, there were no differences in anthropometric variables. However, significant differences were found (p ≤0.05) in ULL, LLL and cognitive performance. Strength training in elderly overweight women exerts positive effects on upper and lower limb strength and also increases cognitive performance.

Associations Of Objectively Measured Physical Activity With Executive Functioning In Chinese Young Adults

Tao Huang[1], Lirun Zhao[2], Jun Lin[3]. *[1]Shanghai Jiao Tong University, Shanghai, China. [2]Shanghai Normal University, Shanghai, China. [3]Wuyi University, Shanghai, China.*
(No relevant relationships reported)

Purpose: The purpose of study was to examine the associations of objectively measured physical activity with executive functioning in Chinese young adults.
Methods: Participants were 162 university students (45.7% females, mean age =19.0 ± 1.1 years) recruited from a university in Shanghai, China. Participant's daily physical activity was measured by hip-mounted accelerometers (Actigraph wGT3X-BT, Pensacola, FL, USA). The accelerometer data were analyzed using Actilife 6 software (Pensacola, FL, USA). Executive functioning was assessed by a task-switching paradigm programed using E-Prime 2 professional (Psychology Software Tools, Inc., Sharpsburg, PA, USA). Global switch costs and local switch costs were derived and used as the outcomes of the task. Anthropometrics were measured using standardized procedures.
Results: After controlling for wear time of accelerometers, age and gender, moderate-to-vigorous physical activity (MVPA, β = -0.19, 95% CI, -0.35 to -0.03, p = 0.02) and light physical activity (LPA, β=-0.17, 95% CI, -0.34 to -0.01, p = 0.04) were associated with smaller global reaction time (RT) switch costs. The findings suggested that higher levels of both MVPA and LPA were associated with better task-switching performance, as indicated by smaller global RT switch costs. No significant association was observed between total PA and global RT switch costs, despite a trend toward near statistical significance (β = -0.15, 95% CI, -0.31 to 0.01, p = 0.06). PA indicators were not associated with global accuracy switch costs, and no associations were observed between PA indicators and local RT or accuracy switch costs. Taken together, the results indicated that higher levels of MVPA and LPA were associated with some aspects of executive functioning measured by a task-switching paradigm.
Conclusion: Higher levels of objectively measured MVPA and LPA were associated with better performance on some aspects of executive functioning in Chinese young adults.

The Effects Of High-Cadence Cycling On Emotional Recognition In Individuals With Parkinson'S Disease

Angela L. Ridgel, Sara A. Harper, Bryan T. Dowdell, Brandon S. Pollock. *Kent State University, Kent, OH.* (Sponsor: J Derek Kingsley, FACSM)
(No relevant relationships reported)

Parkinson's disease (PD) is a progressive neurodegenerative disease that can lead to cognitive dysfunction including deficits in emotional recognition, which is the ability to identify facial expression of happiness, sadness, fear, anger and disgust. This deficit has been shown to lead to difficulties in social interaction and communication. High cadence cycling is a unique rehabilitation modality that has been shown to improve motor function in PD, but it is not known how this modality alters cognition. **PURPOSE:** To examine if three bouts of high-cadence cycling improved emotional recognition in individuals with PD. **METHODS:** Individuals (N=17) completed three sessions of high cadence cycling, on a custom motorized stationary cycle, consisting of a 5-minute warm-up at 50 revolutions per minute (rpm), 30 minutes of high cadence cycling between 75-85 rpm, and a 5-minute cool down. Emotional recognition was assessed using a computerized cognitive assessment battery at baseline and after (post-test) the three cycling sessions. The percentage of accurately identified emotions and the average reaction time to correctly select an emotion (emotion bias) was used for the analysis. Z-scores were used for the analysis and negative numbers represented scores below expected normal values. **RESULTS:** Three bouts of high-cadence cycling resulted in a significant improvement in the accuracy of identifying emotions from baseline to post-test for disgust (0.007±1.2 vs. 0.71±1.17, p=0.013). There were also improvements in emotion bias from baseline to post-test for sad (-1.37±1.29 vs. -0.66±1.00, p=0.003), anger (-1.18±1.08 vs. -0.41± 1.21, p=0.006) and fear (-1.60±1.33 vs. -1.10±1.25, p=0.030), but there were no significant changes in emotion bias for disgust (-1.55±1.28 vs. -1.23±1.15, p=0.130). **CONCLUSIONS:** Three bouts of high-cadence cycling improved several measures of emotional recognition, specifically negative-bias emotions. These findings suggest that high-cadence cycling could be a valuable rehabilitation modality for improving emotional recognition and potentially social interactions in individuals with PD. Support: Kent State University's School of Health Sciences, Midwest American College of Sports Medicine, Ohio Parkinson Foundation Northeast Region Grant.

Impact of Physical Activity on Cognition in Older Mexican Americans

Kamiah Moss, Stephanie Large, Sid E. O'Bryant, Leigh A. Johnson. *The University of North Texas Health Science Center, Fort Worth, TX.*
(No relevant relationships reported)

Alzheimer's disease (AD) is a devastating public health problem that affects over 5.4 million Americans. Exercise is considered a modifiable risk factor for Alzheimer's disease and cognitive decline. Physical activity has been found to improve cognitive function in older adults. However, few studies have examined the relationship between self-reported PA and cognitive functioning in Mexican American elders.
PURPOSE: To examine to impact of PA levels (inactive vs. highly active) on cognition in Mexican Americans elders.
Methods: Data was analyzed from HABLE (Health and Aging Brain among Latino Elders), which is an epidemiological study of aging among Mexican Americans. The IPAQ-long form was administered to 361 cognitively normal participants (59+7yrs). IPAQ scores were stratified into two groups inactive and high PA. Cognition was assessed via neuropsychological test scores in five domains: Memory (Logical Memory I & II), Executive (CLOX 1, Trails A), Visual Spatial (CLOX 2, Trails B), Attention (Digit Span), Language (Animal Naming), and global cognition (MMSE). An independent samples t-test was used to compare inactive and high PA groups on cognitive performance.
RESULTS: The inactive group scored significantly lower on WMS III Logical Memory I (32+9 vs. 35+9, p<0.01), WMS III Logical Memory II (19+7 vs. 22+7, p<0.01), CLOX 1 & 2 (24+3 vs. 25+3, p<0.05), and MMSE (26+3 vs. 27+2, p<0.01). There were no significant differences found among the groups on Trails A (59+31 secs vs. 54+23 secs), Trails B (141+68 secs vs. 145+69 secs), Digit Span (11+3 vs.11+3), and Animal Naming (16+4 vs.17+4).
CONCLUSION: High levels of physical activity was associated with better performance in memory, executive functioning, and global cognition among Mexican American elders with normal cognition. Inactivity was associated with poorer cognitive performance.

Safety, Enjoyment, And Physiological Responses Of Kinect-based Exergames In Older Adults At Risk For Falls

Elisa F. Ogawa, Haikun Huang, Lap-Fai Yu, Tongjian You, FACSM. *University of Massachusetts Boston, Boston, MA.* (Sponsor: Tongjian You, FACSM)

(No relevant relationships reported)

Exergaming has the potential to improve physical function, cognition and dual-task function, and could be an effective new strategy for reducing risk of falling in older adults. **PURPOSE:** To evaluate and test the safety, enjoyment, and physiological responses on custom Microsoft Kinect-based motion-tracking games that train specific dual-task function in older adults at risk for falls. **METHODS:** Community-dwelling older adults who reported current mobility difficulties or falling in the past year were included in the study. Participants played three newly developed exergames (Double Decision, Target Trackers, and Visual Sweeps, 5 minutes each) in random order. Heart rate (HR) was measured during each exergame, and blood pressure (BP), rating of perceived exertion (RPE) and rating of the Physical Activity Enjoyment Scale were recorded immediately after each exergame. Student t-tests were used to examine the differences in variables at resting state and during/after exercise. Repeated measure analyses of variance were used to examine the differences in variables among the three exergames. **RESULTS:** Seven participants (aged 76±6 years; 4 females) completed the study. The exergames did not cause any injuries. Average exercise HRs for Double Decision, Target Tracker, and Visual Sweeps were 87.57±6.58 bpm, 84.71±8.48 bpm, and 82.00±9.72 bpm; post-exercise BPs were 129.29±12.35/78.14±9.06 mmHg, 129.86±7.99/81.86±13.28 mmHg, 132.86±14.31/79.43±13.01 mmHg; post-exercise RPEs were 11.14±1.07, 10.14±1.21, and 9.86±1.86; and post-exercise enjoyment ratings were 81.22±0.14%, 90.61±0.18%, and 79.59±0.16%, respectively. Average exercise HRs were significantly higher than resting HRs for all three exergames (p<0.01). Visual Sweep had significantly lower average exercise HR compared to Double Decision (p<0.05) and Target Tracker (p<0.05), and there was a significant difference in post-exercise RPE between Double Decision and Target Tracker (p<0.05). There was a significant difference between Target Tracker and Double Decision in post-exercise enjoyment ratings (p<0.05). **CONCLUSION:** The newly developed exergames were safe, enjoyable, and light for older adults who are at risk for falls. Future intervention studies are needed to examine the benefits of exergames for this special population.

Acute Dose-response Effects Of Aerobic Exercise On Cerebrovascular Hemodynamics

Sophy J. Perdomo[1], Bethany Barone Gibbs[2], John M. Jakicic, FACSM[2], Christopher E. Kline[2], Jeffrey R. Balzer[2]. *[1]University of Kansas Medical Center, Kansas, KS. [2]University of Pittsburgh, Pittsburgh, PA.* (Sponsor: John M Jakicic, FACSM)

(No relevant relationships reported)

Exercise may influence cerebrovascular hemodynamics. Few studies have evaluated acute effects of aerobic exercise on cerebral blood flow and cerebral pulsatile flow. **PURPOSE**: To evaluate acute effects of aerobic exercise on cerebrovascular hemodynamics following sitting, a 10-minute exercise bout and a 30-minute exercise bout. **METHODS:** Fifteen adults (age = 45.4±8.9 years) participated in this randomized crossover study comprised of three experimental sessions: 30 minutes of sitting (SIT), 20 minutes of sitting followed by 10-minutes of exercise (EX10), and 30-minutes of exercise (EX30). The exercise consisted of walking on a treadmill at 70-75% of age-predicted maximum heart rate. Cerebrovascular hemodynamics were measured using transcranial Doppler ultrasonography before the experimental session and at 30- and 60-minutes post-session. Beat-to-beat peak systolic, mean systolic and diastolic cerebral blood flow velocities (CBFv) as well as pulsatility index were recorded bilaterally for 1 min via insonation of the middle cerebral artery (MCA). **RESULTS**: Pulsatility index was 4.7% (P=0.08) higher in EX30 vs. SIT at the 30-minute but not the 60-minute post session assessment. There was no difference in pulsatility index at the 30 or 60-minute post-session between SIT and EX10 (P>0.33) or EX30 and EX10 (P>0.27). Peak systolic, mean and diastolic CBFv were not different across conditions at either post-session assessment (P>0.10). **CONCLUSIONS**: Exercise that is either 10 or 30 minutes in duration does not

improve cerebrovascular hemodynamics in the MCA within one hour of following the exercise session. Research may be necessary to understand affects cerebrovascular dynamics in response to acute and chronic exercise.

Endocannabinoid Responses to Exercise in Individuals with Substance Use Disorders

Angelique G. Brellenthin[1], Kevin M. Crombie[2], Cecilia J. Hillard[3], Kelli F. Koltyn, FACSM[2]. *[1]Iowa State University, Ames, IA. [2]University of Wisconsin-Madison, Madison, WI. [3]Medical College of Wisconsin, Milwaukee, WI.* (Sponsor: Kelli Koltyn, FACSM)

(No relevant relationships reported)

The endocannabinoid system (eCB) is downregulated in substance use disorder (SUD) patients. Pharmacologically targeting the eCB system has led to improved SUD treatment outcomes in both preclinical and clinical studies. Exercise is a non-pharmacological method of augmenting the eCB system in healthy adults, but it is unknown whether exercise can activate the eCB system in SUD patients. **PURPOSE:** To examine eCB responses to acute and chronic aerobic exercise in SUD patients. **METHODS:** Twenty-one SUD patients (35 ± 9 yrs) were recruited from local intensive outpatient treatment programs. Participants were randomized to either treatment-as-usual (TAU, at their outpatient clinic) or TAU plus aerobic exercise training (EX). EX participants engaged in supervised, moderate-intensity exercise sessions 3 x/wk for 6 wks. TAU participants came into the laboratory once per week for assessments and a quiet rest session. At 0- (baseline), 3- (mid), and 6- (post) wks, participants provided blood samples before and after exercise or quiet rest to assess plasma eCB concentrations (anandamide [AEA] and 2-arachidonoylglycerol [2-AG]). Data were analyzed using mixed model ANOVAs and Cohen's d effect size calculations. **RESULTS:** There was a significant group X time interaction for AEA (p < 0.001). Simple effects indicated that AEA increased acutely after exercise in the EX group (p < 0.001) but did not change after quiet rest in the TAU group (p = 0.39). There were no group differences or significant changes in 2-AG (p > 0.05). Effect size calculations indicated there were small to moderate increases in AEA (d = 0.36) and 2-AG (d = 0.37) concentrations from 0 to 6 weeks in the EX group but small to moderate decreases in AEA (d = -0.42) and 2-AG (d = -0.40) concentrations in the TAU group, though these changes were not statistically significant. **CONCLUSION:** These results indicate that aerobic exercise is able to activate the eCB system in SUD patients, which may contribute to improved treatment outcomes. Exercise may also increase basal eCB concentrations over time, suggesting that exercise could be one method to restore eCB function in SUD patients. Additional investigations with larger sample sizes and longer exercise program durations are warranted. Supported by NIH R36DA040140 and the UW Virginia Horne Henry Fund.

Impact of High-Intensity Interval Exercise on Executive Function and Brain Derived Neurotrophic Factor

Charles S. Schwartz, Aaron L. Slusher, Virginia T. Patterson, Edmund O. Acevedo, FACSM. *Virginia Commonwealth University, Richmond, VA.*

(No relevant relationships reported)

PURPOSE: Prefrontal cortex (PFC)-dependent executive function (EF) is enhanced immediately following completion of high-intensity interval exercise (HIIE). Brain-derived neurotrophic factor (BDNF) is a key protein that enhances EF at rest and in

response to acute exercise. However, no studies have examined the possible utility of plasma and/or serum BDNF as a biomarker of improved EF in response to a single session of HIIE.
METHODS: Thirteen subjects performed the Wisconsin Card Sorting Task (WCST) to assess EF immediately following a 5 min seated rest and participation in a HIIE (10 x 20 s bouts of maximal cycling against 5.5% of the subject's body weight). Whole blood was collected prior to and immediately following HIIE and the WCST to assess plasma and serum BDNF concentrations.
RESULTS: HIIE increased the number of correct responses (p = 0.048) and reduced the number of total and non-preservative errors (p = 0.048; p = 0.027, respectively) on the WCST compared to the seated rest. Elevated plasma and serum BDNF concentrations prior to exercise were also associated with enhanced WCST performance during the seated rest, and in response to HIIE, BDNF concentrations in plasma, and to a lesser extent in serum, predicted a faster and more accurate performance on the WCST. However, while plasma BDNF concentrations were unaltered and serum BDNF concentrations increased in response to HIIE (F[2,48] = 6.759, p = 0.003), these response were not associated with improved WCST performance.
CONCLUSIONS: These data provide evidence supporting circulating BDNF in plasma, and to a lesser extent in serum, as a biomarker of enhanced PFC-dependent EF at rest and in response to HIIE.

Effect Of A Single Session Of High-intensity, Resistance Or Combination Exercise Training On Neurotrophic Factors In Overweight Collegiate Men: The Brainfit Study

Maria Andrea Domínguez-Sanchéz[1], Gina Paola Velasco-Orjuela[2], Andrea del Pilar Quintero[2], Jorge Enrique Correa-Bautista[2], Antonio García-Hermoso[3], Rosa Helena Bustos-Cruz[1], Carlos Andrés Peña-Guzmán[4], Luis Andrés Téllez-T[2], Robinson Ramírez-Vélez[2]. [1]Universidad de La Sabana, Chia, Colombia. [2]Universidad del Rosario, Bogotá D.C, Colombia. [3]Universidad de Santiago de Chile, USACH, Santiago de Chile, Chile. [4]Universidad Santo Tomás, Bogotá D.C, Colombia.
(No relevant relationships reported)

PURPOSE: To compare the neurotrophic factor response following one session of high-intensity exercise, resistance training or both in a cohort of physically inactive overweight adults aged 18-30 years old.
METHODS: A randomized, parallel-group clinical trial of fifty-one men (23.6±3.5 years; 83.5±7.8 kg; 28.0±1.9 kg/m^2) who are physically inactive (i.e., <150 min of moderate-intensity exercise per week for greater than 6 months) and are either abdominally obese (waist circumference ≥ 90 cm) or have a body mass index ≥ 25 and ≤ 30 kg/m^2 were randomized to the following four exercise protocols: high-intensity exercise (4×4 min intervals at 85-95% maximum heart rate [HRmax] interspersed with 4 min of recovery at 75-85% HRmax) (n=14), progressive resistance training (25 to 30 repetitions per set, at 70% of one repetition maximum with 60 s of recovery) (n=12), combined high-intensity and resistance exercise (n=13), or non-exercising control (n=12). The plasma levels of neurotrophin-3 (NT-3), neurotrophin-4 (also known as neurotrophin 4/5; NT-4 or NT-4/5), and brain-derived neurotrophic factor (BDNF) were determined before (pre-exercise) and 1-min post-exercise for each protocol session.
RESULTS: Resistance training induced trivial increases in BDNF, NT-3 and NT-4/5 (15.5 ng/mL [95% CI, 1.2 to 32.3; *d*=0.14], 39.6 ng/mL [95% CI, 2.5 to 76.6; *d*=0.19], and 1.3 ng/mL [95% CI, 0.3 to 2.3; *d*=0.17], respectively). Additionally, combined training results in favorable effects on both BDNF (22.0, 95% CI, 2.6 to 41.5; *d*=0.19) and NT-3 (32.9, 95% CI, 12.4 to 53.4; *d*=0.25). In the per-protocol analyses, the combined training group but not the other interventions showed greater changes in BDNF (99.7, 95% CI, 22.4 to 176.7; *d*=1.01), NT-3 (89.9, 95% CI, 2.2 to 172.1; *d*=0.79), and NT-4 (7.5, 95% CI, 1.7 to 13.3; d=1.07) compared to the control group.
CONCLUSIONS: The findings indicate that acute resistance training and combined exercise increase neurotrophic factors in physically inactive overweight adults. Further studies are required to determine the biological importance of changes in neurotrophic responses in overweight men and chronic effects of these exercise protocols.

Effects Of Prior Endurance And Resistance Training On PD: Role Of Autophagy And Apoptosis

Ning Jiang[1], Zhen Xu[1], Zhe Wang[1], Yong Zhang[1], Li Li Ji, FACSM[2]. [1]Tianjin Key Laboratory of Exercise Physiologyand Sports Medicine,Tianjin University of Sport, TIAN JIN, China. [2]School of Kinesiology, University of Minnesota, MN, MN.
(No relevant relationships reported)

PURPOSE: To determine the relationship between autophagy and apoptosis in midbrain striatum in PD model mice and to investigate whether prior endurance and resistance training can intervene the pathogenesis.
METHODS: Male C57BL/6J mice aged 12 months were randomly divided into 3 groups: control (C), endurance training (E), or resistance training (R). E were exercised on a treadmill for 12 weeks. R was subjected to ladder training for 12 weeks. After training, each group was randomly administered with either MPTP (2*30mg/kg×2, i. p., 16 hr apart, M) or saline (S). Mitochondrial function, proteins in autophagy and apoptosis were measured in the midbrain striatum.
RESULTS: Compared with C, M suppressed mitochondria state 3 respiration (-42%, p<0.01) , respiratory control ratio (RCR, -44%, p<0.01) , and ATP synthesis activity (-40%, p<0.01); and elevated Beclin1 (+35%, p<0.05), LC3-II (+26%,p<0.05), BCl2 (+41%,p<0.01) , and BAX (+21%,p<0.05) protein levels(p<0.05). Both ME and MR significantly elevated mitochondria state 3 (+72%,+101%, p<0.01), RCR (+47%,+98%, p<0.01), and ATP synthesis activity (+27%,+45%, p<0.01), and elevated Beclin1 (+28%, p<0.05; +57%, p<0.01), LC3-II (+30%,+39%; p<0.05), BCl2 (+23%,+38%; p<0.01), and BAX (+30%,+48%, p<0.01) protein levles. MR increased mitochondria state 3 respiration (+16%, p<0.05), RCR (+34%, p<0.01), ATP synthesis (+14%, p<0.05), Beclin1 (+23%, p<0.01), LC3-II (+7%, p<0.05) , BCl2(+12%,p<0.05) protein levels , compared to ME.
CONCLUSIONS:MPTP can damage mitochondrial respiratory function in the midbrain and striatum possibly related to an up-regulation of autophagy and apoptosis. Prior training increases autophagy and apoptotic tendency in PD mice. Resistant training appears more effective in ameliorating autophagy and apoptosis and mitochondrial function. (Supported by NSFC No.31000523 and 31370021).

Impacts of Cerebellar tDCS During a Dual-Task: Sustained Balance Improvement

Kira G. Oberle, Caroline J. Ketcham. *Elon University, Elon, NC.*
(Sponsor: Dr. Eric Hall, FACSM)
(No relevant relationships reported)

The importance of accurate cognitive performance during a complex motor task is essential for professions including athletes, police and military personnel. Cerebellar transcranial direct current stimulation (tDCS) has been used as a low-cost, non-invasive technique to enhance performance of individuals in a variety of isolated motor and cognitive tasks but not in a dual-task. **PURPOSE**: The purpose of this study was to examine the effect of cerebellar tDCS during a dual task. **METHODS**: Twenty healthy college-age individuals completed this study. A baseline dual-task was conducted with participants completing four cognitive tasks: Reaction Time (simple, choice) and Working Memory (Stroop and N-Back) while simultaneously maintaining balance on an unstable BioDex Balance platform. Each participant received anodal (n=10) or sham (n=10) cerebellar tDCS at 1mA for a total of 40mA (~45mins). During this time, participants completed cognitive and balance training. Participants repeated the dual-task testing immediately following training, and again one week later. **RESULTS**: Results showed no differences in cognitive performance between the tDCS and sham groups (p>0.05). Balance continued to show improvements during the simple cognitive tasks in the tDCS group one week later (p<0.05). **DISCUSSION**: Overall there were limited dual-task performance improvements of cerebellar tDCS in a 45-minute training session. It is possible the dual-task was too complex and the training session too short for this population. There is potential of cerebellar tDCS in an athletic population who rely on peak performance in both cognitive and motor skills simultaneously.

Aerobic Exercise Training Effects on NrF2 and the Antioxidant Defense System

Lauren S. Vervaecke, Allan H. Goldfarb, FACSM, Laurie Wideman, FACSM, Joseph Starnes, FACSM, Keith Erikson. *University of North Carolina Greensboro, Greensboro, NC.*
(No relevant relationships reported)

Nuclear factor erythroid 2 related factor 2 (NrF2), is an essential transcription factor and master regulator of the antioxidant defense system aiding in cellular protection and survival. **PURPOSE**: To determine the effect of chronic aerobic exercise on NrF2 and antioxidant factors in individual brain regions. **METHODS**: Male Sprague Dawley

rats (n=12-13/group), 6 weeks of age, were exercise trained (ET) or were sedentary controls (SD). The exercised rats ran on a treadmill using a ramped protocol for 5-7 weeks at an intensity equal to ~75% VO_{2max}. Five hours after the final exercise session rats were euthanized and the cortex, hippocampus, and cerebellum brain regions were collected and stored at -80°C until further analysis. NrF2 protein concentration was measured via western blot analysis. Total glutathione (TGSH) and reduced glutathione (GSH) concentration were measured via HPLC. Manganese superoxide dismutase (Mn-SOD) activity was measured using a spectrophotometric assay. All samples were analyzed in duplicate. The significance level was set a-priori at p<0.05 and the results are displayed as the mean ± SEM. **RESULTS**: Hippocampal NrF2 was significantly elevated with exercise (ET=3.62±0.20 vs. SD=2.28±0.10 arbitrary units), but was significantly reduced in the cortex (ET=3.20±0.24 vs. SD=6.39±0.26 arbitrary units) and cerebellum (ET=2.02±0.11 vs. SD=3.12±0.16 arbitrary units). TGSH and GSH significantly increased in the hippocampus (ET=182.76±4.64 vs. SD=135.54±4.89 umol/mg protein) (ET=178.94±4.59 vs. SD=131.36±4.83 umol/mg protein), respectively, but were unchanged in cortex and cerebellum regions. No significant differences were detected in Mn-SOD with aerobic exercise in any brain region. **CONCLUSIONS**: NrF2 and antioxidant factors were up-regulated in the hippocampus only with chronic aerobic exercise training compared to sedentary controls. However, other brain regions respond differently to aerobic exercise. This merits notation as the hippocampus is a primary brain region susceptible to neurodegenerative diseases.

The Effects of Acute Aerobic Exercise On Primary Motor Cortical Excitability in Healthy Older Adults

Bea A. Francisco, Jason L. Neva, Katlyn E. Brown, Kristin L. Campbell, Lara A. Boyd. *University of British Columbia, Vancouver, BC, Canada.*
(No relevant relationships reported)

Age-related motor deficits are associated with a decreased ability to modulate primary motor cortex (M1) excitatory and inhibitory circuits. In young healthy adults, an acute bout of lower-limb aerobic exercise modulates upper-limb corticospinal excitability and intracortical circuitry. Importantly, these changes are associated with improved performance on skilled upper-limb motor tasks. However whether these effects extend to healthy older adults is not known.
PURPOSE: To determine whether an acute bout of lower-limb aerobic exercise alters corticospinal and intracortical excitability using single and paired pulse transcranial magnetic stimulation (TMS) of the extensor carpi radialis muscles in healthy older adults. **METHODS:** Corticospinal excitability, short-interval intracortical inhibition (SICI), and intracortical facilitation (ICF) were assessed in 16 healthy older adults (10 female, aged 65.3 ± 6.4 years) at two time-points prior to (30 minutes pre- and immediately pre-exercise) and two time-points following an exercise bout (immediately and 30 minutes post-exercise) to evaluate the time course of cortical excitability modulation. The exercise bout consisted of 20 minutes of continuous cycling at moderate-intensity (50% peak power output (watts) from a maximal stress test performed in a pre-experimental session). **RESULTS:** Due to no significant difference between baseline time-points, the two pre-exercise time-points were collapsed to provide an average baseline value for all measures. To control for baseline fitness levels ($VO2_{peak}$), a one-way repeated measures ANCOVA revealed an increase in SICI by 12 ± 7% immediately after and by 11 ± 9% 30 minutes post-exercise compared to baseline levels ($F_{(2,14)}$=3.829, p=.034). There was no effect of exercise on any of the other measures. **CONCLUSION:** This study is the first to show that primary motor cortical inhibitory circuits may be modulated by a single bout of aerobic exercise in healthy older individuals. These findings imply that short bouts of moderate intensity exercise promote motor cortical plasticity in healthy older people.

Pathways To Functional Hypothalamic Amenorrhea: Role Of Energetic And Psychosocial Factors

Nicole C. Aurigemma. *Pennsylvania State University, University Park, PA.* (Sponsor: Mary Jane De Souza, FACSM)
(No relevant relationships reported)

Functional hypothalamic amenorrhea (FHA) can occur due to the independent or combined effects of psychogenic and energetic stressors. In exercising women, research has primarily focused on energy deficiency related to restrictive eating as the cause of FHA while other psychogenic stressors known to contribute to FHA have been ignored.
PURPOSE: To assess psychosocial and energetic factors associated with FHA in exercising women.
METHODS: We performed a cross-sectional comparison of exercising women (≥2 hours/week, age 18-35 years, BMI 16-25 kg/m²) who were eumenorrheic or who had hypothalamic amenorrhea. Menstrual status was determined using daily urine samples assayed for estrogen and progesterone metabolites and menstrual calendars. Blood samples, exercise logs, DXA, and resting metabolic rate (RMR) testing provided data on metabolic hormones, physical activity, anthropometrics, and energy expenditure.

Psychosocial factors were assessed with these scales: Beck Depression Inventory (BDI), Dysfunctional Attitudes Scale (DAS), Daily Stress Inventory (DSI), Perceived Stress (PSS), Brief Resilience Coping Scale (BRCS), Profile of Mood States (POMS), Eating Disorder Inventory (EDI-3), and Three-Factor Eating Questionnaire (TFEQ). Differences between groups were assessed using ANOVA and Mann-Whitney tests. **RESULTS**: Participants did not differ with respect to weight, lean body mass, and fat free mass; however, amenorrheic women had significantly lower body mass index (p=0.010), percent body fat (p=0.017), and fat mass (p=0.018). Amenorrheic women also had significantly lower serum T4 (p=0.008), T3 (p<0.001), leptin (p<0.001), and ratio of measured to predicted RMR (p=0.011) as well as elevated PYY (p<0.000) and scores for drive for thinness (p=0.016), cognitive restraint (p=0.001) subscales. **CONCLUSIONS**: FHA in exercising women is associated with energy deficiency but only mild indications of psychosocial factors known to be associated with the suppression of reproductive function. FHA in women may vary in its etiology depending on the population studied.

Objective Sleep Characteristics of Young Elite Female Gymnasts

Jasmien Dumortier[1], Jan Boone[1], An Mariman[2], Liesbeth Delesie[2], Els Tobback[2], Dirk Vogelaers[2], Jan G. Bourgois[1]. *[1]Ghent University, Ghent, Belgium. [2]Ghent University Hospital, Ghent, Belgium.*
(No relevant relationships reported)

PURPOSE: Sleep is considered one of the most important recuperation techniques for elite athletes, with its specific features implicating different aspects of learning skills and physical recuperation. The aims of this study were (1) to assess objectively the sleep characteristics of elite gymnasts and (2) to correlate these findings with their age. **METHODS**: Twelve elite female gymnasts (15.1 ± 1.5 years old; VO_{2MAX}: 53.18 ± 5.1 ml·min⁻¹·kg⁻¹; 30.7 ± 1.7 training hours/week) underwent a nocturnal polysomnography (PSG) after a regular training day (6 - 6.5 h of training). The PSG was scored according to the guidelines of the American Academy of Sleep Medicine (AASM). Time in bed (min), Total Sleep Time (TST, min), Sleep Efficiency (SE, %), Non Rapid Eye Movement 1 (NREM1, %), NREM2 (%), Slow Wave Sleep (SWS, %), REM (%), Wake After Sleep Onset (WASO, min), Sleep Onset Latency (SOL, min), Awakening Index (/h) and Apnea-Hypopnea-Index (/h) were measured and analyzed. Furthermore, the gymnasts completed the Epworth Sleepiness Scale (ESS) and Pittsburgh Sleep Quality Index (PSQI). Sleep parameters were correlated with age using a Pearson Correlation.
RESULTS: The following objective values were attained: time in bed 487 ± 13 min, TST 437 ± 27 min, SE 89.5 ± 4.1 %, NREM1 4.9 ± 3.6 %, NREM2 38.7 ± 10.2 %, SWS 36.9 ± 11.4 %, REM 19.3 ± 3.8 %, WASO 32.4 ± 9.2 min, SOL 18.3 ± 16.5 min, Awakening Index 16.1 ± 6.3 /h, Apnea-Hypopnea-Index 0.9 ± 0.8 /h, ESS 5.3 ± 2.5 (/24), PSQI 2.6 ± 1.9 (/21). Age-matched correlations for %SWS (R=-0.693, P=0.013) and arousals from SWS (R=-0.622, P=0.031) were found. The younger the gymnasts, the higher %SWS was found, with higher amounts of arousals from SWS in the younger gymnasts.
CONCLUSIONS: Objective sleep assessments through PSG in elite female athletes suggest a higher amount of SWS compared to non-elite athletic peer students (Suppiah et al., Ped. Ex. Sc. 2016; 28:588-595) as a salient feature in their sleep architecture. This may represent an advantage towards higher performance, as sleep deficits are related with lower performance. Hence, it needs to be explored whether a thorough analysis of elite athletes' sleep should be incorporated in health screenings.

---

421   Board #262   May 30 11:00 AM - 12:30 PM
Impact of a Carbohydrate Mouth Rinse on Motor Performance and Corticospinal Motor Excitability

Darrin C. LaForge[1], Julie Hibbard[1], Madison Moon[1], Stephen Folger[1], Gabriel K. Harris[2], Stephen Bailey, FACSM[1]. *[1]Elon University, Elon, NC. [2]North Carolina State University, Raleigh, NC.*
(No relevant relationships reported)

Application of a carbohydrate (CHO) mouth rinse (MR) prior to exercise has been shown to improve physical performance and facilitate corticospinal motor excitability. It is unclear if different forms of CHO impact this phenomenon. PURPOSE: The purpose of this investigation is to determine the effects of different forms of a CHO MR on muscular performance and corticospinal motor excitability. METHODS: Ten normal healthy subjects (5 females, 5 males; 25±1 years; 1.71±0.03 m 73±5 kg) completed 4 trials each separated by at least 48 hours. A different MR condition was applied during each trial (Placebo (PLAC), 6.4% glucose (GLU), 6.4% maltose (MAL), 6.4% maltodextrin (MDX)). Maximal voluntary contraction (MVC) of the right knee extensors and motor-evoked potential (MEP) of the right vastus medialis was determined pre (10 min before), immediately after, and post (10 min after) application of the MR. MEP was precipitated by applying transcranial magnetic stimulation (TMS) during muscle contraction (50% of MVC). The MR was held

in the mouth for 20 sec and MR treatments were applied using a Latin square design. RESULTS: No differences were found in the change of MEP from pre to immediately after the MW across the conditions (PLAC=1.5±4.4%; GLU=-6.2±11.2%; MAL=3.9±3.4%; MDX=8.9±7.9%). In contrast, the increase in MEP was greater at the post time point in CHO conditions (GLU=-11.3±14.7%, p=0.01; MAL=12.9±7.9%, p=0.07; MDX=28.0±14.4%, p=0.02) as compared to PLAC (PLAC=-14.3±7.8%). MVC was similar at pre (PLAC=260±26 Nm; GLU=241±19 Nm MAL=245±21 Nm; MDX=248±25 Nm), after (PLAC=269±26 Nm; GLU=249±18 Nm MAL=257±19 Nm; MDX=250±23 Nm), and 10 min after (PLAC=262±28 Nm; GLU=256±17 Nm MAL=269±25 Nm; MDX=253±21 Nm) the MW. CONCLUSIONS: CHO MR increased corticospinal motor excitability 10 min after application; however, the form of CHO used did not influence this response. The increase in corticospinal motor excitability did not translate into an improvement in motor performance.

422 Board #263 May 30 11:00 AM - 12:30 PM

Endocannabinoid System Involvement in Exercise-Induced Enhancement of Fear Extinction in Mice

Kevin M. Crombie[1], Angelique G. Brellenthin[1], Cecilia J. Hillard[2], Kelli F. Koltyn, FACSM[1]. [1]University of Wisconsin - Madison, Madison, WI. [2]Medical College of Wisconsin, Milwaukee, WI. (Sponsor: Kelli F. Koltyn, FACSM)
(No relevant relationships reported)

The endocannabinoid (eCB) system has emerged as a promising target for enhancing fear extinction learning, which has therapeutic implications for the treatment of stress and anxiety disorders that rely primarily on exposure-based therapies. Although previous investigations have used pharmacological approaches to enhance fear extinction, there is a strong rationale to investigate the efficacy of non-pharmacological approaches (e.g., exercise) shown to activate the eCB system. **PURPOSE:** To examine the effects of exercise on the extinction of conditioned fear, anxiety-like behaviors, and eCB adaptations in cortico-limbic regions. **METHODS:** ICR/CD1 male mice (N = 26) completed a series of behavioral tests prior to and following a fear-conditioning (day 1; FC) and fear-extinction (days 2-5; FEXT) protocol. Following FC, mice were randomly assigned to caging containing either an unlocked (EX) or locked (CON) running wheel, with unlimited access until 24 hours following the last FEXT session. Mice were sacrificed 48 hours after the last behavioral test in order to examine central eCB tissue content. Data were analyzed using a series of one-way and mixed model ANOVAs, Pearson correlations, and Cohen's d effect sizes. **RESULTS:** EX mice exhibited a significant reduction in anxiety-like behaviors from pre to post compared to the CON mice ($p < 0.05$). Although both groups experienced less freezing over time, EX mice exhibited significantly less freezing on days 2 ($d = 0.39$), 3 ($d = 0.50$), 4 ($d = 1.16$), and 5 ($d = 0.89$) compared to CON mice ($p < 0.05$). Additionally, moderate to strong negative correlations were found between wheel running revolutions and freezing time on days 2 through 5, indicating that mice who ran more in between extinction sessions tended to freeze less during subsequent sessions. Lastly, EX mice exhibited significantly greater amygdalar eCB content and significantly less hippocampal eCB content compared to CON mice ($p < 0.05$). **CONCLUSION:** These preliminary results suggest that voluntary exercise enhances fear-extinction and reduces anxiety-like behaviors in mice, possibly due to eCB system adaptations in brain regions involved in regulating fear and anxiety responses.

Moderate Risk of the Female Athlete Triad Predicts Injuries in Division II Female Athletes

Jennifer L. Scheid, Morgan E. Stefanik, Michelle Copolo-Ziemer, Karen L. Roehling. *Daemen College, Amherst, NY.*
(No relevant relationships reported)

BACKGROUND: The female athlete triad is the interrelation of low energy availability, menstrual dysfunction, and low bone mineral density. Previously, the components of the female athlete triad have been linked to stress fractures and tendinopathies. However, limited research exists regarding the female athlete triad beyond the relationship of these injuries. **PURPOSE:** The purpose of this study was to explore the relationship between risk for the female athlete triad and musculoskeletal injuries. We hypothesized that athletes who presented with a higher risk of the female athlete triad would have a greater occurrence of musculoskeletal injuries during their competitive season. **METHODS:** Fifty-seven female athletes from a NCAA Division

II college completed questionnaires that assessed female athlete triad cumulative risk using 5 factors (low energy availability, low body mass index, delayed menarche, oligomenorrhea or amenorrhea, and stress fractures). Women were grouped according to how many risk factors they had for the female athlete triad. At the end of each sport season, injury data was compiled using SportsWare (an electronic medical record database used by the athletic trainers to manage injury data). **RESULTS:** Forty-one women were considered low risk for the female athlete triad (Low Risk Triad group) and 16 women were considered moderate risk for the female athlete triad (Moderate Risk Triad group). No women in our study were at high risk for the female athlete triad. Forty-seven of the 57 women (82%) incurred 90 musculoskeletal injuries. The most prevalent injuries included: low back pain/spasm/strain (n=12), followed by shin splints/medial tibial stress syndrome (n=9), general knee pain (n=7), quadriceps strain (n=6), and knee sprain (anterior cruciate ligament, posterior cruciate ligament, medial collateral ligament and lateral collateral ligament sprains; n=5). The number of in-season injuries in the Moderate Risk Triad group (2.1±0.4) was higher (p<0.05) than the Low Risk Triad group (1.3±0.2). **CONCLUSION**: Moderate risk of the female athlete triad appears to increase the risk of injury during the competitive season beyond stress fractures and women with a moderate risk of the female athlete triad should be monitored closely by athletic trainers and coaches.

424 Board #265 May 30 11:00 AM - 12:30 PM

Perceptions Regarding Injury and Training in Elite, Adolescent Rock Climbers

Rachel N. Meyers[1], Morgan N. Potter[2], Steven L. Hobbs[1], Aaron J. Provance[2]. [1]University of Colorado Boulder, Boulder, CO. [2]Children's Hospital Colorado, University of Colorado School of Medicine, Aurora, CO.
(No relevant relationships reported)

PURPOSE: Our objective was to examine the awareness and knowledge of youth-specific climbing injuries and risk factors amongst elite, adolescent rock climbers. **METHODS**: We surveyed elite adolescent rock climbers, ages 8-18 competing in the 2017 USA Climbing Sport and Speed National Championships. Subjects answered questions on their knowledge and awareness of the most common youth climbing injury and safe training practices. One-way ANOVAs and Bonferroni post hoc tests identified misperceptions about youth climbing injuries and the safe age to start double dyno campusing, a climbing-specific training exercise. Risk ratios were used to compare the proportion of athletes who self-reported as "informed" and "uninformed" when asked about common finger injuries in adults and youth.
RESULTS: 267 climbers completed the survey (age =13.99±2.66, 51.9% male, 48.1% female). The adult-specific A2 pulley injury, was erroneously reported by the subjects to be the most common youth climbing injury, with an average ranking of 3.09±2.20 on a scale of 1 (most common) to 8 (least common). The youth-specific and most common injury in adolescent climbers, growth plate finger injuries, ranked second most common, with an average of 4.0±2.22. These rankings were significantly different (p<0.001). Only 5.7% of climbers correctly reported the safe age to begin double dyno campusing, a risk factor for growth plate injuries. 48.9% of climbers reported they were aware of growth plate injuries to the finger; yet only 54% of these climbers correctly identified the injuries as stress fractures. 73.5% overall reported growth plate finger injuries to either be a type of A2 pulley injury or did not know.
CONCLUSION:
Adolescent climbers demonstrated the misconception that skeletally immature climbing-specific injuries and training techniques do not need to be treated differently from skeletally mature climbers. As climbing enters the 2020 Olympics, it is imperative that adolescent climbers, coaches, and parents be better educated on pediatric-specific climbing injuries and when to seek medical attention. Improved knowledge can help reduce the risk of these injuries and the potential for permanent finger deformity and/or loss of function.

425 Board #266 May 30 11:00 AM - 12:30 PM

The Relationship Between Flexibility and Low Back Pain in Female Adolescent Gymnasts

Morgan N. Potter, David R. Howell, Emily A. Stuart. *Children's Hospital Colorado, Aurora, CO.*
(No relevant relationships reported)

PURPOSE: Our objective was to elucidate the association between lower back pain, flexibility, and individual characteristics in adolescent female gymnasts.
METHODS: Female gymnasts ages 6-18 years competing in the USA Women's Artistic Junior Olympic Program levels 3-10 were enrolled in the study. Subjects underwent active and passive flexibility measurements at the shoulder, hip, quadriceps, and hamstrings. They were then asked if they experienced back, shoulder, and/or hip pain in the last 12 months. Those with a history of back pain then completed the Micheli Functional Scale and Oswestry Low Back Pain Scale. Demographic information, clinical characteristics, and flexibility measurements were compared between gymnasts with and without back pain in the previous 12 months using t-tests

WEDNESDAY, MAY 30, 2018

and Chi square tests. A binary multivariable logistic regression model was used to assess the association between back pain in the past 12 months, flexibility, and participant characteristics.
RESULTS: Fifty-one gymnasts participated: 19 who reported back pain in the past 12 months (age= 13.3±3.3 years; BMI= 18.6±2.6) and 32 who did not (age= 11.1±2.4 years; BMI= 17.5±1.9). Those with back pain reported more hours per week of gymnastics participation (22.7±6.9 vs. 18.5±5.9 hours/week; p= 0.026), and a higher proportion reported experiencing menarche (37% vs. 6%; p= 0.009) than those who did not. Passive Hookline shoulder flexion (178.6±6.1 vs. 180.0±0.0 degrees; p= 0.008) and active right prone knee flexion (131.1±9.2 vs. 132.0±5.1 degrees; p= 0.07) were lower among those who reported back pain. When considered together, having experienced menarche at the time of assessment was independently associated with the presence of self-reported back pain the past 12 months (adjusted odds ratio= 7.317, 95% CI= 1.22-43.87; p= 0.029).
CONCLUSION: Risk factors for back pain in adolescent female gymnasts may be more complex and multifaceted than the simple flexibility measurements we used. While the history of low back pain and flexibility were not significantly associated, low back pain was more common in gymnasts with a history of menarche. As back pain etiology is likely related to many factors,
clinicians should be aware of intrinsic patient factors, such as pubertal maturation, when considering risk of future back injury.

426   Board #267   May 30 11:00 AM - 12:30 PM
Sex Differences in Objective and Subjective Sleep in Collegiate Athletes

Janelle L. Adomeit[1], Brett M. Gervais[1], Stephanie L. Dietrich[1], Babak Mokhlesi[2], Jason R. Carter[1]. [1]*Michigan Technological University, Houghton, MI.* [2]*University of Chicago, Chicago, IL.*
(No relevant relationships reported)

Despite the importance of sleep in athletic performance, objective assessments of sleep are not well characterized in collegiate athletes, and the impact of sex (i.e., male vs. female) on subjective and objective sleep in collegiate athletes remains equivocal. **Purpose:** To establish normative estimates of subjective and objective sleep in male and female collegiate athletes, and determine if sex differences exist.
Methods: Subjective and objective sleep were assessed during the off-season in 108 collegiate athletes (56 males, 21 ± 1 years; 52 females, 20 ± 1 years) recruited from the Michigan Tech University varsity football, basketball, volleyball, soccer, hockey, track, and nordic ski teams. Subjective assessments included Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS), and 3-5 consecutive weeknights of sleep diary to determine subjective total sleep time (TST). Objective assessments of TST, sleep efficiency (SE), and wake after sleep onset (WASO) were determined using wrist actigraphy in parallel with sleep diaries. The apnea-hypopnea index (AHI) was determined using an at-home apnea screening test during one of the actigraphy nights. **Results:** Actigraphy revealed that 94% of all athletes received <8 hrs of objective TST, with 61% receiving <7 hrs. Male athletes reported significantly higher subjective TST (i.e., sleep diary) compared to female athletes (7.6±0.1 vs. 6.9±0.1 hrs, p<0.001). However, objective TST (i.e., actigraphy) was not different between males and females (6.9±0.1 vs. 6.8±0.1 hrs, p=0.56). Moreover, females demonstrated significantly higher SE (87±1 vs. 82±1%, p<0.001) and lower WASO (31±2 vs. 38±2 min, p=0.02) compared to males. PSQI, ISI, and ESS were not significantly different between sexes. AHI was significantly higher in male athletes (1.2±0.2 vs. 0.5±0.1 episodes/hr, p<0.001), but both groups were well below the threshold for clinical sleep apnea. **Conclusion:** Subjective and objective assessments of sleep differed in male and female subjects, yet both groups were well below recommended levels of sleep for collegiate athletes. These findings suggest that different sleep education strategies and interventions may be necessary in male and female collegiate athletes to improve sleep duration and/or quality.

Can Ultrasound Subcutaneous Fat Thickness be used to Estimate Percent Body Fat in Older Adults?

Robert Thiebaud[1], Takashi Abe[2], Jeremy Loenneke[2], Eiji Fujita[3], Takuya Akamine[3]. [1]*Texas Wesleyan University, Fort Worth, TX.* [2]*University of Mississippi, Oxford, MS.* [3]*National Institute of Fitness and Sports in Kanoya, Kagoshima, Japan.*
(No relevant relationships reported)

Ultrasound imaging has been used to estimate body composition, which includes percent body fat (%BF), in young and middle-aged adults. However, it is unknown whether ultrasound imaging can predict %BF in older adults when using dual-energy x-ray absorptiometry (DXA) as the criterion method. **PURPOSE**: To develop prediction equations to estimate %BF in older men and women using ultrasound subcutaneous fat thickness. **METHODS**: Four-hundred and nineteen men (n=176) and women (n=243) participated in this study. The average age, BMI and %BF of participants were 70.6 ± 6.4 yrs, 23.5 ± 3.0 kg/m[2] and 28.2 ± 7.4%. Participants were randomly separated into a model development group (n=260) and cross-validation

group (n=159). B-mode ultrasound using a 5-MHz scanning head imaged subcutaneous fat thickness on the right side of the body at the anterior forearm, anterior and posterior upper arm, anterior trunk, posterior trunk, anterior and posterior thigh, and anterior and posterior lower leg. A whole body scan using DXA was used to determine %BF. IBM SPSS Statistics 24 was used to analyze the data. For multicollinearity assumption, variables with a variance inflation factor (VIF) > 10 were excluded from analysis. Stepwise multiple linear regression analysis was used to develop prediction equations. Bland-Altman plots were used to validate the prediction equations. **RESULTS**: Variables included in the stepwise linear regression analysis were height, sex, and all fat thicknesses. Age and weight were not significantly correlated with %BF (p<0.05). The prediction equation for %BF was the following: %BF = 27.075 + (3.284*Anterior Trunk) + (4.916*Posterior upper arm) + (2.166*Sex) - (0.099*height) where males = 1 and females = 2. The adjusted r-square of the prediction equation was 0.701 with a standard error of the estimate of 4.1%. Bland-Altman plots revealed a mean bias of 0.2266 ± 7.9772 (95% confidence intervals). A significant correlation (r = 0.245, p=0.002) between the difference in %BF (measured - predicted) and the average %BF [(Measured + predicted %BF)/2] suggests some systematic error in the prediction equation.
CONCLUSIONS: Ultrasound imaging can be used to predict %BF in older adults; however, there is some systematic error in the prediction equation.

Menstrual Cycle Influence on Iron-Status Markers in Female Athletes. IronFEMME Pilot Study

Ana B. Peinado[1], Laura Barba[1], Ángel E. Díaz[2], Javier Butragueño[1], Nuria Romero-Parra[1], Francisco J. Calderón[1], Pedro J. Benito[1], Rocío Cupeiro[1]. [1]*LFE Research Group, Universidad Politécnica de Madrid, Madrid, Spain.* [2]*Ministry of Education, Culture and Sport, Highest Spanish Sports Council, Madrid, Spain.*
(No relevant relationships reported)

Female athletes may experience an elevated risk of iron deficiency as iron status may decline during physical training. Further, the interaction between hormones involved in regulating the menstrual cycle and its effect on iron status still remains unclear. **PURPOSE:** To study the influence of the menstrual cycle phases on iron-related parameters in women after endurance exercise. **METHODS:** Thirteen healthy eumenorrheic endurance-trained women (34.9± 4.2 years; 163.9±6.1 cm; 58.4±5.5 kg; peak oxygen consumption (VO$_{2peak}$) 49.7±3.1 ml·min[-1]·kg[-1]) participated in the study. Each participant performed 40 min running at the speed corresponding to the 75% of VO$_{2peak}$. Exercise was completed on a treadmill and was performed in three different phases of menstrual cycle randomly assigned: early follicular (EFP), mid-follicular (MFP) and luteal phase (LP). Blood samples were obtained at baseline and immediately (Post0h) and 3 hours (Post3h) after exercise and analyzed for serum iron, ferritin and transferrin. Mixed linear models were conducted to analyze the data. **RESULTS:** Serum iron (µg/dl) was not different across menstrual cycle phases (EFP: 59.7±36.1; MFP: 80.2±39.6; LP: 83.6±58.2; p=0.101), although we observed lower values at EFP. Time was not significant on serum iron (Baseline: 69.9±45.4; Post0h: 76.6±49.3; Post3h: 77.0±45.6; p=0.247). Ferritin (ng/ml) values were similar across menstrual cycle phases (EFP: 27.9±21.7; MFP: 31.8±25.2; LP: 32.0±27.4; p=0.451); however there was a significant effect for time (p=0.017) with higher values at Post0h (33.1±27.0) compared to baseline (28.8±23.1). We observed similar values of transferrin (mg/dl) across menstrual cycle phases (EFP: 300.8±40.4; MFP: 298.6±44.6; LP: 300.5±47.2; p=0.902). Time was significant on transferrin (p=0.001) with higher values at Post0h (307.7±47.8) compared to baseline (293.7±41.5) and Post3h (298.5±41.8). No significant menstrual cycle phases × time interactions were found for any of these variables. **CONCLUSION:** Based on the preliminary results from this pilot study, iron-status markers are not influenced by the menstrual cycle, although serum iron values seem to be lower at EFP. Ferritin and transferrin values were increased after exercise along the menstrual cycle. Funding: DEP2016-75387-P (Spanish National Plan 2013-2016)

Menstrual Cycle Influence on Hepcidin Secretion and Inflammatory Reponses in Female Athletes. IronFEMME Pilot Study

Laura Barba[1], Rocío Cupeiro[1], Ángel E. Díaz[2], Elena Santiago[3], Víctor Alfaro[1], Beatriz Rael[1], Cristina Maestre-Cascales[1], Juan Orellana[4], Ana B. Peinado[1]. [1]*LFE Research Group, Universidad Politécnica de Madrid, Madrid, Spain.* [2]*Ministry of Education, Culture and Sport, Highest Spanish Sports Council, Sports Medical Center, Madrid, Spain.* [3]*Tambre Clinic, Madrid, Spain.* [4]*ETSIAAB, Universidad Politécnica de Madrid, Madrid, Spain.*
(No relevant relationships reported)

Deficient iron absorption may be conditioned by an increase in inflammatory markers and hepcidin levels after exercise. The interaction between inflammatory markers

and hepcidin along menstrual cycle is still unknown. **PURPOSE:** To elucidate the effect of hormonal fluctuations during menstrual cycle on inflammatory and hepcidin responses after endurance exercise **METHODS:** Thirteen healthy eumenorrheic endurance-trained women (34.9± 4.2 years; 163.9±6.1 cm; 58.4±5.5 kg; peak oxygen consumption (VO_{2peak}) 49.7±3.1 ml·min^{-1}·kg^{-1}) participated in the study. Subjects performed 40 min running on a treadmill at the speed corresponding to the 75% of VO_{2peak}. Exercise was performed in three different moments: during early follicular (EFP), mid-follicular (MFP) and luteal phase (LP). Blood samples were obtained at baseline and immediately (Post0h) and 3 hours (Post3h) after exercise and were analyzed for interleukin-6 (IL-6), C-reactive protein (CRP) and hepcidin. Mixed linear models were conducted to analyze the data. **RESULTS:** Hepcidin (ng/ml) was not different across menstrual cycle phases (EFP: 76.5±25.3; MFP: 78.4±19.5; LP: 78.0±23.0; p=0.762). Time was significant (p=0.001) on Hepcidin with higher values at Post0h (81.9±21.5) compared to Baseline (74.2±24.1) and Post3h (76.8±21.9). IL-6 (pg/ml) levels were not different over menstrual cycle (EFP: 3.5±3.0; MFP: 3.0±1.5; LP: 5.4±6.6; p=0.079); however time (p<0.001) at Post3h (5.4±6.3) showed significant higher values compared to Baseline (2.6±2.1) and Post0h (3.9±3.2). We found an interaction between menstrual cycle phases and time (p=0.038) with greater values at Post3h during LP (8.7±9.9) compared to EFP (3.7±2.90) and MFP (3.7±1.9). Increased CRP (mg/dl) levels were reported (p=0.033) during EFP (2.0±3.3) related to MFP (1.0±1.1) and LP (0.8±1.4). Time had no significant effect on CRP (Baseline: 1.3±2.4; Post0h: 1.3±2.3; Post3h: 1.2±2.0; p=0.707). **CONCLUSION:** According to our preliminary results, inflammatory responses seem to be influenced by menstrual cycle even though hepcidin levels may not be affected by hormonal fluctuations. Hepcidin and IL-6 peak levels were found Post0h and Post3h after exercise respectively. CRP levels did not show an increase after exercise at any phase. Biolosical Matulity for Japanese Soccer Player 2007-2015
Ryo Takahara, Akihiro Kanamori, Shumpei Miyakawa.
University of Tsukuba, TSUKUBA, Japan.
(No relevant relationships reported)

PURPOSE: The soccer is one of the sports loved all over the world. Many children will dream of professional football player and being National team member in the future.Upbringing of the player is begun than low age and the player selection of the athlete spreads among lower aged people. The Late maturity player is not found in many cases when a coach select player by only physical ability. U-17 international championship of the soccer had many early maturity players. This study predicted a biological maturity degree and final height prediction of the Japanese soccer players. **METHODS:** The sample included 483 male soccer players(12.4±0.6y,154.7±8.9 cm,182.2-134.1cm) who were professional soccer club under category team(2007-2015). Players were evaluated the skeletal maturity degree, skeletal age and final height in Tanner-Whitehouse 2 Method (JAPAN) and Tanner-Whitehouse 3 Method. The biological maturity classification method assumed it mature early,on time,late divided differences between chronological age and skeletal age by ±1.0 year. The statistics processing assumed it less than level of significance 5% with, SPSS ver.25. **RESULTS:** The Bone maturation score(Radius-ulna-short bone score) was 465.4 ± 156.3pt. Average of skeletal age was 12.5 ± 1.3 years old with Tanner-Whitehouse 2 Method(Japan). Biological maturity classification was Late 68 players, On time 318 players, Early 90 Players and Adult 4 players. Final height prediction average was 173.3±5.2cm(187.7-149.8cm) with Tanner-Whitehouse 2 Method(TAKAI). **CONCLUSION:** In this study, 7 players were adults by biological maturity. The difference of the skeletal age was 7.3 years old in early and late. When a team performs the player selection, Coach and recuiter should select in consideration of the difference of the biological maturity degree.

The Effect of Pre-Sleep Consumption of Casein Protein on Resting Metabolic Rate and Appetite in Postmenopausal Women
Christopher Schattinger[1], Joeseph Leonard[2], Ashley Artese[1], Michael Ormsbee, FACSM[1], Cara Pappas[1], Lynn Panton, FACSM[1]. *[1]Florida State University, Tallahassee, FL. [2]Florida State University College of Medicine, Tallahassee, FL.* (Sponsor: Lynn B. Panton, FACSM)
(No relevant relationships reported)

PURPOSE: To determine the acute effects of nighttime pre-sleep consumption of casein protein (CP) and a placebo (PLA) supplement on next-morning measures of resting metabolic rate (RMR) and appetite in postmenopausal women. METHODS: This study was a randomized crossover double-blind placebo-controlled trial. Eight postmenopausal (N=8, age: 57±5 yrs, BMI= 28±6 kg/m2) women participated. Subjects had body composition (DXA), RMR (indirect calorimetry), and appetite (visual analog scale; VAS) measured. Subjects consumed either CP (35 g, 130

kcals) or PLA (7.2g, 10 kcals) 30 min prior to bed time on two separate occasions separated by 48-hours. RMR and measures of hunger, desire to eat, and satiety were analyzed using Paired T-tests. Significance was accepted at p≤0.05. RESULTS: RMR (CP:1286±175; PLA:1278±201 kcals/day) and relative oxygen consumption (CP:2.66±0.33; PLA 2.67±0.26 ml/kg/min) were not different between CP and PLA. There were also no effects of CP and PLA on measures of appetite (Hunger: CP: 3.44±2.98; PLA: 3.75±3.06 cm; Satiety: CP: 4.06±2.09; PLA:4.79±3.11 cm; Desire to Eat: CP:4.28±3.58; PLA:4.06±3.17 cm). CONCLUSION: There were no differences in RMR and measures of appetite between CP and PLA. There is growing evidence that a small snack before bed (150-200 kcal) is not harmful to metabolism or appetite. This study was supported with product by Dymatize Nutrition.

Cardiometabolic Prediction Equations Overestimate Cardiorespiratory Fitness for Treadmill and Cycle Ergometry in Multiple Sclerosis Patients
Garett Griffith[1], Alexander J. Rosenberg[1], Georgios Grigoriadis[1], Kanokwan Bunsawat[2], Sang Ouk Wee[3], Elizabeth C. Schroeder[1], Badeia Saed[1], Tracy Baynard, FACSM[1]. *[1]University of Illinois at Chicago, Chicago, IL. [2]University of Utah, Salt Lake City, UT. [3]California State University, San Bernardino, San Bernardino, CA.*
(No relevant relationships reported)

Multiple sclerosis (MS) patients exhibit a decreased peak oxygen uptake (VO_{2peak}) compared to age-matched peers, and therefore have the potential for increased relative gains in VO_{2peak} in response to chronic exercise training. Individualized exercise prescriptions and monitoring improvement both rely on accurate assessment of VO_{2peak}; however, expired gas analysis is not always available. Therefore, prediction equations have been established to estimate VO_{2peak} for both treadmill (TM) and cycle ergometry (CE) tests based on work rates. Whether or not these equations are appropriate for MS patients has yet to be investigated. **PURPOSE:** To compare VO_{2peak} obtained via TM and CE maximal exercise tests to previously established cardiometabolic prediction equations. **METHODS:** MS patients (44 ± 11 yrs, 28.1 ± 8.0 kg/m², 11 ± 10 yrs since dx) performed a maximal graded exercise test on both a TM and CE. Twenty-five subjects completed the TM test, and 26 completed the CE test. TM tests consisted of 2 min stages with a constant, self-selected pace, with a 2% increase in grade per stage. CE tests increased by 15 Watts/min. VO_{2peak} was compared to previously established mode-specific cardiometabolic prediction equations using paired samples *t*-tests and further examined with Bland-Altman plots. **RESULTS:** Predicted VO_{2peak} was higher than measured values for both TM and CE (*p*<0.05). The TM had a mean bias, upper limit of agreement (LOA), and lower LOA of -2.35, 6.63, and -11.32 mL/kg/min, respectively. The CE had a mean bias, upper LOA, and lower LOA of -2.20, 3.31, and -7.72 mL/kg/min, respectively. **CONCLUSION:** Cardiometabolic prediction equations resulted in higher VO_{2peak} estimates for both TM and CE in MS patients. The wide limits of agreement (Bland-Altman plots) suggest the accuracy in predicting individual VO_{2peak} values is compromised among individuals with MS.

	Measured VO_{2peak} (mL/kg/min)	Predicted VO_{2peak} (mL/kg/min)
Treadmill	26.6 ± 6.3	28.9 ± 7.0*
Cycle Ergometry	24.1 ± 7.0	26.3 ± 6.0*

Data are mean ± SD. *$p<0.05$ between measured and predicted VO_{2peak}.

Relationship Between Dorsiflexion Strength Asymmetry, Walking Performance, and Disability in Multiple Sclerosis Patients
David J. Lantis[1], Gregory S. Cantrell[2], John P. Hintz[3], Cameron D. Owens[3], Debra A. Bemben, FACSM[3], Christopher D. Black, FACSM[3], Daniel J. Larson[3], Rebecca D. Larson[3]. *[1]St. Ambrose University, Davenport, IA. [2]Northern State University, Aberdeen, SD. [3]University of Oklahoma, Norman, OK.*
(No relevant relationships reported)

Multiple sclerosis (MS) is one of the most common progressive neurological diseases in young adults and is characterized by neurologic disruption within the

central nervous system. Previous research has shown strength asymmetry (SA) in the quadriceps of MS patients to be correlated with a decrease in functional walking performance (FWP). Due to limited ankle mobility in MS patients during walking, an investigation of the relationship between dorsiflexion SA and walking ability is necessary to better understand the impact on quality of life in MS patients. **PURPOSE:** To investigate SA during isometric/isokinetic dorsiflexion in MS patients compared to healthy individuals (Non-MS), and investigate the relationship between SA and FWP in both groups. **METHODS:** 26 individuals participated in the study (MS = 13, Age = 50.3 $\pm$ 9.1 years; Non-MS = 13, Age = 50.8 $\pm$ 8.5 years). Visit 1 consisted of test familiarization. Visit 2 consisted of maximal isometric (MVC) and isokinetic (MVIC) dorsiflexion contractions performed at 60º/s in both legs. SA ratio was calculated from the peak torque achieved. On visit 3, subjects performed three tests of FWP: 25 Foot Walk Test (25W), Timed Up-and-Go Test (TUG), and 6-Minute Walk Test (6MW). **RESULTS:** The mean expanded disability status score (EDSS) for the MS patients was 3.5 ± 1.8, indicating mild-moderate disability. There was a significant difference in MVC SA between groups (MS vs NON-MS = 13.7 ± 18.1 vs. 3.3 ± 2.6, p = 0.03) however no difference was observed in MVIC SA between groups (p > 0.05). Differences were observed between groups for all three FWP tests and gait speed (p < 0.05). There was a significant relationship between MVC SA and two FWP tests in the MS group (25W: r = 0.76, p = 0.002; TUG: r = 0.61, p = 0.03) and a significant relationship between MVIC SA and all four FWP variables (25W: r = 0.93, p < 0.001; gait speed: r = -0.76, p = 0.002; TUG: r = 0.81, p < 0.001; 6MW: r = -0.67, p = 0.01). There was no significant relationship between MVC or MVIC SA and the FWP tests in the Non-MS group (p > 0.10). There was no significant relationship between MVC SA or MVICSA and EDSS in the MS patients (p > 0.05). **CONCLUSION:** SA differed between groups, and dorsiflexion SA appears to be related to impaired walking performance in MS patients. This relationship may be independent of disease severity based on EDSS.

Relationship between Soleus H Reflex and Balance Metrics in People with Multiple Sclerosis

Greg Cantrell[1], David Lantis[2], Mike Bemben, FACSM[3], Chris Black, FACSM[3], Dan Larson[3], Rebecca Larson[3]. [1]*Northern State University, Aberdeen, SD.* [2]*St. Ambrose, Davenport, IA.* [3]*University of Oklahoma, Norman, OK.*
(No relevant relationships reported)

Multiple Sclerosis (MS) is a disease of the central nervous system with poor balance as one of the most reported symptoms. Previous research has shown limb to limb differences in a number of physiological measures (e.g., leg strength). One measure yet to be evaluated between limbs in MS patients is the soleus Hoffmann (H) reflex, which is regarded as the electrical analogue to the stretch reflex. **Purpose:** The intent of this study was to 1) quantify the soleus H reflex in both legs to determine whether asymmetry was present and 2) correlate H reflex asymmetry to balance performance. **Methods:** The study consisted of six visits. The first visit consisted of paperwork and familiarization. The soleus H reflex was measured twice in both legs over four visits (V2 - V5) to assess bilateral differences in 17 participants (MS=9, Age=49.3±11.3 years; Non-MS=8, Age=48.6±11.3 years). Balance testing was conducted on the final visit, and consisted of a sensory organization test (SOT) and limits of stability (LOS). **Results:** One MS participant was unable to complete balance testing, leaving 16 participants in the balance analyses. The mean expanded disability status score for the MS participants was 3.4±2.2 (range=1 to 6; median=2), indicating mild-to-moderate disability. No difference was observed between limbs in the soleus H reflex for either group; however, when converted into an asymmetry score (AS) the MS group had significantly more asymmetry (MS=26.1±16.6, Non-MS=4.6±3.9; p=0.01). The MS group had a significantly lower SOT composite score (MS=80.4±4.0, Non-MS=85.8±2.9, p < 0.05). Sagittal plane endpoint excursion (EPE) and maximum excursion (ME) were significantly less in the MS group (EPE: MS=36.8±9.2, Non-MS=69.0±11.4, p <0.001; ME: MS=61.5±16.4, Non-MS=83.0±10.2, p <0.01) during LOS testing. A significant negative relationship was observed between AS and EPE (r=-0.625), ME (r=-0.709), and directional control (r=-0.615) during LOS testing in the sagittal plane. A significant positive relationship (r=0.518) was observed between AS and reaction time in the sagittal plane during LOS testing. **Conclusion:** Differences in the soleus H reflex asymmetry was observed between groups, which appears to significantly influence balance performance as the Non-MS participants generally performed better than the MS participants.

Body Temperature Regulation In Ms Patients Performing Physical Activity In The Heat

Georgia Chaseling[1], Davide Filingeri[2], Scott Davis, FACSM[3], Ollie Jay, FACSM[1]. [1]*University of Sydney, Sydney, Australia.* [2]*University of Loughborough, Loughborough, United Kingdom.* [3]*Southern Methodist University, Dallas, TX.* (Sponsor: Dr Ollie Jay, FACSM)
(No relevant relationships reported)

PURPOSE: The impact of heat intolerance and associated fatigue among people with multiple sclerosis (MS) is well documented, particularly during physical activity in the heat. However to date it is unclear whether an impaired thermoregulatory capacity is evident in people with MS. It is also unknown whether any such impairment is manifested in the sudomotor (sweating) system or vasomotor (skin blood flow) system. Therefore the aim of this study was to determine whether thermoregulatory responses are independently altered in MS patients relative to healthy controls during physical activity in a warm/hot environment. **METHODS**: Sixteen participants with relapsing-remitting MS (EDSS 2.8±0.9; 47±8 y; 77.6±14.0 kg; 1.7±0.1 m) and 14 age- and mass-matched healthy controls (43±11 y; 78.6±17.0 kg; 1.70±0.09 m) cycled at a fixed metabolic heat production of 4 W.kg^{-1} on a semi-recumbent ergometer for a maximum of 40 minutes in a 30°C, 30%RH environment. A subset of 8 MS (EDSS: 2.6±0.5; 44±8 y; 82.3±18.2 kg; 1.7±0.1 m) and 8 healthy controls (44±12 y; 81.2±21.1 kg; 1.7±0.1 m) also completed the same exercise bout in a 35°C, 30%RH environment. In both trials, rectal temperature (T_{re}), mean skin temperature (T_{sk}), and local sweat rate (LSR) and cutaneous vascular conductance (CVC) on the upper-back was measured throughout. **RESULTS**: At 30°C, end-exercise T_{re} (MS:37.2±0.3, CON:37.3±0.4°C; P=0.31), T_{sk} (MS:34.5±0.5, CON:34.6±0.5°C; P=0.43), LSR (MS:0.44±0.22, CON:0.47±0.21 mg.cm^{-2}.min^{-1}; P=0.71), and CVC (MS:344±256, CON:268±157% of baseline; P=0.35) were similar between groups. Likewise, at 35°C, end-exercise T_{re} (MS:37.2±0.4, CON:37.3±0.3°C; P=0.70), T_{sk} (MS:35.5±0.5, CON:35.5±0.5°C; P=0.87), LSR (MS:1.26±0.44, CON:1.34±0.38 mg.cm^{-2}.min^{-1}; P=0.61), and CVC (MS:425±163, CON:378±236% of baseline; P=0.68) were not different. **CONCLUSIONS**: Individuals with relapsing-remitting MS do not demonstrate any clear impairments of sweating or skin blood flow control during moderate levels of physical activity at air temperatures as high as 35°C.

Physical Activity is Associated with Walking Capacity in Persons with Multiple Sclerosis

Brooks A. Hibner[1], Garett Griffith[1], Elizabeth C. Schroeder[1], Alexander J. Rosenberg[1], Rachel E. Bollaert[2], Robert W. Motl[3], Abraham Murua Kick[1], Tracy Baynard, FACSM[1], Bo Fernhall, FACSM[1]. [1]*Integrative Physiology Laboratory, University of Illinois at Chicago, Chicago, IL.* [2]*Beckman Institute for Advance Science and Technology University of Illinois Urbana-Champaign, Champaign, IL.* [3]*UAB/Lakeshore Research Collaborative, University of Alabama at Birmingham, Birmingham, AL.*
(No relevant relationships reported)

Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system which affects 1 in 1000 persons in the United States. MS results in functional limitations, including impairments in walking capacity, balance, and increases in overall fatigue, leading to decreased physical activity. However, the potential associations between physical activity, walking ability and functional capacity are not clear in this population. **Purpose:** To evaluate the association between physical activity, walking ability and functional capacity in individuals with MS. **Methods:** Fifty-eight individuals with MS between the ages of 18-70 (Male = 15, 47 ± 12 years, BMI = 28.8 ± 6.5, EDSS = 0-4) performed a maximal incremental cycle test to assess peak aerobic capacity (VO$_2$ peak). Subjects completed a timed 25-foot walk test (T25FW), 6 minute walk test (6MW), and wore an accelerometer for one week to determine physical activity. Moderate / vigorous physical activity (MVPA) was defined as >1722 counts per minute. **Results:** MVPA was correlated with 6MW, T25FW and VO$_2$peak (p<0.05, Table 1). In stepwise regression analyses, MVPA was a stronger predictor of T25FW (β: −0.44, p<0.01) and 6MW (β: 0.48, p<0.01) than VO$_2$peak (β: −0.29, p=0.03; β: 0.32, p<0.01). **Conclusion:** Although both MVPA and VO$_2$ peak provide unique contributions to the prediction of 6MW and T25FW, MVPA is a stronger predictor. These results suggest that improving both physical activity and cardiovascular fitness may improve walking ability in persons with MS.

Table 1				
	6MW	T25FW	VO$_2$ peak	MVPA
6MW	--	--	--	--
T25FW	-0.793*	--	--	--
VO$_2$ peak	0.568*	-0.504*	--	--
MVPA	0.630*	-0.580*	0.478*	--

*Significant correlation, $p < 0.05$

Reduced Cognitive Function and Preserved Physical Function in Cannabis Users with Multiple Sclerosis

Nathaniel B. Ketelhut, John H. Kindred, Felix Proessl, Thorsten Rudroff, FACSM. *Colorado State University, Fort Collins, CO.* (Sponsor: Thorsten Rudroff, FACSM)

(No relevant relationships reported)

Multiple Sclerosis (MS) is an inflammatory disease of the central nervous system characterized by a variety of symptoms including reduced physical and cognitive function. Cannabis is known to improve spasticity and pain in MS, but its effects on physical function are unknown.**PURPOSE**: The purpose of this study was to compare physical/cognitive function and overall quality of life in cannabis users and non-users with MS.
METHODS: Twenty-two people with relapsing-remitting MS (Users, N = 13, age: 51.0 (14.2); Non-users, N = 9, age: 53.4 (14.7)) completed the following evaluations: 25ft walk test, timed up and go, 9-hole peg test, mCTSIB (balance), handgrip strength, and the Paced Auditory Serial Addition Test (PASAT). The MS Quality of Life-54, Patient Determined Disease Steps (disability status), Activities of Balance Confidence, Numerical Rating Scale of Spasticity, and Fatigue Severity Scale questionnaires were also completed by all participants. Cannabis use status was confirmed via urinalysis. Comparisons between the groups were made using independent T-Tests.
RESULTS: Cannabis users and non-users were similar in all measures of physical function and overall quality of life ($P \geq 0.12$). Cannabis users scored significantly lower on cognitive function than non-users (PASAT, Users 32.4 ± 9.9 vs. Non-users 43.0 ± 8.4, $P = 0.02$).
CONCLUSIONS: People with MS currently using cannabis perform similarly on physical tasks as non-users. However, the performance of the cannabis users during abstinence from the drug is not known. These results suggest that cannabis may not have an impact on physical function and overall quality of life in people with MS, although cannabis likely has negative effects on cognitive function, which is consistent with findings from healthy individuals. Longitudinal and/or interventional studies with on/off drug testing are needed to better quantify the positive and negative effects of cannabis in MS.

438   Board #279   May 30 11:00 AM - 12:30 PM

Body Fatness is Associated with Lower Aerobic Fitness in Persons with Multiple Sclerosis

Emerson Sebastião[1], Robert W. Motl[2]. *[1]Northern Illinois University, DeKalb, IL. [2]University of Alabama, Birmingham, AL.*

(No relevant relationships reported)

Multiple sclerosis (MS) is an unpredictable disorder of the central nervous system that results in a varied of symptoms and is often disable. Studies conducted in large samples of persons with MS (pwMS), estimate a combined prevalence of overweight (body mass index; BMI ≥ 25kg/m^2) and obesity (BMI ≥ 30 kg/m^2) ranging from approximately 50 to 65 percent. This is a concern as this measure appears to be strongly correlated with various adverse health outcomes. Excess body fat may have negative implications in health-related fitness and consequently in participation in this population. However, little is known about the impact of body fatness on components of health-related fitness in pwMS. **PURPOSE:** To examine the impact of body fatness on aerobic fitness (AF) in pwMS with similar levels of disability. **METHODS:** This study involved a secondary data analysis and interpretation from a previous work where 62 pwMS were assessed. For the purpose of this study participants were separated in three different groups based on established BMI categories (i.e., normal, overweight, obese). BMI was used as an indirect measure of body fatness and AF was measured using peak oxygen consumption (i.e., VO$_{2peak}$). ANCOVA with a priori linear contrast analysis on the outcome controlling for age, sex, disease duration and disability was performed. The univariate F-ratio, and η^2 were used to examine the presence and magnitude of linear differences in the dependent outcome (i.e., AF) per BMI category. Statistical significance was set at $p < .05$. **RESULTS:** The average AF (i.e., VO$_{2peak}$) for the entire sample was 19.5 (7.2) mL.kg^{-1}.min^{-1} and differed significantly between the subsamples of BMI categories (normal: 20.8 (.85); overweight: 19.7 (1.13); obese: 16.9 (1.73) mL.kg^{-1}.min^{-1}) based on the linear contrast analysis; F (2, 55) = 3.33, $p = 0.043$; $\eta^2 = 0.11$. **CONCLUSION:** The findings suggest that body fatness (i.e., BMI) has a negative impact on AF in pwMS, with a marked

difference for those classified as obese. This is important as low AF and excess body fatness are important risk factors for developing cardiovascular diseases and the potential devastating impact of co-morbidities in this population.

Hemodynamic and Functional Variables in Parkinson Disease Patients: High Intensity Interval versus Continuous Moderate Exercise Training

Bianca Fernandes[1], Júlia L. Balbo[1], Guilherme V. Guimarães[2], Fábio A. Barbieri[1], Emmanuel G. Ciolac[1]. *[1]São Paulo State University – UNESP, School of Sciences, Physical Education Department, Bauru, Brazil. [2]University of São Paulo (USP), School of Medicine, Heart Institute, São Paulo, Brazil.*

(No relevant relationships reported)

PURPOSE: To assess the effects of high-intensity interval training (HIIT) versus continuous moderate exercise training (CME) on hemodynamic and functional capacity in subjects with Parkinson disease (PD). **METHODS**: 20 subjects (13/7 men/women) with PD were randomly assigned to a twice-weekly HIIT ($N = 12$) or CME ($N = 8$) for 12 weeks, and have hemodynamic (resting heart rate and blood pressure, carotid femoral pulse wave velocity, endothelial reactivity and heart rate variability) and functional variables (5-time seat-to-stand (STS), timed-up and go and 6 min walking test (6MWT)) assessed before and after training period. Exercise training intensity was regulated by the 6-20 rating of perceived exertion scale (RPE), and consisted of 25 min of HIIT (4 min walking warm-up at 9-11 RPE level, followed by 21 min alternating 1 min of briskly walking/jogging/running at 15-17 RPE level with walking at 9-11 RPE level) or 30 min of CME (4 min walking warm-up at 9-11 RPE level, followed by 26 min of walking/jogging at 11-13 RPE level). **RESULTS**: No significant differences between HIIT and CME were found in all variables at baseline. Endothelial reactivity tended to increase after HIIT, but not after CME, which result in improved level (~8%, P < 0.01) of this variable in HIIT versus CME during follow-up (Figure 1). 6MWT improved (10.4 ± 3.8 %, P < 0.05) after HIIT, but did not changed after CME. STS improved similarly after HIIT (27.2 ± 6.1 %, P < 0.05) and CME (21.5 ± 5.4 %, P < 0.05). No significant changes were found after HIIT or CME in any other variable assessed. **CONCLUSIONS**: There different adaptations of endothelial reactivity and 6MWT after HIIT and CME, whereas no changes between group were found in the other assessed variables. The present results suggest that exercise intensity may influence the training-induced adaptation on endothelial reactivity and walking capacity in PD patients.
Figure 1. Endothelial reactivity pre and post 12 weeks of high-intensity interval (HIIT) and continuous moderate exercise training (CME). * denotes significant difference from CME during the same period ($P < 0.05$)

Inflammation And Denervation In Skeletal Muscle Of Parkinson'S Disease Patients: Impact Of High-intensity Exercise Training

Kaleen Lavin, Neil Kelly, Kelley Hammond, Irina Isakova-Donahue, Marcas Bamman, FACSM. *University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Marcas Bamman, FACSM)

(No relevant relationships reported)

PURPOSE: Parkinson's disease (PD) is a neurodegenerative condition that compromises skeletal muscle function in ~1% of the population over 60y. Increasing evidence indicates PD has an inflammatory component, which may contribute to denervation in skeletal muscle and eventual motor unit loss. However, while the effects of aging on muscle inflammation are reasonably well-studied, the effects of aging with PD are unclear. Compared to age-matched controls, we have previously shown exaggerated architectural changes in PD muscle (e.g., type I myofiber grouping

resulting from dynamic denervation/renervation cycling) along with increased expression of indices of neuromuscular junction instability, and some signs of reversal with high intensity exercise training. The purpose of this study is to further investigate PD skeletal muscle pathology, examine the role of muscle inflammation, and explore the impact of exercise training.

METHODS: Vastus lateralis skeletal muscle biopsies were obtained from three cohorts of individuals: PD patients (n=30, 67±7y, Hoehn & Yahr stage 2-3), age-matched older adults (OA) and young adults (YA). To assess the effect of exercise training, a subset of PD patients (n=16) underwent 16wk high intensity training. Markers of denervation (e.g., neural cell adhesion molecule (NCAM) and sodium channel $Na_v1.5$) and inflammation [e.g., IL-1β, TNF-α, and TNF-like weak inducer of apoptosis (TWEAK)] are being assessed across the three groups and within the PD group pre- and post-training.

RESULTS AND CONCLUSION: We expect the study findings to aid in differentiating the effects of primary aging vs. aging with PD in skeletal muscle. Further, we anticipate high intensity exercise training will improve the inflammatory profile of PD muscle.

Complete results will be available for presentation at the 2018 ACSM national meeting.

Effects Of Boxing Training On Cognitive And Physical Function In Patients With Parkinson's Disease

Kristina Y. Shearon, Alexa V. Convers, Tjahane Holmes, Shannon L. Mathis. *University of Alabama Huntsville, Huntsville, AL.*
(No relevant relationships reported)

Boxing training is a community based exercise program incorporating high intensity exercise for patients with Parkinson's disease (PD). A 90 min boxing session consists of performing footwork to improve balance and agility, performing punching combinations to develop coordination, and engaging in vocal exercises to strengthen the voice. Flexibility exercises are performed to reduce muscle rigidity. Core strengthening and weight lifting exercises are performed to strengthen muscles. Long-term benefits of boxing training include improvements in gait, balance, activities of daily living, and quality of life. An immediate effect of this nontraditional form of exercise on cognitive function, strength, and fall risk has not been explored.

PURPOSE The purpose of the study was to investigate the immediate effect of a single boxing training session on cognitive and physical function in patients with PD. The hypothesis was that cognitive function, fall risk, and functional strength would improve immediately following a boxing training session. **METHODS** Cognitive function was measured with the Montreal Cognitive Assessment (MoCA). The MoCA assesses attention, concentration, executive function, orientation, language, memory, conceptual thinking, and calculation. The physical function tests included an assessment of fall risk with the Timed-Up-and-Go (TUG) test. The Sit-to-Stand (STS) test was used to assess functional strength. Measurements were performed before and immediately after the boxing session. **RESULTS** Participants were male and female persons with PD (*N* = 13) with a mean age of 70 (±8.2) years, who attended a mean of 2.5 (±0.7) boxing sessions weekly. Mean body mass index was 31.1 (±7.0) kg·m⁻². The MoCA score increased from pre (24.2 ± 3.8) to post (25.7 ± 4.4) boxing session, *t*(12) = -2.9, *p* =.01. TUG times did not statistically improve from pre (7.8 s ± 2.2) to post (7.4 s ± 2.4) exercise, *t*(12) = 1.6, *p* = .13. Participants were able to perform more chair stands after (18.31 ± 6.61) compared to before the training session (16.4 ± 6.4), *t*(12) = 2.4, *p* = .03. **CONCLUSION** An improvement in cognitive and physical function was observed following a single session of boxing training in patients with PD. Performing a single boxing session may lead to improved cognitive function and functional strength throughout the day.

The Influence of Long-Term Transcranial Direct Current Stimulation on Gait Function in Parkinson's Disease

Lidio Lima de Albuquerque, Irwin Munoz, Ashley Mangahas, Merrill Landers, Brach Poston. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: Jack Young, FACSM)
(No relevant relationships reported)

INTRODUCTION: Transcranial direct current stimulation (tDCS) is a non-invasive brain stimulation form capable of improving motor performance in the upper limbs in healthy individuals as well as in Parkinson's disease (PD). One of the major motor symptoms of PD is impaired gait function. PURPOSE: The purpose of this study was to determine the long-term influence of tDCS on gait function in PD. METHODS: The study was a sham-controlled, double-blind, between-subjects design. Ten PD patients were allocated to either a tDCS or a SHAM stimulation group. Each subject performed 9 training similar sessions involving gait training on an instrumented treadmill with online feedback of performance during either tDCS (motor cortex contralateral to their primarily affected leg (dominant hemisphere). Stimulation lasted 20 minutes with a current strength of 2 mA. Gait function was quantified in testing sessions performed before the first training session, after the last training session, as well as two and four weeks post training using an instrumented walkway (Zeno Walkway). The following variables related to gait performance were quantified in the test sessions: gait velocity, step length, stride length, and gait cycle time. The dependent variables were analyzed with a 2 (group) x 4 (test session) ANOVA. RESULTS: For all of the dependent variables, there was no main effect for group (*P* value range: 0.09-0.555), no main effect for testing session (*P* value range: 0.332-.88), and no group x testing session interaction (*P* value range: 0.212-0.786). Main comparison across groups with means and SD for the variables after baseline were: gait velocity (116.22 ± 13.35 vs 123.45 ± 11.38 cm/s); step length (63.31 ± 8.12 vs 65.34 ± 7.22 cm); stride length (126.75 ± 15.87 vs 131.21 ± 14.59 cm); gait cycle time (1.08 ± 0.05 vs 1.06 ± 0.04 s), tDCS and SHAM, respectively. CONCLUSION: These preliminary findings indicate that long-term tDCS applied to the motor cortex does not seem to elicit improvements in gait function in Parkinson's disease. Therefore, tDCS may not be as effective for improving complex, whole body movements compared to upper limb movements involving fine motor control. The first author is a CAPES PhD student grantee (BEX 13509/13-6). This research was supported by an intermural research grant to Brach Poston.

The Behavior of Activity Tracker Usage in Trained Users

Mary M. Yoke, FACSM, Susan E. Middlestadt, David K. Lohrmann, Andrea K. Chomistek, Carol A. Kennedy-Armbruster, FACSM. *Indiana University, Bloomington, IN.*
(No relevant relationships reported)

Purpose: The purpose of this cross-sectional study was to assess the continued activity tracker (AT) usage of a convenience sample of 165 university faculty and staff, determine the prevalence of various behaviors that comprise AT usage, and elucidate the relationship between usage and number of steps per day.

Methods: Participants were recruited by email from five cohorts of faculty/staff in the Ready-to-Move (RTM) coaching program during 2014-2016; all had been previously trained to use ATs as part of the program. In the summer of 2016, an online Qualtrics survey was utilized to discern usage patterns and steps/day; various quantitative analyses were performed using SPSS.

Results: In a sample of 165 trained users (mean age: 47.6 years; 84.8% female), a pattern variable frequency analysis showed that a total of 61.2% of previously trained users continued to do some, or all, of three usage behaviors (wearing, looking, and adjusting) on the day prior to data collection. There was a significant difference in the number of self-reported steps between those who did all 3 usage behaviors yesterday (M = 9032.4) and those who did not (M = 6459.2); $p \leq .005$.

Conclusion: Results showed that about half of trained-users from a physical activity program continued to use their trackers for months or even years after an initial period of coaching, depending on the cohort. This finding contrasts with findings from other studies where AT owners' usage dropped off more dramatically. We also found that those who consistently performed wearing, looking, and adjusting behaviors took significantly more steps than those who did not. The findings from this study indicate that AT use can be sustained in trained users and that the application of three usage behaviors can lead to an increased number of steps/day.

The Effects of Exercise and Cortisol on Cognitive Functioning

Ryan T. Albright, Kelly Massey, Lauren Black, Brittany Haoui, Emily Simonavice, Thomas Toney. *Georgia College, Milledgeville, GA.*
(No relevant relationships reported)

PURPOSE: To examine effects of cortisol and an acute bout of moderate intensity, aerobic exercise on Cognitive Functioning. **METHODS:** A counterbalanced, random selection repeated measures design was implemented for this study. 19 subjects (M=6, F=13; 20.3 +/- 1.6yrs) completed two testing sessions separated by one week. During the first session, participants filled out a PAR-Q, medical health history, and informed consent paper. Saliva samples were taken to measure cortisol levels. The CogState Brief Battery Assessment was administered. Body composition was assessed using DXA. Subjects rested quietly for 30 minutes while listening to soothing music. During the exercise testing, subjects cycled on a Monark cycle ergometer for 20 minutes at a submaximal exercise intensity against 1 kp and self-selected rpm's to elicit at 70% HRR (or RPE of 15). Subjects then performed a cool-down for 5 minutes where

salivary samples were again taken to determine post-treatment cortisol levels. The CogState Brief Battery Assessment was administered a second time. **RESULTS:** Changes in Speed of Performance (SOP) for working memory (WM) was found to be significantly quicker in post cognitive assessments for both resting and exercise trials (Resting $\Delta = 0.044$ +/- 0.0519, p= 0.002; Exercise $\Delta = 0.036$ +/- 0.0516, p= 0.007). However, accuracy of performance (AOP) for WM was only shown to increase in the resting trial (p > 0.05). SOP for Visual Learning (VL) was significantly enhanced only after exercise (Pre = 2.99 +/- 0.0768; Post = 2.96 +/- 0.0892, p= 0.016). Significant differences were not seen in the AOP for VL between the two trials. Subsequent analysis showed that there was no significant interaction between cortisol and the cognitive tests (p > 0.05). **CONCLUSION:** An acute bout of moderate intensity exercise was found to significantly improve the SOP of VL. The SOP during the WM assessment was significantly improved after both the resting and exercise trials. Supported by Georgia College and State University Faculty Grant, 2016.

The Effects of Pilates on Mental Health Outcomes: A Meta-Analysis of Controlled Trials

Karl M. Fleming, Matthew P. Herring. *University of Limerick, Limerick, Ireland.*

(No relevant relationships reported)

Population-based and experimental evidence supports the mental health benefits of exercise among otherwise healthy adults, chronically-ill patients and adults with anxiety and depressive disorders. Mental health benefits have been supported for traditional modes of exercise, including aerobic exercise training. However, the mental health benefits of non-traditional modes of exercise such as yoga, tai chi, and qigong remain understudied. Pilates, an alternative form of exercise, is posited to provide a valuable tool for every individual, regardless of age, gender, capacity, or ability to utilise in order to enhance both physical and mental states. **PURPOSE:** This meta-analysis estimated the population effect size for Pilates effects on mental health outcomes. **METHODS**: Articles published prior to August 2017 were located with searches of Pubmed, Medline, Cinahl, SportDiscus, Science Direct, PsychINFO, Web of Science, and Cochrane Controlled Trial Register using combinations of: *Pilates*, *Pilates method*, *mental health*, *anxiety*, and *depression*. Eight English-language peer-reviewed articles that included both allocation to a Pilates intervention or non-active control condition that lacked exercise training and a validated measure of depressive and/or anxiety symptoms assessed at baseline and after the Pilates intervention were selected. Extracted data included participant and intervention characteristics, anxiety and depression outcomes, and other relevant mental health outcomes, including feelings of energy and fatigue and quality of life. Hedges' d effect sizes were computed, study quality was assessed, and random effects models were used to estimate sampling error and population variance for the observed effects. **RESULTS**: Pilates resulted in significant, large, heterogeneous improvements in depressive ($\Delta=1.27$, 95%CI: 0.44, 2.09, $z=3.02$, $p\leq0.003$) and anxiety symptoms ($\Delta=1.29$, 95%CI: 0.24, 2.33, $z=2.40$, $p\leq0.02$), and feelings of energy ($\Delta=1.49$, 95%CI: 0.67, 2.30, $z=3.57$, p<0.001) and fatigue ($\Delta=0.93$, 95%CI: 0.21, 1.66, $z=2.52$, $p\leq0.012$). Though statistically non-significant, a large increase was also found for quality of life ($\Delta=0.79$, 95%CI: -0.04, 1.61, $z=1.87$, P>0.06). **CONCLUSIONS**: The available evidence supports that Pilates improves mental health outcomes.

Sleep Quality Moderates the Association Between Physical Activity Frequency and Feelings of Energy and Fatigue in Adolescents

Matthew P. Herring[1], Derek C. Monroe[2], Christopher E. Kline[3], Patrick J. O'Connor, FACSM[4], Ciaran MacDonncha[1]. [1]*University of Limerick, Limerick, Ireland.* [2]*University of California Irvine, Irvine, CA.* [3]*University of Pittsburgh, Pittsburgh, PA.* [4]*University of Georgia, Athens, GA.*

(No relevant relationships reported)

Physical activity (PA) can improve sleep quality, low energy, fatigue. Though poor sleep quality may induce feelings of low energy and fatigue, the potential moderating effect of sleep quality on associations between PA and feelings of energy and fatigue among adolescents is unknown. **PURPOSE:** This study examined the moderating effect of sleep quality on associations between PA frequency and feelings of energy and fatigue among adolescents in Ireland. **METHODS:** Adolescents (N=481; 281 male, 200 female) aged 15.1±1.7y self-reported PA frequency (Patient-Centered Assessment and Counselling for Exercise Plus Nutrition; low-, moderate- and high PA frequency were classified as 0-2, 3-4 and ≥5d/wk), the intensity of feelings of energy and fatigue (Profile of Mood States - Brief), and sleep quality (Pittsburgh Sleep Quality Index; criterion for poor sleep was a global score >5). Two-way ANCOVAs examined variation in feelings of energy and fatigue according to the interaction of PA and sleep quality. Standardized mean differences (d) quantified the magnitude of differences. **RESULTS:** A statistically significant two-way interaction between poor sleep status and PA was found for feelings of fatigue ($F_{(2,413)}$=5.91, $p\leq0.003$, η_p^2=0.028). Poor

sleepers with low PA reported greater feelings of fatigue compared to normal sleepers with low PA (d=1.02; 95%CI: 0.60, 1.44), and poor sleepers with moderate PA reported greater feelings of fatigue compared to normal sleepers with moderate PA (d=0.50; 0.17, 0.82). Poor sleepers with low PA reported greater feelings of fatigue compared to both poor sleepers with moderate PA (d=0.44; 0.05, 0.83) and poor sleepers with high PA (d=0.87; 0.46, 1.28). Poor sleepers with moderate PA reported greater feelings of fatigue compared to poor sleepers with high PA (d=0.52; 0.14, 0.91). Poor sleep did not moderate the association between PA and feelings of energy (p>0.57). **CONCLUSIONS:** Sleep quality moderated the association between PA frequency and intensity of feelings of fatigue. Among adolescents with good sleep quality, fatigue scores were invariant across PA frequency categories. However, a dose-response relationship was suggested among adolescents with poor sleep quality, with less fatigue symptoms with greater PA frequency among adolescents with poor sleep quality.

Exercise Referral for Major Depressive Disorder

Chad Rethorst. *UT Southwestern Medical Center, Dallas, TX.*

Reported Relationships: C. Rethorst: *Contracted Research - Including Principle Investigator; NIH.*

PURPOSE: Despite its proven efficacy in research trials, exercise is rarely used as a treatment for Major Depressive Disorder (MDD) in real-world clinical settings. Clinicians cite a lack of training in exercise prescription as a barrier, and indicate a preference for referral to community resources. The purpose of this project was to assess the feasibility and preliminary efficacy of referral from primary care to a research-tested exercise program in the treatment of MDD. **METHODS**: Patients diagnosed with MDD in a primary care clinic were provided a written Exercise Is Medicine prescription by their provider and referred to a research-tested exercise program. Patients met weekly for 12 weeks with an exercise specialist at a community recreation center. In addition, patients received access to the recreation center for 6 months and a Fitbit Charge HR to monitor their activity. Depressive symptoms were assessed on a weekly basis. **RESULTS**: To date, 24 patients have been referred to the program and 17 patients (70.8%) have been enrolled. Patients have attended 73.75% of supervised exercise sessions. Based on Fitbit data, patients have engaged in a mean of 150.66 minutes of moderate-vigorous physical activity per week ("Very Active" minutes + Fairly Active" minutes). Depressive symptoms, as assessed by the PHQ-9, reduced from 9.06 at baseline to 4.76 at last observation (p < 0.01). **CONCLUSIONS**: Patient adherence data indicates exercise referral is a feasible intervention in patients with MDD. Furthermore, patients experienced a significant reduction in depressive symptoms demonstrating the potential of referral to exercise as a viable treatment option.

Factors Influencing Firefighters' Perceptions of Worksite Exercise

Charity L. Lane, O'Dane Brady, Thomas Janus, John M. Mayer, FACSM. *University of South Florida, Tampa, FL.*

(No relevant relationships reported)

PURPOSE: Firefighters have physically demanding jobs resulting in high rates of cardiovascular disorders, musculoskeletal injuries, and disabilities. Many fire service stakeholders advocate worksite exercise to counteract the impact of these disorders in firefighters. However, implementation of worksite exercise is fragmented in this population, and barriers and facilitators have not been fully explored. The purpose of this study was to assess factors influencing firefighters' perceptions about implementation of worksite exercise. **METHODS**: A cross-sectional study was conducted in career firefighters (n = 181; 23 F, 158 M; age 35.3 +/- 8.6 yr) from 3 fire departments in the Tampa Bay region of Florida. The participants completed a 45-item implementation questionnaire after a 12-month worksite exercise injury prevention trial. The questionnaire inquired about implementation outcomes, such as uptake, adherence, access, resources, and stakeholder engagement. Relationships were assessed between items responses and independent variables, including department, age, BMI, physical activity, and low back pain history. **RESULTS**: Significant departmental differences were noted for perceptions in leadership support for exercise (p = 0.03), fitness personnel availability (p < 0.001), regular off-duty exercise (p = 0.03) and gym memberships (p = 0.01). Respondents with lower BMI values were more likely to report that regular exercise was important (p = 0.04). Younger respondents were more likely to have gym memberships (p = 0.003) and to report sufficient fitness personnel availability (p = 0.01). Respondents without low back pain history were more likely to exercise off-duty (p = 0.05). No significant relationships were observed between questionnaire responses and physical activity. **CONCLUSIONS**: Intrapersonal, interpersonal, and institutional factors influence firefighters' perceptions about the implementation of worksite exercise. Stakeholder engagement (leadership support) and available resources vary across departments and

impact implementation. Potential barriers related to these factors need be addressed to successfully implement worksite exercise programs to reduce the adverse effects of injuries, illnesses, and subsequent disabilities in firefighters.

WEDNESDAY, MAY 30, 2018

B-02   Highlighted Symposium - **The Past, Present and Future of ACL Injury Prevention: Biomechanics Screening and Neuromuscular Interventions that Work!**

Wednesday, May 30, 2018, 1:00 PM - 3:00 PM
Room: CC-101AB

This symposium will highlight previous and current work related to reducing the risk of anterior cruciate ligament (ACL) injuries in athletes. The future of implementing evidence based lab and field screening with targeted neuromuscular interventions will be discussed.

Focused Interventions for Special Populations
Jeffrey B. Taylor. *High Point University, High Point, NC.*
(No relevant relationships reported)

Anterior cruciate ligament injury prevention programs (ACL-IPP) are generally successful at reducing injury rates; however, these ACL-IPP are more effective with women's soccer (SOC) than basketball (BB) athletes. Purpose: To compare the biomechanical profiles and responses to an ACL-IPP in women's BB and SOC players. Methods: 87 single-sport athletes (38 BB, 49 SOC) were cluster randomized into intervention (6-week ACL-IPP) and control groups. 3D biomechanical analyses of drop vertical jump (DVJ), double- (SAG-DL) and single-leg (SAG-SL) sagittal, and double- (FRONT-DL) and single-leg (FRONT-SL) frontal plane jump landing tasks were tested before and after the intervention. Baseline peak angles, excursions, and joint moments were analyzed using repeated measures MANOVA, while delta (Δ) scores of the same biomechanical measures were analyzed using two-way MANCOVAs controlling for pre-test scores. Results: At baseline, BB players landed with less hip and/or knee excursion during all tasks (p<0.05) except for the SAG-SL task. The FRONT-SL task elicited the most distinct differences, including decreased hip adduction angles (mean difference: 5.0±1.3°, p<0.001), increased hip internal rotation excursion (mean difference: 2.8±0.9°, p=0.003), greater knee abduction moments (mean difference: 0.07±0.02 N·m/kg·m, p=0.003) and lower hip adduction moments (mean difference: 0.15±0.05 N·m/kg·m, p=0.001) in basketball players. After completing the ACL-IPP, the basketball intervention group exhibited a lower reduction in peak knee abduction angles (Δ=0.9±3.5°) compared to the basketball control group (Δ=2.6±3.0°, p=0.004) and soccer intervention group (Δ=1.5±3.4°, p=0.01) during the SAG-SL. During FRONT-SL, the basketball intervention group exhibited greater knee flexion excursion (Δ=1.5±4.5°) after training than the control group (Δ=-1.8±5.5°, p=0.01). Conclusion: Soccer players exhibit a more protective landing strategy than basketball players, yet women's basketball and soccer players largely exhibit similar biomechanical adaptations to ACL-IPP. These data indicate that ACL-IPP may need to account for sport-specific biomechanics, including technique training that emphasizes soft landings during basketball-specific frontal plane and single-leg jumping activities.

457   May 30 1:55 PM - 2:10 PM
Modeling of ACL Injury Mechanism
Nathaniel A. Bates. *Mayo Clinic, Rochester, MN.*
(No relevant relationships reported)

Invasive biomechanical techniques and the unpredictable nature of anterior cruciate ligament (ACL) injury events limit direct in vivo investigations. Instead, researchers have developed in vitro models such as the mechanical impact simulator to recreate ACL injury events. Purpose: To quantify the biomechanical response of the ACL and medial collateral ligament (MCL) in a simulated landing environment capable of producing ACL ruptures consistent with clinical injury presentation. Methods: 39 cadaveric full lower extremity specimens (19M:20F) completed testing with impulse forces delivered to sole of the foot in the mechanical impact simulator. Pneumatic pistons mounted on the mechanical impact simulator generated knee abduction moments (KAM), internal tibial rotation moments (ITR), anterior tibial translation

forces (ATS), hamstrings, and quadriceps forces <1 sec prior to impulse load delivery. KAM, ATS, and ITR magnitudes corresponded to in vivo recorded kinetics from athlete cohorts exhibiting high, medium, low, and no relative risk for ACL injury. Each kinetic input was independently randomized and a series of impulses was repeated on each specimen until hard or soft tissue failure occurred. ACL and MCL strains were recorded with implanted sensors, while a 6-axis load cell recorded forces and torques at the knee. Results: 87% of specimens produced ACL failures during simulation, with 92% presented at the femoral insertion or midsubstance and concomitant MCL failures in 31%. Peak strain was greater in the ACL (15.3 ± 8.7%) than the MCL (5.1 ± 6.3%; P < 0.01). Overall ACL strain across all external loading conditions was 3.5% greater in females than males (P = 0.04), but no sex differences were noted in the MCL (P = 0.36). Under identical external loading conditions, female specimens also exhibited larger KAM moments than males (P = 0.04). Conclusion: The mechanical impact simulator is the first in vitro model to reliably create ACL ruptures consistent with clinical presentation. Female specimens were more susceptible to ACL injury and KAM than males, which supports the established association between sex, KAM, and ACL injury risk. Future iterations of this model could be manipulated to investigate efficacy of injury prevention interventions and ACL reconstructions during simulated ACL injury events.

Static And Dynamic Cognitive Task Performance In Youth And Collegiate Athletes With Concussion
Anna N. Brilliant[1], William P. Meehan, III[1], David R. Howell[2].
[1]*Boston Children's Hospital, Waltham, MA.* [2]*Children's Hospital Colorado, Aurora, CO.*
(No relevant relationships reported)

PURPOSE: To determine if individuals with a concussion demonstrate worsened cognitive task performance while standing still or walking, relative to uninjured controls.
METHODS: Athletes seen at a local sports medicine clinic and college were recruited. Participants were diagnosed with a concussion by a physician and assessed within 10 days of injury. All participants were asked to stand still for 30 seconds while completing a cognitive task and to walk along a 16m pathway while completing the same cognitive task. Each condition was repeated five times. One of three different cognitive tasks were completed on each trial, including subtraction by 7s from a 2-digit number, spelling five-letter words backwards, and reciting the months in reverse order from a random month. Cognitive task accuracy and the number of responses were recorded for both conditions. We used ANCOVAs to evaluate the effect of group (concussion vs. control) on cognitive accuracy and total number of responses, while controlling for the independent effect of age, gender, and prior concussion history.
RESULTS: Two hundred and eighteen participants completed the study (n=76 with concussion, 5.5±3.0 days post-injury, 51% female, 16.7±3.3 years of age; n=142 controls, 31% female, 18.0±1.9 years of age). Controlling for the effect of age, gender, and prior concussion history, the concussion group was significantly less accurate than the control group while walking (89.3±15.1% vs. 95.0±6.0%; p=0.04) but similar while standing (93.6±9.9% vs. 96.4±5.0%; p=0.15). The concussion group had fewer total responses than the control group while standing (34.8±14.3 vs. 44.5±17.3 total responses; p < 0.001) and walking (22.2±7.7 vs 32.4±12.6 total responses; p < 0.001).
CONCLUSIONS: Athletes displayed lower cognitive task accuracy rates after concussion compared to controls while walking, but similar levels of accuracy while standing. Walking during cognitive processing may be a more accurate representation of sport-like activity than movement or cognitive based assessments performed in isolation. Following concussion, understanding the ability to perform a cognitive task while walking may be crucial when determining readiness to return to full athletic participation, as deficits may not be otherwise identified.

Persistent Vestibular Symptoms and Impairment following Concussion in Adolescents

Aaron M. Sinnott[1], Valerie L. Reeves[2], Cyndi L. Holland[2], Nicholas A. Blaney[2], Andrew M. Rosse[2], Hannah B. Blitzer[2], R.J. Elbin[3], Michael W. Collins[2], Anthony P. Kontos[2]. [1]University of Pittsburgh, Pittsburgh, PA. [2]University of Pittsburgh Medical Center, Pittsburgh, PA. [3]University of Arkansas, Lafayette, AR.
(No relevant relationships reported)

Vestibular impairment following concussion is associated with higher symptom burden, worse cognitive performance, and longer recovery. However, the role of persistent vestibular symptoms and impairment on these outcomes among adolescents is unknown. **PURPOSE:** Determine the role of persistent vestibular symptoms and impairment following concussion on recovery time and clinical outcomes among adolescents. **METHODS:** 50 (F-22/M-28) adolescents aged 12-20 years completed the Vestibular/Ocular Motor Screening tool (VOMS), Immediate Post-concussion Assessment and Cognitive Testing (ImPACT), and Post-concussion Symptom Scale (PCSS) at 0-10 and 11-21 days after concussion. Participants were grouped into: 1) persistent vestibular (PV), 2) vestibular improvement (VI), and 3) no vestibular (NoV). A 3 (group) X 2 (time) ANOVA with Bonferroni correction was performed for cognitive and symptom scores, and one-way ANOVA was performed for recovery time. **RESULTS:** Participants included 17 (35%) PV, 12 (25%) VI, and 20 (40%) NoV with one being excluded based on outlier analyses. Results supported group differences on PCSS at 11-21 days (p=.004), with PV (29.0±24.9) reporting higher symptoms than VI (13.0±15.5; p=.045) and NoV (5.45±10.0; p=.005). The VP group took longer to recover (34.9±11.6 days, p=.03) than the NoV (22.9±14.9 days) group. There were no significant group by time interactions for cognitive scores. However, all groups improved on verbal (p=.007) and visual (p=.03) memory, visual motor speed (p=.02), and reaction time (p=.03) from 0-10 to 11-20 days. Females were 5.7x more likely than males to be in the PV versus NoV group (p=.02, *95% CI*=1.3-24.6). **CONCLUSION:** Persistent vestibular symptoms and impairment following concussion may play a role in higher symptom burden and prolonged recovery that warrants attention from clinicians. Females may be more likely to experience these persistent vestibular symptoms and impairment.

Influence Of Motion Sensitivity On Baseline Symptoms, Cognitive, And Vestibular/oculomotor Scores In Adolescent Athletes

R.J. Elbin[1], Mallory McElroy[1], Katie Stephenson-Brown[1], Anthony Kontos[2]. [1]University of Arkansas, Fayetteville, AR. [2]University of Pittsburgh Medical Center, Pittsburgh, PA.
(Sponsor: Dr. Matthew Ganio, FACSM)
(No relevant relationships reported)

Researchers report that a history of motion sensitivity is associated with vestibular/oculomotor impairment and symptoms in non-concussed collegiate athletes. However, previous research did not include other commonly used baseline concussion assessments (e.g., neurocognitive, symptoms) or adolescent athletes. **PURPOSE**: To examine the effects of motion sensitivity on baseline neurocognitive, symptom, and vestibular/oculomotor scores in high school athletes (HS). **METHODS**: A total of 423 HS athletes (15.04 $\pm$ 1.24 years; 97 females - 24%) completed the Motion Sickness Sensitivity Questionnaire (MSSQ), the Immediate Post-concussion Assessment and Cognitive Testing (ImPACT), Post-Concussion Symptom Scale (PCSS), and Vestibular/Ocular Motor Screening tool (VOMS) at baseline. Athletes were categorized into three groups: 1) NONE- MSSQ score=0 (33%, 142/421), 2) LOW-MSSQ score >0<7.07 (34%, 144/421) or 3) HIGH- MSSQ score >7.20 (32%, 135/421) based on median split of MSSQ scores >0. A series of ANOVAs were performed to examine between group differences on VOMS item scores, near-point convergence (NPC) distance, cognitive testing, and symptoms. A series of chi-square analyses with odds ratios (ORs) were used to analyze the association of motion sensitivity to clinical cutoffs on VOMS (i.e., ≥2 on any item) and NPC distance (≥ 5cm). **RESULTS**: A total of 34% (150/441) and 30% (18/62) of athletes exceeded clinical cutoffs on at least one VOMS item and NPC distance, respectively. Total PCSS scores were greater for the HIGH compared to the NONE group (p=.003). There were no differences between motion sensitivity groups on cognitive performance (p >.05). The HIGH group had higher total VOMS scores than the NONE group for horizontal saccades, horizontal vestibulo-ocular reflex (VOR), vertical VOR, and visual motion sensitivity (p < .01). The HIGH group was 2.94x (p≤ .001) more likely than the NONE group to exceed clinical cutoffs on VOMS. **CONCLUSION**: Motion sensitivity was associated with scores above clinical cutoffs on VOMS. Sports medicine professionals should assess motion sensitivity in athletes at baseline to inform better SRC care.

489   Board #4   May 30 1:00 PM - 3:00 PM

Longitudinal Multimodal Assessment To Quantify Concussion Recovery Trajectory Among Youth Athletes

David R. Howell[1], Gregory D. Myer[2], Anna N. Brilliant[3], Kim Barber Foss[2], William P. Meehan, III[3]. [1]Children's Hospital Colorado, Aurora, CO. [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH. [3]Boston Children's Hospital, Waltham, MA. (Sponsor: Louis R. Osternig, FACSM)
(No relevant relationships reported)

PURPOSE: Our aim was to evaluate a quantitative and multifaceted approach for determination of concussion recovery among youth athletes across different functional domains.
METHODS: Youth athletes 8-18 years of age and diagnosed with a concussion were tested 3 times: within 10 days of injury (T1), approximately 3 weeks post-injury (T2), and after clinical recovery, defined as symptom resolution and return to sport clearance (T3). Control participants completed the protocol in similar temporal increments as concussion participants. All participants completed a multifaceted protocol that included a symptom inventory (PCSS), a dual-task gait evaluation, an electroencephalography (EEG)-based auditory oddball task, and objective eye tracking. Repeated measures ANCOVAs were used to evaluate between group differences with sex, age, and prior concussions as covariates. We also examined if the rate of change across time for each outcome variable was different between groups using analysis of response profiles for longitudinal data.
RESULTS: Sixty-seven athletes participated: 36 post-concussion (age= 14.0±2.6 years; 44% female) and 31 controls (age=14.6±2.2 years; 39% female). Concussion symptoms were significantly higher for the concussion group compared to controls at T1 (PCSS=31.7±18.8 vs. 1.9±2.9; p<0.001) and T2 (PCSS=10.8±11.2 vs. 1.8±3.6; p=0.001), but resolved by T3 (PCSS=1.7±3.6 vs. 2.0±3.8; p=0.46). The concussion group walked significantly slower during dual-task gait than controls at each of the three tests (0.83±0.19 vs. 0.95±0.15 m/s; p=0.049). We found no significant differences between groups for the EEG oddball task or objective eye tracking measures. The EEG auditory oddball connectivity recovery trajectory differed significantly between groups, where the concussion group scores decreased and the control group scores increased across the testing timeline (χ2=14.1, p=0.001).
CONCLUSIONS: Despite symptom resolution, athletes with concussion displayed altered dual-task gait speeds at their final visit and their auditory oddball connectivity scores worsened throughout the test timeline. A multimodal and objective approach to concussion monitoring may support clinicians in the detection of brain function deficits that are undetectable with standard clinical assessments.

Association Between Sleep Quality and Symptoms Following a Sports-Related Concussion in the Pediatric Population

Aaron J. Zynda[1], Jane Chung[1], Shane M. Miller[1], Meagan J. Sabatino[1], Chan-Hee Jo[2], Cason Hicks[3], Nyaz Didehbani[3], Kathleen Bell[3], Munro Cullum[3]. [1]Texas Scottish Rite Hospital for Children, Plano, TX. [2]Texas Scottish Rite Hospital for Children, Dallas, TX. [3]University of Texas Southwestern Medical Center, Dallas, TX.
(No relevant relationships reported)

PURPOSE: To determine if there is an association between reported sleep quality and concussion symptoms in pediatric athletes. **METHODS:** A review of prospectively collected data from subjects diagnosed with a sports-related concussion between October 2015 and June 2017, and enrolled in the North Texas Concussion Network Prospective Registry (Con-Tex), was performed. Subjects were treated at one of four outpatient clinics, in North Texas, specializing in concussions. Records were reviewed for sleep quality, indicated by composite scores on the Pittsburgh Sleep Quality Index (PSQI). According to PSQI guidelines, good sleep quality (GOOD SLEEP group) is indicated by a composite score of ≤5 (possible total=21), and poor sleep quality (POOR SLEEP group) by a score of >5. Demographics, symptoms, and total symptom score, as assessed by the Sports Concussion Assessment Tool 3 (SCAT3) at initial visit and 3-month follow-up, were compared between groups. **RESULTS:** Of 356 eligible subjects, 180 (50.6%) were girls and 176 (49.4%) were boys, with a mean age of 14.38 years (7-18). 261 subjects had a PSQI composite score of ≤5 at their initial visit (GOOD SLEEP), while 95 had scores >5 (POOR SLEEP). At initial visit, the POOR SLEEP group had a higher mean PSQI composite score (8.7) and total symptom score on SCAT3 (39.2) compared to the GOOD SLEEP group (2.6 and 20.4, respectively, p<.0001). The POOR SLEEP group also had a higher mean PSQI composite score (5.7) and total symptom score (12.2) at 3 months compared to the GOOD SLEEP group (3.0 and 4.2, respectively, p<.0001), although both groups improved. Additionally, subjects in the POOR SLEEP group reported more fatigue, drowsiness, and trouble falling asleep on the SCAT3 at both the initial visit and 3-month follow-up when compared to the GOOD SLEEP group (p<.005). Gender was also significantly different between the two sleep groups with more girls included in the POOR SLEEP

group than boys (61.1% vs 38.9%, respectively, p=.017). **CONCLUSIONS:** Poor sleep was strongly associated with increased symptom burden within pediatric athletes both at initial visit and 3-month follow-up post-concussion. Clinicians should include an evaluation of sleep quality in young athletes treated for a sports-related concussion.

Functional Near Infrared Spectroscopy Identifies Changes in Cognitive Workload Following Pediatric Concussion

christina lin master[1], Eileen Storey[1], Lei Wang[2], Olivia Podolak[1], Matthew Grady[1], Andrew Mayer[3], Hasan Ayaz[2]. [1]*The Children's Hospital of Philadelphia, Philadelphia, PA.* [2]*Drexel University, Philadelphia, PA.* [3]*Mind Research Network, Albuquerque, NM.*
(No relevant relationships reported)

PURPOSE: To determine if functional near infrared spectroscopy (fNIRS), a noninvasive imaging modality detecting oxygenation changes reflective of cognitive workload, distinguishes physiologic differences between concussion subjects and healthy controls during King-Devick (KD) testing, a rapid number naming task **METHODS**: We recruited 57 cases, ages 7 to 21 years, 51% female, and 17 controls, ages 10-21 years, 47% female from a subspecialty referral concussion program for this prospective case control study where the subjects performed the KD test while wearing a fNIRS device consisting of a headband which records anterior prefrontal cortex oxygenation changes with 4 optodes at a 4Hz sampling rate. The main outcome measures were KD times, symptom provocation and oxygenation change during KD testing. **RESULTS**: Concussion subjects demonstrated longer times and greater oxygenation change on fNIRS compared to healthy controls. However, within the group of concussion subjects, KD times did not distinguish between those with and without symptom provocation upon testing. In contrast, fNIRS was able to detect oxygenation change differences between these two subgroups, with the symptomatic group exhibiting greater oxygenation change with testing.
CONCLUSIONS: Based on our data, the prolongation of KD times observed following concussion has physiologic correlates with increased cognitive workload. Among subjects with concussion, KD times did not distinguish between those with and those without symptom provocation upon testing. In contrast, fNIRS was able to differentiate between these two subgroups of concussion, with symptomatic subjects exhibiting a pattern of greater cognitive workload compared to asymptomatic. fNIRS has utility in detecting subclinical differences in cognitive workload in concussion. In addition, our data supports the concept that the physiologic basis for symptom provocation in concussion may be related to cognitive overload.

fNIRS with Symptom Provocation on KD testing

The Effect of Anxiety on Baseline Concussion Assessment in Adolescent Females

Christopher P. Tomczyk, Jody Langdon, George Shaver, Tamerah Hunt, FACSM. *Georgia Southern University, Statesboro, GA.* (Sponsor: Tamerah Hunt, FACSM)
(No relevant relationships reported)

Anxiety occurs in approximately 15-20% of adolescent females. The potential for the interaction between anxiety and impaired cognition commonly assessed by concussion batteries require clinicians and researchers to examine the effect of anxiety on baseline concussion test scores. **PURPOSE**: Examine the effects of trait anxiety on concussion baseline testing in adolescent female athletes. **METHODS**: Prior to their competitive season, 35 adolescent female athletes ranging from 13-18 years of age (mean age: 15.66 ± 1.28) were administered the Immediate Post-Concussion Assessment and Cognitive Test (ImPACT) and the State Trait Anxiety Inventory during baseline testing. Participants were divided into groups, based off a previously validated T-Anxiety

cutoff score of 35, which was derived from the literature (low n=18, high n=17). ImPACT composite scores served as dependent variables. Multiple one-way ANOVAs were calculated to examine group differences on ImPACT composite scores. All statistical analyses were conducted using SPSS 23.0 (IBM, Armonk, NY). Significance level was set *a priori* at 0.05 with a Bonferroni correction (p<.008) **RESULTS:** Significant differences were found between high and low trait anxiety groups for total symptom score ($F_{(1, 33)}$ = 9.58, p = .004; High: 12.30 ± 10.57, Low: 4.12 ± 5.57), and composite visual motor speed ($F_{(1, 33)}$ = 10.11, p = .003; High: 37.31 ± 4.96, Low: 40.31 ± 5.82). Athletes with high trait anxiety reported more symptoms and performed slower on visual motor speed. No statistical differences existed for composite: verbal memory, visual memory, reaction time and impulse control (p>0.05). **CONCLUSION:** This study provides preliminary evidence that adolescent females with high trait anxiety during baseline concussion assessment present with higher symptoms and slower visual motor speed. In order to subscribe to a holistic approach of concussion management, anxiety needs to be incorporated into the clinical decision process. Without examining adolescent levels of anxiety the clinician may be vulnerable to making inaccurate interpretations of baseline test scores.

Concussion Recovery In Adolescents: The Influence Of Race And Sex On Neurocognition

Seema S. Aggarwal, Summer D. Ott, Nikhil S. Padhye. *The University of Texas Houston Health Science Center, Houston, TX.*
(No relevant relationships reported)

An estimated 500,000 to 800,000 concussions occur annually among U.S. high school athletes. However, the association of sex and race/ethnicity with recovery remains unclear. **PURPOSE:** The aim of this study was to examine influence of sex and race/ethnicity on the Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT) in adolescents. **METHODS:** This was a retrospective cohort study of adolescents, 13-19 years old, evaluated for an acute concussion (≤10 days from injury) at a university-based concussion clinic. General linear models (GLM) were used to examine race and sex interaction on post-concussion ImPACT composite scores on verbal memory, visual memory, visual motor, reaction time, and symptoms. **RESULTS:** A total of 227 charts that met inclusion criteria. There were no differences in the distributions of age and sex. The sample (N = 227) was primarily male (75%), and the median age was 15 years. Minorities (Blacks and Hispanics) constituted 46% of the sample. White females had the longest recovery time (median 27.5 days) and minority males had the shortest recovery time (median 11 days). Univariate tests indicated that the interaction of sex and race was statistically significant for visual memory ($F(3,223)$ = 3.83, p = .011, η_p^2 = .049), reaction time ($F(3,223)$ = 2.87, p = .037, η_p^2 = .037), and symptoms ($F(3,223)$ = 9.46, p < .001, η_p^2 = .113). On these ImPACT subscales, White females had the poorest performance, and minority males had the best performance. Compared to the scores for minority males, ImPACT scores for White females on these subscales were as follows: visual memory (70.67±14.1 vs. 60.95±14.5), reaction time (.67±.17 vs. .76±.19), and symptom scores (12.19±14.5 vs. 28.29±22.04). Multivariate tests for the main effect of the interaction of race and sex ($F(15,663)$ = 3.00, p = <.001, η_p^2 = .06) were statistically significant. **CONCLUSION:** This study found that both race and sex appear to influence concussion recovery. White females took longest to recover and had worse ImPACT visual memory, reaction time, and symptoms scores than White males, minority females, and minority males. In contrast, minority males had shorter recovery times and better ImPACT scores on these subscales than all other race-sex categories.

Multidimensional Stress influencing Mental Health of Chinese Professionals and the Health Promotion of Physical Activity

Chunmei Zheng. *Shandong University, Jinan, China.*
(No relevant relationships reported)

Social and economic changes in China have seriously influenced the mental health of citizens. Although work stress has been studied by scholars within China and

abroad. little is known about multidimensionality of stress factors and their effects among various populations. **PURPOSE:** The purpose of this study was to examine the influence of multidimensional stressors on the mental health in Chinese adults and identify the impact of physical exercise on mental health. **METHODS:** Participants for the survey were randomly recruited from Jinan institutions, parks, squares and streets. A total of 1000 questionnaires were distributed, of which 819 questionnaires were returned (response rate 81.9%), 110 invalid excluded. A total of 709 valid questionnaires were used for the data analysis. Using SPSS version 16.0, descriptive statistics, T-test, Multivariate Analysis of Variance (MANOVA) and hierarchical regression analysis were used to analyze the data. **RESULTS:** Analysis of variance ($P = 0.046 < 0.05$) indicated that the stress levels of professionals across the ranks are significantly different. Descriptive Statistic analysis showed that the main sources of stress across different occupational groups are work (35.8%), education (36.1%), and health (18.1%). MANOVA (Wilkslambda Criterion = 0.86) showed that satisfaction, emotional balance, self-awareness, and interpersonal relationship are significantly different among different occupations ($p < 0.01$, respectively). T-test indicated that there was significant differences in life satisfaction, emotional balance, self-awareness, and interpersonal relationships between physical activity and non-physical activity group (all $p < 0.05$). **CONCLUSION:** It can be concluded that China has distinct social classes, whose mental health conditions vary; The stress levels of professionals across the ranks are significantly different; Work, education, and healthcare were identified as main sources of stress among working professionals; Respondents who regularly engaged in physical activity far better in terms of mental health compared to the non-exercise group. Supported by the China Scholarship Council; Shandong Soft Science. [2015RKE27016]; National science and technology basic work. [2015FY111600].

Effects of Voluntary Wheel Running Exercise on the Depressive-Like Behavior and Circadian Alterations of Neuroendocrine Induced by Chronic Unpredictable Mild Stress in Rats

YAN ZHAO. *CHENGDU SPORT UNIVERSITY, CHENGDU, China.*

(No relevant relationships reported)

PURPOSE: To investigate effects of voluntary wheel running exercise on circadian rhythmic alterations of plasma hormone and peptide induced by Chronic Unpredictable Mild Stress (CUMS).
METHODS: Ninety male SD rats were divided into three groups: CUMS, EC (Exercise plus CUMS), and Con (Control) group. Rats were under a 12h/12h light/dark cycle (19:00 light up; 07:00 light off). The CUMS procedure consists of a variable sequence of 11 stressors. Rats were randomly exposed to two stressors every day for 3 weeks. Rats in EC group were trained in a voluntary wheel running program for a total of 8 weeks, plus CUMS procedure during the last three weeks. Blood samples were collected at each of six time points (ZT1 and 5, 9, 13, 17, 21). Plasma concentrations of corticosterone (CORT), melatonin (MT) and vasoacutive intestinal peptide (VIP) were detected by ELISA. Data were analyzed by one-way ANOVA, and the circadian rhythms by single cosinor method.
RESULTS: Rats in Con group showed robust circadian rhythms in plasma CORT, MT and VIP. Rats in CUMS group showed an obvious disorder in circadian rhythm of plasma CORT, including phase advance and decrease in amplitude, and markedly blunted circadian rhythm. There also showed a markedly blunted circadian rhythm and decreased levels of plasma melatonin in CUMS rats compared to Con rats. VIP still has 24-hour rhythm, but the amplitude was significantly lower than that of the Con group, peak phase also delayed for 6 hours, expression was significantly higher than that of the Con group. 8-week voluntary wheel running exercise can significantly inhibit the disturbance of MT, CORT and VIP circadian rhythm, and also the abnormal expression of these hormones secretion.
CONCLUSION: CUMS induce these peptides and hormones desynchronized from SCN and voluntary wheel running exercise can rescue the disturbed circadian rhythms of these synchronizers.
Supported by the Innovation Project of Sports Medicine and Health Institute of Chengdu Sport University

A Comparison Of Stress Levels And Coping Skills Of Collegiate Freshmen Athletes And Non-athletes

Jessica E. Jochum, Nicole Vetroczky, Marina Kuchenberg, Lauren Dybwad. *University of Indianapolis, Indianapolis, IN.* (Sponsor: Amy Jo Sutterluety, FACSM)

(No relevant relationships reported)

Despite knowing the factors that increase stress levels in collegiate freshmen, there is limited research that compares the stress levels and coping mechanisms between collegiate, freshmen athletes and freshmen non-athletes. **PURPOSE:** To investigate differences in perceived stress levels and coping mechanisms in collegiate freshmen athletes and non-athletes. **METHODS:** One hundred and forty-seven NCAA Division II freshmen ($n_{athlete} = 68$, $n_{non-athlete} = 69$) ($n_{female} = 86$, $n_{male} = 49$) completed three self-report questionnaires: Perceived Stress Scale (PSS-10), Brief COPE, and demographic information questionnaire. The 10-item PSS-10 was used to measure the degree to which an individual appraises his/her situation as stressful. The 28-item Brief COPE was used to measure frequency of positive, neutral and negative coping mechanisms on fourteen different scales. An alpha level of $p \leq .05$ was set for statistical significance. An independent t-test was conducted to compare mean scores of the PSS-10, and Mann-Whitney U tests were used to compare Brief COPE scales. A Spearman's rho correlation was used to determine relationships between perceived stress and coping mechanisms. **RESULTS:** Analysis revealed no statistical difference between athletes and non-athletes on perceived stress or coping mechanisms. All participants rated a high level of perceived stress on the PSS-10, (females 29 (SD = 6) males 26 (SD = 5)) out of 40 possible points, yielding a statistical difference between genders, $t(133) = -3.117$, $p = 0.002$. Of the 14 coping strategies measured, four were found to be statistically significant for females: emotional support ($p = 0.001$), instrumental support ($p = 0.03$), venting ($p = 0.001$), and self-blame ($p = 0.05$). A positive correlation exists between increased stress levels and eight coping mechanisms. The two highest correlations were disengagement r_s =.422, p<.001 and self-blame r_s =.523, p<.001. **CONCLUSION:** No difference was observed in perceived stress levels between collegiate freshmen athletes and non-athletes, all freshmen perceive high levels of stress. Females perceive higher levels of stress than males, and tend to select negative coping mechanisms. The higher levels of perceived stress, the more likely the person would be to use disengagement and self-blame as coping mechanisms.

Relationships Among Physical Fitness, Sleep-wake Behavior, And Hemodynamic And Cortisol Responses To Stress In Women

Shannon K. Crowley, Julia Rebellon, Abigail J. Leonard, Christina Huber, Lyndsay Wolfe, Andrea Tobar, Sierra Hayden, Daniel Henderson, Meir Magal, FACSM. *North Carolina Wesleyan College, Rocky Mount, NC.*

(No relevant relationships reported)

PURPOSE: Dysregulation in the physiological stress response has been proposed as one mechanism by which disturbed sleep increases risk for the development

Abstracts were prepared by the authors and printed as submitted.

of psychiatric diseases. Being physically fit has been associated with improved sleep. However, to date, there has been limited investigation of physiological stress responding as a mediating factor in the relationship between physical fitness and improved sleep, and even fewer which have investigated this relationship in women while experimentally controlling for the influence of the ovarian cycle on the physiological stress response. This study aimed to investigate relationships among physical fitness, sleep disturbances, and physiological responses to psychosocial stress in women. **METHODS:** Following a two-tiered screening process, 30 healthy women (18-45y) who were medication-free and had regular menstrual cycles completed: (1) enrollment visit, (including mood and sleep assessment and assessment of cardiorespiratory fitness via maximal oxygen consumption during exercise); (2) one-week sleep monitoring period (objective and subjective measures of sleep-wake behavior); and (3) psychosocial stressor protocol for the collection of heart rate (HR) and cortisol stress responses. Psychosocial stress testing sessions occurred during the follicular phase of the menstrual cycle to control for hormone fluctuations which have been shown to influence the physiological response to stress. **RESULTS:** Higher levels of physical fitness were significantly associated with reduced objectively measured wake after sleep onset (WASO) duration ($r = -.38$, $p = 0.04$), higher self-reported sleep quality (higher scores reflect poorer sleep quality; $r = -.37$, $p = 0.05$), and lower HR during the psychosocial stressor ($r = -.39$, $p = 0.04$). Consequently, lower self-reported sleep quality was significantly associated with a higher HR during the psychosocial stressor ($r = .41$, $p = 0.02$), and increased WASO duration was significantly associated with blunted cortisol responses to the psychosocial stressor ($r = -.41$, $p = 0.04$, $n=26$). **CONCLUSIONS:** Results suggest that, in women, physical fitness may be protective against the deleterious effects of stress via improved sleep-wake behavior.

Correlations Between Serum Biomarkers Of Stress And Subjective Measures Of Well-being In Collegiate Swimmers

Connor A. Kuremsky[1], Wang Haoyan[1], Neil M. Johannsen[1], Jack Marucci[1], Shelly Mullenix[1], Brian A. Irving[1], Rick L. Sharp, FACSM[2], Brian Harrell[3], Guillaume Spielmann[1]. *[1]Louisiana State University, Baton Rouge, LA. [2]Iowa State University, Ames, IA. [3]Baton Rouge General Sports Medicine, Baton Rouge, LA.* (Sponsor: Rick Sharp, FACSM)
(No relevant relationships reported)

Collegiate student-athletes experience prolonged physical, psychological and academic stressors, putting them at risk for impaired athletic performance and overall well-being. Practical feasibility undermines the use of objective physiological measures of stress, such as serum cortisol, alternatively favoring subjective measures of well-being by using self-reported questionnaires. **Purpose**: To determine the relationship between serum cortisol and various subjective measures of well-being in NCAA D1 swimmers over a 6-month training period. **Methods**: Early morning resting serum samples were collected from sixteen NCAA Division 1 swimmers (8 M, 8 F: 19.81 ± 0.65 yrs) at 2 timepoints (early season and immediate post-season), and an additional mid off-season timepoint was collected in a subset of 10 swimmers. Self-reported subjective measures of well-being were collected at each timepoint by using questionnaires for overtraining (DALDA), sleep quality (PSQI) and mood state (AD-ACL). The gold-standard physiological biomarker of stress, serum cortisol, was measured using commercially-available ELISA kits (R&D Systems). Pearson's correlation coefficients determined linear correlations between serum cortisol concentration and questionnaire responses ($\alpha=0.05$). **Results**: At the pre-season timepoint, higher serum cortisol concentrations (138.99 ± 33.9 ng/mL) were observed in swimmers reporting less calmness ($r=-0.79$, $p=0.006$), while this association disappeared at the early season timepoint ($p=0.935$). At the post-season timepoint, serum cortisol concentrations (123.3 ± 76.7 ng/mL) were negatively correlated with calmness ($r=-0.46$, $p=0.035$) and tension ($r=-0.45$, $p=0.041$). Surprisingly, however, swimmers reporting greater symptoms of overtraining at the post-season timepoint had reduced cortisol concentration ($r=-0.44$, $p=0.046$). **Discussion**: Subjective questionnaires have been used as a surrogate to objective biomarkers of stress, such as serum cortisol concentration. Although the results obtained from self-reported questionnaires were highly correlated with serum cortisol levels during periods of high academic and athletic stress (post-season), the correlation between cortisol concentration and mood states did not remain consistent throughout the competitive season.

Resting Heart Rate Variability Moderates a Relationship Between Attentional Bias and Stress Response

Derek C. Monroe[1], Zachary Rader[2], Matthew P. Herring[3], Jonathan Golden[2]. *[1]University of Califorina--Irvine, Irvine, CA. [2]Georgia College & State University, Milledgeville, GA. [3]University of Limerick, Limerick, Ireland.*
(No relevant relationships reported)

University students report greater symptoms of psychological distress compared to age-matched controls, which plausibly contribute to a greater incidence of anxiety and depressive disorders. Maladaptive responses to, and recovery from, stress may be partially explained by cognitive (e.g., threat bias) and physiological (e.g., poor autonomic balance) correlates of affective dysfunction that may be modifiable through exercise training. Thus, elucidating interactions among psychological and physiological predictors of stress has implications for better understanding the mental health benefits of exercise training.
PURPOSE
To quantify the moderating effect of heart rate variability on a relationship between threat bias and perceived stress during exam week in healthy, undergraduate students.
METHODS
45 undergraduate students completed a Spielberger Trait Anxiety Inventory, a computerized Dot-Probe Task, and a 5-minute assessment of resting heart rate variability (HFTF). Threat bias was operationalized as a positive bias score (discordant vs. concordant trials), and HFTF was computed as a ratio of power density in the high frequency spectrum (.15-.40 Hz) to power density in the entire spectrum (.04-.40 Hz). The Perceived Stress Scale was completed online during exam week 4-8 weeks later. Bivariate correlations were computed between trait anxiety and threat bias and HFTF. Moderation was tested using hierarchical linear regression with interaction effects.
RESULTS
Trait anxiety was inversely associated with HFTF ($r_= -.35$, $p =.01$) and positively associated with bias scores ($r_= .34$, $p =.01$). The relationship between threat bias and perceived stress during exam week was moderated by HFTF, $F(1,26)=26.04$, $p<.001$, $\Delta R^2=.2605$. Lower stress was only predicted by a lack of attentional bias among participants who also had the highest resting HFTF, $b= 6.60$, $SE_b= 1.43$, $p < .001$. There was no association between trait anxiety and perceived stress.
CONCLUSION
Findings suggest that in young, healthy individuals the protective effects of high parasympathetic tone are only revealed among those who do not exhibit threat biases. Cognitive and physiological correlates of affective dysfunction should be measured when determining the efficacy of exercise training programs designed to improve mental health outcomes.

Appraisals Significantly Influence Endurance Performance and Psychophysiological Response: Stress Appraisals, Emotions, Coping, and Cortisol Responses

Mark A. Thompson, John Toner, John L. Perry, Rachel Burke, Adam R. Nicholls. *University of Hull, Hull, United Kingdom.*
(No relevant relationships reported)

Athlete stress appraisals have been associated with athletic performance, which is purported to be mediated by emotions and coping behaviours. However, our understanding of how these psychological mechanisms underpin endurance performance is equivocal. **PURPOSE:** To assess the causal psychophysiological and performance impact of past- (e.g., harm/loss and benefit) and future-oriented (e.g., challenge and threat) stress appraisals on performance. **METHODS:** Thirty trained and gender-matched athletes were randomly engendered with one of five stress appraisals (challenge, threat, benefit, harm/loss, or control) and completed three 16.1km cycling time trials on a SRM cycle ergometer. Salivary cortisol concentration was measured via an ELISA to assess neuroendocrine response, whilst psychometrics measuring appraisals, emotions, and coping behaviours were also completed. **RESULTS:** Penalized Multinomial Logistic Regression analyses of performance change revealed that temporal orientation of appraisal was a causal influence upon performance, with benefit ($\beta = 5.13$, 95% CI = 1.90, 10.93, $p < 0.001$, OR = 169.00) and harm/loss ($\beta = 3.15$, 95% CI = .46, 8.18, $p = 0.019$, OR = 23.40) groupings significantly facilitating and inhibiting performance respectively. Threat appraisals lead to a performance dichotomy, with both significant improvement ($\beta = 3.41$, 95% CI = .52, 8.54, $p = 0.018$) and significant deterioration ($\beta = 3.08$, 95% CI = 0.06, 8.23, $p = 0.046$) more likely to occur than a non-significant change (OR = 30.33 and 21.67 respectively). Variation across temporal orientation also translated into neuroendocrine response, with cortisol spikes found in threat ($g = -0.9$), compared to a decrease in harm/loss ($g = 0.74$). **CONCLUSION:** Stress appraisals significantly influence psychophysiological response and performance, with past-oriented appraisals as autonomous and influential as future-oriented appraisals. Spikes in cortisol levels in

the future-oriented stress appraisal threat, compared to a decline in the past-oriented harm/loss, suggest that the fear of defeat may be physiologically more stressful than losing itself. Practitioners are advised to engender benefit stress appraisals in order to facilitate both psychophysiological well-being and subsequent performance proficiency among their athletes.

(No relevant relationships reported)

Some leucine metabolites like β-hydroxy-β-methylbutyrate (calcium: HMB-Ca and free acid: HMB-FA) and α-hydroxy-isocaproic acid (α-HICA or leucic acid) have been suggested to augment training-induced adaptations in body composition and performance. **PURPOSE:** To compare the effects of commercially available supplements, HMB-Ca, HMB-FA and α-HICA, on resistance training-induced changes in fat mass and fat-free mass (FFM) and performance. **METHODS:** Forty men were block-randomized (based on handgrip strength, age, and fat-free mass [FFM]) to one of four groups: HMB-FA (n=11, age 30 ± 2.4 y, FFM 62.7 ± 10.5 kg), HMB-Ca (n=9, age 34 ± 1.5 y, FFM 65.6 ± 10.1 kg), α-HICA group (n=10, age 31 ± 2.7 y FFM 62.0 ± 7.1 kg), and placebo (PLA) group (n=10, age 31 ± 2.1 y FFM 64.2 ± 5.7 kg). The training program consisted of whole body thrice weekly training for 8wk (7 exercises/session, 3-4 sets per session, 70-80% 1RM). Whole body fat and FFM were assessed by DXA, and performance measures (vertical jump, 1RM for bench press, squat and Wingate test) were all assessed at baseline and at the end of weeks 4 and 8. Participants were instructed to consume at least 45 kcal/kg FFM/d and 1.6 g protein/kg body weight/d. **RESULTS:** Time-dependent changes were observed for 1RM bench press (p < 0.001), 1RM Squat (p < 0.001), vertical jump height (p = 0.028) and vertical jump power (p = 0.006). No significant between-group or time-group interactions were observed for body weight, Wingate peak and average power, handgrip, whole body fat or whole body FFM (Δ changes: HMB-FA 0.1 ± 1.5 kg; PLA 0.6 ± 0.8 kg; α-HICA -0.1 ± 1.0 kg; HMB-Ca 0.6 ± 2.0 kg) **CONCLUSION:** When consuming sufficient protein while in an estimated positive energy balance, none of the leucine metabolites studied resulted in any ergogenic effects on any outcome variable. We do not recommend leucine metabolites as a supplement strategy to augment training-induced gains in performance or body composition.

Human Skeletal Muscle Lipid Mediator Responses to Resistance Exercise and Anti-inflammatory Drugs

Tommy R. Lundberg[1], Mats Lilja[1], Mirko Mandić[1], Krishna Rao Maddipati[2], Thomas Gustafsson[1], Eric Rullman[1]. *[1]Karolinska Institutet, Stockholm, Sweden. [2]Wayne State University, Detroit, MI.*

(No relevant relationships reported)

Exercise has been found to induce bioactive lipid mediators which possess both pro- and anti-inflammatory activity, yet the role of these mediators in the muscle adaptive response to resistance exercise (RE) remains to be explored. **PURPOSE:** The present study aimed to characterize the presence of polyunsaturated fatty acid-related bioactive lipids in human skeletal muscle. Specifically, we hypothesized that high doses of anti-inflammatory drugs (NSAIDs) would hinder the action of both pro-inflammatory and pro-resolving lipid mediators in response to acute RE, thereby providing a mechanistic

link to the negative effect of high (compared with low) doses of NSAIDs on the muscle hypertrophic response to RE reported by us. **METHODS:** Thirty-one men and women (18-35 years old) performed 8 weeks of RE with daily consumption of either a high dose of ibuprofen (IBU; 1200 mg) or a low dose of aspirin (ASA; 75 mg). Muscle biopsies were obtained before the training/treatment period and 3 h after an acute RE bout at week 4 of the intervention. We used a targeted lipidomics approach (High-Performance Liquid Chromatography with Tandem Mass Spectrometry) to compare the response of over 140 pro- and anti-inflammatory lipid mediators in IBU and ASA as well as in relation to untreated controls (CON). **RESULTS:** We could reliably detect 71 lipid metabolites in skeletal muscle, where 12/71 belonged to the cyclooxygenase pathway but the majority of the mediators were from the lipoxygenase and epoxygenase pathways. Overall, both the pro-inflammatory and the pro-resolving lipid mediator signature was decreased in both IBU and ASA, yet remained unchanged with exercise in CON. Pathway analysis revealed significant differences between drug treatments in the lipoxygenase pathway, specifically in mediators derived from the 5-LOX and 15-LOX enzymes, where levels after exercise were significantly lower in ASA compared with IBU. Specific metabolites driving these differences were 5-HETE, 13-OxoODE and 17-HDoHE. **CONCLUSIONS:** The results show that both high and low doses of NSAIDs markedly affect the skeletal muscle lipid mediator response to RE. We put forth the idea that lipid mediators from the lipoxygenase pathway may have a role in explaining the differential muscle hypertrophic response to RE noted with different doses of NSAID treatment.

Hyperbaric-oxygen Reduces Inflammation And Regenerates Rats Skeletal Muscle Via Macrophage And Satellite Cell Activation.

Takuya Oyaizu, Mitsuhiro Enomoto, Naoki Yamamoto, Masaki Horie, Atsushi Okawa, Kazuyoshi Yagishita. *Tokyo Medical and Dental University, Tokyo, Japan.*

(No relevant relationships reported)

Muscle contusion injury is the most common sport-related injury. Hyperbaric oxygen treatment (HBO) promotes rapid recovery from soft tissue injuries. **PURPOSE:** Uncover a potential mechanism of the restorative effect of HBO on injured muscle. **METHODS:** A muscle contusion injury was performed by the drop-mass method on the rat calf muscle. Rats were divided into non-treated (NT) and HBO-treated (HBO). HBO consisted of 2.5ATA 100% oxygen for 120 minutes once per day. Circulating CD11b, CD68 positive cells were measured with flow cytometry. Injured muscles were homogenized and interleukin-6 (IL-6) and signal transducer and activator of transcription 3 (STAT3) were measured with enzyme-linked immune-sorbent assay (ELISA). Calf muscles sections were immunostained with CD68 and CD163 (macrophage markers), Pax7 and MyoD (satellite cell markers). **RESULTS:** Expression of IL-6 (NT vs. HBO: 995 ± 144 vs. 1964 ± 396 pg/mg, p<0.05) and the ratio of phosphorylated to total STAT3 (0.42 ± 0.05 vs. 1.17 ± 0.07, p<0.01) are increased at 3 hrs in HBO. The percentages of circulating CD11b-positive cells 6 hrs (NT vs. HBO: 65.5 ± 4.6 vs. $42.2 \pm 4.1\%$, p<0.001) and 24 hrs (45.6 ± 6.1 vs. $21.9 \pm 1.1\%$, p<0.001) were deceased in HBO. In the injured muscle, peak infiltration of CD68-positive cells occurred 2 days earlier in HBO. CD163-positive cells were higher at 3 days (NT vs. HBO: 9.3 ± 0.75 vs. 12.7 ± 0.83/HPF, p<0.05), 5 days (13.3 ± 0.63 vs. 17.2 ± 0.89/HPF, p<0.01) and 7 days (11.9 ± 0.86 vs. 17.3 ± 1.70/HPF, p<0.05) after injury. In muscle tissue, the number of Pax7+MyoD- cells was higher at 3 days (NT vs. HBO: 8.7 ± 0.75 vs. 17.2 ± 0.99/HPF, p<0.01) and 5 days (14.73 ± 2.7 vs. 24.89 ± 2.2/HPF, p<0.05) after injury. The number of Pax7+MyoD+ cells was higher at 1 day (NT vs. HBO: 9.9 ± 1.4 vs. 15.4 ± 0.48/HPF, p<0.01) and 3 days (12.6 ± 1.5 vs. 21.96 ± 1.4/HPF, p<0.05) and the number of Pax7-MyoD+ cells was higher at 1 day (NT vs. HBO: 4.4 ± 0.21 vs. 8.2 ± 1.0/HPF, p<0.05), 3 days (6.9 ± 1.1 vs. 15.5 ± 2.6/HPF, p<0.05) and 5 days (13.0 ± 1.4 vs. 23.4 ± 1.4/HPF, p<0.01). **CONCLUSIONS:** HBO increased levels of a tissue inflammatory cytokine, reduces circulating inflammatory cells and induces a rapid macrophage response. These early-onset inflammatory responses appear to enhance satellite cell proliferation and differentiation, leading to rapid recovery of injured skeletal muscle.

Muscle Fiber Type Adaptations To Exercise Differ In Obese And Non-obese Volunteers

Maxime Moreillon, Yannick Morard, Nicholas T. Broskey, Sonia Conde Alonso, Cyril Besson, Francesca Amati, FACSM. *University of Lausanne, Lausanne, Switzerland.*

(No relevant relationships reported)

Human skeletal muscle is composed of slow fibers (type I), fast fibers (IIa and IIx), and a continuum of hybrid fibers co-expressing different myosin heavy chains. Cellular responses to exercise involve changes in fiber type proportions and cross sectional area (CSA). To our knowledge, the impact of obesity on these responses is not yet known. **PURPOSE:** To determine if obesity impacts changes in fiber type proportions and CSA in response to endurance exercise in a sedentary population.

METHODS: Twenty-two obese sedentary healthy men and women (O, BMI>30kg/m²) and 15 non-obese (Lean, L, BMI<26kg/m²) volunteers participated in a 4 months supervised endurance exercise intervention. 18 endurance trained volunteers matched by gender and age (60-79) served as controls (C). *Vastus lateralis* muscle biopsies were analyzed using immunohistochemistry to determine fiber type distribution and CSA. Baseline group comparisons were made using 1-way ANOVA. Pre/post-intervention changes were assessed by paired *t* tests.
RESULTS: At baseline, both L and O had less type I fibers than C. No difference was found in proportions of type IIa, IIx or hybrid I-IIa fibers. The proportion of hybrid type IIa-IIx was higher in O than C. Type I CSA was larger in O than L. No difference in CSA was found for type IIa, IIx or hybrid fibers. With intervention, proportions of type I, IIa, IIx and hybrid type IIa-IIx were not modified. An increase in proportion of hybrid type I-IIa was seen in L but not in O. Type I CSA increased in O and L, while IIa CSA increased only in L.
CONCLUSION: Different adaptations in proportion of fiber types and CSA were observed in O and L previously sedentary volunteers. The increased proportion of hybrid I-IIa fibers with intervention observed in L could be interpreted as a shift of fibers towards a more oxidative muscle such as the profile of C. This transition was not observed in O. As exercise dose was similar in both groups, this unequal shift may be time-dependent, thus not yet apparent here in O. Although fiber CSA was on average 1.5x larger in O than L at baseline, similar CSA increments were observed with endurance exercise in both groups. In previously sedentary seniors, increments of CSA with exercise, even if concurrent to a significant weight loss in the obese subjects, are crucial to prevent age related muscle atrophy.

2000 Steps/Day Does Not Prevent Muscle Atrophy or Strength Loss During Bed Rest
Emily Arentson-Lantz, Elfego Galvan, Sneha Nagamma, Adam Wacher, Christopher Fry, Doug Paddon-Jones, FACSM. *University of Texas Medical Branch, Galveston, TX.* (Sponsor: Douglas Paddon-Jones, FACSM)
(No relevant relationships reported)

Bed rest rapidly compromises muscle health in older adults. Physical activity interventions in an inpatient setting often include periods of walking, but are hampered by key knowledge gaps that limit our ability to provide efficient, evidence-based exercise prescription.
PURPOSE: To determine if 2000 steps/day can protect key markers of skeletal muscle health during 7 days of bed rest.
METHODS: Healthy, community-dwelling older adults (N=17, 11M/6F; 68 ± 2 y; 72.5 ± 3.2 kg; 169.4 ± 2.4 kg) were subjected to 7-days bed rest, with and without a 2000 steps/day intervention. This model mimics the physical inactivity experienced during hospitalization, while isolating the intrinsic catabolic effects of skeletal muscle disuse.
RESULTS: Performing 2000 steps/day during 7 days of bed rest corresponded to 155 minutes/week of walking at a moderate intensity (50% heart rate reserve: 102 ± 5 bpm). The intervention partially preserved lean leg mass (Δ STEP: -609 ± 129 vs. Δ CON: -1035 ± 159 g), glucose tolerance; OGTT AUC (Δ STEP: -0.5 ± 6.3 vs. CON: 9.6 ± 5.5 %) and type 1 muscle fiber cross sectional area (Δ STEP: 27 ± 745 vs. CON: -698 ± 343 μm²), but had no effect on muscle strength (Δ STEP: -14.4 ± 3.8 vs. CON: -16.2 ± 2.4 Nm), or aerobic capacity (Δ STEP: 0.3 ± 1.1 vs. CON: -1.2 ± 1.0 mL/kg/min).
CONCLUSIONS: Performing 2000 steps/day is broadly consistent with cardiovascular fitness guidelines, but in isolation does not fully counter the negative effects of bed rest in healthy older adults.

Muscle Size and Strengths and their Associations with Sports Participation among Young Adults
Harold H. Lee[1], Theodore J. Angelopoulos, FACSM[2], Paul M. Gordon, FACSM[3], Niall M. Moyna[4], Paul S. Visich[5], Robert F. Zoeller[6], Heather Gordish-Dressman[7], Paul D. Thompson, FACSM[8], Eric P. Hoffman[7], Joseph M. Devaney[7], Linda S. Pescatello, FACSM[9]. *[1]Brown University, Providence, RI. [2]University of Central Florida, Orlando, FL. [3]Baylor University, Waco, TX. [4]Dublin City University, Dublin, Ireland. [5]Florida Atlantic University, Boca Raton, FL. [6]7Children's National Medical Center, Washington, DC. [7]Children's National Medical Center, Washington, DC. [8]Hartford Hospital, Hartford, CT. [9]University of Connecticut, Storrs, CT.* (Sponsor: Linda Pescatello, FACSM)
(No relevant relationships reported)

PURPOSE: A decision to participate in physical activity is heavily influenced by one's self-efficacy related to exercise capacity, but it is not clear if muscle size and strength influence one's decision to engage in sports and recreation. We examined this relationship and hypothesized that those with stronger and larger muscle would engage in more sports and recreation.
METHODS: Subjects were young (23.4 ± 5.6yr), normal weight (24.4 ± 4.6 kg/m²) European-American women (n=227) and men (n=192). The Paffenbarger Physical Activity Questionnaire assessed self-reported weekly Kcal expended in sport and recreational physical activity. We obtained muscle size and strength on the dominant and non-dominant arms. Muscle strength was measured with the maximum voluntary contraction (MVC) and one repetition maximum (1RM), and muscle size by cross sectional area (CSA) using magnetic resonance imaging. Weekly sport and recreation participation was categorized by the median for purposes of statistical analysis. Logistic regression tested the associations among muscle size and strength and sport and recreation participation by gender adjusting for age and body mass index (BMI). Akaike Information Criterion was used to identify the most parsimonious model.
RESULTS: On average, men spent about 1568.7±2397.5 kcal/wk and women spent 1732.2±2184.8kcal/wk in sports and recreation. Among men, a one-unit increase in dominant arm 1RM and MVC was associated with 16.9% (95%CI: 5.0-31.1%) and 2.3% (95%CI: 0.6-4.2%) higher odds of engaging in sports and recreation, respectively. Among women, a one-unit increase in non-dominant arm MVC was associated with 5.3% (95%CI = 2.2-8.7%) higher odds of engaging in sports and recreation, while a one-unit increase in non-dominant arm CSA was associated with 19.8 % (95%CI = 8.9-30.0%) lower odds of engaging in sports and recreation.
CONCLUSIONS: As hypothesized, greater MVC predicted engaging in more sport and recreation for both men and women, but greater 1RM predicted engaging in more sport and recreation among men only. Contrary to our hypothesis, greater CSA (i.e., muscle size) predicted engaging in less sports and recreation among women only. The interactions among putative psychosocial mediators, muscle capacity, and sport and recreation participation warrants future investigation.

Aerobic Exercise Training Alters The Lipopolysaccharide-induced Cytokine Secretory Profile Of Skeletal Muscle In Mice
Alex J. Mattingly, Orlando Laitano, Thomas L. Clanton. *University of Florida, GAINESVILLE, FL.*
(No relevant relationships reported)

Skeletal muscles secrete cytokines in response to engagement of toll-like receptors (TLR) with pathogen associated molecular patterns (PAMPS), such as lipopolysaccharides (LPS). Though acute exercise is a known stimulus for cytokine secretion, it is unknown if chronic exercise training alters the cytokine secretory response to LPS. PURPOSE: To determine if spontaneous free-wheel aerobic exercise training in mice alters the cytokine secretory profile from isolated soleus muscles in response to LPS. METHODS: Age-matched (12 weeks old) C57BL6 mice (N=4) were given 24-hour access to running wheels for 69 days (EX). Their daily running distance was recorded. Results were compared to matched sedentary controls (CON; N=8). Solei from the mice were excised in Krebs-Ringer and placed in 2 ml, 35°C muscle baths with 1 μg/ml LPS for 2 hours. Bath samples were drawn after hours 1 (T1) and 2 (T2), flash frozen, and analyzed via Luminex multiplex analysis. Cytokine accumulations at T1 and T2 were compared via one-way parametric or nonparametric ANOVA, as appropriate. RESULTS: Mean daily running distance for EX mice was 3406 m/day, with a peak of 5477 m/day at day 21. At T1, EX muscles secreted less IL-12p70 (6.03 vs. 56.17pg/ml; p=0.016), and more TNFα (1.89 vs. 1.60pg/ml; p=0.020) than CON. At T2, the concentrations of IL-12p70 (8.08 vs. 46.56pg/ml) and KC (36.54 vs. 572.43pg/ml) were reduced in EX baths compared to CON (p=0.016 for both), but TNFα was elevated (1.99 vs. 1.60pg/ml; p=0.020). All other cytokines (MIP-1β, IL-13, IL-12p40, MIP-1α, IL-6, GCS-F, MCP-1, IL-10, RANTES, GM-CSF, IL-15, IP-10, IL-1β, IL-1α, MIP-2, and IFN-y) were not significantly different. CONCLUSION: Spontaneous free wheel running in mice alters the cytokine secretory profile of isolated mouse solei in response to LPS. Since endurance exercise training has been shown to reduce mortality in rodent models of septic shock, the results raise the possibility that conditioned muscles may be participating in improvements in host defense associated with aerobic exercise training. *Supported by NIGMS 1R01GM118895-01*

Activation of G Protein-Coupled Estrogen Receptor Contributes to Muscle Force Potentiation in Ovariectomized Mice

Gengyun Le[1], Gordon L. Warren, FACSM[2], Dawn A. Lowe, FACSM[1]. [1]*University of Minnesota, Minneapolis, MN.* [2]*Georgia State University, Atlanta, GA.* (Sponsor: Dawn Lowe, FACSM)
(No relevant relationships reported)

Estrogens influence force generation of skeletal muscle. When estrogen is deficient, post-tetanic potentiation (PTP) of force is low and estradiol treatment can rescue potentiation in ovariectomized mice both in vivo and in vitro. However, it is not known whether this estrogenic influence is through estrogen receptors, and if so, activation of which specific receptor augments PTP is also unknown. **PURPOSE:** We hypothesized estrogens utilize G protein-coupled estrogen receptor (GPER) to enhance in vivo skeletal muscle PTP in ovariectomized mice. **METHODS**: Adult female C57BL/6J mice (n = 7-12 per treatment) had a nerve cuff surgically implanted on the left common peroneal nerve. Six weeks later mice were ovariectomized (OVX). Four weeks later, PTP of the anterior crural muscles was measured immediately before and 1 h after treatment with either vehicle (OVX+vehicle), GPER agonist G1 (OVX+G1; 2.4 nM G1) or GPER antagonist G15 (OVX+G15; 27 nM G15) via tail vein injection. PTP was measured and calculated as the percent increase in twitch torque from baseline to the highest torque of the post-tetanic twitches. One-way ANOVAs with Holm-Sidak post hoc tests were used for data analysis of PTP. Results are reported as mean ± SE. **RESULTS**: Peak torques of unpotentiated, baseline twitches were not different among OVX+vehicle, OVX+G1, and OVX+G15 mice (0.51 ± 0.03, 0.48 ± 0.03 and 0.54 ± 0.02 N*mm, respectively; p=0.25). Potentiated twitches generated 15-108% more torque than unpotentiated twitches. However, the extent of PTP depended on the presence of GPER modulator (main effect, p=0.03). PTP of OVX+vehicle and OVX+G15 mice were not significantly different from each other (35 ± 5% and 46 ± 4% increase, respectively; p=0.26). PTP of OVX+G1 mice resulted in a 61 ± 7% increase which was significantly greater than that of OVX+vehicle mice (p=0.02), but not different from OVX+G15 mice (p=0.26). **CONCLUSION**: Acute treatment with a GPER agonist increased in vivo PTP of the anterior crural muscles in anesthetized mice, supporting our hypothesis that estrogens mediate their effects on skeletal muscle force potentiation through specific estrogen receptors. Supported by NIH grants R01-AG031743 and T32-AR050938.

The Role Of Dynamin-related Protein 1 (drp1) In The Adaptations To Exercise

Timothy M. Moore[1], Zhenqi Zhou[2], Amanda J. Lin[2], Nareg Kalajian[2], Kevin Corey[2], Kate Whitney[2], Joe Lee[2], Timothy Ho[2], Theodore Ho[2], Lorraine Turotte, FACSM[1], Andrea Hevener[2]. [1]*University of Southern California, Los Angeles, CA.* [2]*University of California, Los Angeles, Los Angeles, CA.* (Sponsor: Lorraine Turcotte, FACSM)
(No relevant relationships reported)

Mitochondria are highly dynamic organelles within eukaryotic cells that function primarily to produce energy. Exercise has been known to positively impact mitochondria for over 50 years. Our previous work indicated that one novel factor, dynamin-related protein 1 (Drp1) that is responsible for splitting mitochondria, was impacted by exercise. However, it is not known whether Drp1 is essential for the development of exercise adaptations. **Purpose:** To determine the impact of reduced Drp1 expression in skeletal muscle on muscle strength, exercise performance, and long-term exercise induced adaptations. **Methods:** For each protocol, skeletal muscle specific heterozygous (mDrp1[+/-]) and littermate control mice were used. Animals were sacrificed and tissues harvested at the times indicated. <u>Protocol 1</u>: Treadmill exercise at 15 m/min (5° grade) for 90 minutes for controls and 13 m/min for mDrp1[+/-] mice. <u>Protocol 2</u>: Thirty days of in cage voluntary wheel running (VWR) after which wheels were locked. Animals were sacrificed 30 hours later. Exercise effects were statistically assessed with two-way ANOVA or t-test (*P*<0.05 established *a priori*; values presented as mean ± SEM). **Results:** Muscle strength was reduced in mDrp1[+/-] mice resulting in a reduction in protocol 1 exercise speed but not relative intensity. Following protocol 1, signaling molecules and cellular factors regulating mitochondrial life cycle were not different between mDrp1[+/-] and control exercised mice. Additional metabolites including plasma lactate and triglyceride and muscle glycogen levels post exercise were not different between groups. In untrained mice, endurance exercise capacity was not different between groups; however, following VWR, mDrp1[+/-] mice had a reduced increase in exercise capacity when compared to control trained mice. Several cellular factors and signaling molecules regulating mitochondrial life cycle showed similar expression levels in mDrp1[+/-] animals when compared to control exercise trained animals. **Conclusions:** Our results indicate that Drp1 is particularly important for muscle strength in untrained mice and may play a role in the improvement of exercise capacity.

Effect of Inflammation on Ribosome Biogenesis during Myotube Hypertrophy in Primary Human Myogenic Cells

Brandon M. Roberts, Derek Wiggins, Sam Windham, Marcas Bamman, FACSM. *University of Alabama at Birmingham, Birmingham, AL.* (Sponsor: Marcas Bamman, FACSM)
(No relevant relationships reported)

Background: Ribosomal biogenesis and protein translation are finely coordinated with and essential for cell growth, proliferation, differentiation, and muscle development. Furthermore, there is a significant positive correlation between the fold change in total muscle RNA content from pre- to post- resistance training and the increase in muscle fiber cross sectional area. Our previous findings in vitro indicate de novo ribosome biogenesis is necessary for myotube hypertrophy. Because chronic muscle inflammation appears to impair myofiber hypertrophy in vivo, we hypothesize this inhibitory influence of inflammation may manifest by disrupting ribosome biogenesis. **PURPOSE**: The aim of the present study was to determine if inflammation inhibits myotube hypertrophy by interfering with ribosome biogenesis in human primary myogenic cells.
METHODS: Skeletal muscle satellite cells were isolated from untrained older (69 ± 4 y, *n* = 6) adults after percutaneous needle biopsy of the vastus lateralis. Cells were grown in DMEM containing 20% FBS, 5 ng/ml fibroblast growth factor, 100 μl/ml streptomycin, and 100 U/ml penicillin until they reached ~70% confluence. They were then placed in differentiation media (DMEM containing 2% horse serum, 100 μl/ml streptomycin, and 100 U/ml penicillin) for seven days to induce formation of multinucleated myotubes. Myotubes were then treated for 48 hours with 20% FBS, TNFa (5ng/mL), 20% FBS + TNFa (5ng/mL), or control (differentiation) media. Cells were subsequently harvested for analysis of mRNA, muscle protein synthesis, ribosomal RNA (rRNA) and constituent ribosomal proteins, myotube size and myofusion index.
RESULTS: Myotubes treated with FBS increased myotube diameter by 20% compared to control. TNFa (5ng/mL) induced 16% atrophy, while a combination of both treatments caused 7% hypertrophy compared to control. Total RNA concentration (ng/ul) increased 32% in FBS treated cells but only 20% in response to the combination of FBS + TNFa. Phase II fusion was decreased in myotubes treated with TNFa or a combination of FBS + TNFa.
CONCLUSIONS: TNFa-mediated inflammation impairs human myotube hypertrophy, which may be driven by impairments in both ribosome biogenesis and phase II myoblast-myotube fusion

Skeletal Muscle Gene Expression Study of Monozygous Twins with 35 Years of Divergent Exercise History

Adam Osmond[1], Robert J. Talmadge[1], Katie E. Bathgate[2], James R. Bagley[3], Lee E. Brown, FACSM[2], Jared W. Coburn, FACSM[2], Andy J. Galpin[2], Kevin A. Murach[4], Edward Jo[1]. [1]*Cal Poly Pomona, Pomona, CA.* [2]*California State University Fullerton, Fullerton, CA.* [3]*San Francisco State University, San Francisco, CA.* [4]*University of Kentucky, Lexington, KY.* (Sponsor: Lee Brown, FACSM)
(No relevant relationships reported)

Variations in physical ability and capacities among individuals depend on both genetic inheritance and lifestyle. Previous research has yet to utilize a human model of monozygous (MZ) twins with substantial and long-term differences in exercise backgrounds to identify molecular and cellular mechanisms underlying exercise-mediated adaptations in muscle and whole-body phenotype. **PURPOSE**: In particular, this study examined skeletal muscle expression of genes related to muscle growth, inflammation, metabolism, and fiber type distribution in MZ twins with 35 years of substantially differing exercise history. **METHODS**: Muscle biopsies were collected from the vastus lateralis of male, 52-year-old MZ twins. Reverse transcriptase-polymerase chain reaction was used for the quantification of mRNAs associated with the following gene markers of various adaptive responses: a) skeletal muscle fiber type shift: MyHC-1, MyHC-2a, and MyHC-2x; b) adaptations in oxidative capacity: transcription factor A of the mitochondria (TFAM), and citrate synthase; c) angiogenesis: endothelial nitric oxide synthase, and vascular endothelial growth factor; d) muscular growth and satellite cell activation: myostatin, Pax7 (PAX7), mechano-growth factor (IGF1Ec), insulin-like growth factor a (IGF1Ea), and MyoD; and e) the inflammatory response: TWEAK (TNFSF12), the FN14 TWEAK receptor (TNFRSF12A) and tumor necrosis factor-α (TNF). **RESULTS**: MyHC-2x was expressed at a lower level in the trained subject relative to the untrained subject. No differences were observed for other markers of fiber type or metabolic or angiogenesis gene products. Some differences were observed in the expression of genes related to muscle growth including elevations in PAX7, MGF and IGF1Ea, and a reduction in MyoD. Finally, the only difference in expression of markers for the inflammatory

---

response was an elevation in TNFRSF12A in the trained twin. **CONCLUSIONS**: At the mRNA-level, differences in expression of some key markers related to muscle fiber type, muscle growth, and the inflammatory response were observed in the trained vs the untrained twin. These data highlight the adaptability of skeletal muscle at the molecular level with decades of divergent physical activity patterns.

Exercise Training Attenuates the Muscle Genomic Response to Bed Rest

Shlomit Aizik, Fadia Haddad, Gregory R. Adams. *University of California Irvine, Irvine, CA*. (Sponsor: Kenneth M Baldwin, FACSM)

(No relevant relationships reported)

Long stays in space can have deleterious effects on the body homeostasis. Significant adverse effects of long-term weightlessness include loss of skeletal muscle mass, strength and endurance that can lead to fatigue and poor performance of astronauts during space missions and put them at high risk of injury when they return to earth. Bed rest studies have been proven to be a reliable model to study the effect of spaceflight on muscle. **PURPOSE:** To characterize the vastus lateralis (VL) gene and microRNA (miR) responses to 70-day bed rest with and without countermeasures to mitigate the negative consequences of weightlessness. **METHODS**: 22 healthy young adults participated in a NASA 70 day bed rest study with and without 2 different modes of exercise interventions (6 participants bed rest only; 8 bed rest + flywheel exercise; 8 bed rest + standard aerobic training). RNA extracted from the VL was hybridized to Agilent Human Gene (V3) and miR (V2) microarrays. Data was analyzed using GeneSpring 14.5 and differential gene and miR expression was determined using ANOVA, (FDR<0.05, Fold Change>2 for GE, >1.1 for miR). Kegg pathway was used to classify the genes into pathways (EASE<0.05). **RESULTS:** 70 day bed rest significantly altered the level of 268 VL genes and 83 miRs. 16 oxidative phosphorylation pathway genes (e.g., ATP5G1, ATP5G3, ATP5J, NDUFS1, COX7A2, SDHB and UQCR10) and 37/40 metabolic pathway genes (e.g., HMGCS2, NDUFS3, ACY1 and FH) that were significantly altered had reduced expression in all 3 conditions. All genes in the oxidative phosphorylation pathway and 31 out of 40 genes in the metabolic pathway had attenuated response when exercise was introduced with no significant difference between the two different modes of exercise. Five let-7 family miRs were significantly upregulated and miR-1 and miR-133a were downregulated (30 and 50% respectively in the bed rest only group), all of which known to be linked to muscle atrophy. Both exercise modes mitigated the miRs response. **CONCLUTION:** 70-day bed-rest altered the expression of genes and miRs that could affect muscle metabolism and promote muscle atrophy. Introducing exercise as countermeasures mitigated the expression of almost all bed rest altered genes and miRs, with no significant difference in the 2 modes of exercise. Altered Skeletal Muscle IGF-1 and miR-206 at Rest and Following Resistance Exercise in Obese Humans

Brian P. Sullivan[1], Jessica A. Weiss[2], Ron T. Garner[1], Yaohui Nie[1], Tim P. Gavin, FACSM[1]. *[1]Purdue University, West Lafayette, IN. [2]Bellarmine University, Louisville, KY. [3]Harvard University, Cambridge, MA*. (Sponsor: Tim Gavin, FACSM)

(No relevant relationships reported)

Obesity is a significant health problem and is associated with numerous changes in skeletal muscle. Obesity increases muscle mass and muscle fiber cross sectional area (FCSA) of type I and II fibers. Resistance exercise (RE) promotes muscle fiber hypertrophy. Activation of the IGF-1/Akt/mTOR pathway is critical for muscle mass maintenance and muscle hypertrophy. **PURPOSE**: To investigate: 1) if obesity alters basal muscle IGF-1/Akt/mTOR expression; and 2) if obesity alters the muscle response to acute RE. **METHODS**: Vastus lateralis biopsies were obtained to investigate mRNA, miRNA, and protein expression between lean (LN) and obese (OB) sedentary subjects at rest, and 15 min and 3 hr post-acute RE. **RESULTS**: Type II FCSA in OB was larger than FCSA of type I in OB and type I and II in LN (Type 1: LN=4804.53 vs. OB=6044.78 μm, Type II: LN=4609.71 vs. OB=8114.34 μm). Skeletal muscle expression was lower in OB for IGF-1 mRNA (Pre: LN=1.00 vs. OB=0.53 AU; 15 min: LN=1.00 vs. OB=0.58 AU; 3 hr: LN=0.96 vs. OB=0.54 AU) and IGF-1 protein (Pre: LN=0.82 vs. OB=0.56 pg/μg; 15 min: LN=3.98 vs. OB=2.19 pg/μg; 3 hr: LN=4.98 vs. OB=2.91 pg/μg). The expression of miR-206, a post-translational inhibitor of IGF-1 expression, was higher in OB (Pre: LN=1.00 vs. OB=1.60 AU; 15min: LN=0.97 vs. OB=1.66 AU; 3hr: LN=1.18 vs. OB=1.61 AU), but there was no difference in pri-miR-206 (Pre: LN=1.00 vs. OB=0.81 AU; 15min: LN=0.95 vs. OB=0.94 AU; 3hr: LN=1.04 vs. OB=1.20 AU). A negative relationship was observed between miR-206 and IGF-1 mRNA at rest (r = -0.54) consistent with miR-206 regulating IGF-1 expression. **CONCLUSIONS**: In spite of greater muscle FCSA, obesity decreases muscle IGF-1 expression suggesting a negative feedback mechanism may be limiting muscle mass expansion in obesity.

The Effects of the VK Performance Insole on Running Economy in Highly-Trained Distance Runners

Robert W. Gregory, William R. Lunn, Marc I. Robertson, Robert S. Axtell, FACSM. *Southern Connecticut State University, New Haven, CT*. (Sponsor: Robert S. Axtell, FACSM)

(No relevant relationships reported)

Several design features of running shoes such as decreased mass, appropriate midsole cushioning, and increased longitudinal bending stiffness are associated with improved running economy (RE). While increased longitudinal bending stiffness has been achieved through the use of carbon fiber plates inserted into shoe midsoles, there are several limitations associated with this construction method. An alternative solution to increase longitudinal bending stiffness in running shoes is to utilize a carbon fiber shoe insole (CFI) tuned for optimal mechanical efficiency of the athlete-footwear system. **PURPOSE**: To determine if a carbon fiber shoe insole (VK Performance Insole; VKTRY Gear; Milford, CT) can improve running economy in highly-trained distance runners. **METHODS**: Ten highly-trained male distance runners (age: 24.7 ± 6.8 years, height: 177.9 ± 5.59 cm, mass: 67.7 ± 5.7 kg) participated in this study. To measure RE, participants ran for 6 min at 16 km·hr^{-1} for the following three conditions: 1) control footwear (no CFI), 2) medium flex CFI (VK Pro 4), and 3) stiff flex CFI (VK Pro 5). Indirect calorimetry was used to measure oxygen consumption (VO_2). The first 4 min were to allow the athlete to reach a steady state and metabolic data from the last 2 min were used to determine submaximal VO_2. The shoe insole conditions were presented in random order; each RE test was separated by a period of 6 min to minimize the effects of fatigue. A repeated-measures ANOVA was used to determine the effects of shoe insole condition on RE. **RESULTS**: The submaximal VO_2 values for each of the shoe insole conditions were as follows: 1) control (no CFI): 49.8 ± 3.0 ml·kg^{-1}·min^{-1}; 2) medium flex CFI (VK Pro 4): 50.2 ± 3.5 ml·kg^{-1}·min^{-1}; and, 3) stiff flex CFI (VK Pro 5): 51.3 ± 3.1 ml·kg^{-1}·min^{-1}. Based on these submaximal VO_2 values, there was no difference in RE between the three different shoe insole conditions [$F(2,8) = 0.97$, $p = 0.44$]. **CONCLUSIONS**: Previous studies have shown that increased longitudinal bending stiffness achieved through the use of carbon fiber plates inserted into shoe midsoles can significantly improve RE by 1-4%. However, the use of a CFI did not result in similar improvements in RE. Further design work and testing of the CFI is required to determine the optimal longitudinal bending stiffness for improved RE at submaximal velocities.

The Effectiveness of Compression Socks on Aerobic Running Performance and Heart Rate Response

Christopher Ball, Elaina Biechler. *Loras College, Dubuque, IA*. (Sponsor: Vincent Paolone, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of the present investigation was to determine the effect of compression socks on maximal aerobic running performance and heart rate response. **METHODS**: Moderately fit college aged students (n=28) were recruited as subjects for the study. Each subject completed four exhaustive treadmill runs utilizing the McConnell Treadmill Protocol. Each phase included two testing sessions, 24 hours apart. Each phase was separated by a minimum of seven days to ensure proper recovery. The two phases included a control phase, and a compression phase. In the compression phase, subjects wore compression socks during the 24 hours separating trial one and two. The assignment of phases was determined by a randomized crossover design. During each treadmill test, time to exhaustion was recorded, as well as maximal heart rate achieved during the run and 20 minutes post run. **RESULTS**: Time to exhaustion was significantly higher (p = .012) in the compression phase in comparison to the control phase (15.82 min; 15.11 min, respectively). Maximal heart rate achieved during the treadmill run was significantly lower (p = .024) while wearing the compression socks compared to the control phase (189.65 BPM; 192.39 BPM, respectively). Heart rate measurement 20 minutes post run was significantly lower (p = .032) in the compression phase when compared to the control phase (99.89 BPM; 101.46 BPM, respectively). **CONCLUSIONS**: Time to exhaustion was significantly improved while wearing compression socks, which indicated an improvement in fatigue resistance and enhanced running performance. Moreover, heart rate, both maximal and recovery (20

WEDNESDAY, MAY 30, 2018

minute) was significantly lower while wearing compression socks, which indicated a reduction in cardiovascular stress. Compression socks have a positive effect on running performance and heart rate responses associated with maximal aerobic exercise for moderately fit college aged individuals. It is hypothesized that this change is brought about as the compression applied decreases venous pooling in the lower leg, assisting in venous return. The applied compression allows for a more efficient circulation path back to the heart, promoting increased clearance rates of muscle metabolites while also lowering the workload on the heart.

The Effects Of Training Load On Salivary Amylase, Testosterone And Performance In Collegiate Runners

Dylan Mariano, Christopher Peterson, Richard Feinn, Thomas Martin. *Quinnipiac University, Hamden, CT.*

(No relevant relationships reported)

PURPOSE: To determine the effects of training load on salivary amylase and testosterone levels and their association with race performance in Female Division I cross-country athletes. **METHODS:** 18 female athletes (18.9 ± 0.86 yrs old) were monitored during the 2015 cross-country season. VO_2 max, and baseline salivary amylase and testosterone levels were assessed during the pre-season. Participants also underwent tri-weekly data collection sessions in which saliva samples were collected. Salivary levels of amylase and testosterone were analyzed using ELISA kits from Salimetrics (State College, PA) according to the manufacturers instructions. Athletes utilized a GPS/HR monitor system daily during practice sessions to record training load. Training load was calculated using the Running Training Stress Score (rTSS) according to a commercial website (www.TrainingPeaks.com). Race performance was also monitored during the season. Linear mixed models were used to analyze the effect of cumulative training load on amylase and testosterone levels and race performance during the season. **RESULTS:** There were no significant effects of training load on salivary amylase levels however, training load was a significant predictor of weekly salivary testosterone levels (p=0.009). Athletes, who had a high weekly training load, expressed lower levels of testosterone for that week. While controlling for race distance and baseline VO2 max, both salivary amylase and testosterone were predictive of race performance. Athletes who expressed higher than normal salivary amylase levels for a particular week, showed a decline in performance (p=0.006). However, the higher the weekly salivary testosterone level, the better the athletes performed (p=0.002). **CONCLUSION:** In this study, higher levels of weekly salivary testosterone were associated with optimal training and improved race performance. While higher levels of salivary amylase, were associated with a decline in race performance. Periodic measurements of salivary amylase and testosterone could be an important diagnostic marker for monitoring overtraining and predicting performance in collegiate athletes. Funding was provided by the School of Health Science Faculty Grant.

521   Board #4   May 30 1:00 PM - 3:00 PM

Evaluating The Effects of Two-Minutes Active Recovery On A "Booster" VO_2max Test Using Ultramarathon Runners

Andy Bosak[1], Will Peveler[1], John Houck[2], Matt Sokoloski[3], Hannah E. Nelson[1], Jimmy Kelly[1], Austin Smith[4], Robert T. Sanders[1]. *[1]Liberty University, Lynchburg, VA. [2]The University of New Mexico, Albuquerque, NM. [3]Texas Woman's University, Denton, TX. [4]East Tennessee State University, Johnson City, TN.* (Sponsor: James Schoffstall, FACSM)

(No relevant relationships reported)

Maximal oxygen consumption (VO_2max) tests typically end at the point of volitional exhaustion. However, prior research with averagely fit females and males as well as highly fit female collegiate athletes suggest that concluding a maximal treadmill test with 2min active recovery and allowing subjects to exercise a second time (ie. a booster test) at the workload eliciting the initial volitional exhaustion results in significantly greater VO_2max values (1.4% and 4.2% mean increase, respectively). The potential effects of this testing sequence (ie. 2min active recovery) on VO_2max treadmill graded exercise tests (GXT) has not been evaluated utilizing ultramarathon runners, yet accurate assessment of these unique athletes' VO_2max is crucial for training program design, implementation, and evaluation of training adaptations. **PURPOSE:** To examine changes in VO_2max values, in fit ultramarathon runners, following 2min of active recovery at the conclusion of a treadmill GXT to volitional exhaustion. **METHODS:** Twenty-nine (19 males and 10 females) ultramarathon runners completed a max treadmill GXT by reaching volitional exhaustion (MX1). Following 2min active recovery (at 0% grade & 2.5 mph) after reaching MX1, subjects had an immediate return to the ending MX1 speed and grade and exercised (ie. a booster test) to volitional exhaustion a second time (MX2). MX1 and MX2 values were compared using a Paired-Samples t-Test with significant differences occurring at $p \leq 0.05$. **RESULTS:** MX1 (53.9 ± 6.0 ml/kg/min) was significantly different (p = 0.03) than MX2 (52.7 ± 7.0 ml/kg/min). The mean change from MX1 to MX2 was

-2.2%, yet 37.9% of the subjects benefited (+2.9% mean increase) from the booster test with individual increases of +0.2% up to +8.0%. **CONCLUSION:** Mean results suggest that 2min active recovery may not allow significantly greater VO_2max values to be achieved by fit ultramarathon runners during a max treadmill GXT, yet 37.9% of the subjects increased their VO_2max during the "booster VO_2max test" treadmill protocol. Future research may examine if fitness level, training experience, age, ultramarathon distance specialty, or other variables might affect this exercise testing protocol.

Effect of 8 Weeks of Eccentric Cycling Training on Running Economy in Healthy Males

Albino G. Schifino, Andrew J. Weiler, Jonathan Huaqui, Chee Hoi Leong. *Central Connecticut State University, New Britain, CT.* (Sponsor: Dr. Sean Walsh, FACSM)

(No relevant relationships reported)

Running economy (RE) has been shown to be a determinant of running performance. Evidence from recent investigations suggests that various forms of resistance and plyometric training can improve RE by augmenting changes in leg spring stiffness and/or exaggerating the stretch-shortening cycle. While eccentric cycling training (ECT) has been demonstrated to elicit improvements in muscular hypertrophy, muscular power, and increased leg spring stiffness, it remains unclear if ECT will improve running economy and/or performance. **PURPOSE**: The purpose of our investigation was to examine if an 8-week ECT intervention could improve RE and in healthy males. **METHODS**: Seven healthy males (age=29 ± 9 yrs; mass=76.6 ± 15.6 kg; height=1.72 ± 0.1 m; BMI=25.6 ± 3.7 kg/m²) performed modified 10-second Wingate tests to obtain peak power output (PPO). ECT intensity was prescribed based on baseline PPO values. Participants performed ECT for 8 weeks (2x/week; 5-10.5 min; 20-55% of PPO). RE was obtained through metabolic analysis during treadmill running at 3 randomized speeds (2.24m/s, 2.68m/s, and 3.13m/s) for 4 minutes consecutively. PPO (W) and RE (ml/kg$^{0.75}$/min) were assessed prior to, and following the 8-week ECT intervention. Pre- versus post training changes in RE were analyzed using paired sample t-tests, alpha level was set at 0.05. Cohen's d effect size (ES) were calculated for all analyses and ES magnitudes of 0.10, 0.30, and 0.50 were interpreted as small, medium, and large effects, respectively. **RESULTS**: Post-training RE was significantly improved while running at 2.24m/s ($P=0.002$, $ES=0.91$; Table 1). **CONCLUSIONS**: These results demonstrate that 8 weeks of ECT was effective in improving RE in healthy individuals. We speculate that the improvement in RE may be attributed to an increase in leg spring stiffness. To the best of our knowledge, this is the first report of a significant improvement in RE following ECT. Improvement in RE would be beneficial for both coaches and athletes.

Table 1. Pre- versus post-training changes in Running Economy (RE) Data presented as mean±SD.

Running Speed (m/s)	Running Economy (ml/kg$^{0.75}$/m)			
	Pre-training	Post-training	P	ES
2.24	0.71 ± 0.08	0.67 ± 0.08	0.002*	0.91
2.68	0.65 ± 0.04	0.63 ± 0.04	0.085	0.64
3.13	0.66 ± 0.04	0.63 ± 0.04	0.153	0.20

*Significantly different compared to pre-training ($P<0.05$).

The Impact of a Novel Wrist Cooling Device on 10km Running Performance in the Heat

Kelsey Denby, Emily Schlicht, Ronald Caruso, Michael Lopez, Stephen Ives. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Paul Arciero, FACSM)

(No relevant relationships reported)

The combination of environmental heat stress and exercise is a potent physiological challenge and is known to impair performance. While pre-cooling might improve performance in the heat, it may prove impractical. PURPOSE: to investigate the impact of a novel wrist cooling device (DhamaSport™), which can be worn during exercise, on exercise performance and physiological responses in the heat. METHODS: In a single-blind, counterbalanced, crossover design, 13 male athletes (33 ± 9 yrs, 15 ± 7 %body fat, and VO_2max 59 ± 5 ml/kg/min, range 50-71) completed three 10km running time trials in the heat (80°F, 60% relative humidity), while wearing two

DhamaSport™ bands: 1) both bands were off (off/off), 2) one band on (off/on), 3) both bands on (on/on). Heart rate (HR), core temperature (T_{CO}), running speed (RS), rating of perceived exertion (RPE) and thermal sensations (TS) were recorded at baseline, during the 10km TT, and during recovery. To understand potential impacts on recovery and fatigue post-exercise, heart rate variability (root mean square of successive differences; RMSSD, and standard deviation of N-N intervals; SDNN), mean arterial pressure (MAP), and visual analog scale (VAS) for fatigue were measured. Due to safety constraints, trials were terminated if $T_{CO} \geq 39.2°C$, in which average speed was used to estimate 10km time. RESULTS: Use of the cooling bands had no effect ($p<0.05$) on resting T_{CO}, MAP, TS, VAS, RPE, RMSSD, or SDNN, but modestly increased ($p>0.05$) HR (Δ3-5 beats/min). During exercise, use of the bands significantly ($p<0.05$) increased RS (-0.25 Δmi/hr), HR (5 Δbeats/min), but had no significant effects on T_{CO} (Δ0.3°C), RPE, or TS were observed over time. The increased RS with the use of the bands, tended to reduce projected 10km time (~10-30s). Use of the cooling bands did not impact RMSSD, SDNN, MAP, or fatigue post-exercise ($p>0.05$). CONCLUSION: Our data demonstrate that use of the cooling bands improves running speed, decreasing projected 10km time. This modest improvement in performance comes at a cost of increased HR; although, interestingly, sensations of effort and thermal comfort were not impacted, despite the faster speed and higher HR. Taken together, use of the cooling bands has the potential to improve exercise performance in the heat perhaps due to altered thermal sensation. Support: Dhamausa.

The Influence of AlterG Treadmill Training on Lower Extremity Muscle Performance in Cross Country Runners

Tracy A. Dierks[1], Vincent C. Nittoli[2], Todd W. Arnold[2], Jason Pociask[3], Jacquelyn Fletcher[1]. [1]Indiana University, Indianapolis, IN. [2]St. Vincent Sports Performance, Indianapolis, IN. [3]Community Health Network, Indianapolis, IN.
(No relevant relationships reported)

Running on an AlterG® Treadmill (AGT) at reduced bodyweight requires speed to be increased if heart rate response is to match overground running. This can be beneficial as one can run at faster speeds for longer durations, without increasing impact forces or heart rate intensity beyond typical training, all while increasing lower extremity muscle demands. However, it is unknown if AGT training influences lower extremity muscle performance. **PURPOSE:** Investigate the effect of an AGT training program on lower extremity muscle performance. **METHODS:** As an offseason supplement, 19 uninjured high school boys cross country runners replaced 2 overground running sessions/week with AGT runs for 6 weeks. AGT runs were 80-85% of bodyweight with speed increased to elicit a heart rate intensity and distance/time consistent with each runner's mile pace for that day. Bilateral isokinetic muscle performance testing was completed at baseline and post program; 10 concentric/eccentric contractions at a speed of 180º/s for sagittal motions at the hip, knee, and ankle. A 2-way ANOVA (side x time) was used to assess pre-post changes (torque, work, power) and side-to-side symmetry ($p\leq0.05$). **RESULTS:** Significant interactions were found for almost all hip variables for pre-post and side-to-side comparisons, while both the knee and ankle generally showed no differences. At the hip, the right generally improved pre-post for all variables, while the left decreased. This resulted in side-to-side asymmetries at pre, but improved to mostly symmetric at post. **CONCLUSION:** The AGT program seemed to primarily influence hip musculature, possibly related to pre-existing asymmetry. However, after training in the AGT environment for 6-weeks, both sides were generally symmetric post-program, mostly due to right side improvements. Thus, AGT training appears to be associated with improved symmetry of hip muscle performance, which may be significant when considering the role of the hip in overuse injuries.

Table 1. Outcome variables for the hip flexor and hip extensor muscle groups at pre and post program for the right and left sides. Contraction type (Concentric or Eccentric) indicates the type of muscle contraction performed during isokinetic testing. ^The hip extensors eccentric contraction variables displayed a similar outcome pattern to the extensors concentric, with the exception of mean power where no difference was observed.

Nocturnal Heart Rate Variability and Morning Orthostatic Test as Tools to Monitor Training Load

Ville Vesterinen, Ari Nummela. KIHU - Research Institute for Olympic Sports, Jyväskylä, Finland.
(No relevant relationships reported)

Both the nocturnal heart rate variability (HRV) and the morning Orthostatic Test are widely used to monitor training load and recovery status of athletes. Both measurements have been observed to be associated with cardiac autonomic regulation. But less is known whether the measurements show similar responses to training load. **PURPOSE:** This study investigated the effects of easy and hard training days on the nocturnal HRV and the Orthostatic Test. In addition, the aim was to investigate relationships between nocturnal and morning HRV variables. **METHODS:** Thirty-four recreational endurance runners performed nocturnal R-R interval recordings and the morning Orthostatic test (5 min supine + 3 min standing) after an easy and a hard training day (moderate- or high-intensity endurance training). Nocturnal HRV was analyzed as four-hour period starting 30 min after going to bed for sleep. Morning HRV was analyzed over 4 min supine (00:30-04:30) and 2 min standing position (06:00-08:00). In addition, peak HR after stand-up and Orthostatic heart rate (HR) (HRstanding - HRsupine) were analyzed. **RESULTS:** Training load (session RPE) of hard training day (638 ± 638) was significantly ($P < 0.001$) greater compared to easy training day (50 ± 100). Nocturnal HR was lower (52 ± 6 vs. 57 ± 9, $P < 0.001$) and all nocturnal HRV variables were higher (Total power: 8.86 ± 0.63 vs, 8.41 ± 0.79, $P < 0.001$) after easy training day. HR in supine position was lower (53 ± 7 vs. 56 ± 7, $P = 0.011$) and high frequency power in supine position was higher (8.06 ± 0.89 vs. 7.74 ± 0.93, $P = 0.027$) after easy day. Other Orthostatic test variables were not different between easy and hard training days. Nocturnal HR and HRV variables showed moderate correlations ($r = 0.62 - 0.78$, $P < 0.001$) to the morning supine variables, but trivial and small correlations ($0.19 - 0.39$) to standing variables. **CONCLUSIONS:** Different training load after easy and hard training days can be observed in both nocturnal HRV and Orthostatic Test. However, the differences are greater in nocturnal HRV recordings compared the morning Orthostatic Test. In addition, it seems that standing variables are not able to evaluate the training load of the previous day. The results suggest that both nocturnal HRV and selected, supine variables of the Orthostatic test can be used in monitoring training load.

Fitness Level Does Not Impact Cardiovascular Drift and Decreased Maximal Oxygen Uptake during Heat Stress

Tori M. Stone, Jonathan E. Wingo, FACSM. *The University of Alabama, Tuscaloosa, AL.* (Sponsor: Jonathan E Wingo, FACSM)

(No relevant relationships reported)

Cardiovascular drift (CV drift) has been shown to be related to reduced maximal oxygen uptake (VO_{2max}) during heat stress. At a given relative metabolic intensity (%VO_{2max}), individuals with higher fitness levels would be expected to experience greater CV drift, and thereby greater decrements in VO_{2max}, because of a greater metabolic heat production resulting from exercising at a higher absolute intensity. However, this has not been directly investigated. PURPOSE: To test the hypothesis that individuals with a higher initial VO_{2max} (i.e., fitness level) will experience a greater magnitude of CV drift and accompanying decrement in VO_{2max} compared to those with a lower initial VO_{2max} during prolonged, moderate-intensity exercise in the heat. METHODS: Data from 7 studies ($n = 62$) were used to assess the relationships between fitness level and 1) CV drift (change in heart rate and stroke volume) and 2) VO_{2max}. CV drift and VO_{2max} were assessed between 15 and 45 min or between 15 and 60 min of cycling at 60% VO_{2max} in 35 °C or 30 °C. RESULTS: Initial VO_{2max} (i.e., fitness level) was not related to change in heart rate (r=0.17, p=0.20), change in stroke volume (r=-0.06, p=0.63), and decrease in VO_{2max} (r=-0.14, p=0.28). CONCLUSION: Contrary to our hypothesis, fitness level was unrelated to the magnitude of CV drift or decrement in VO_{2max} during prolonged submaximal exercise in the heat. However, these findings support the results of previous studies in that the greater the magnitude of CV drift—regardless of fitness level—the greater the decrement in VO_{2max} during constant-rate, moderate-intensity exercise in the heat.

24 Hour Naproxen Dose On Core Temperature And Il-6 During Cycling In The Heat

Dawn M. Emerson[1], J. Mark Davis, FACSM[2], Toni M. Torres-McGehee[2], Stephen CL Chen[3], Charles C. Emerson[4], Craig E. Pfeifer[5], Joseph D. Bivona[2], Justin V. Stone[2], J. Larry Durstine, FACSM[2]. [1]*University of Kansas, Lawrence, KS.* [2]*University of South Carolina, Columbia, SC.* [3]*Bob Jones University, Greenville, SC.* [4]*University of Missouri - Kansas City, Kansas City, MO.* [5]*Lander University, Greenwood, SC.*

(No relevant relationships reported)

Due to anti-pyretic and anti-inflammatory effects, non-steroidal anti-inflammatory drugs (NSAIDs) are theorized to blunt core temperature (Tc) rise during exercise. On the other hand, the adverse events from NSAID use (eg, gastrointestinal and renal damage) can cause an inflammatory response. Existing literature examining NSAIDs on Tc during exercise in the heat is limited and conflicting. **PURPOSE:** To determine the effects of naproxen on Tc and interleukin-6 (IL-6) in hydrated, exercising humans. **METHODS:** We utilized a double-blind, randomized and counterbalanced, cross-over design. Independent variables were a 24 hr naproxen dose (220 mg naproxen/dose) or placebo (0 mg naproxen/dose) and an ambient (22.7 ± 1.8°C, 52.4 ± 5.5% humidity) or hot (35.7 ± 1.3°C, 53.2 ± 3.2% humidity) environment. Participants (n = 11; 6 male, 5 female; age = 27.8 ± 6.5 yrs, weight = 79.1 ± 17.9 kg, height = 177 ± 9.5 cm) completed 4 conditions: 1) placebo and ambient (Control); 2) placebo and heat (Heat); 3) naproxen and ambient (Npx); and 4) naproxen and heat (NpxHeat). Participants cycled 80 min at a heart rate corresponding to 70% VO_{2max} followed by a 10 min time trial for maximum distance. Participants then rested 3 hrs in an ambient environment. Tc and IL-6 were assessed pre-, during, post-, and 3 hrs post-cycling. **RESULTS:** Tc significantly increased pre- to post-cycling (37.1 ± 0.4°C to 38.2 ± 0.3°C, $P < 0.001$) and decreased during rest ($P < 0.001$), reaching baseline by 75 min post-

cycling. Rate of Tc change and maximum Tc were not significantly different between conditions. IL-6 increased pre- to post-exercise (0.54 ± 0.06 pg/ml to 2.46 ± 0.28 pg/ml, $P < 0.001$) and remained significantly higher than pre- at 3 hrs post- (1.17 ± 0.14 pg/ml, $P = 0.001$). No significant IL-6 differences were found between conditions. **CONCLUSION:** A 24 hr over the counter naproxen dose did not significantly affect Tc or IL-6 among hydrated males and females cycling at moderate intensity in hot or ambient conditions. These results are important for physically active individuals and those working with persons who may be taking naproxen. Future research should examine stronger naproxen doses, longer usage, and more intense exercise to determine potential effects on the thermoregulatory and inflammatory systems.

Music Mitigates Heat-Related Reductions In Exercise Performance, But At What Cost?

Timothy English, Yorgi Mavros, Ollie Jay, FACSM. *The University of Sydney, Lidcombe, Australia.* (Sponsor: Dr Ollie Jay, FACSM)

(No relevant relationships reported)

PURPOSE: It is well established that reductions in exercise performance are observed in hot environmental conditions relative to cooler environments. Listening to motivational music is known to improve exercise performance, by enhancing positive affect and reducing ratings of perceived exertion. However, it is not known if listening to motivational music mitigates heat-related reductions in exercise performance, and if any additional work leads to a greater rise in core temperature and/or cardiovascular strain. Our aim was to determine if listening to motivational music during a 15-minute cycling time trial (15TT) mitigates the decrement in cumulative work output typically observed in the heat, leading to a greater increase in core temperature and cardiovascular strain.
METHODS: 7 participants (27 ± 6 y; 71 ± 13 kg) completed a VO_2max test on a cycle ergometer with a VO_2max verification stage (48 ± 7 ml·kg^{-1}·min^{-1}). Each participant completed 30 mins of cycling at 50% VO_2max, followed by a 5-min rest, a 15TT and 5 mins of post-exercise recovery on six occasions. The protocol was completed three times for familiarisation in a neutral (~20°C) environment, and then another three trials in a counterbalanced crossover order under the following conditions: i) 21°C/50%RH (CLD); ii) 36°C/50%RH (HOT); and iii) 36°C/50%RH with motivational music during the 15TT (HOT-MUSIC). Cumulative work output, the rise in rectal temperature (ΔT_{re}) and Rate Pressure Product (RPP) were measured throughout.
RESULTS: Cumulative work output was lower (p<0.001) in HOT (155 ± 54 kJ) compared to CLD (180 ± 50 kJ). However, work output was greater (p<0.001) in HOT-MUSIC (166 ± 51 kJ) compared to HOT, but still lower than CLD (p<0.001). The greater work output in HOT-MUSIC resulted in a greater ΔT_{re} (0.82 ± 0.35°C, p<0.05) at the end of the 5-min post-exercise recovery period compared to HOT (0.67 ± 0.36°C). By the end of the 15TT, there was a trend for a higher RPP (p=0.06) in HOT-MUSIC (31696 ± 4871 mmHg·beats·min^{-1}) compared to HOT (26696 ± 3035 mmHg·beats·min^{-1}).
CONCLUSIONS: Listening to motivational music partially mitigated (by approximately half) the observed heat-related decrements in exercise performance. However, the greater work output resulted in a greater increase in core temperature, and a trend towards a greater cardiovascular strain.

Acute Response to Skeletal Muscle Heating via Pulsed Short-wave Diathermy

Paul Hafen, Rob Hyldahl. *Brigham Young University, Provo, UT.*

(No relevant relationships reported)

The heat stress response is associated with several beneficial adaptations to promote cell health and survival. Specifically, *in vitro* and animal investigations have shown that exposure to a mild heat stress (~40°C) elicits mitochondrial adaptations within skeletal muscle that are similar to those observed with exercise. **Purpose:** To investigate the acute effects of deep tissue heating on heat shock protein (HSP) expression and signaling pathways associated with mitochondrial adaptation. **Methods:** Twenty healthy men (n = 10) and women (n = 10) volunteered for the study (21 ± 2 yrs, 172 ± 11 cm, 65 ± 13 kg). From each volunteer, a randomly selected leg underwent a 2-hr heating session via pulsed short-wave diathermy. Intramuscular temperature was measured with the insertion of a temperature probe to the approximate depth at which muscle tissue would be sampled (≈ 3.5 cm). Muscle biopsies were taken immediately after heating from the vastus lateralis muscles of both legs (treatment and control). From the collected tissue, we measured HSP phosphorylation and protein expression. In addition, we explored whether the heating protocol was able to elicit phosphorylation of AMPK and several well-defined MAPKs (p38, JNK, and ERK1/2) associated with mitochondrial biogenesis. **Results:** Muscle temperature increased significantly in response to the diathermy treatment (3.96 ± 0.51°C, p<0.0001). In response to the 2-hr heating session, we found the phosphorylation of HSP27 to be significantly depressed (-28 ± 0.08%, p = 0.0016), with no changes in overall total protein expression of any of the measured HSPs (HSP27, 60, 70, and 90). Additionally,

in the heated muscle we found significant increases in the phosphorylation of AMPK ($32 \pm 16\%$ p = 0.0365) and ERK1/2 ($205 \pm 77\%$, p = 0.0246). There were no changes in the phosphorylation of either p38 or JNK. **Conclusion:** The altered phosphorylation status of HSP27, together with the increased phosphorylation of AMPK and ERK1/2, suggest that a single, 2-hr heating session is capable of eliciting a significant cellular stress response, which may influence metabolic adaptive processes.

Sustained Metabolic Switch to Lipid Oxidation In Murine Cardiac Muscle After Exertional Heat Stroke

Orlando Laitano[1], Brian Ingram[2], Christian K. Garcia[1], Gerard P. Robinson[1], Alex J. Mattingly[1], Danielle L. Ippolito[3], Lisa R. Leon[4], Thomas L. Clanton[1]. *[1]University of Florida, Gainesville, FL. [2]Metabolon, Morrisville, NC. [3]US Army, Ft Detrick, MD. [4]US Army, Natick, MA.* (Sponsor: Scott K. Powers, FACSM)
(No relevant relationships reported)

Cardiac dysfunction has been documented after exertional heat stroke (EHS), but little is known about the metabolic (mal)adaptations occurring in the heart after exposure to EHS. **PURPOSE:** To identify metabolic biomarkers in a preclinical model of EHS that could indicate long-term cardiometabolic complications or adaptations to EHS. **METHODS:** 56 male mice ran on an incremental forced running wheel while exposed to 37.5°C/ ~40% humidity to induce EHS. Mice ran 124.1 ± 7.2 min, reaching a core temperature of 42.2 ± 0.07 °C at the time of collapse. Animals lost 7.5 ± 0.9 % body weight. Plasma and heart ventricle tissue were obtained at 0.5, 3, and 24 h and at 4, 9 and 14 days post EHS and compared to exercise-matched controls at 4 days post-exercise. Metabolites were extracted from biospecimens and analyzed by mass spectrometry. Ions were matched to a library of standards for identification and quantification. **RESULTS:** At 0.5-3 h after EHS, there was a marked loss in carbohydrate availability (1.6-1.9-fold reduction in plasma glucose, pyruvate and lactate). During the immediate post-EHS period there was also evidence for mobilization of a variety of amino acids. Elevations in acetylated amino acids were also observed. Elevated nucleic acid breakdown products were evident until 24 h post EHS, then recovered. By 3 h, 1.4-12.1-fold increases in acyl carnitine and ketone bodies were evident in the plasma. In cardiac muscle, most species of acyl carnitines were 2.2-25.0-fold lower than control at 0.5 h, suggesting rapid intracellular turnover of available free fatty acids (FFA). Interestingly, in the heart, carnitine FFA remained 2.0-16.7-fold lower than control through 14 d. **CONCLUSION:** Our results are consistent with an acute "energy crisis" following EHS that resolves within 3-24 hours, primarily via a sustained, persistent (≥ 14 day) shift toward fatty acid metabolism in the heart. Other metabolic changes reflect responses to injury, inflammation or wound repair during the recovery phase. *The opinions or assertions contained herein are the private views of the author(s) and are not to be construed as official or reflecting the views of the Army or the DoD.*

Physical Factors Related To Heat Exchange In Male And Female Mice During Exertional Heat Stroke

Christian K. Garcia, Alex Mattingly, Gerard P. Robinson, Orlando Laitano, Thomas L. Clanton. *University of Florida, Gainesville, FL.* (Sponsor: Scott K Powers, FACSM)
(No relevant relationships reported)

Physical factors related to heat exchange in male and female mice during exertional heat stroke
Christian Kyle Garcia, Alex Mattingly, Gerard Patrick Robinson, Orlando Laitano, and Thomas Clanton
Physical and biological characteristics such as body surface area (BSA), mass and power production can influence heat tolerance during exercise. The extent of their influence has yet to be determined in a comprehensive model of exertional heat stroke in mice. We hypothesize that differences observed in performance between male and female mice in the heat may be attributed to their physical factors related to heat exchange. **PURPOSE:** To determine the effects of sex, body surface area to mass (BSA/mass), and rate of thermal radiation on heat stroke defense in a preclinical exertional heat stroke model. **METHODS:** 84 mice were separated by sex and given exertional heat stroke within an environmental chamber. Mice ran on a forced running wheel with incremental increases in speed. Environmental conditions included an ambient temperature and humidity of 37.5°C/~40%RH. **RESULTS**: Using analysis of covariance, with BSA/mass, power and sex as the factors determining place ran in the heat, we found the following in both sexes. Power output and the BSA/Mass were significant predictors for run distance (P<0.000001 for both). Crossed effects between sex and power output as well as sex and BSA/mass were highly significant (P<0.000001 for both). We also hypothesized that females may have had a physical advantage in terms of capacity for thermal radiation in the heat and indeed females exhibited a ~44% higher maximal rate of thermal radiation when normalized for BSA (P<0.03). **CONCLUSION**: In both sexes the rate of power production and body surface area to mass were strong determinants of performance in the heat; however,

sex remained a significant factor over and above these variables. When thermal radiation is normalized per area available for net exchange females had higher heat radiation capacity. Therefore, the results are consistent with a biological advantage in females that incorporates an elevated rate of heat radiation capacity independent of other physical factors. *Author views not official US Army or DoD policy. Comparison of Rectal Temperature Responses During a Modified Heat Tolerance Test

Yuri Hosokawa, Kelsey M. Rynkiewicz, Luke N. Belval, Courteney L. Benjamin, Ryan M. Curtis, Gabrielle E.W. Giersch, Rachel K. Katch, Rebecca L. Stearns, Douglas J. Casa, FACSM. *Korey Stringer Institute, Storrs, CT.*
(No relevant relationships reported)

Heat tolerance testing (HTT) has been used in clinical settings to determine readiness to return to activity after exertional heat stroke. However, published HTT data are mostly limited to a walking protocol (5km·h[-1] at 2% grade) in a climatic chamber set at 40°C and 40% relative humidity (RH), which may limit application in determining one's ability to achieve thermoregulatory equilibrium during exercise. **Purpose:** To investigate factors that are associated with differences in temperature response during a modified HTT (mHTT). **Methods:** Thirty-two participants completed mHTT on a treadmill set at 60% of the velocity at VO_2max in a climatic chamber set at 27.3 ± 0.4°C and $51.1\pm1.7\%$RH. Within this cohort, we identified three pairs of participants (A, B, C) who tested at the same treadmill speed respectively, with body mass (BM) and body surface area (BSA) difference <5% but exhibited rectal temperature (T_{REC}) difference ≥0.75°C at the end of mHTT. Pooled data of participants with lower end T_{REC} (LOW) and higher end T_{REC} (HIGH) during the first 60 min of the mHTT were compared using a two-way ANOVA. **Results:** BM and BSA %difference in pairs A, B, C were 3.8%, 4.8%,1.0% and 3.4%, 3.5%, 1.1%, respectively. Starting T_{REC} difference was largest in pair A (HIGH-LOW: A, 0.72°C; B, 0.06°C, 0.27°C). The ten-minute average of the slope of T_{REC} change was greater at all time points in HIGH than LOW with no statistical significance (*p>0.05*). However, all LOW exhibited a plateau in slopes during the last 20 min (slope ≤0.01°C·min[-1]). Greater SR (sweat rate) was observed in HIGH in two pairs (SR %difference: A, 26.1%; C, 16.3%). Overall RR was greater in HIGH in all pairs but the difference observed in pair A was negligible (0.001°C·min[-1]). **Conclusions:** Fluid was not replaced during mHTT, which may have served as the limiting factor for high sweaters in pair A and C to sustain thermoregulatory equilibrium and contributed in the greater slope, SR, and overall RR. In designing a mHTT that accounts for physical demands greater than walking, SR should be recorded to understand the influence from dehydration. Starting T_{REC} may have also affected the negligible difference observed in RR in pair A. Future studies should investigate the normative values for T_{REC} response during mHTT under a setting where the treadmill speed, BM, BSA, and body mass loss are controlled.

Thoracic Blood Volumes and Periodic Breathing in Chronic Heart Failure

Caitlin C. Fermoyle, Steven C. Chase, Bruce D. Johnson. *Mayo Clinic, Rochester, MN.*
(No relevant relationships reported)

Purpose: Half of all heart failure (HF) patients have a reduced left ventricular ejection fraction (LVEF) and cannot achieve a cardiac output sufficient to meet the metabolic demands of the body. Reduced ejection of the left ventricle causes a centralization of blood volume, specifically an increase of blood within the pulmonary vasculature, which can alter the compliance of the lung tissue leading to changes in breathing patterns. Periodic breathing (PB), defined as cyclic oscillations in ventilation, has been observed in stable HF patients at rest. However, the mechanism underlying the disturbance in ventilation control is unknown. We investigated the relationship between PB and thoracic blood volumes in patients with stable HF. **Methods:** Eleven stable HF subjects (10M, age=69 ± 12years, height=178.0 ± 9.5cm, weight=92.2 ± 12.6kg, BMI=29.0 ± 2.4kg/m[2]) and twelve healthy controls (8M,

age=65±9years, height=168.5±9.3cm, weight=70.8±12.8kg, BMI=24.7±2.6kg/m^2) participated in the study. PB was determined by the presence of a distinct peak in the 0.003-0.04 Hz frequency range of the flow signal during six minutes of resting breathing. Blood volumes in the thorax (V_t), heart (V_h), and pulmonary circulation (V_p) were quantified using CT perfusion imaging from the mean transit time of iodinated contrast moving through the pulmonary circulation.
Results: PB was observed in 7 HF subjects and was associated with poorer functional status and lower LVEFs. HF subjects with PB had blood volumes that were nearly doubled compared to healthy and HF subjects without PB. This relationship persisted when blood volumes were normalized to body surface area (Volumes reported as ml·m^{-2}, p-values vs. healthy; V_t, Healthy = 779.2±257.4, HF without PB = 821.6±160.7, p=0.981, HF with PB = 1579.2±549.9, p=0.002; V_p, Healthy = 393.9±104.9, HF without PB = 434.2±57.5, p=0.874, HF with PB = 748.3±187.7, p=0.000; V_h, Healthy = 385.3±169.4, HF without PB = 387.5±107.8, p=1.000, HF with PB = 830.9±373.3, p=0.008).
Conclusions: HF patients with PB at rest have augmented central blood volumes, which is consistent with previous studies demonstrating a relationship between PB and high pulmonary pressures. Supported by NIH grant HL71478.

Elastic and Resistive Work of Breathing in Older and Younger Adults
Joshua R. Smith, Troy J. Cross, Erik H. Van Iterson, Thomas P. Olson, FACSM. *Mayo Clinic, Rochester, MN.* (Sponsor: Thomas Olson, FACSM)
(No relevant relationships reported)

Aging results in significant alterations in the structure and function of the pulmonary system. For example, aging is associated with the loss of elastic recoil, stiffening of the chest wall as well as decreased airway caliber, and expiratory flow rates. During exercise, older adults exhibit greater expiratory flow limitation (EFL) and increased operating lung volumes than younger adults; however, it is not known if these translate to a higher total work of breathing (WOB) owing to elevated elastic and resistive WOB. **PURPOSE:** To compare the total WOB and its components (inspiratory and expiratory elastic and resistive WOB) in older and younger adults at matched ventilations (V_E). We hypothesized that older compared to younger adults would exhibit a greater total WOB as a result of greater inspiratory and expiratory elastic and resistive WOB.
METHODS: Older (OA: n=9; 60±8 yrs) and younger (YA: n=9; 38±7 yrs) adults were recruited for this study. Participants performed an incremental cycling test to volitional fatigue. Esophageal pressure, lung volumes, EFL, and ventilatory variables were measured at matched V_E (i.e. 25, 50, and 75 L/min) during exercise. Modified Campbell diagrams were used to determine the inspiratory and expiratory elastic and resistive WOB.
RESULTS: At V_E of 75 L/min, older adults had greater % EFL and tidal volume to forced vital capacity ratio (p<0.05), while end-expiratory and inspiratory lung volumes were not different (p>0.19). Older compared to younger adults had greater total WOB at V_E of 50 (OA: 47±20 vs. YA: 31±7 J/min) and 75 L/min (OA: 97±41 vs. YA: 64±18 J/min) (p≤0.05 for both). At V_E of 50 L/min, older adults had a greater inspiratory resistive WOB (OA: 13±8 vs. YA: 6±2 J/min, p<0.03). At V_E of 75 L/min, older adults had a greater inspiratory elastic and resistive WOB (OA: 44±27 vs. YA: 24±22 and OA: 23±15 vs. YA: 11±3 J/min, respectively) (p<0.02 for both) and expiratory resistive WOB (OA: 23±19 vs. YA: 14±9 J/min, p=0.04) than younger adults.
CONCLUSIONS: These data demonstrate that aging-induced pulmonary alterations result in a greater WOB during exercise owing to greater inspiratory (elastic and resistive) and expiratory resistive WOB. These findings suggest that the respiratory muscles necessitate an increased blood flow demand in older than younger adults for a given V_E during exercise.

Experimentally Manipulating Mechanical Ventilatory Constraint During Exercise Does Not Influence Dyspnea in Older Men and Women
Yannick Molgat-Seon[1], Andrew H. Ramsook[1], Carli M. Peters[1], Michele R. Schaeffer[1], Paolo B. Dominelli[2], Lee M. Romer, FACSM[3], Jeremy D. Road[1], Jordan A. Guenette[1], A. William Sheel, FACSM[1]. *[1]University of British Columbia, Vancouver, BC, Canada. [2]Mayo Clinic, Rochester, MN. [3]Brunel University London, Uxbridge, United Kingdom.* (Sponsor: Bill Sheel, FACSM)
(No relevant relationships reported)

During exercise at a standardized metabolic work load, the perception of dyspnea is higher in older women than older men, which is thought to be related to sex-differences in mechanical ventilatory constraint; however, this hypothesis has yet to be experimentally tested. **PURPOSE:** To determine the effect of manipulating the magnitude of mechanical ventilatory constraint during submaximal exercise

on dyspnea in older men and women. **METHODS:** Thirteen healthy subjects (60-80 y; n=7 women) completed two days of testing. On Day 1, subjects performed pulmonary function testing and a maximal incremental cycle exercise test. On Day 2, esophageal pressure (P_{es}) and diaphragm electromyography (EMG_{di}) were recorded during three constant load cycle exercise tests (6 min each) at ventilatory threshold (V_{Th}). Constant load exercise tests were performed under three conditions in a single blind, randomized, counterbalanced fashion: i) breathing normoxic helium-oxygen gas (HeO_2) to reduce the work of breathing (W_b) and alleviate expiratory flow limitation (EFL); ii) inspiratory resistance (RES) of 5 cmH$_2$O·l^{-1}·s^{-1} to increase W_b; and iii) control (CON) breathing room air. During exercise on Day 2, P_{es}-derived measures of W_b, EMG_{di}, and EFL were assessed. **RESULTS:** During the HeO_2 condition, there was a significant decrease in W_b (men= -20±4%, women= -16±5%) and EMG_{di} (men= -11±7%, women= -9±7%) relative to CON (both $p<0.01$). Moreover, if EFL was present during the CON condition (n=3 men, n=5 women), it was alleviated during HeO_2. Conversely, during the RES condition, there was a significant increase in W_b (men= 34±11%, women= 50±12%) and EMG_{di} (men= 32±15%, women= 23±12%) relative to CON (both $p<0.01$). The effect of condition on W_b and EMG_{di} was not significantly different between the sexes (both $p>0.05$). Across conditions, women reported significantly higher levels of dyspnea than men (3.3±0.4 vs. 1.9±0.4 Borg units, $p<0.05$). However, despite significant differences in the degree of mechanical ventilatory constraint between conditions, there was no effect of condition on the perception of dyspnea intensity, regardless of sex ($p=0.46$). **CONCLUSION:** Our results suggest that during short bouts of exercise at V_{Th}, sex-differences in dyspnea in older adults are not related to sex-differences in mechanical ventilatory constraint.

Alterations In Pulmonary And Respiratory Muscle Function In Response To 10 Marathons In 10 Days
Nick B. Tiller[1], Louise A. Turner[1], Bryan J. Taylor[2]. *[1]Sheffield Hallam University, Sheffield, United Kingdom. [2]University of Leeds, Leeds, United Kingdom.*
(No relevant relationships reported)

Alterations in pulmonary and respiratory muscle function in response to 10 marathons in 10 days
Tiller NB, Turner LA, Taylor BJ.
[1] Academy of Sport and Physical Activity, Sheffield Hallam University, UK
[2] Faculty of Biological Sciences, School of Biomedical Sciences, University of Leeds, UK
Background: Marathon and ultramarathon running are sufficient to induce pulmonary dysfunction and respiratory muscle fatigue. However, it is unknown how the respiratory system responds to multiple, consecutive days of endurance exercise.
Methods: Eleven well-trained endurance runners (8 male, 3 female) contested an ultra-endurance challenge comprising 10 marathons in 10 consecutive days. Lung function (FVC, FEV$_1$, FEV$_1$/FVC, PEF) and maximal static inspiratory and expiratory mouth pressures (MIP and MEP) were measured before and after marathon 1, 4, 7 and 10. Perceptual ratings of breathlessness (Borg CR10), respiratory muscle soreness (Visual Analogue Scale), and symptoms of upper-respiratory tract infection (URTI) were also recorded. **Results:** Group mean time for the 10 marathons was 276 ± 35 min, and post-marathon breathlessness was 2.0 ± 0.3 (range 1.0 to 3.0). Relative to pre-challenge baseline (159 ± 32 cmH$_2$O), MEP was reduced after marathon 1 (136 ± 31 cmH$_2$O, $p = 0.017$), marathon 7 (138 ± 42 cmH$_2$O, $p = 0.035$) and marathon 10 (130 ± 41 cmH$_2$O, $p = 0.008$), but there were no consistent reductions in baseline (pre-marathon) MEP. There were no changes in FVC, FEV$_1$, FEV$_1$/FVC, PEF, MIP, perception of breathlessness or respiratory muscle soreness throughout the challenge ($p > 0.05$). Moreover, there was no change in symptoms of URTI during and up to 2-weeks following the challenge ($p > 0.05$). **Conclusions:** Ten days of marathon running did not induce a chronic reduction in resting pulmonary or respiratory muscle function, despite acute pre-to-post-marathon reductions in maximal expiratory muscle strength. These data underscore the robustness of the healthy respiratory system.

540   May 30 2:00 PM - 2:15 PM
Work of Breathing Influences Muscle Sympathetic Nerve Activity During Whole-Body Exercise
Paolo B. Dominelli[1], Keisho Katayama[2], Tyler D. Vermuelen[3], Troy JR Stuckless[3], Courtney V. Brown[3], Glen E. Foster[3], Andrew W. Sheel, FACSM[1]. *[1]University of British Columbia, Vancouver, BC, Canada. [2]Nagoya University, Nagoya, Japan. [3]University of British Columbia, Kelowna, BC, Canada.*
(No relevant relationships reported)

Manipulating the work of breathing (Wb) during exercise influences: quadriceps and respiratory muscle blood flow, locomotor and respiratory muscle fatigue, exercise performance and sensations of dyspnea. The mechanism underpinning these changes is hypothesized to be a sympathetically mediated respiratory muscle metaboreflex. However, no direct evidence for altered muscle sympathetic nerve activity (MSNA) during whole-body exercise has been demonstrated. **PURPOSE:** To determine if

lowering the Wb decreases MSNA during whole-body cycle exercise. **METHODS**: Healthy active subjects (n=12, 3 female) performed semi-recumbent cycling to exhaustion (VO_{2peak}= 45±2 ml kg^{-1} min^{-1} means ± SE). On a subsequent day, three constant load exercise trials at 40, 60 and 80% of peak workload were performed. Each trial was 7 min long and consisted of: 3 min spontaneous breathing, 2 min reduced Wb followed by 2 min spontaneous breathing. MSNA was recorded via microneurography of the right median nerve at the elbow. A proportional assist ventilator (PAV) was used to reduce the Wb. All statistical comparisons were made within each workload between PAV and post-PAV. **RESULTS**: The 40, 60 and 80% trials resulted in 57±1, 79±1 and 96±2 % of VO_{2peak}, respectively. At 40%, the PAV resulted in a similar Wb (62±7 vs. 67±7 J min^{-1}, P=0.4), decreased MSNA as (27±2 vs. 30±2 burst min^{-1} P>0.05) and increased V_E (67±3 vs. 55±2 l min^{-1}, P>0.05); for PAV and post-PAV, respectively. At 60%, the PAV significantly (P<0.05) reduced Wb (103±2 vs. 144±14 J min^{-1}), MSNA (35±3 vs. 42±2 burst min^{-1}), heart rate (151±4 vs. 154±4 beats min^{-1}) and VO_2 (2.4±0.2 vs. 2.6±0.1 l min^{-1}) without influencing V_E (86±3 vs. 82±3 l min^{-1} P>0.05); for PAV and post-PAV, respectively. At 80% (n=8) the PAV reduced (P<0.05) Wb (235±39 vs. 361±53 J min^{-1}), MSNA (48±2 vs. 53±4 burst min^{-1}), heart rate (173±4 vs. 176±4 beats min^{-1}) and VO_2 (2.9± 0.2 vs. 3.2±0.2 l min^{-1}) but not V_E (121±7 vs. 123±7 l min^{-1}) compared to post-PAV. **CONCLUSIONS**: During whole-body aerobic exercise above ~57% of VO_{2peak}, attenuating the normally occurring Wb has a significant effect on sympathetic vasomotor outflow. Our findings support the theory of a respiratory muscle metaboreflex that influences the integrative response to exercise.

Lack of Association Between Muscle and Ventilatory Chemoreflexes

James A. Pawelczyk, FACSM[1], Nathan Garvin[1], Nathan Raver[1], Christopher I. Schrock[2]. [1]*Pennsylvania State University, University Park, PA.* [2]*Gettysburg College, Gettysburg, PA.*
(No relevant relationships reported)

PURPOSE: Ventilation and blood pressure during exercise are mediated, in part, by chemoreflex activation in medullary and muscle interstitial spaces, respectively. We therefore hypothesized that intra-subject variability in the responsiveness to both reflexes would be similar.
METHODS: Ventilatory chemoreflex and exercise pressor reflexes were assessed in 30 healthy, normotensive college-aged men and women. Ventilatory responsiveness was measured as the slope of the relation between breath-by-breath ventilation and end-tidal PCO_2 elicited by hyperoxic, hypercapnic rebreathing. Sensitivity of the exercise pressor reflex was assessed as the slope of the relation between systemic systolic blood pressure (SBP, Finapres) and estimated forearm perfusion pressure (SBP minus cuff pressure) during steady-state rhythmic handgrip exercise (30 contractions/minute at 10% maximum) with progressive forearm blood flow restriction induced by a pneumatic cuff inflated at 3 mmHg/15 sec. For both tests, inflection points defining thresholds for reflex engagement were determined using cumulative sums (Changepoint package, R 3.3.2). Linear regression was used to quantify stimulus:response slopes beyond inflection points to relate the two reflex slopes.
RESULTS: 14 subjects were eliminated because the responses were not amenable to statistical analysis. The remaining data were normally distributed. Across subjects there were wide differences in ventilatory (mean=2.4 L/min/mmHg, range=0.9-5.0) and exercise pressor (mean=0.5 mmHg/mmHg, range=0.1-1.4) reflex responsiveness. However, there was no correlation between the two reflexes (r²=0.02, P=NS).
CONCLUSION: We suggest that neural pathways invoked by ventilatory and muscle chemoreflexes are sufficiently different that a "stress sensitive" phenotype does not exist.

542 May 30 2:30 PM - 2:45 PM
Effect Of Daily, High-intensity Voluntary Hyperpnea On Maximal Expired Airflow And Maximal Voluntary Ventilation

Hans C. Haverkamp, Adriane Morrison-Taylor, Jeni Demar, Andrew Klansky, Kasie Craig, Eden Towers. *Johnson State College, Johnson, VT.*
(No relevant relationships reported)

Repeated bouts of voluntary isocapnic hyperpnea (i.e., hyperpnea training) has been used in both healthy and diseased populations as a potential means to improve exercise capacity and functional status. However, the repeated episodes of high airflow may cause airway inflammation and subsequently compromise airway function. **PURPOSE**: To determine if repeated, daily bouts of voluntary isocapnic hyperpnea alters airway function in healthy adults. **METHODS**: Eleven subjects (age, 21 yrs; ht, 1.7 m; wt, 65 kg) completed ten days of hyperpnea training (HYP) over the course of no more than 15 days. Hyperpnea sessions were 20-minutes in duration with the targets for minute ventilation based on percentage of maximal voluntary ventilation (MVV): days 1-4, 70% MVV; days 5-7, 75% MVV; days 8-10, 80% MVV. During

hyperpnea, dead space was added to maintain end-tidal CO2 at baseline levels. Maximal forced exhalations and MVV were performed at baseline prior to each hyperpnea session. Eight control subjects (CON) completed ten days of spirometry but no hyperpnea training. Outcome variables included peak expiratory flow (PEF), forced vital capacity (FVC), forced expiratory volume 1.0 second (FEV1) and MVV. **RESULTS**: In both HYP and CON subjects, PEF, FVC, and FEV1 did not change during the ten experimental days. In CON subjects, MVV did not change during the ten experimental days (MVV10-MVV1, +0.05 ± 0.3 L/min). In HYP subjects, MVV decreased gradually over time during the ten experimental sessions, reaching its nadir during the final day of training (MVV10-MVV1, -14 ± 22 L/min; -7 ± 14%); however, the decrease was not statistically significant (P=0.07).
CONCLUSIONS: These findings suggest that repeated bouts of high airflow hyperpnea do not compromise airway function in healthy adults. In the absence of any changes in the maximal forced exhalations, we speculate that the decreased MVV in HYP subjects may be due to respiratory muscle fatigue.

B-15 Clinical Case Slide - **Cardiovascular I**

Wednesday, May 30, 2018, 1:00 PM - 3:00 PM

Exercise Induced Electrocardiogram Abnormalities In Elite Swimmer

Dalya Navot-Mintzer[1], Naama W. Constantini, FACSM[2]. [1]*Wingate Institute and Clalit Health Services, Netanya, Israel.* [2]*Shaare Zedek Medical Center, Jerusalem, Israel.*
(No relevant relationships reported)

HISTORY: A 17-year-old male national team swimmer came for an intake examination at The Academy for Sports Excellence at Wingate Institute. He reported being a non-symptomatic carrier of familial long QT mutation of the LQT2 type (KCNH2 mutation (R744X)) which was diagnosed through a family screening examination. He is taking Bisoprolol 2.5 milligrams once daily since he was 10 years old. Three other family members were diagnosed with the same long QT mutation (brother, mother and maternal grandfather). None of the family members have ever developed cardiac symptoms or arrhythmia, except for the grandfather who had one event of Torsade de Pointes at an old age, following acute MI. The whole family was screened following this event.PHYSICAL EXAMINATION: PE revealed no pathological finding, including normal cardiac examination. Resting ECG at supine position was within normal limits (Herat rate (HR)=49/min, QTc=415 msec). QT interval became elongated (HR=88/min, QTc=550 msec) at the first minute on the treadmill stress test. During the stress test the swimmer was asymptomatic, had a normal blood pressure response and reached maximal oxygen consumption of 65ml/min/Kg. Exercise ECG showed two patterns of wide premature beats with few bigeminis that started at a HR of 95/min.DIFFERENTIAL DIAGNOSIS: 1- Benign ventricular pre-mature beats during exercise.2- Electrical myocardial instability, due to channelopathy.3- Co-existence of CPVT in the family.TESTS AND RESULTS:1- Repeated resting ECG, normal.2- Echo-cardiography, normal.3- Repeated family history and family ECG examination. No evidence of any cardiac symptoms except for the index event of the maternal grandfather.4- Repeated 24h holter, normal. 5- Expert consultation. WORKING DIAGNOSIS:Asymptomatic elite swimmer. A carrier of benign familial LQT2 type mutation. No evidence of QT elongation on resting ECG and therefore does not meet QTc elongation criteria. Exercise induced ventricular pre-mature beats should be evaluated separately. Channelopathy expert physicians concluded that there is no justification for disqualification.TREATMENT AND OUTCOME:Cleared for swimming with no limitations. Repeated stress test and switching to a non-selective beta-blocker drug was recommended.

547   May 30 1:20 PM - 1:40 PM

Cardiac Rehabilitation: A Gateway to the Senior Olympics

Kirk D. Hendrickson. *Beaumont Health, Royal Oak, MI.* (Sponsor: Barry A. Franklin, FACSM)

(No relevant relationships reported)

HISTORY: An 81 year old male with a history of hypertension in 2012 initially underwent graded exercise testing (GXT) followed by cardiac catheterization that revealed severe multivessel coronary artery disease (CAD). He underwent urgent coronary artery bypass surgery (CABG x 4) and enrolled in an exercise-based cardiac rehabilitation program (CR).
PHYSICAL EXAM: (1/2012): Lipid values: Total cholesterol (TC), HDL-C, LDL-C, and triglycerides (TG) were 118, 25, 56, and 186 mg/dL, respectively. Resting heart rate (HR) and blood pressure (BP): 59 bpm and 102/80 mmHg; body mass index (BMI), 29.2 kg/m^2.
DIFFERENTIAL DIAGNOSIS: CAD
TEST AND RESULTS:
Baseline GXT with myocardial perfusion imaging (MPI): patient achieved 94% HRmax and 4.8 METs; no symptoms or diagnostic ST segment depression were noted. However, MPI revealed a transient inferoapical wall and a fixed posterior wall perfusion defect. Peak HR and BP: 136 bpm and 192/110 mmHg. Resting ejection fraction (EF) = 55%.
Cardiac Cath 1/13/2012: Left anterior descending coronary artery (LAD) had 70-80% stenoses in the proximal and distal LAD. There were multiple 80-95% lesions in the left circumflex coronary artery (LCx), obtuse marginal artery (OM), and right coronary artery (RCA). EF=55%.
CABG x 4, 1/16/2012: LAD, OM1, OM2, and RCA.
Most recent GXT 2/18/2015: 8.3 METs, negative for symptoms or ischemic ST segment shifts. MPI showed mild reversible defects in the anterior and lateral wall. Follow-up coronary computed tomography angiography was unremarkable. Lipid values (9/2017) were largely unchanged from his 2012 profile, except for an increased HDL-C, 41 vs 25 mg/dL, formerly. His BMI also decreased, 27.1 vs 29.2 kg/m^2 at baseline.
FINAL/WORKING DIAGNOSIS: CAD; previous CABG
TREATMENT AND OUTCOMES: Patient initiated CR in 2012, follows a plant-based diet, is currently taking a beta-blocker, ACE inhibitor, aspirin, and statin and exercises in our CR program 5 d/wk (cycle
ergometer, graded treadmill walking) complemented with outdoor biking, ≤25 miles/wk. In 2016 he won a silver medal in the Senior Olympics, 10 Km Cycling, 80-84 year old class and in 2017 won silver medals in the 5 and 10 Km events. By improving his lifestyle, risk factors, and fitness, and by attaining silver medal status in the Senior Olympics, he serves as a role model for our CR program.

548   May 30 1:40 PM - 2:00 PM

Chest Pain and Palpitations - Lacrosse

Elizabeth E. Barton, Vicki R. Nelson, Irfan M. Asif. *Steadman Hawkins Clinic of the Carolinas, Greenville Health System, Greenville, SC.* (Sponsor: Kyle J. Cassas, FACSM)

(No relevant relationships reported)

HISTORY:
A 15-year-old female HS lacrosse player presented for episodes of chest pain and palpitations, initially at rest for minutes and then became exertional with SOB. She denied nausea, HA, and syncope. Family history was negative for congenital heart disease and sudden cardiac death, but her mother had atrial fibrillation and MGF died before age 60 from an MI.
PHYSICAL EXAMINATION:
T 97.7°F, HR 56, BP 116/68, RR 20, SpO$_2$ 98% RA, BMI 20.7
Well appearing with clear breath sounds. Cardiac exam: regular rhythm, normal S1 and S2, no S3 or S4, and a 2/6 low frequency systolic murmur best heard at the left upper sternal border. 2+ pulses. No peripheral edema, cyanosis, or hepatomegaly.
DIFFERENTIAL DIAGNOSIS:
1. arrhythmia - SVT, WPW, aflutter, afib, PACs
2. pulmonary valve stenosis, tricuspid valve regurgitation
3. cardiomyopathy—hypertrophic cardiomyopathy, ARVD
4. ASD
5. anemia
6. hyperthyroidism
TEST AND RESULTS:
-ECG- sinus bradycardia, no chamber enlargements or pre-excitation, normal QTc
-28 day event monitor- two episodes of chest pain and rapid heart beat correlate with nsr and sinus tachycardia
-Transthoracic echocardiogram- normal cardiac segmentation, valvular function, biventricular size, and systolic function. No effusion. There is a small coronary cameral fistula entering the main pulmonary artery.
-Exercise stress with 2D echocardiogram performed showed normal EF with no wall motion abnormalities, ischemia, or arrhythmias

FINAL WORKING DIAGNOSIS:
Coronary-cameral fistula
TREATMENT AND OUTCOMES:
1. The patient was cleared to play after symptoms spontaneously resolved and serial echocardiograms over a 5 year period demonstrated a stable coronary-cameral fistula.
2. Cardiology consultants recommended a rest/stress MRI to further determine the anatomical nature of the fistula given the symptom history. However, they believe that the fistula was an incidental finding and likely not the cause of her symptomatology.
3. Coronary-cameral fistula is a rare cause of congenital cardiac anomalies. Although most are small and asymptomatic, larger ones may cause MI or CHF, thus requiring intervention.
4. There are no published reports of this condition in athletes, highlighting provocative issues surrounding risks of incidental findings of unknown significance and return to play considerations.

549   May 30 2:00 PM - 2:20 PM

Painful Arm Mass-Weight Lifting

Jenna Crowder, Franklin Sease, FACSM, Irfan Asif, Vicki R. Nelson. *Greenville Health System, Greenville, SC.* (Sponsor: Franklin Sease, FACSM)

(No relevant relationships reported)

HISTORY:
A 29 year old male reports acute onset of pain and palpable mass in his right distal bicep while weight lifting 2 weeks prior to presentation. He reports a dull ache that has persisted despite heat and ibuprofen. He developed bruising which resolved. He has continued lifting. He has no paresthesia, weakness, or radiculopathy. He has no exertional pain. He has a known history of multiple aneurysms diagnosed at the age of 7 with negative genetic testing. **PHYSICAL EXAMINATION**: There are no overlying skin changes or deformity. There is a tender, non-pulsatile 2cm mass within the medial distal bicep with firmness of the surrounding soft tissues. Active range of motion at the shoulder and elbow are full and symmetric. Pain cannot be recreated with manual muscle testing. Brachial and radial pulses are symmetric and equal. Right ulnar pulse is difficult to palpate. Allen's test reveals reduced right ulnar blood flow. Lower extremity pulses are symmetric and equal. Cervical spine motion is normal. Spurling's test is negative bilaterally. **DIFFERENTIAL DIAGNOSIS**:
Superficial phlebitis
Intramuscular hemorrhage
Biceps or brachioradialis muscle tear
Neoplasm (vascular, sarcoma, nerve sheath)
Brachial artery aneurysm or pseudoaneurysm
TEST AND RESULTS: Bilateral extremity angiogram - Right arm: multiple aneurysms proximal to the antecubital fossa, the largest measures over 1.5 cm. Aneurysms at the origin of the ulnar and radial arteries without distal abnormality. Left arm: 1.5 cm aneurysm proximal to the antecubital fossa. Right mid vertebral artery aneurysm (1.4 cm); prior coil embolization of the left vertebral artery. Lower extremities: 33 discrete aneurysms. Pseudoaneurysm at the proximal anastomosis of the aorto-bi-iliac graft that measures 4 cm proximally and 2.2 cm on the right iliac limb. **FINAL WORKING DIAGNOSIS**:
Multiple aneurysmal disease of unknown origin **TREATMENT AND OUTCOMES**: This case highlights provocative issues of a rare vascular disorder with no literature related to physical activity recommendations. Increased intravascular pressure related to heavy resistance likely accelerates disease progression, and as such, the athlete was advised to refrain from weightlifting. Vascular surgery was consulted for evaluation of abdominal aortic pseudoaneurysm and right vertebral artery aneurysm.

550   May 30 2:20 PM - 2:40 PM

Cardiovascular Disease—Ice Hockey

Bradley Changstrom[1], Robert Quaife[1], Matt Sokolowski[2], Nicholas Edwards[1], Gregory Coe[3], William Cornwell[1]. [1]*University of Colorado Hospital, Denver, CO.* [2]*Colorado Avalanche Hockey Club, Denver, CO.* [3]*University of Colorado Denver- Anschutz Medical Campus, Denver, CO.*

(No relevant relationships reported)

History:
An 18 year-old healthy male semi-professional ice hockey player presented with a chief complaint of dizziness during a graded oxidation and lactate bike test. During the episode, he exhibited fluctuating levels of consciousness, gagging and cough. Following this episode, he mentioned two similar episodes while performing bike fitness tests. During hockey activities, he denied chest pain, dyspnea, dizziness, or syncope.Physical Examination: On examination following the episode, he was responsive to verbal commands but appeared dizzy and confused. He was frequently coughing and appeared dyspneic. Blood pressure 120/70. Heart rate was in the 120s. Pulse oximetry was 93%. Heart was regular rhythm without murmurs, rubs or gallops. Pulmonary exam demonstrated upper respiratory rhonchi.
The patient was transferred to the emergency room.

Differential Diagnosis:
1) Cardiac arrhythmia
2) Structural heart disease
3) Seizure disorder
4) Hypoglycemia
5) Exercise induced asthma
Test and Results:
An electrocardiogram was normal. A complete blood count, comprehensive metabolic panel, cardiac troponin and brain natriuretic peptic were normal. A chest radiograph was normal. The patient was discharged with follow up.
The following day, a transthoracic echocardiogram was normal.
A stress echocardiogram on a bike was performed under the same graded exercise protocol as the provoking bike test. At similar sub-maximal effort for heart rate and lactate levels, the patient developed recurrent symptoms. A continuous EKG did not demonstrate arrhythmia; however, the stress echocardiogram demonstrated hyperdynamic left ventricular contractility. At the same time, a cerebral perfusion monitor demonstrated a decrease in cerebral blood flow. No left ventricular outflow tract gradient was noted.
A cardiac magnetic resonance imaging (MRI) was normal.
A dobutamine stress echocardiogram was performed which confirmed an abnormal cardioinhibitory reflex response.
Final Diagnosis:
Bezold-Jarisch (Cardioinhibitory) response to exercise due to a hyperdynamic left ventricle.
Treatment and Outcomes:
1) He was cleared for full athletic participation.
2) He has returned to hockey activities without issues.

551 May 30 2:40 PM - 3:00 PM
Palpitations, Diaphoresis, Left-sided Chest, And Shoulder Pain - Football
James N. Cornwell, David Wilhelm. *LECOM Health Sports Medicine, Erie, PA.* (Sponsor: Patrick F. Leary, DO FACSM, FACSM)
(No relevant relationships reported)

Palpitations, Diaphoresis, Left-sided Chest and Shoulder pain – Football
James N. Cornwell, LECOM Health Sports Medicine, Erie, PA
e-mail: james.cornwell@med.lecom.edu
(Sponsor: Patrick F. Leary, FACSM)
HISTORY: A 19 year-old freshman division II football player presented to the athletic training staff at a local university with palpitations, abdominal discomfort, left-sided chest and shoulder pain along with severe diaphoresis. At that time, the football player had denied trauma to the chest or abdomen during the practice. The athletic training staff immediately arranged for transport of the patient to a local hospital for evaluation.
PHYSICAL EXAMINATION: Upon evaluation in a local emergency department, the athlete was found to be in moderate distress, but A+Ox3. Skin was cool and diaphoretic. Cardiovascular - tachycardia, distal pulses present. Pulmonary - tachypnic, breath sounds present in all fields. Abdominal tenderness in epigastric & left upper quadrant regions, bowel sounds present. Musculoskeletal examination of left shoulder normal
DIFFERENTIAL DIAGNOSIS:
1. Blunt force trauma to spleen
2. Pneumothorax
3. Liver laceration
4. Pancreatitis
5. Left Kidney trauma
TEST & RESULTS:
Vital Signs – 98.4, 112, 24, 108/68, 98% RA
Labwork – slight anemia
CXR – wnl, no pneumothorax
CT of Abdomen and Pelvis
- Grade 3 splenic laceration, free blood
Repeat CT of Abdomen and Pelvis
- Grade 4 splenic laceration, free blood
FINAL/WORKING DIAGNOSIS:
Splenic Laceration (Grade 4) secondary to blunt force trauma to left abdomen
TREATMENT & OUTCOMES:
1. After initial ED eval and diagnosis of splenic laceration, athlete transferred to hospital with interventional radiology capabilities
2. Athlete did remember getting a direct helmet hit to the left side of the abdomen, that "knocked his wind out," 2 days prior
3. Diagnosed with grade 4 splenic laceration
4. Endovascular embolization procedure performed with optimal results - no complication
5. ICU for post-surgical care
6. After an uncomplicated hospital course, the patient was discharged home
7. Follow-up instructions included serial labwork and repeat CT of the abdomen/pelvis in 3 months

8. The aim of this case presentation is to review into current literature and practice and to discuss what is advisable versus safe for return to play in this case of abdominal organ injury

---

B-16 Clinical Case Slide - **Musculoskeletal: Spine to Ankle**

Wednesday, May 30, 2018, 1:00 PM - 3:00 PM
Room: CC-200F

552 **Chair:** Joshua Blomgren. *Rush University Medical Center, Chicago, IL.*
(No relevant relationships reported)

553 **Discussant:** Kaleigh Suhs. *Advocate Lutheran General, Park Ridge, IL.*
(No relevant relationships reported)

554 **Discussant:** Kyle J. Cassas, FACSM. *Greenville Health System, Greenville, SC.*
(No relevant relationships reported)

555 May 30 1:00 PM - 1:20 PM
Ankle Pain--Volleyball Player
Jacob Reisner[1], Cara Prideaux[2], Edward Laskowski, FACSM[2]. [1]*Mayo School of Graduate Medical Education, Rochester, MN.* [2]*Mayo Clinic, Rochester, MN.* (Sponsor: Edward Laskowski, FACSM)
(No relevant relationships reported)

HISTORY:
An otherwise healthy 24 year old female volleyball player presented to the sports medicine clinic with a two week history of atraumatic severe left ankle pain and swelling. She localized the pain to her tibiotalar area. She described a sensation of "tightness" in the ankle. She denied any numbness or tingling or mechanical features to her pain, and she denied focal weakness. She did not endorse any other swollen or painful joints. She denied any history of autoimmune disease, inflammatory arthritis, or exposure to ticks. She had tried Ibuprofen and Tylenol with no significant relief.
PHYSICAL EXAMINATION:
Exam revealed a left ankle effusion and tenderness to touch over the anterior tibial-talar joint but not on the medial, lateral or posterior ankle. No laxity was noted with anterior drawer test. External rotation stress test was not painful. No pain was produced with resisted ankle motion in all planes. Neurologic exam did not reveal any focal strength or sensory changes in the lower extremities. Distal pulses and capillary refill were symmetric.
DIFFERENTIAL DIAGNOSIS:
1. Septic Arthritis
2. Inflammatory Arthritis/Synovitis
3. Crystalline Monoarthritis
4. Lyme Arthritis
5. Internal Derangement
6. Occult Fracture
7. Pigmented Villonodular Synovitis
8. Synovial Chondromatosis
TEST AND RESULTS:
Laboratory testing showed normal white blood cell count. Sedimentation rate and C-reactive protein were slightly elevated. Lyme disease ELISA, rheumatoid factor, and CCP were all negative.
X-ray showed left ankle effusion but no fractures. Attempted ultrasound guided aspiration showed extensive tibiotalar synovitis but did not produce any fluid for analysis. MRI of the left ankle showed extensive nodular synovial thickening of the anterior compartment consistent with Diffuse PVNS.
FINAL WORKING DIAGNOSIS:
Diffuse Pigmented Villonodular Synovitis(PVNS)
TREATMENT AND OUTCOMES:
1. Modest improvement of pain with activity reduction
2. Orthopedic Foot and Ankle Surgery consult for planned arthroscopic nodule excision and synovectomy

556   May 30 1:20 PM - 1:40 PM

Rare Cause of Second Webspace Interdigital Neuritis Diagnosed with Ultrasound

Marissa L. Dombovy-Johnson[1], Brennan J. Boettcher[2], Jonathan T. Finnoff, FACSM[2]. *[1]Mayo Clinic, Rochester, MN. [2]Mayo Clinic Sports Medicine Center, Minneapolis, MN.* (Sponsor: Jonathan T. Finnoff, FACSM)

(No relevant relationships reported)

HISTORY: A 68 year-old male with history of right second metatarsal Weil osteotomy, third webspace interdigital neuroma removal and third hammertoe correction presented with non-traumatic, burning pain in his second webspace that radiated into his second and third toes over the last four years. His pain was present at rest and worsened with activity.

PHYSICAL EXAMINATION:

He had full, symmetric, and painless ankle and subtalar joint range of motion. Strength and sensation to light touch were full and normal. There was tenderness to palpation in right second webspace but no tenderness over the second and third MTP joints. No pain or click was elicited on Mulder's test. He walked without a limp.

DIFFERENTIAL DIAGNOSIS:

- Interdigital neuroma
- Intermetatarsal bursitis
- Metatarsophalangeal joint instability
- Metatarsalgia
- Metatarsal stress fracture

TEST AND RESULTS:

Foot Radiographs

- Healed osteotomy right 2nd metatarsal neck with screw fixation
- Post-operative changes right 2nd and 3rd PIP joints

Diagnostic Ultrasound

- No neuroma or intermetatarsal bursitis was noted
- Third digit flexor tendons were dislocated medially between the second and third metatarsal heads compressing the adjacent neurovascular structures

L15-7io
58Hz
RS

2D
60%
Dyn R 64
P Low
Gen

3RD MT   2ND MT

THIRD DIGIT
FLEXOR TENDON

R FOOT
Foot MRI

- Confirmed US findings of medial dislocation of the third flexor digitorum longus and brevis tendons in between the second and third metatarsal heads

FINAL/WORKING DIAGNOSIS:

- Medial dislocation of third flexor digitorum longus and brevis tendons between the second and third metatarsal heads likely causing mass effect on the interdigital nerve in the second interspace

TREATMENT AND OUTCOMES:

- It was felt that relocation of the tendons was not a technically feasible surgery
- An ultrasound-guided second webspace corticosteroid injection along the interdigital nerve provided immediate relief of all patient's symptoms, however the pain and burning returned within one week
- Definitive treatment with an interdigital neurectomy was planned

557   May 30 1:40 PM - 2:00 PM

Low Back Pain in a First-year Medical Student

Michael S. Antonis. *MedStar Georgetown University, Washington, DC.*

(No relevant relationships reported)

HISTORY:

A 22-year-old male presents to MedStar Sports Medicine clinic from Student Health physician with complaint of hamstring and back pain for the last year. Patient describes the pain is worse when he rides his bike to school (5 miles) improved with walking to class and through the day, but worsens when he tries to run at night beyond 4 miles.

PHYSICAL EXAMINATION:

Gait: antalgic gait

Palpation -- Tone: [abnormal]

Tenderness: [paraspinous area at level of T10 through S1]

Range of Motion: Forward Flexion - [90 +] Deg

Extension - [15] Deg

Forward bending: [symmetric / normal]

Extension: [exacerbates pain] [R] and [L]

Stork test: [exacerbates pain] [R] and [L]

Straight Leg Raise (Laseague) Test: [negative]

DIFFERENTIAL DIAGNOSIS:

1. Lumbago
2. Stress Fracture
3. Hamstring/ITB Syndrome
4. Psychosomatic
5. Spondylarthropathy

TEST AND RESULTS:

Lumbar Xray (obtained via fax from PCP visit in New York): There is mild lumbar scoliosis. There is narrowing of all intervertebral disc spaces from T12-L5. Schmorl node endplate deformities and discogenic changes are present. No fracture or subluxation. Facet joints and SI joints are normal.

MRI Lumbar: Degenerative changes greater than expected for age and multiple Schmorl's nodes. No spondylolisthesis or spondylolysis. Consider ordering thoracic MRI as concern exists for Scheuermann's disease. There is subchondral sclerosis along the iliac sides of bilateral sacroiliac joints.

MRI Thoracic: Scattered endplate irregularities and small Schmorl's nodes with disc space narrowing throughout the thoracic spine with associated endplate change.

LABS:

HLA B-27: negative

CRP: 7.4

ESR: 4

Quantiferon Gold TB: negative

ANA: positive

DS-DNA and Anti-Sm: negative

FINAL/WORKING DIAGNOSIS:

Schueuermann's Disease and HLA-B27 seronegative Axial Spondyloarthritis

TREATMENT AND OUTCOMES:

Patient is doing well in medical school and currently being managed on naproxen 500mg twice a day with no gastrointestinal side effects.

Patient has followed up with Rheumatology who recommends naproxen at this time and if symptoms flair will consider initiating an anti-TNF agent with monitoring of CRP values.

558   May 30 2:00 PM - 2:20 PM

Rib Injury in a Professional Baseball Player

Christopher Trinh, Brian Coleman, James Barrett. *University of Oklahoma Health Science Center, Oklahoma City, OK.*

(No relevant relationships reported)

History: A 24 year old previously healthy left handed male professional baseball pitcher was warming up on the mound before a game when he suddenly felt a vague pain in his lower left anterior-lateral rib cage region but denied hearing a pop. Pain was a localized deep ache on the lower anterior rib cage. Although he felt discomfort the player was able to complete his warm up regimen and start the game. During the game he was only able to throw four pitches prior to unbearable pain during the acceleration phase of pitching causing him to be pulled from the game and seek medical attention.

Physical Exam: Normal appearance of the chest wall. Point tenderness to palpation and a 1x1cm soft tissue mass on the lower left anterior chest wall on palpation. Any active and passive motion of the torso exacerbated the pain and the mass was exquisitely tender to palpation. Bilateral shoulder exams were within normal limits and pain was not affected by inhalation or exhalation. On exam, he was neurologically and vascularly intact. There was no winging of the scapula or crepitus along the rib cage.

Differential Diagnosis:

1. Oblique muscle strain
2. Rib stress fracture
3. Costochondral junction avulsion fracture
4. Serratus anterior avulsion fracture
5. Intercostal muscle strain

Test and Results:

Thoracic MRI findings suggested either a fracture or stress injury of the costochondral cartilage along the left anterior-inferior aspect of the ribcage. There was extensive edema present along the region that measured 8x10 cm but there was no evidence of rib fractures.

Chest CT without contrast revealed edema around the costochondral junction of ribs 7 and 8 on the left with anterior prominence of the cartilage but no focal displacement or rib fractures.

Final Working Diagnosis: Based on Imaging, injury most likely to be costochondral junction avulsion fracture of ribs 7 and 8.

Treatment and Outcomes:

WEDNESDAY, MAY 30, 2018

The player was initially treated with 6 weeks of activity restriction and rest. Surgery was not warranted due to lack of significant separation of the fragment. Repeat radiographs were obtained at 6 weeks which revealed proper healing. After 6 weeks he began a graduated pitching regimen. Pain improved throughout his rehabilitation with rest and NSAIDS once he began physical activity. He returned to full activity at 8 weeks.

---

559   May 30 2:20 PM - 2:40 PM
Acute Lumbar Pain - Football
Timothy J. Durkin, Katherine Edenfield, Guy Nicolette, Stephen Carek, Jay Clugston. *University of Florida, Gainesville, FL.*
(No relevant relationships reported)

HISTORY:
A freshman collegiate football player presented to the athletic training facility after his first official practice, complaining of worsening, severe pain in his R greater than L lumbar region without radiation or radicular symptoms. He denied any injury during practice. He had previously reported mild low back tightness during summer conditioning workouts that resolved with rest. He and the sports health staff were aware that he has sickle cell trait.
PHYSICAL EXAMINATION:
Pt in severe distress with diaphoresis, agitation and restlessness Limited lumbar ROM. Tenderness in lumbar paraspinal muscles R greater than L. Non-tender abdomen, symmetric pulses x4 extremities, no neurologic deficits or costa-vertebral tenderness. HR and BP elevated. Afebrile. High-flow oxygen by mask initiated and athlete transported to ED.
DIFFERENTIAL DIAGNOSIS:
Lumbar muscle/myofascial strain
Lumbar disc rupture
Lumbar paraspinal myonecrosis
Ureteral calculus
Renal angiomyolipoma
TESTS AND RESULTS:
CMP Cr 1.7, Ca 10.6, Glu 140; otherwise normal WBC 11.8, Hgb 15.5, Hct 47.5, Plt 178 CK 747 U/L Urinalysis SpGr 1.010, Pro 30, Small blood, 2 RBC, 4 WBC, myoglobin negative
MRI lumbar spine: T2 hyperintense signal in the paraspinous muscles bilaterally, R greater than L. Spine and nervous structures normal. *Impression*: Multifocal paraspinous muscular edema. Considerations would include strain, acute myonecrosis (given clinical history), or acute blood products
FINAL DIAGNOSIS:
Acute lumbar paraspinal myonecrosis in athlete with SCT
TREATMENT AND OUTCOMES:
1. High-flow oxygen continued
2. IV fluids initiated and 3L NS bolus given by pressure infusion
3. IV hydromorphone prn for pain control
4. Rapid improvement in pain post IV fluid bolus
5. Inpatient admission, transitioned from IV hydromorphone to PO oxycodone
6. Peak CK of 10,169 approximately 13 hours post event
7. Discharged home hospital day 2 with CK down trending at 7,060 ,Cr 0.98, off all pain meds
8. Cleared for activity at 7 days post event
9. Completed return to play activities, returned to full practice at 11 days post event
10. No related medical issues, no visible loss of muscle bulk/tone and continued full team participation as of abstract submission

---

560   May 30 2:40 PM - 3:00 PM
Low Back Pain - Recreational Soccer Player
Sean Matsuwaka, Brian Liem. *University of Washington, Seattle, WA.*
(No relevant relationships reported)

HISTORY: A 21-year-old female recreational soccer player presented with intermittent right-sided low back pain for two years. She denied any trauma or inciting event. Pain was localized to the right lumbosacral region without radiating leg pain and was described as dull and aching. It was rated on average 5/10 on a numerical rating scale and associated with nausea when pain worsened. Symptoms were worse with prolonged sitting, and several times in the last month she reported worsening of typical pain with alcohol intake. She denied leg weakness, numbness, or bowel/bladder dysfunction. She participated in six weeks of physical therapy, which helped with nausea and pain with sitting, but she continued to have pain with alcohol consumption.
PHYSICAL EXAM: Full and symmetric strength, sensation, and reflexes. Mild lumbar dextroscoliosis. No palpable step-offs. Tenderness over right lumbar paraspinals and above right iliac crest. No tenderness over PSIS. Full, non-painful range of motion with lumbar flexion and extension. No pain with facet loading. Full, non-painful hip range of motion. Negative FABER, FADIR, and straight leg raise test bilaterally.

DIFFERENTIAL DIAGNOSIS: 1. Discogenic pain 2. Facet-mediated pain 3. Disc herniation 4. Muscular strain 5. Sacroiliac joint dysfunction 6. Intrabdominal/intrapelvic etiology 7. Neoplasm
TESTS AND RESULTS: 1. Lumbar spine X-rays: -Normal alignment, normal vertebral body and disc space height -Partial lumbarization of S1 vertebral body -Five degrees of lumbar dextroscoliosis 2. MRI lumbar spine: -Lumbarization of S1 vertebral body -Normal disc heights and signal -Normal central canal and neural foramen size throughout lumbar spine -T1/T2 hyperintensity within S2 vertebral body, likely lipoma -Increased T2 signal medial to right kidney suggestive of hydronephrosis
3. Renal ultrasound:-Moderate right hydronephrosis with extrarenal pelvis. No nephrolithiasis. 4. Renogram with furosemide: - Right kidney with blunted flow and delayed clearance improved slightly with furosemide, consistent with partial obstruction at right ureteropelvic junction
FINAL/WORKING DIAGNOSIS: Ureteropelvic junction obstruction causing Dietl's crisis
TREATMENT AND OUTCOMES: 1. Referral to urology 2. Resolution of pain and improvement in renal function after pyeloplasty

---

B-17   Clinical Case Slide - **Shoulder**

Wednesday, May 30, 2018, 1:00 PM - 3:00 PM
Room: CC-Mezzanine M100F

561   **Chair:** Tracy Ray, FACSM. *Duke University, Durham, NC.*
(No relevant relationships reported)

562   **Discussant:** C. Mark Chassay, FACSM. *IRONMAN Sports Medicine Institute, Houston, TX.*
(No relevant relationships reported)

563   **Discussant:** David Olson, FACSM. *University of Minnesota, St. Paul, MN.*
(No relevant relationships reported)

---

564   May 30 1:00 PM - 1:20 PM
Pectoralis Muscle Rupture While Lifting Weights
Mimi Zumwalt, Thomas Githens, Adam Wooldridge. *Texas Tech University Health Science Center, Lubbock, TX.* (Sponsor: Jacalyn McComb, FACSM)
(No relevant relationships reported)

HISTORY: 41 y/o male RHD sustained an injury to his chest area while performing a heavy bench press. His arm gave out when his spotter failed to assist him during the eccentric phase. He felt a painful snapping sensation near his right shoulder with subsequent throbbing, swelling and bruising. He suddenly felt nauseated/lightheaded, unable to perform any more exercises so he immediately sat down. He was evaluated by a fitness specialist, obtained an MRI study within 2 days, then seen 3 days later in Sports clinic. He denies any supplement usage or paresthesias but relates some weakness when using his arm.
PHYSICAL EXAMINATION: Right upper extremity/chest region reveals asymmetry of pectoralis muscle with less fullness/dimpling upon "hands on hips" pose; ecchymosis of proximal arm area with loss of axillary fold; tender over medial humerus with difficulty palpating the tendon; weakness with resisted shoulder internal rotation/adduction maneuvers.
DIFFERENTIAL DIAGNOSIS:
1. Right arm contusion/tendon strain
2. Right partial pectoralis muscle tear
3. Right pectoralis major tendon rupture
TESTS AND RESULTS:
Right shoulder radiographs: AP, Y and axillary lateral views show no bony avulsion
MRI films: reveal "extensive edema around musculotendinous junction of right pectoralis"; "small amount of linear fluid" in area of humeral insertion and "absence of tendon" with "retraction" into chest wall
FINAL/WORKING DIAGNOSIS:
Right pectoralis major tendon rupture
TREATMENT AND OUTCOMES:
1. Underwent primary open right pectoralis tendon repair/reattachment 6 days post injury
2. Wore shoulder immobilizer for 6-8 weeks
3. Participated in formal physical therapy rehabilitation at 1month post-surgery
4. Progressed to light weightlifting at 4 months
5. Experienced transient scar hypersensitivity-resolved with local massage
6. Discharged himself at 5 months
7. Follow-up 2 years 9 months later for another complaint-doing well, back to working out (lighter weights/higher reps)

565   May 30 1:20 PM - 1:40 PM

Teen With Acute Shoulder Pain Four Years After A Car Accident.

Natalie Ronshaugen, Kyle Nagle. *University of Colorado, Aurora, CO.* (Sponsor: John Hill, FACSM)

(No relevant relationships reported)

HISTORY: 18yo male with sudden onset, severe right shoulder pain occurring while sitting in class 11 days prior to presentation. He had a history of a posterior shoulder dislocation at age 14 in a car accident, requiring relocation under sedation without known complication. He completed PT at that time, however was unable to return to football or overhead throwing activities. At the start of his new onset pain, he suspected re-dislocation of his shoulder and went to the ED. X-rays were abnormal but with unclear diagnosis. He was referred to sports medicine clinic for further evaluation and treatment.
PHYSICAL EXAMINATION: Inspection: Significant atrophy of the supraspinatus and infraspinatus. Right shoulder was held elevated. Intertrigo noted in right axilla. Range of motion of the shoulder: 20 degrees forward flexion, 20 degrees forward flexion, 0 degrees external rotation, and internal rotation to T12. Strength: 4/5 empty can, 4/5 internal rotation, 3+/5 external rotation. Neurovascular: Brisk pulses, 2 second capillary refill, intact motor exam, and sensation intact in all dermatomes. Special tests: Neer's positive pain with no increased ROM, Speed's test positive, O'Brien's test positive, cross over test negative, and Hawkin's positive.
DIFFERENTIAL DIAGNOSIS: Recurrent shoulder dislocationMalignant or benign bony lesionPathologic fracture of proximal humerusRotator cuff tearDisruption of suprascapular nerve **TEST AND RESULTS**: X-rays of the right shoulder:- Patchy sclerosis and irregular shape of the humeral head. - Decreased joint space of the glenohumeral joint and elevation of the humeral head.- Hill-Sachs deformity with small adjacent osseous fragment. - Curvilinear osseous density superior to the humeral head - likely calcification of the rotator cuff or loose body. MRI with and without contrastiv>
FINAL WORKING DIAGNOSIS: Osteonecrosis of the humeral head
TREATMENT AND OUTCOMES: Referred to orthopedic shoulder specialist who plans to do a hemiarthroplasty without a stem. Surgery is planned for December 1, 2017. Follow-up will be available by May 2018.

566   May 30 1:40 PM - 2:00 PM

Back and Shoulder Pain in a Weightlifter with Ehlers Danlos

James Kelley. *Wellspan, York, PA.* (Sponsor: Mark Lavallee, FACSM)

(No relevant relationships reported)

Back and Shoulder Pain in a Female Weight Lifter with Ehlers Danlos
History: The Patient is a 44 yo woman who is a former fitness model, power lifter, and police office. She has a past medical history consisting of, pituitary tumor, Macromastia (C to DDD), right and left temporal aneurysms, Bilateral hip subluxation, Chiari Type I herniation – nonoperable and Ehlers Danlos. She is treated for chronic pain and her regimen consists of Tylenol, Tramadol and Oxycodone based on severity. NSAIDs are contraindicated due to the Xarelto use. In her most recent EDS clinic visit, she was referred to the sports medicine clinic for pain in her back and right shoulder. She was swimming and performing rehab exercises and presented with her 9/10 shoulder pain. The pain is worse with motion and is located on her posterior and lateral shoulder.
Physical Exam:
GENERAL: Healthy appearing, Alert and Oriented, no acute distress, mood appropriate, respiratory rate non-labor, hearing intact
THORACIC:
PALPATION: TENDER over Bilateral Trapezius, splenius captius, rhomboids
ROM: LIMITED inflexion-extension lateral rotation B/L
EXTREMITY EXAM
SENSATION:
Upper Extremity: intact bilateral, no deficits
Lower Extremity: intact bilateral, no deficits
STRENGTH:
Upper extremity: full strength in all major muscle groups
Lower extremity: full strength in all major muscle groups
SPECIAL TESTS
(+) Hawkins right side
(+) Spurling's away from affected
Differential Diagnosis : 1. Complex Regional Pain Syndrome 2. Thoracic outlet syndrome 3. Acute shoulder instability Nerve entrapment (i.e. suprascapular nerve) 4. Strain of her rhomboids/trapezius/splenus capitus 5. Brachial artery aneurysm 6. RTC injury 7. Spinal Stenosis/Radiculopathy 8. Polymyalgia Rheumatica Syringomelia
Final Working Diagnosis: Chronic Rotator Cuff tendonosis from chronic subluxation, and bilateral trapezius, rhomboid and splenus capitus strain, likely from overly active rehab and her Macromastia
Treatment: Subacromial shoulder injection with glucocorticoids and dry needling of her splenus capitus, rhomboids, and trapezius muscles
Outcome: Significant reduction in her pain, reduced narcotic use and continuing with her rehab and swimming. Receiving dry needling on a monthly basis.

567   May 30 2:00 PM - 2:20 PM

Shoulder Pain - Builder with Chronic Calcifications

Lauren Nadkarni, Krystian Bigosinski, Heather Gillespie, FACSM. *Maine Medical Center, Portland, ME.* (Sponsor: Heather Gillespie, FACSM)

(No relevant relationships reported)

History:
A 48 year old right hand dominant male smoker who works as a builder presents with chronic left shoulder pain. 15 years ago, he dislocated his left shoulder while breaking up a fight. Since then, he has dislocated it several times, most recently 5 years ago, but is able to replace it on his own. Two years ago, he had x-rays at an outside hospital emergency room and was diagnosed with calcium in his shoulder (images were unavailable). Last year, he felt a "squishy mass" and then "felt like something left my shoulder" when he was getting out of his car, and has had pain since then. He feels his shoulder is weaker and has less muscle mass, but denies hand weakness. However, he has had some neck issues and had numbness in his left arm secondary to cervical stenosis at C5-7, spondylolisthesis of C2-3, disc herniation at C4-5, and radiculopathy of C5-6, which improved after physical therapy which was prescribed by a physiatrist (PM&R, neuro/spine).
Physical Exam:
Office examination of his left shoulder revealed mild pain at terminal motion with overhead movements, full range of motion, 5/5 rotator cuff and distal strength, and negative AC joint testing. Impingement tests (Hawkins and Neer), and instability tests (apprehension and relocation) were positive. Distal neurovasculature was intact. His elbow and contralateral shoulder exam were normal.
Differential Diagnosis:
Rotator cuff tear, shoulder impingement, osteoarthritis, osteochondromatosis, labrum tear, lipoma, ganglion cyst, foreign body, erosive arthritis, pigmented villonodular synovitis, synovial sarcoma, intra-articular fracture fragments, neuropathic joint, and multidirectional instability
Tests and Results:

WEDNESDAY, MAY 30, 2018

Left shoulder x-rays (AP/Outlet/Axillary): "innumerable calcific loose bodies consistent with synovial osteochondromatosis as well as significant osteoarthritic changes at the glenohumeral joint with close to bone-on-bone narrowing seen best on the axillary view. The loose bodies are dispersed throughout the joint capsule and into the bicipital groove."
Final/Working Diagnosis:
Synovial osteochondromatosis
Treatment and Outcomes:
- Continued physical therapy
- Over the counter analgesics, ice/heat as needed
- Referral to orthopedic surgeon for loose body removal vs. shoulder joint replacement

---

568   May 30 2:20 PM - 2:40 PM
Shoulder Pain in a Youth Hockey Player

Brennan J. Boettcher, Jeffrey M. Payne, Jonathan T. Finnoff, FACSM. *Mayo Clinic, Minneapolis, MN.* (Sponsor: Jonathan T. Finnoff, FACSM)
(No relevant relationships reported)

HISTORY: A 14 year-old male hockey player presented for right shoulder pain. He checked an opponent with his left shoulder and developed right shoulder pain immediately. There were no associated neurovascular symptoms. The pain was sharp, and radiated down the lateral shoulder to the mid-arm with abduction. Outside shoulder radiographs were normal.
PHYSICAL EXAMINATION: Athletic male resting with his right hand on his abdomen. Asymmetric depression of his right acromion with arms unsupported at his side. Right shoulder range of motion was slightly limited due to pain. He had tenderness just posterior to the distal mid-third of the clavicle diaphysis over the trapezius insertion. Neurologic and strength examination were normal.
DIFFERENTIAL DIAGNOSIS: -Trapezius strain -Occult clavicle fracture -ACJ separation -Physeal injury -Brachial plexus injury -Rotator cuff injury -Labral tear
TEST AND RESULTS: Diagnostic Ultrasound revealed an avulsion of the deep fibers of the trapezius from the clavicle, with ACJ sprain and distal clavicular hypermobility. Repeat radiographs demonstrated subtle periosteal lifting of the inferior clavicle near the avulsion visualized on sonographic evaluation indicative of a clavicular physeal injury.
FINAL WORKING DIAGNOSIS: Grade 1 right ACJ separation with trapezius avulsion off of the clavicle and distal clavicular physeal injury.
TREATMENT AND OUTCOMES: The patient was placed in a sling for comfort for 2 weeks. At the 3 week follow-up, he was about 95% of normal, repeat ultrasound demonstrated a small amount of distal clavicular callus formation. He was cleared to resume non-contact aerobic activity (e.g.skating) and gentle, non-painful shoulder isometrics. Re-evaluation at 6 weeks demonstrated full, pain-free shoulder range of motion, normal strength, and distal clavicular callus formation on radiographs. He was released to unrestricted activity.

---
569   May 30 2:40 PM - 3:00 PM
"OCD": A Zebra In The Glenoid Fossa

Elizabeth Barchi. *New York University, New York, NY.*
(No relevant relationships reported)

History:
A 19-year-old female Division 1 volleyball player presented with 5 months of right shoulder pain and decreased range of motion. The pain was localized to "inside" the shoulder and aggravated by serving and setting (right hand dominant). 2 months after the onset of symptoms, she noticed an acute increase in pain following a collision that resulted in a cervical strain. The symptoms persisted despite 3 months of physical therapy in the training room and 2 months of post-season rest. She denied neurological or instability symptoms.

Physical exam:
Right shoulder: Tenderness to palpation over AC joint. Limited active and passive range of motion: Forward flexion 160deg, Abduction 160deg, External rotation 60deg, Internal rotation to T12. Mild supraspinatus weakness. Positive Neer and Hawkins tests. Positive Obrien test. Negative cross arm adduction and anterior apprehension.
Differential Diagnosis:
1. Impingement Syndrome
2. Labral tear
3. Rotator cuff tendinopathy
4. Osteochondral defect of the glenoid fossa
5. Osteochondroma
Testing and Results:
MRI Right Shoulder: Large osteochondral defect centered in the posterior superior aspect of the glenoid measuring approximately 1.6 x 1.7 cm. Associated marked irregularity and bone loss of the subchondral plate and subchondral bone, suspicious for an instable osteochondral fragment. Tear of the adjacent posterior superior labrum.
Final Diagnosis
Osteochondral defect of the glenoid fossa
Treatments/Outcomes:
1. Hyaluronic acid injection into glenohumeral joint with no change in symptoms
2. PRP injection into glenohumeral joint with excellent reduction in pain and eventual return to baseline range of motion
3. Physical therapy- rotator cuff strengthening, range of motion exercises, joint mobilization, and manual modalities
4. Returned to full sports 8 weeks following PRP injection. After complete resolution of symptoms, she played volleyball in the following season as a setter.

B-36   Thematic Poster - **Get Up, Get Moving: New Research in Sedentary Behavior**

Wednesday, May 30, 2018, 3:15 PM - 5:15 PM

Association Between Exercise And Prolonged Television Viewing Days On Time-use And Physical Activity Energy Expenditure In Older Us Adults

Charles E. Matthews, FACSM[1], Sarah Keadle[2], Pedro Saint-Maurice[1], Steven C. Moore[1], Erik A. Willis[1], Joshua N. Sampson[1], David Berrigan[1]. *[1]National Cancer Institute, Rockville, MD. [2]Cal Poly, San Luis Obispo, CA.*
(No relevant relationships reported)

PURPOSE. Our goal was to estimate the time-use exchanges associated with exercise, prolonged television viewing, and work days on the amount and type of sedentary and physically active behaviors and physical activity energy expenditure. **METHODS.** Participants were 1,020 older adults who completed up to 6 detailed previous-day recalls over 12-months that provided a profile of the use of time in sedentary and physically active pursuits. We predicted time-use and physical activity energy expenditure (PAEE) outcomes for 1) days with and without exercise, 2) days with or without prolonged television (2+h/day), and 3) work vs non-work days. To estimate time-use exchanges we used repeated measures and linear mixed models, adjusting for age, sex, season of the year, and day of the week. **RESULTS.** Exercise days were associated with less sedentary time (-0.37 hrs/d) and light activity (-0.29 hrs/d), and less household, work, and shopping activities. Compared to non-exercise days, the increase in total PAEE on exercise days (2.83 MET-hrs/d) was only about half that expended during exercise (5.98 MET-hrs/d). Prolonged television viewing was associated with an increase in total sedentary time (0.86 hrs/d) and less light (-0.45 hrs/d) and moderate-vigorous intensity activity (-0.41 hrs/d), and thus lower total PAEE (-2.43 MET-hrs/d). Work days were associated with less sleep (-0.91 hrs/d) and an increase in total sedentary time (1.32 hrs/d). **DISCUSSION.** Exercise was associated with an increase in PAEE, but due to reductions in other activities, only about half of the energy expended during exercise trickled-up to total daily PAEE. Prolonged television viewing was associated less PAEE and less moderate-vigorous activity. These findings provide new insights into possible compensation associated with exercise training, and suggest a strong link between television viewing and physical inactivity.

Prolonged Uninterrupted Sitting Impairs Vascular Function and Increases Biomarkers of Atherosclerotic Risk in Overweight Adults

Megan S. Grace[1], Rachel E D Climie[1], Michael Wheeler[1], Elisabeth Lambert[2], Carolina Ika Sari[1], Farzaneh Rezai[3], Hamza Ali[3], Gavin Lambert[2], Neville Owen[1], Daniel J. Green[4], Bronwyn A. Kingwell[1], David W. Dunstan[1]. *[1]Baker Heart and Diabetes Institute, Melbourne, VIC, Australia. [2]Swinburne University, Melbourne, VIC, Australia. [3]Monash University, Melbourne, VIC, Australia. [4]University of Western Australia, Perth, WA, Australia.*

(No relevant relationships reported)

Purpose. Prolonged uninterrupted sitting amplifies postprandial glucose, insulin and lipid responses in overweight/obese adults with or without type 2 diabetes; and, impairs lower limb endothelial-mediated vasodilation in healthy adults. It is unknown whether prolonged sitting impairs vascular function or modulates other vascular inflammatory and pro-atherogenic mechanisms in those at heightened risk of cardiometabolic disease. In overweight/ obese adults, we examined the potential pro-atherogenic effects of an acute bout of prolonged sitting, compared to sitting interrupted with brief activity breaks.
Methods. In a randomised crossover trial, following a standardised breakfast meal, 19 (11 Male, 8 Female) overweight/obese participants (BMI 30.6±3.4 kg/m²; age 57±12 years; mean±SD) either: (i) sat uninterrupted for 5h (SIT); or, (ii) interrupted 5h of sitting with 3min light-intensity simple body-weight resistance activities every 30min (SRA). Brachial and femoral artery endothelial-mediated vasodilation were measured using flow mediated dilation (FMD). Circulating levels of vasoactive and pro-atherosclerotic biomarkers (total nitrate+nitrite, ET-1, ICAM-1 and VCAM-1) were measured. Sympathetic nervous activity was also estimated (peroneal microneurography and circulating catecholamines). Data were analysed using generalised linear mixed models controlling for age, sex, BMI, baseline values and treatment order, and are presented as marginal mean±SEM.
Results. Femoral artery FMD was impaired in the SIT condition, compared to SRA (5.1±0.5% vs 9.0±0.5%, respectively, p<0.05). Significantly higher circulating levels of the potent vasoconstrictor and pro-inflammatory mediator ET-1 (1.6±0.1 vs 1.4±0.1 pg/ml) and pro-atherogenic adhesion biomarker VCAM-1 (616±33 vs 564±26 ng/ml) were observed in SIT compared to SRA, respectively (p<0.05). There were no differences between conditions for any other outcomes.
Conclusion. In overweight/obese adults, an acute bout of uninterrupted sitting impaired femoral artery endothelium-mediated vasodilation and increased circulating levels of pro-atherosclerotic biomarkers. Prolonged sitting may have implications for vascular function, leukocyte adhesion and atherogenesis in those at heightened risk of cardiometabolic disease.

Sedentary Behavior and Physical Activity are associated with Sleep Duration and Sleep Quality in Postmenopausal Women

Seth A. Creasy[1], Cynthia A. Thomson[2], David O. Garcia[2], Tracy E. Crane[2], Betsy C. Wertheim[2], Laura Baker[3], Mace Coday[4], Lauren Hale[5], Catherine R. Womack[4], Kenneth P. Wright Jr.[6], Edward L. Melanson, FACSM[1]. *[1]University of Colorado Denver, Aurora, CO. [2]University of Arizona, Tucson, AZ. [3]Wake Forest University, Winston-Salem, NC. [4]University of Tennessee, Knoxville, TN. [5]Stony Brook University, Stony Brook, NY. [6]University of Colorado Boulder, Boulder, CO.* (Sponsor: Edward L. Melanson, FACSM)

(No relevant relationships reported)

PURPOSE: There is a general decline in sleep duration and sleep quality with aging. It is unclear whether lifestyle behaviors such as physical activity and sedentary behavior are related to these declines in sleep health. In this analysis, we evaluated the associations between sedentary behavior (SB), total physical activity (total-PA), light physical activity (LPA), moderate physical activity (MOD-PA), and vigorous physical activity (VIG-PA) with self-reported sleep quantity and quality in a cohort of postmenopausal women.
METHODS: Baseline Data from the Women's Health Initiative Observational Study (N=89,853, age: 63.6±7.4 years, BMI: 27.2±5.8 kg/m², 84% Non-Hispanic White) were used in this cross-sectional analysis. Total-PA, LPA, MOD-PA, and VIG-PA were categorized by metabolic equivalents of the activity (MET-hrs/wk) and were measured using self-reported questionnaire. SB was categorized by hrs/day and was also measured via questionnaire. Logistic regression was used to examine the relationships between these activity variables and the odds of having self-reported short sleep (<7 hours), subjective sleep disturbance, and reduced subjective sleep quality. Odds ratios (OR, 95% confidence intervals) were adjusted for age, race, neighborhood SES, BMI, health status, depressive symptoms, smoking status, alcohol use, hormone therapy, and history of CVD, diabetes, and cancer.
RESULTS: Higher SB (>11 hrs/day) was associated with increased odds of short sleep (1.87, 1.79-1.96), poor sleep quality (2.21, 2.10-2.33), and sleep disturbance (1.56, 1.49-1.64). Conversely, more LPA (>4.5 MET-hrs/wk) was associated with a reduced odds of short sleep (0.96, 0.92-1.00). Furthermore, higher Total-PA (0.90, 0.84-0.97), LPA (0.94, 0.89-1.00), and MOD-PA (0.91, 0.86-0.97) were associated with reduced odds of poor sleep quality.
CONCLUSIONS: In postmenopausal women, physical activity at the light or moderate level was associated with better sleep quality. Whereas, engaging in more sedentary behavior increased the risk for shortened and lower quality sleep. Future investigations may focus on reducing sedentary behavior as a novel method for improving overall sleep health in older women.

Association of Combined Sedentary Behavior and Diabetes Mellitus with All-Cause Mortality in Brazilian Adults

Italo R. Lemes[1], Xuemei Sui, FACSM[2], Bruna C. Turi-Lynch[3], Leanna M. Ross[4], Steven N. Blair, FACSM[2], Rômulo A. Fernandes[1], Jamile S. Codogno[1], Henrique L. Monteiro[5]. *[1]São Paulo State University, Presidente Prudente, Brazil. [2]University of South Carolina, Columbia, SC. [3]São Paulo State University, Rio Claro, Brazil. [4]Duke University, Durham, NC. [5]São Paulo State University, Bauru, Brazil.*

(No relevant relationships reported)

Diabetes mellitus (DM) is associated with increased specific and all-cause mortality in different populations. Although sedentary behavior (SB) has been identified as a modifiable risk factor for DM, cardiovascular disease, and all-cause mortality, investigations regarding the combined effect of DM and SB on all-cause mortality are scarce. **PURPOSE:** To investigate the combined effect of DM and SB on all-cause mortality in adults from the Brazilian National Health System (NHS). **METHODS:** Data were obtained from 970 adults (709 women; mean age 64.7 ± 9.1 years) enrolled in the Brazilian NHS from 2010-2016. Participants were 50 years or older, registered for at least one year in the NHS, and received at least one medical visit in the past six months. SB was estimated via self-reported TV viewing frequency on the Baecke questionnaire and was subsequently classified into thirds: low, middle, and high. For our analysis the low and middle groups were combined to indicate lower level of SB due to the small sample size. Presence of physician-diagnosed DM was assessed via medical record. Mortality was reported by participants' relatives and confirmed via medical records of the Brazilian NHS. Cox regression determined hazard ratios (HRs) and its 95% confidence intervals (95%CIs). Reference group was lower SB without DM at baseline (health status, sociodemographic and behavioural covariates were potential confounders). **RESULTS:** In overall sample, 276 (28%) had DM, 210 (21.6%) had high SB, and 62 (6.4%) had both DM and high SB at baseline (89 deaths were registered). In the adjusted model, the combination of DM and high SB was associated with greater risk of all-cause mortality (HR: 3.38; 95%CI = 1.86-6.13) compared to those without DM who also did not have high SB at baseline. The presence of DM (HR: 1.33; 95%CI = 0.76-2.34) or high SB alone (HR: 1.16; 95%CI = 0.62-2.17) were not significantly different from referent group. **CONCLUSION:** In this sample, the combination of both DM and high SB (but not DM and SB alone) had more than three times greater risk for all-cause mortality compared to those without DM and high SB. Supported by São Paulo Research Foundation (FAPESP) Grant 2015/17777-3 and 2016/11140-6.

636   Board #5   May 30 3:15 PM - 5:15 PM

Within-Day Trajectories of Sedentary Time at Work Among Sedentary Office Workers

Kristina Hasanaj[1], Meynard L. Toledo[1], Sarah L. Mullane[1], Miranda L. Larouche[1], Sarah A. Rydell[2], Mark A. Pereira[2], Matthew P. Buman, FACSM[1]. *[1]Arizona State University, Phoenix, AZ. [2]University of Minnesota, Minneapolis, MN.* (Sponsor: Matthew Buman, FACSM)

(No relevant relationships reported)

Office workers can spend 70-80% of their workday sedentary; however, little is known about the trajectory of sedentary time over the course of the workday and if it varies by worker characteristics such as age, gender, job type (executive, professional, or clerical), or weight status.
PURPOSE: To understand within-day trajectories of sedentary time by age, gender, job type, and weight status among sedentary office workers.
METHODS: Participants (N=632, 72% female, 71% white, 45 ± 11 years of age) were recruited from 24 worksites in Phoenix and Minneapolis areas to participate in the 'Stand & Move @ Work' cluster randomized controlled trial to reduce sedentary time and increase light-intensity physical activity in the workplace. Participants wore

an activPAL accelerometer/inclinometer on the thigh continuously across workdays (n = 5.8 ± 1.8 days/person) to assess sedentary time prior to any intervention. Work time was segmented using daily work logs and time of day was temporally aligned based on "work time" (i.e., minutes since starting workday) or "clock time" (i.e., minutes since midnight). Mixed-effects regression models (clustered by time within workdays) were used to account for within person time variations and to examine intercept (i.e., main effects) and time trajectory differences by worker characteristics.
RESULTS: Based on work time (min/hour), there was a small negative trajectory for sedentary time (b [SE] = -0.31 [0.12], p=0.010). Women were less sedentary overall (b [SE] = -2.90 [0.62], p<0.001); however, men had greater decreases in sedentary time over the workday (b [SE] = 0.278 [0.10], p=0.002).
Obese individuals were less sedentary than overweight (b [SE] = 4.90 [0.65], p<0.001) and normal weight (b [SE] = 6.61 [0.63], p<0.001) individuals overall; however, overweight individuals (b [SE] = -0.26 [0.10], p=0.006) had greater decreases in sedentary time over the workday relative to obese (whose sedentary time remained stable). These patterns were similar when time was aligned by clock time.
CONCLUSION: Sedentary time was modestly reduced over the work day. This pattern varied by gender and weight status, but not by age or job type. These findings inform potential tailoring strategies by identifying when and for whom to optimally target interventions to reduce sedentary time in the workplace.

637   Board #6   May 30 3:15 PM - 5:15 PM
Effect Of A Worksite Sedentary Behavior Intervention On Energy Intake In Adult Men And Women

Junia N. Brito[1], Nathan R. Mitchell[1], Sarah A. Rydell[1], Sarah L. Mullane[2], Meynard L. Toledo[2], Miranda L. Larouche[2], Matthew P. Buman, FACSM[2], Mark A. Pereira[1]. [1]*University of Minnesota, Minneapolis, MN.* [2]*Arizona State University, Phoenix, AZ.* (Sponsor: Matthew Buman, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to investigate the effects of a worksite sedentary behavior intervention on energy intake and perceived appetite in full-time sedentary office workers over the first three months of intervention.
METHODS: Data were derived from the ongoing study 'Stand & Move at Work', a multi-level group randomized trial aimed at reducing employee sedentary time with a socio-ecological approach. Dietary intake was assessed through the online ASA24 24-hr dietary recall, while self-reported appetite was assessed with an ecological momentary assessment measure. Using baseline and 3-month time-point data, linear mixed models, accounting for clustering of individuals within the 24 worksites, were built for each outcome (self-reported total energy intake, macronutrient and fiber intake, and feelings of hunger). Model covariates included age, BMI, ethnicity, gender, education, and income. **RESULTS:** 641 men and women were available for analyses, with mean age (± se) = 44.5 ± 0.44 yr, and 69% overweight or obese. Worksite-level energy intake decreased over time by 132 kcal/day (95% CI: 8 - 256; p <.05). There was a trend towards decreased feelings of hunger over time (p = 0.20). While macronutrient and fiber intake appeared to decrease over time, no differences were observed in macronutrients or fiber after adjusting for energy intake.
CONCLUSIONS: Self-reported energy intake decreased among sedentary workers participating in the 'Stand & Move at Work' intervention over the first three months. Results from fiber and macronutrients suggest the decreased energy intake was not explained by a change in diet quality. Future analysis will incorporate a relative comparison of the intervention arms to explore any differential effects on energy intake, diet composition, and subjective feelings of hunger.

638   Board #7   May 30 3:15 PM - 5:15 PM
Cardiometabolic Effects of Interrupting Sitting with Resistance Exercise Breaks

Robert J. Kowalsky[1], John M. Jakicic, FACSM[2], Andrea L. Hergenroeder[2], Renee J. Rogers[2], Bethany Barone Gibbs[2]. [1]*Texas A&M University Kingsville, Kingsville, TX.* [2]*University of Pittsburgh, Pittsburgh, PA.*
(No relevant relationships reported)

Research indicates prolonged occupational sitting may have detrimental effects on cardiometabolic health. This may suggest that interrupting prolonged sitting with physical activity may have an acute beneficial effect on cardiometabolic health. However, it is unclear if brief resistance exercise bouts would result in these acute benefits.
PURPOSE: To examine the acute effect of hourly, brief resistance exercise bouts that disrupt prolonged sitting on cardiometabolic health outcomes over a 4-hour simulated work period.
METHODS: Fourteen adults (age 53.4±9.5 years, BMI 30.9±4.8 kg/m^2) completed two 4-hour simulated work conditions in random order and on separate days: prolonged sitting (SIT) and sitting combined with hourly resistance exercise breaks (REX). Prior to the SIT or REX conditions the participants were fed a standardized breakfast. REX consisted of a brief exercise session (approximately 3 minutes)

performed at 0.5, 1.5, 2.5, and 3.5 hours post-meal. Glucose, triglycerides, and blood pressure were measured at baseline 1, 2, 3, and 4 hours post-meal. Pulse wave velocity (PWV) was measured before and following each condition. Linear mixed models evaluated overall condition effects and differences at each hour that was Boneferroni adjusted for multiple comparisons. Cohen's d estimated the magnitude of effects. **RESULTS:** Average glucose across the simulated workday did not differ by condition (β= -0.35 mmol/L, p=0.278, d=0.51). However, pairwise comparisons demonstrated an attenuation of postprandial glucose at 1 hour (β= -0.69 mmol/L, p=0.004, d=1.02) in REX compared to SIT, but not at the other time points. Blood pressure, triglycerides, and PWV did not differ significantly across conditions (all p ≥ 0.102, d = 0.01 to 0.21) or at any time point. **CONCLUSIONS:** Disrupting sitting with a brief resistance exercise bout performed at 0.5 hours after consuming a meal may have beneficial effects on 1-hour postprandial glucose. However, this initial benefit does not appear to be sustained beyond that time point. Moreover, these findings do not support an acute benefit of brief resistance exercise bouts compared to sitting on other cardiometabolic outcomes. Additional research is needed to assess optimal strategies for disrupting sedentary behavior that may have cardiometabolic benefits.

Association between Weather Condition, Ambient Temperature and Objectively Measured Sedentary Time in Chinese Adults

Xu Wen, Bing Yuan. *Zhejiang University, Hangzhou, China.* (Sponsor: STANLEY SAI-CHUEN HUI, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the association between weather condition, ambient temperature and objectively measured sedentary time in Chinese adults.
METHODS: 3,426 Chinese (2,116 men and 1,310 women) users of a brand of smart bracelet from July to October in 2015 were recruited in this study. With a novel algorithm, the gravity component of the acceleration signal collected by the activity monitor was extracted from the raw data to identify different types of activities and determine sedentary time. Using the information of GPS and time, the data of ambient temperatures and weather condition were collected from the meteorological data released by China Central Meteorological Observatory.
RESULTS: Compared with the days with rain, shower, haze and clouds, Chinese adults spent less time in sedentary behaviors in sunny days. There is no significant difference in sedentary time in rainy days in adults with different weight status. However, obese adults had significant longer sedentary time in non-rainy days than their counterparts with normal weight. Chinese women have shorter daily sedentary time when the mean ambient temperature lower than 20 °C, as compared with 20-24°C, 25-29°C and ≧30°C groups, whereas no difference was found in Chinese men.
CONCLUSIONS: Weather condition and ambient temperature are important factors associated with sedentary behaviors. Sedentary time in Chinese adults is longer in rainy days and high ambient temperature as compared with non-rainy days and cool weather. Long sedentary time especially in non-rainy days could be one of the factors contribute to the development of obesity in Chinese adults.

B-37   Thematic Poster - **Health Technology for Physical Activity: Just Do It!**

Evaluation of Free Exercise Apps and Ability to Promote Physical Activity

Cynthia M. Ferrara, FACSM[1], Christopher Burke[1], Allison Fahey[2]. [1]*Merrimack College, North Andover, MA.* [2]*University of Massachusetts Lowell, Lowell, MA.*
(No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate free exercise apps and the potential for promoting physical activity. METHODS: Study investigators identified 153 free exercise apps. Written descriptions posted by the app developers were evaluated by two investigators using enabling and reinforcing components of the Precede-Proceed Health Promotion Model as a guide. Six factors (three enabling and three reinforcing) were evaluated, with one point recorded for each factor included in an app. RESULTS: Enabling scores ranged from 0 to 3. One hundred and thirty-

four (87.6%) apps included videos or pictures, while 123 apps (80.4%) included written instructions on how to perform exercises. Thirty-eight apps (24.8%) included the ability to track daily exercise. Reinforcing scores also ranged from 0 to 3. Fifty-five (36%) apps interfaced with a social networking site, while thirty-three (21.6%) provided feedback and support from a personal trainer. Fifteen (9.8%) included rewards for daily exercise. Total scores ranged from 0 to 5. No apps included all six factors. CONCLUSIONS: The present study suggests that the majority of free exercise apps include videos, pictures, or written instructions on how to exercise. Many free exercise apps do not include basic features that may help to maintain an exercise program, including social support, feedback from a personal trainer, or rewards. Additional research is needed on how exercise apps can be utilized to promote physical activity and what features might be most important for success.

642   Board #2   May 30 3:15 PM - 5:15 PM

The Feasibility of a Gender- and Culturally-Sensitive Weight Loss Intervention Plus Mobile Health Technology for Hispanic Males

David O. Garcia, PhD[1], Luis A. Valdez, PhD, MPH[1], Benjamin Aceves, MPH[1], David Campas, BS[1], Julio Loya, BSN, RN[2], Melanie Hingle, PhD, RD[1], Kyle Humphrey, MS[1], Melanie L. Bell, PhD[1], Marylyn McEwen, PhD, RN[1], Steven P. Hooker, PhD, FNAK, FACSM[3]. [1]University of Arizona, Tucson, AZ. [2]University of Missouri-Columbia, Columbia, MO. [3]Arizona State University, Tempe, AZ. (Sponsor: Steven Hooker, FACSM)
(No relevant relationships reported)

Background: Hispanic males suffer disproportionate rates of overweight and obesity compared to other racial/ethnic groups. However, few weight loss interventions have been developed for this high-risk group. Further, the use of mobile health (mHealth) technologies to support lifestyle behavior changes in weight loss interventions for Hispanic men are untested. **Purpose:** This pilot study examined the feasibility and acceptability of integrating mHealth technology into a 12-week gender- and culturally-sensitive weight loss intervention (GCSWLI) for sedentary, overweight/obese Hispanic males. **Methods:** Eighteen Hispanic males (age: 38 ± 11 years; BMI: 34 ± 5 kg/m[2]; 56% Spanish monolingual) received a GCSWLI including weekly in-person individual sessions, a daily calorie goal, and prescription of ≥ 225 minutes of moderate-intensity physical activity/week. mHealth technology support included tailored text messaging and behavior and weight self-monitoring support using the Fitbit Charge 2, a consumer-wearable physical activity tracker, and a Fitbit Aria Wi-Fi Smart Scale. Participants were encouraged to use the Fitbit tracker during all waking hours and weigh themselves daily using the provided scale. Participants received biweekly SMS customized to address self-reported barriers to behavior change and in response to objective data collected via tracking tools. Changes in weight from baseline to 12-weeks were estimated using a paired t-test. Descriptive analyses characterized use of the Fitbit and the smart scale. **Results:** Sixteen of 18 participants completed 12-week assessments; overall attrition rate was 11.1%. Mean weight loss at week 12 was 4.7 kg (95% CI [-7.1, -2.3], p < 0.001). Participants wore the Fitbit 71.6% of intervention days and logged body weight using the smart scale 30.5% of intervention days. Participants identified barriers for use of the technology, including strenuous work activities prohibiting them from wearing the Fitbit. In addition, reliable internet access was cited as a barrier to using the smart scale. **Conclusions:** While significant weight loss was achieved integrating mHealth technology into a GCSWLI, the use of technology was modest. Addressing barriers identified in our work may help to refine an mHealth intervention approach for Hispanic men.

643   Board #3   May 30 3:15 PM - 5:15 PM

Metabolic Cost and Exercise Intensity during Active Virtual Reality Gaming

Dulce H. Gomez, Nicole Bolter, C. Matthew Lee, James R. Bagley, Marialice Kern, FACSM. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)
(No relevant relationships reported)

PURPOSE: Sedentary behavior remains a critical health promotion target because it increases risk of morbidity and mortality. Virtual reality (VR) exergaming is a new avenue of physical activity that may be preferred over "traditional exercise" in historically inactive populations. Use of active VR games (AVRGs) could be an effective strategy for meeting the ACSM exercise guidelines. To investigate the efficacy of AVRGs, we assessed the intensity of three games on a VR system by measuring oxygen consumption (VO_2) and rating of perceived exertion (RPE) during gaming sessions. A secondary purpose was to compare the exercise intensities of the three games to current ACSM exercise guidelines using percent oxygen consumption reserve (%VO_2R) and metabolic equivalents (METs). **METHODS**: Forty-one [male (n=21); female (n=20)] healthy volunteers [age: 25.2 ± 4.4y; BMI 24.4 ± 3.7kg/m[2]] were assessed for body composition, completed a graded exercise test to determine maximal VO_2 and familiarization period 3 VR games (Thrill of the Fight [TOF], Audioshield

[AS], and Holopoint [HP]) during visit one. At least 48-hrs later, VO_2 and RPE were measured during 10-min supine rest and 10-min sessions of each game. Data was analyzed by gender and gaming experience and no statistical difference were found by category. **RESULTS**: Compared to resting values (4.5 ± 0.6ml/kg/min), VO_2 was higher during TOF, AS, and HP (30.5 ± 7.1, 19.1 ± 5.8, and 24.8 ± 6.6ml/kg/min, respectively; $p \leq 0.05$). Using %VO_2R 95% Confidence Interval (95%CI), TOF was classified as vigorous, HP was moderate, and AS was light intensity depending on gaming experience. Using METs (95%CI), TOF was classified as vigorous, HP ranged from moderate to vigorous, and AS was moderate intensity. Using RPE (95%CI), TOF was classified as moderate, whereas HP and AS were light intensity. **CONCLUSIONS**: Our data suggests the three VR games examined can elicit least a moderate exercise intensity based on ACSM guidelines. Participants perceived the physical exertion to be lower during the games than their measured exertion, which might allow participants to continue playing AVRGs for longer durations before feeling fatigued. Data on metabolic cost for movement specific games may aid consumers and health/fitness specialists in developing exercise programs with AVRGs.

Interest in Virtual Reality for Injury Rehabilitation and Performance Enhancement Among Collegiate Soccer Athletes

Leilani Madrigal, Makenna Henry, Alison Ede, Tiffanye Vargas. *California State University Long Beach, Long Beach, CA.* (Sponsor: Diane L. Gill, FACSM)
(No relevant relationships reported)

Interventions using virtual reality (VR) in three or two-dimensional, multi-sensory, synthetic worlds have been used to enhance rehabilitation and performance (e.g., combat PTSD in military personal, increase motor control in stroke-recovery patients). VR also has potential as a method for rehabilitation from sporting injuries. **PURPOSE**: To assess athletes' interest in VR as an intervention to enhance performance and injury rehabilitation, and to identify preferred components within a VR world. We also explored gender influences on these preferences. We focused on one collegiate sport, soccer, at three levels (NCAA, NAIA, Junior College). **METHODS**: Sixty-eight collegiate soccer (25 male; 43 female) athletes completed an electronic survey which included demographics, as well as the virtual reality interest survey created to assess VR use, interest and specific factors athletes may find useful in a VR environment. **RESULTS:** Participants' responses on a 10-point Likert-type scale from not interested (1) to extremely interested (10), indicated strong interest in using VR, both in recovery from injury (M=7.06, SD=2.67), and to improve sport performance (M=7.89, SD=2.59). Additional items asked about interest in specific forms of VR with the same 10-point response scale. Athletes indicated strong interest in viewing sport-specific scenarios (M=7.26, SD= 2.66), sport-specific skills (M=6.89, SD=2.73), and physically touching a soccer ball while submerged in a virtual world (M=6.89, SD=2.83). Other items, such as seeing a crowd in the stands, presence of an avatar coach, or viewing a teammate perform a sport skill unsuccessfully, were rated of less interest. In terms of gender, men were more interested than women in using VR both for injury recovery (Male: M=8.24, SD=2.18; Female: M=6.34, SD=2.70) and to enhance performance (Male: M=9.00, SD=1.84; Female: M=7.21, SD=2.77) **CONCLUSION**: VR interest is high among collegiate soccer athletes, both for injury recovery and performance enhancement. The athletes were particularly interested in a VR environment that incorporates sport-specific scenarios and physically touching a soccer ball. Men had stronger interests in VR, but both men and women athletes at all levels indicated interest in engaging in VR to assist in injury recovery and performance enhancement.

Playing Pokemon Go is Associated with Higher Daily Total Energy Expenditure

Tyler Langford. *Middle Tennessee State University, Murfreesboro, TN.*
(No relevant relationships reported)

PURPOSE: To compare daily energy expenditure (DEE) of Pokémon Go (PoGo) players to non-player counterparts. **METHODS:** Upon arrival, a self-reported PoGo usage questionnaire was used to identify "players" and "non-players". Participants then received a SenseWear Armband (SWA), with clear instruction to wear the device for 7 consecutive days. After 7 days, participants returned the SWA and completed an additional set of questionnaires. Mean differences in DEE between players and non-players were examined using a one-way between groups ANCOVA ($p \leq 0.05$). Control variables included in the ANCOVA were on-body time and body weight. Inclusion criteria for use of data included at least 4 days of wear time, with at least 12 hours of data per day. **RESULTS:** Data for 5 participants were excluded based on the previously mentioned criteria. leaving a final sample of 9 players and 11 non-players. Players demonstrated a significantly greater DEE than non-players when controlling on-body time [F (1, 17) = 5.556, p = 0.031] (Figure 1). There was a significant effect

---

on DEE for on-body time [F (1, 17) = 4.892, p = 0.041]. When weight was included in the model, there was a trend towards a significant effect on DEE [F (1, 16) = 4.366, p = 0.053]. However, weight was not used for analysis in the main ANCOVA model as it is outside the significance level. **CONCLUSION:** Pokémon Go players exhibited a significantly greater DEE than their non-player counterparts (Players: 2735 ± 666 kcal vs non-players: 2274 ± 474 kcal, p = 0.031).
Figure 1. Differences in daily energy expenditure between Players and Non-players. * indicates significant difference (p ≤ 0.05)

Table 1. Demographic data.		
	Players	Non-players
Age (yrs)	27.89 +/- 6.62	25.73 +/- 3.85
Weight (kg)	78.99 +/- 16.00	73.02 +/- 12.35
BMI (Kg/m²)	27.66 +/- 4.20	24.73 +/- 3.69

Home-basedexergaming For Preschoolers' Cognition And Health Outcomes: A Randomizedcross-over Study

Zan Gao, FACSM[1], Jung Eun Lee, 55812[2], Zachary Pope, 55455[1], Nan Zeng[1], Xianxiong Li[3], Ying Zhang[4]. *[1]University of Minnesota, Minneapolis, MN. [2]University of Minnesota, Duluth, MN. [3]Hunan Normal University, Changsha, China. [4]Zhejiang Normal University, Hangzhou, China.*
(No relevant relationships reported)

Purpose: The effects of exergaming physical activity (PA) interventions on preschoolers' cognition and health outcomes remain largely unexplored. Therefore, the purpose of this study was to discern the effectiveness of a home-based exergaming intervention on preschoolers' cognition and health outcomes in a randomized cross-over trial.
Methods: Participants were 32 preschoolers (16 girls; 59.4% Asian; M_{age} = 4.72, SD = ± .73) recruited from the Twin Cities area in MN. During baseline testing, preschooler's cognition, cardiovascular fitness, body fat percentage (BFP), and daily energy expenditure (EE) were assessed via validated instruments. Participants were then randomly assigned to 1) an intervention (INT) condition: engaged in home-based LeapTV exergaming at least 30 minutes/session 5 times/week for the first 12 weeks and then resumed their regular PA patterns without exergaming during the second 12 weeks; or 2) a delayed-intervention control (DIC) condition: maintained their regular PA patterns for the first 12 weeks, and participated in the same dose of home-based exergaming during the second 12 weeks. Identical assessments were conducted at the end of the 12th and 24th weeks.
Results: Data were analyzed with PROC GLM in SAS. Results suggested significant interaction effects of treatment by period for cognition, F(1,28) = 2.02, p = 0.04; and BFP, F(1,28) = 16.90, p < 0.01. Significant carry-over (period) effects emerged for fitness, F(1,28) = 15.24, p < 0.01; and EE, F(1,26) = 4.48, p = 0.04. In addition, there was a significant order (sequence) effect for BFP, F(1,28) = 16.90, p < 0.01. No other effects were identified. Detailed descriptive data are shown in table.

	INT group			DIC group		
	0 week	12 week	24 week	0 week	12 week	24 week
Cognition	50.89	59.39	61.65	59	62.36	62
Fitness	10.22	7.56	14.47	10.64	10.57	14.58
BFP	19.20	20.36	19.25	20.12	20.20	19.83
EE	361.70	363.42	340.64	337.69	384.59	392.41

Conclusions: Home-based exergaming may positively impact cognition, fitness, and BPF for some preschoolers, with slight positive effects on EE possible for most preschoolers. Therefore, an exergaming program might be a good option for home-based PA interventions.

647   Board #7   May 30 3:15 PM - 5:15 PM
Effects of Exergaming on College Students' Mood and Energy Expenditure Compared to Traditional Treadmill Exercise

Wenxi Liu[1], Zachary Pope[1], Nan Zeng[1], Jung Eun Lee[2], Zan Gao, FACSM[1]. *[1]University of Minnesota Twin Cities, Minneapolis, MN. [2]University of Minnesota Duluth, Duluth, MN. (Sponsor: Zan Gao, FACSM)*
(No relevant relationships reported)

Purpose: To date, no known research concerning exergaming on young adults' affect is available. Thus, this study examined exergaming's effect on college students' mood and energy expenditure compared with traditional treadmill exercise.
Methods: Sixty college students (30 female; M_{age} = 23.6) participated in three separate 20-minute exercise sessions: 1) Xbox 360 Kinect Reflex Ridge; 2) Xbox 360 Kinect Just Dance; and 3) moderate-intensity treadmill walking (4.0 mph). Mood was assessed via the Brunel Mood Scale (BRUMS)—a 24-item questionnaire containing six subscales: anger, confusion, depression, fatigue, tension, and vigor. Participants completed the questionnaire following each exercise session.
Results: The data indicated participants in treadmill session (M = 174.21) had more energy expenditure (in calories) than Just Dance (M = 91.70) and Reflex Ridge (M = 110.20). Significant differences between the three sessions for mood was only observed for fatigue (F (2, 118) = 12.28, p < 0.01, η_p = 0.172), with post hoc Bonferroni comparisons indicating that participants' perceived fatigue levels were significantly lower during Just Dance compared to Reflex Ridge (p = 0.02) and treadmill walking (p < 0.01). However, Reflex Ridge and treadmill walking were not observed to have significantly different levels of fatigue (p = 0.07). It is also notable that feelings of vigor and depression approached significance (F (2, 118) = 2.694, p = 0.07 and F (2, 118) = 3.18, p = 0.06, respectively), with Reflex Ridge promoting the greatest feelings of vigor and treadmill walking resulting in the greatest feelings of depression.
Conclusion: Findings revealed that even though traditional treadmill exercise performed more energy expenditure, however, exergaming may lead to less perceived fatigue and potentially higher vigor among college students compared to traditional exercise. This finding has important implications as college students may be more likely to participate and maintain in PA when less fatigue is perceived and feelings of vigor upon cessation of gameplay are experienced. Future research should examine other exergames to discern what genre of exergaming is most effective in promoting positive affect among young adults.

Effectiveness of Combined Smartwatch and Social Media Intervention on Breast Cancer Survivor Outcomes: Randomized Trial

Zachary Pope, Nan Zeng, Rui Zhang, Hee Y. Lee, Zan Gao, FACSM. *University of Minnesota-Twin Cities, Minneapolis, MN.* (Sponsor: Zan Gao, FACSM)
(No relevant relationships reported)

PURPOSE: Promoting physical activity (PA) among breast cancer survivors (BCS) can improve this population's health and quality of life (QoL). Yet, innovative technology-based PA interventions among BCS remains understudied. This study evaluated the effectiveness of a combined smartwatch and social media PA intervention on BCS's health outcomes.
METHODS: Thirty BCS ($\overline{X}_{age}$ = 52.6 ± 9.3 years; $\overline{X}_{wt}$ = 80.2 ± 19.6 kg) participated in this 10-week, 2-arm randomized trial, with BCS randomized into: 1) intervention group (n = 16): received Polar M400 smartwatch for daily PA tracking and joined a Facebook group where social cognitive theory-related PA tips were provided twice weekly, with a weekly workout program being posted; and 2) comparison group (n = 14): only joined separate, but content-identical Facebook group. Outcomes included PA, physiological, psychosocial, and QoL variables. Specifically, PA and energy expenditure (EE) was assessed by ActiGraph GT3X+ accelerometers, and physiological, psychosocial (e.g., self-efficacy, social support, etc.), and QoL were examined via validated instruments at baseline and post-intervention.
RESULTS: No baseline group differences were observed for any variable. Ten BCS dropped out of the study (intervention = 4; comparison = 6). Compared to completers, dropouts had less private insurance coverage, longer duration since diagnosis, and lower annual income, daily light PA (LPA), moderate-to-vigorous PA (MVPA), EE, and steps. Thus, a per-protocol analysis was performed, revealing significant group differences for changes in social support (t = -2.1, p = 0.05) and barriers (t = -2.2, p = 0.04). Interestingly, the comparison group demonstrated increases for both variables while the intervention group demonstrated slightly decreased social support and no change in barriers. Notably, both groups demonstrated similarly increased daily LPA, MVPA, EE, and steps of 7.7 min, 5.1 min, 25.1 kcals, and 339 steps, respectively, over time.

CONCLUSIONS: Despite extensive user training, several intervention BCS found the Polar M400 difficult to use—possibly decreasing intervention adherence. Future interventions should utilize simpler smartwatches to promote PA among middle-aged clinical/non-clinical populations.

B-38   Thematic Poster - **High Intensity Interval Training**

Blood lactate steady-state level, sustained during rest time, in moderate intensity interval training

Juan C. Mazza[1], Raúl R. Festa[1], Lisandro Ruffo[1], Patricia Cosolito[1], Sandra Prieto[2] and Alvaro Gurovich, FACSM[3]

[1] *Biosystem Institute Sports Sciences, Rosario, Argentina;* [2] *Colombia State University, Bogotá DC, Colombia;* [3] *The University of Texas at El Paso, TX, USA.*

BACKGROUND: Important isotope studies related to lactate metabolism have pointed out that blood lactate level (BLa) is an expression of the balance between Production (RProd), Removal (Rt) and Oxidation (ROx) rates. Also, evidence shows that the relationship between BLa with Rt and ROx rates, is concentration-dependent, close 4 to 7 mmol/l.
PURPOSE: Analyze BLa in the first sec. (BLa-10s) and last sec. (BLa-50s) of 1-min passive rest, during steady-state moderate intensity interval training (IT), considering that BLa is a balance of RProd with Rt and ROx intracellular process. We want to demonstrate that (BLa-10s) and (BLa-50s) levels are similar, so Rt and ROx are maintained, in steady-state conditions, during IT workouts.
METHODS: Ten trained swimmers and eight trained track athletes (19.1±2.6 yr) performed a moderate intensity IT session (BLa: 4 to 7 mmol/l). Swimmer´s protocol was: 10 x 100m, with 60s rest; and Athlete's protocol was: 10 x 400m, with 60s rest. BLa during BLa-10s and BLa-50s were measured with Lactate Plus meter and heart rate (HR) was monitored. Measurements were collected every 2 reps. We compared BLa-10s vs. BLa-50s applying paired t-test with a p<0.05 level, and r between BLa-10s vs. BLa-50s, and BLa-10s vs. HR, in reps. 2-4-6-8 and 10.
RESULTS: We found no significant differences between BLa-10s and BLa-50s. BLa-10s ranged 5.05±1.51 - 6.61±1.10 mmol/l and BLa-50s ranged 5.03±1.80 - 6.71±1.07 mmol/l. Additionally, we found a low r between BLa-10s and HR values (r = -0.06). However, a high r between BLa-10s and BLa50-s values (r = 0.94) was observed.
CONCLUSION: BLa-10s and BLa-50s showed same metabolic steady-state conditions. These results support the evidence that moderate intensity IT produces physiological stress during the whole workout duration (exercise / rest). Also, we determine that HR is not a valid variable to control for physiological demands during IT.

Impact Of The Fractioned Distance On Endurance Training In Soccer Players

Raúl R. Festa[1], Juan C. Mazza[1], Lisandro Ruffo[1], Carlos Groppo[1], Patricia Cosolito[1], Alvaro Gurovich, FACSM[2]. [1]*Rosario Central Soccer Athletic Club, Rosario, Argentina.* [2]*The University of Texas at El Paso, El Paso, TX.*

(No relevant relationships reported)

BACKGROUND: The distance covered by outfield players during a soccer match is approximately 11-12 km. However, most of the distance is covered by walking, jogging, or short periods of moderate / high intensity running. Endurance Training (ET) could improve oxidative metabolic profile making players to run these distances more efficiently. However, the training session design might play a role enhancing physiological stress.

PURPOSE: To determine if Endurance Interval Training (EIT) or Endurance Intermittent Training (EIntT) generates more physiological stress to improve the performance of oxidative system in soccer players.
METHODS: Fifteen male soccer players (17.9±0.6 yr) performed 2 sessions of ET with the same absolute volume and intensity but different design, with a 4-day rest period between sessions. Endurance protocols were: a) 8 x 400 m, at 4.5 m/s, with 60s rest between reps. (EIT volume: 3,200 m); b) 8 sets of 6 x 67.5 m (405 m per set), at 4.5 m/s, with 15s:15s work:rest ratio, and 60s rest between sets (EIntT volume: 3,240 m). Blood lactate (La) and heart rate (HR) were collected at the end of repetitions/sets 2-4-6 and 8. We compared La and HR values between EIT and EIntT, applying paired t-test with a p<0.05 level, and Pearson's correlation coefficient (r) between La and HR for each test.
RESULTS: The session average La and HR were different between EIT and EIntT. 4.55±1.46 vs. 1.28±0.41 mmol/l, respectively (p<0.01) and 182±7 vs. 152±10 bpm, respectively (p<0.01). In addition, La and HR at repetitions/sets 2-4-6 and 8 were different between EIT and EIntT: 3.28±0.86 vs. 1.53±0.55; 4.44±0.91 vs. 1.21±0.33; 4.94±1.31 vs. 1.19±0.32; 5.55±1.64 vs.1.18±0.34 mmol/l, p<0.01, respectively. And 179±6 vs. 153±9; 183±6 vs. 152±7; 186±7 vs. 152±9; 184±7 vs. 153±9 bpm, p<0.01, respectively. Additionally, there we found low r between La and HR, in each test (EIT: r= 0.26; EIntT: r= 0.42).
CONCLUSION: The present study showed that EIT is a more metabolic and cardiovascular stressful stimulus than EIntT. Same volume and intensity, but higher fractioned distance might not produce the same physiological adaptations. In addition, the low correlations between La and HR showed that HR might not be a valid and reproducible variable to control metabolic intensity during ET in soccer.

Effects of Two Types of Exercises on Serum MG53 and Its Relationship with Metabolic Biomarkers

Jing Shao, Naixi Liu, Yingbin Ren, Jinde Fu, Lili Zhou, Baohua Xu, Qi Han, Muqing Yi. *National Research Institute of Sports Medicine, Beijing, China.*

(No relevant relationships reported)

Mitsugumin-53 (MG53), a membrane repair protein, acts as an E3 ligase to induce insulin resistance and metabolic syndrome.**PURPOSE:** To investigate effects of two types of exercises on serum MG53 level, and its relationship with related metabolic biomarkers (testosterone, cortisol, leptin, insulin, glucagon, TG, TC, HDL-C and LDL-C). **METHODS:** Sixteen healthy males (23.1±2.9 yrs, 169.5±6.0 cm in height, 63.2±5.9 kg in weight, 53.2±5.4 ml/min/kg in VO_{2max}) signed the Informed Consent and participated in this study. Subjects performed two trials, high intensity interval exercise (60s*10 with an interval of 4 min, HE) and endurance exercise (65% VO_{2max} for 90 min, EE) with a 3-wk washout before HE. Blood samples were collected at pre-exercise, immediately, 1h, 4h and 24h post-exercise for the measurement of serum MG53 and biomarkers above. **RESULTS:** (1) MG53 significantly elevated immediately post- than pre-exercise in HE, but no statistic difference between HE and EE immediately post-exercise (3.40±2.46 vs. 2.68±2.12 ng/mL, P>0.05). Moreover, serum MG53 showed significant difference among individuals, three ranks of average MG53 can be seen either at pre-exercise (low: 0.58±0.27 ng/mL, n=10; medium: 2.15±1.13 ng/mL, n=12; and high: 4.77±1.34 ng/mL, n=10) or at post-exercise (low: 0.71±0.51 ng/mL, n=40; medium: 2.35±0.90 ng/mL, n=48; and high: 4.95±1.63 ng/mL, n=40). Serum TG, TC, HDL-C and LDL-C demonstrated the maximum immediately post-exercise and then declined in both trails, which is similar to serum MG53 dynamics. (2)MG53 showed a positive correlation with testosterone (r=0.355, P=0.001 in HE; r=0.281, P=0.011 in EE), cortisol (r=0.267, P=0.017 in HE) and TG (r=0.523, P=0.0005 in EE). However, a negative correlation with body mass was seen both in HE and EE (r=-0.459~-0.582, P=0.0000). **CONCLUSION:** High intensity interval exercise, not endurance exercise, induced significantly increased serum MG53. Serum MG53 demonstrated significantly weak positive correlation with some of metabolic biomarkers (testosterone, cortisol, and TG) in HE and/or in EE, a significantly negative correlation with body mass.*Supported by NSFC Grant 31371205 and General Administration of Sport Grant 2011B006

(No relevant relationships reported)

Studies usually compare high-intensity interval exercise (HIIE) protocols of the same exercise bout duration and different exercise-to-interval ratios. Comparisons of HIIE protocols differing in bout duration while having the same exercise-to-interval ratio are missing. **PURPOSE**: To compare the metabolic and cardiorespiratory responses to isoenergetic HIIEs of different bout duration. **METHODS**: Eleven healthy males (age, 28 ± 6 y; height, 1.77 ± 0.07 m; body mass, 70 ± 11 kg; body fat, 9 ± 2 %, all mean $\pm$ SD) performed four trials in random, counterbalanced order, one week apart. Trials included 20 min of cycling with equal mean power output, performed either continuously (CON) or intermittently with 10 s (HIIE10), 30 s (HIIE30), or 60 s (HIIE60) bouts at an intensity corresponding to 100% of VO_2max. Recovery intervals during the HIIE trials were 15, 45 and 90 s, respectively, of cycling at an intensity corresponding to 15% of VO_2max (exercise-to-interval ratio of 1:1.5). Expired air was measured during each trial and venous blood was obtained before, immediately after, and 1 hour post-exercise. Lactate was measured in capillary blood every 5 min during exercise. Results were analyzed using 2-way ANOVA with repeated measures (condition x time) and Tukey's post-hoc test. **RESULTS**: Average VO_2 was similar in the HIIE trials (2.29 ± 0.42, 2.20 ± 0.43, 2.12 ± 0.45 L/min, for HIIE10, HIIE30 and HIIE60, respectively), corresponding to 65-70% of VO_2max. However, respiratory frequency and pulmonary ventilation were significantly higher in HIIE60 compared to HIIE10 and HIIE30 (by 10-19% and 20-23%, respectively, p < 0.01) during the last 10 min of exercise. Blood lactate was higher in HIIE60 compared to HIIE10 and HIIE30 from the 10th min onward (p < 0.01), reaching peak values of 12.5 ± 3.5, 7.2 ± 2.1 and 7.9 ± 2.9 mmol/L, respectively, at the end of exercise. After exercise, white blood cell count (9.7 ± 2.8 x10^9/L), serum urate (0.35 ± 0.10 mmol/L), serum glucose (6.56 ± 1.44 mmol/L), and plasma volume change ($-13.5 \pm 4.4\%$) were greater in HIIE60 compared to all other protocols (p < 0.01). **CONCLUSIONS**: These findings highlight the importance of bout duration in HIIE, since a longer bout resulted in greater cardiorespiratory and metabolic stress compared to shorter bouts despite equal total work, duration, and work-to-rest ratio.

High Intensity Functional Training Improves Flexibility in Overweight and Obese Adults

Justin DeBlauw. *Kansas State University, Manhattan, KS.*
(No relevant relationships reported)

HIGH INTENSITY FUNCTIONAL TRAINING IMPROVES FLEXIBILITY IN OVERWEIGHT AND OBESE ADULTS

Justin A. DeBlauw, Pratik M. Patel, Jesse A. Stein, Thomas J. Barstow, FACSM, Craig A. Harms, FACSM, Katie M. Heinrich.
Functional Intensity Training Lab, Department of Kinesiology, Kansas State University, Manhattan, KS
Sponsor: Craig A. Harms, FACSM

High-intensity functional training (HIFT) has become a popular form of exercise training, however it is unknown how overweight/obese populations may benefit from this type of exercise prescription. **PURPOSE:** To compare the effects of HIFT versus ACSM recommended aerobic and resistance training (A-RT) on physical fitness characteristics in overweight/obese, physically inactive adults. **METHODS:** Twenty-three overweight/obese (BMI 30.3 ± 2.8) and physically inactive (< 30 minutes total activity per week) adults were recruited. Participants were randomized into either 8-weeks of: HIFT (3 d/wk for 60-minute sessions) or A-RT (3 d/wk of aerobic exercise for 50 minutes; 2 d/wk of resistance exercises). Physical fitness was assessed using the Eurofit fitness measures (sit and reach, standing broad jump, vertical jump, 30-seconds of push-ups and sit-ups), 40-meter dash, stork balance test, and peak oxygen consumption (VO_{2peak}) measured using a Modified Balke Protocol. Body composition was determined via dual energy X-ray absorptiometry, with all measures taken at baseline and post-training. Analysis of covariance was used to compare the change in physical fitness between groups while controlling for baseline scores. **RESULTS:** After adjusting for baseline values, there were no significant differences between groups for changes in physical fitness except for flexibility (HIFT = 1.1 ± 2.3cm, A-RT: -0.1 ± 1.1cm, p = 0.05). Additionally, the HIFT group spent 79.3% less time exercising per week than the A-RT group. **CONCLUSION:** Our results indicate that eight weeks of HIFT demonstrate improvements in flexibility in overweight/obese and physically inactive adults. However, longer duration interventions may result in greater

adaptations in physical fitness and health parameters. Future investigations should aim to compare physical fitness adaptations between healthy adults and overweight/obese adults when using a HIFT exercise intervention while monitoring caloric intake.

(No relevant relationships reported)

ABSTRACT
Circuit weight training (CWT) and high-intensity interval training (HIIT) are two popular exercise formats for stimulating both aerobic and anaerobic benefits in a time efficient manner. While some research has established the benefits of both formats, no research has determined if performing HIIT prior to CWT (HICWT) has a different acute response compared to integrated HIIT with mini-CWT (three-exercise clusters; TRIIT). **PURPOSE**: To examine the physiological effects [energy expenditure (EE), oxygen consumption (VO_2), heart rate (HR), blood lactate (BLa^-), blood pressure (BP), excess post-exercise oxygen consumption (EPOC)] and rating of perceived exertion (RPE) of the sequence order of HIIT with CWT. **METHODS**: Fourteen trained men (25.7 ± 4.4 yr) completed two separate (by ≥ 72 hrs) resistance exercise protocols matched for time and load. Both protocols consisted of six HIIT bouts and three sets of nine exercises (50% one-repetition maximum) in a CWT or mini-CWT format. Oxygen consumption, HR and EE were monitored throughout the protocols, while EPOC, BLa^- (five time points), BP (four time points) and RPE were measured post-exercise. **RESULTS**: Oxygen consumption (1.991 ± 0.224 vs. 1.923 ± 0.225 L/min, $p=.024$), EPOC (62.0 ± 7.8 vs. 57.0 ± 6.2 kcal, $p=.034$) and EE (435 ± 48.8 vs. 420 ± 49.0 kcal, $p=.012$) was significantly higher during the HICWT compared to the TRIIT protocol. BLa^- was significantly higher at all post-exercise time points (immediate post, 5 min, 10 min and 20 min post-exercise) following the HICWT compared to the TRIIT protocol. Mean values for HR and RPE were similar ($p>.05$) for both protocols. **CONCLUSION**: Performing HIIT prior to CWT elicits higher metabolic perturbation compared to the integration of HIIT with mini-circuits. HICWT also required greater energy requirements during and after the protocol compared to TRIIT. However, there may not be a practical difference given the protocols only differed by ~25 kcal.

Comparison of Two HIIT Training Formats

Judith A. Ann Juvancic-Heltzel, Mackenzie Conrad, Laura Richardson, Brian Miller. *The University of Akron, Akron, OH.*
(Sponsor: Ronald Otterstetter, FACSM)
(No relevant relationships reported)

High intensity interval training (HIIT) is a safe and effective workout that can be modified to meet all fitness levels. During each session bouts of high intensity exercise are interspersed with active recovery periods. Music has been shown to increase an individual's enjoyment of exercise which may increase adherence. A new HIIT program (SZ) incorporates music with movement using reverse engineered music aligned to match movements. It has been suggested that using music synced with choreographed movement may motivate participants and increase exercise adherence. PURPOSE: To compare HR, RPE, lactate and PACES between two HIIT formats. METHODS: Participants attended two, sixty minute, counterbalanced HIIT sessions – Traditional (T) and SZ. Blood lactate was measured pre and 10 minutes post, while HR and RPE were measured pre, 15, 30, 45 and post session. Physical Activity Enjoyment Scale (PACES) was collected at the end of each session. A 2x2 cross-over design using a repeated measures ANOVA was employed to test for difference by program and pre-post assessment blood lactate, HR, RPE, and PACES with statistical significance set at $p \leq 0.05$. RESULTS: The overall ANOVAs for all factors reached statistical significance (p<0.001). For lactate there was a significant interaction between pre and post assessment by program [$F(1,12) = 6.724$, p<0.001] with SZ having an average adjusted difference of 2.76 ± 3.84mmol/L less compared to T. For HR and RPE, there were no statistically significant differences between SZ and T (p = 0.313 and p = 0.445, respectively). However, there was an overall increase in HR and RPE from pre to post for both programs of 29.18 ± 4.43bpm (p<0.001) and 2.61 ± 0.67 (p = 0.002), respectively. The difference in PACES between programs did not reach statistical significance [$t(13) = 1.097$, p = 0.293] with mean scores of 93.36 ± 16.52 and 87.93 ± 17.47 for SZ and T, respectively. CONCLUSION: Understanding participants perceptions between T and SZ may provide insight for strategies and programming to enhance exercise adherence. The addition of synced music with SZ may motivate participants and promote exercise adherence. Future research on the long term effects of SZ on biometrics is warranted.

Peak Braking Force as a Risk Factor for Running-Related Injuries

Christopher Napier[1], Christopher L. MacLean[2], Jack E. Taunton, FACSM[1], Jessica Maurer[2], Michael A. Hunt[1]. *[1]University of British Columbia, Vancouver, BC, Canada. [2]Fortius Institute, Burnaby, BC, Canada.* (Sponsor: Jack Taunton, FACSM)

(No relevant relationships reported)

Kinetic factors have been implicated in the development of several running-related injuries (RRIs). Most research has focused on measures of vertical loading, such as the average vertical loading rate (AVLR), instantaneous vertical loading rate (IVLR), and vertical impact peak (VIP), as they have all been associated with RRI in retrospective analyses. Less studied has been the horizontal braking force exerted on the body during running.
PURPOSE: To prospectively predict the capacity of vertical and horizontal loading variables on RRI risk.
METHODS: 74 healthy female recreational runners ran at their preferred speed on an instrumented treadmill while ground reaction force data and 3D joint kinematics were collected. Main kinetic outcomes were VIP, AVLR, IVLR, active vertical peak, vertical impulse, and peak braking force (PBF). After baseline testing, participants began a 15-week half-marathon training program. Pain and running volume were recorded via a weekly online log. Exposure time (hours of running) was calculated from the start of the training program until onset of injury (INJ) or right-censoring at non-RRI, loss to follow-up, or end of 15-week program (UNINJ). After converting kinetic variables from continuous to ordinal variables based on tertiles, Cox proportional hazard ratios were fit for each kinetic variable independently.
RESULTS: 65 participants were included in the final analysis. 22 were diagnosed with an RRI (mean exposure of 17.46+/-9.81 hours). 33 completed the program without injury (mean exposure of 43.46+/-10.48 hours). PBF was the only kinetic variable significantly associated with increased injury risk when compared to the middle tertile. Participants with a high PBF were injured at 4.87 (95% CI: 1.54-15.44) times the rate of those in the middle tertile of PBF. INJ participants also had a significantly greater (more negative) PBF than UNINJ (-0.27+/-0.04 BW vs. -0.24+/-0.04 BW; p=.002, ES=0.91). Finally, when analysed in a multivariable model, no other kinetic variables made a significant contribution to predicting injury beyond what had already been accounted for by PBF alone.
CONCLUSIONS: Findings from this study suggest PBF is associated with a significant increased risk of RRI in female recreational runners. Future studies should include this variable in their analysis.

A Comparison Of Ground Reaction Forces And Sagittal Plane Ankle Kinematics Between Runners With Achilles Tendinopathy And Healthy Controls

Weijie Fu[1], Julia Reilly[2], Adam Tenforde[2], Steve Jamison[2], Matthew Ruder[2], Irene Davis, FACSM[2]. *[1]Shanghai University of Sport, Shanghai, China. [2]Spaulding National Running Center, Cambridge, MA.* (Sponsor: Irene Davis, FACSM)

(No relevant relationships reported)

Achilles tendinopathy (AT) is one of the most common injuries in distance running with a rate of 8% to 15% of all running injuries and a 52% lifetime incidence in male runners. The biomechanics of running gait associated with AT has not been well-studied.
PURPOSE: To compare the sagittal plane ankle angle kinematics as well as vertical medial, and lateral ground reaction forces and loadrates in runners with and without AT.
METHODS: 22 rearfoot strike (RFS) runners with AT (15M, 7F) and 22 matched healthy RFS runners (CON) ran on an instrumented treadmill, while sagittal plane video and ground reaction force data were collected. Foot angles (FA) and tibia angles (TA) were measured, and ankle dorsiflexion angles (DF) were calculated. Values were determined at the point of footstrike (FS) and peak, with total excursion also being calculated. Additionally, vertical average and instantaneous loadrates (VALR,

VILR) were calculated. Finally, medial and lateral forces (MF, LF) and medio-lateral instantaneous loadrates (MLILR) were extracted. Comparisons between the AT and CON groups were made using independent t-tests ($p < 0.05$).
RESULTS: Overall, there were no differences in FA, TA or DF angle at footstrike or at peak, or in ankle excursions between the AT and CON groups (Table 1). Additionally, no differences were noted in VALR, VILR, MF, LF and MLILR between groups.
CONCLUSION: These preliminary data suggest that runners with AT do not exhibit ground reaction force differences or differences in sagittal plane ankle kinematics compared their healthy counterparts. Future studies need to include other measures such as frontal plane kinematics and ankle joint kinetics, as well as strength and flexibility measures of the ankle.
Table 1. Ankle kinematics and GRF (mean±SD) in runners with AT and CON

Association Of Isometric Hip And Ankle Strength With Frontal Plane Kinetics In Females During Running

Kathryn Harrison, Bhushan Thakkar, David Pumphrey, Robert Tickes, Gregory Crosswell, D.S. Blaise Williams III, FACSM. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: D.S. Blaise Williams, FACSM)

(No relevant relationships reported)

Frontal plane mechanics have been associated with running-related injuries such as patellofemoral pain. Strengthening and gait retraining programs aimed at reducing hip adduction during running have been shown to be effective at alleviating symptoms, however evidence of their effect on running kinematics is equivocal. It is possible that such programs exert their benefits through altering kinetics rather than kinematics in the frontal plane during running. Further, the contributions of the ankle to frontal plane mechanics have not been well studied. **PURPOSE:** To determine if hip and ankle strength are associated with frontal plane kinetics in female runners.
METHODS: 64 healthy women running at least 16km per week participated in this study. Isometric hip abduction and ankle inversion strength were measured using a handheld dynamometer. 3D gait analysis was conducted as participants ran on an instrumented treadmill at 2.7 m/s. Participants were ranked in order of isometric strength of both the hip and ankle, and divided into tertiles of high, medium and low strength. 2-way MANOVA was used to determine the relationship between strength and peak moment, positive work and negative work in the frontal plane of the hip and the ankle. Tukey post-hoc tests were conducted where applicable (α=0.05).
RESULTS: There was no significant interaction effect, or main effect of hip strength. There was a significant main effect of ankle strength on frontal plane kinetics (p=0.024). Specifically, the strong ankle group compared to the weak ankle group had significantly greater magnitude of peak ankle inversion moment (0.95(0.32) vs 0.68(0.22) Nm/kg, p=0.033), hip abduction moment (-2.78(1.02) vs -1.88(0.24) Nm/kg, p=0.002) and hip frontal plane positive work (0.27(0.19) vs. 0.13(0.03) W/kg, p=0.006).
CONCLUSIONS: Isometric ankle but not hip strength is associated with kinetics in the frontal plane during running in females. Thus ankle strength should not be overlooked in clinical evaluation and treatment of runners.

The Role Of Off-axis Force In Running-related Overuse Injury

John J. Davis, IV, Jacob E. Vollmar, Ashley B. Nguyen, Emily G. Wagoner, Naomi E. Frankston, Allison H. Gruber. *Indiana University Bloomington, Bloomington, IN.* (Sponsor: Joe Hamill, FACSM)

(No relevant relationships reported)

Running-related overuse injuries are endemic among active populations. During the stance phase of running, the ground reaction force vector (GRF) and shank are not always aligned. Thus, some portion of the GRF is directed perpendicular to the shank and causes a bending moment, which may be implicated in the etiology of injury. **PURPOSE:** To examine the portion of the GRF that is directed perpendicular to the shank in injured and uninjured runners. **METHODS:** Twenty-seven runners were followed for a minimum of 43 weeks. Fourteen sustained injury. Overground kinetic and kinematic data were collected at 4.0 m/s (normalized to body weight). Using the sagittal plane angle between the shank and the GRF (GRF/SK angle), the sagittal plane GRF was decomposed into two components: one parallel to the shank (on-axis GRF) and one perpendicular to the shank (off-axis GRF). Group differences were assessed with an independent-samples t-test ($\alpha = 0.05$). **RESULTS:** While impact peak was a prominent feature of the on-axis GRF, it was mostly absent in the off-axis GRF. Peak off-axis GRF occurred at midstance for all subjects (Figure 1). Off-axis GRF at impact was similar ($p = 0.52$, Cohen's $d = 0.25$) between injured (0.22 ± 0.13 BW) and uninjured groups (0.20 ± 0.10 BW). Peak off-axis GRF was also similar ($p = 0.11$, $d = 0.63$) between injured (1.24 ± 0.09 BW) and uninjured (1.31 ± 0.13 BW) groups. GRF/SK angle was highly variable (range -25.0° to 25.3°) during initial contact but means were similar between groups (injured $6.08 \pm 13.5°$; uninjured $7.97 \pm 14.4°$; $p = 0.73$, $d = 0.14$). **CONCLUSION:** Concerning running injury, the off-axis GRF may be 1) not a significant contributor to injury, 2) only important when combined with other factors, or 3) related only to specific injuries.
Figure 1. On-axis and off-axis components of GRF relative to the shank during stance in uninjured and injured runners. The impact peak is not a prominent feature of off-axis GRF. Neither off-axis GRF at impact nor peak off-axis GRF differ between groups.

Effects Of A 4-week Intervention Using Semi-custom Foot Orthoses On Perceived Pain And Patellofemoral Loading In Targeted Sub-groups Of Recreational Runners.

Jonathan Sinclair. *University of Central Lancahsire, Preston, United Kingdom.*

(No relevant relationships reported)

PURPOSE The current study explored the effects of a 4-week intervention using foot orthoses on pain symptoms, psychological wellbeing and patellofemoral loading in recreational runners. **METHODS** Seventeen (10 males & 7 females) runners were firstly administered 6 clinical assessments, used to separate them into specific subgroups. They were then provided with a pair of semi-custom foot orthoses, which they wore for a period of 4-weeks. Lower extremity kinetics/ kinematics and patellofemoral loading during running at 4.0 m/s were obtained using an eight-camera motion capture system and force platform. In addition, participants self-reported knee pain was examined using the Knee injury and Osteoarthritis Outcome Score-Patellofemoral subscale (KOOS-PF). Data were collected before and after wearing the orthoses for 4-weeks. **RESULTS** The subgrouping revealed that 11 participants belonged to the strong subgroup and 6 to the weak and tight group. Patellofemoral loads were significantly reduced in both genders/subgroups (pre: male/strong=3.35BW, male/weak and tight=3.19BW, female/strong=3.50BW, female/weak and

tight=4.17BW & post: male/strong=3.04BW, male/weak and tight=2.15BW, female/strong=3.17BW, female/weak and tight=3.56BW). Significant improvements were also shown for KOOS-PF in both genders/subgroups (pre: male/strong=62.99, male/weak and tight=53.79, female/strong=65.34, female/weak and tight=52.27 & post: male/strong=71.75, male/weak and tight=74.24, female/strong=71.03, female/weak and tight=71.21), although only improvements in the weak and tight group exceeded the minimum threshold required for clinical relevance. **CONCLUSION** The observations from this study indicate that it may be advisable for male and female recreational runners from the weak and tight subgroup of patellofemoral pain patients, to utilize foot orthoses as a mechanism to reduce their symptoms.

Patellofemoral Pain Lead to Greater Joint Motion and Coordination Variability during a Prolonged Run

Jessica A. Mutchler, Klarie Ake, Barry A. Munkasy, Li Li, FACSM. *Georgia Southern University, Statesboro, GA.*

(No relevant relationships reported)

PURPOSE: To examine effects of patellofemoral pain (PFP) on lower extremity kinematics and joint coordination variability during a prolonged run. **METHODS**: Participants included 12 college-aged female runners in two groups: 6 with PFP and 6 healthy (CON), matched by age, height and body mass. Kinematic data was captured at sampling of 100Hz. Sixteen anatomical retroreflective markers, 7 tracking clusters, were placed on the participants' lower extremities for the static trial. Only the clusters remained for the running trial. Participants ran at a self-selected pace on a treadmill until they met exertion or pain criteria. Data for 20 steps from 3 time points (beginning, middle, and end) of the run were processed. Kinematic variability was assessed for each participant by calculating the standard deviation (SD) of peak knee flexion, internal rotation, and adduction angle and their velocities over 20 steps captured at the 3 time points. Continuous relative phase (CRP) mean values were calculated from normalized phase plots for coordination relationships between knee horizontal plane motion and hip sagittal, frontal, horizontal and ankle frontal plane motion. Coordination variability was calculated as the CRP coupling SD over 100% of stance for each time point for each participant. Statistical comparisons were assessed through a 2 (PFP vs CON) x 3 (beginning, middle, and end) repeated measures ANOVA. **RESULTS**: There was an increase in variability for peak knee adduction angle (PFP: 0.6, 0.6, 0.14; CON: 0.5, 0.9, 0.6, group X time interaction: p <.05), peak knee adduction velocity (PFP: 13.1, 14.7, 30.7; CON: 20.4, 13.1, 15.6, group X time interaction: p <.05), hip flexion / knee rotation CRP (PFP: 73.2, 56.7, 125.5; CON: 70.2, 70.0, 57.3, group X time interaction: p <.05), and knee rotation / rearfoot eversion CRP (PFP: 35.4, 47.2, 90.5; CON: 30.7, 27.6, 25.1, group X time interaction: p <.05) over time for the PFP group compared with healthy. **CONCLUSIONS**: The increase in joint kinematics and coordination variability over time observed only in the PFP group may indicate that pain and exertion experienced by the PFP group may decrease movement control towards the end of a prolonged run.

664   Board #7   May 30 3:15 PM - 5:15 PM

The Effect of Base of Gait on Hip and Pelvis Frontal Plane Motion in Collegiate Cross Country Runners

Christa Wille. *University of Wisconsin-Madison, Madison, WI.*

(No relevant relationships reported)

Increased hip adduction and contralateral pelvic drop have been correlated with several running related injuries including iliotibial band syndrome, patellofemoral pain, and tibial stress injuries. A narrow base of gait (BOG), defined as the mediolateral distance between the foot and the body's line of gravity has been suggested as a contributing factor to these increased frontal plane motions of the hip and pelvis. Despite limited investigation into this relationship, narrow BOG is routinely considered an injury risk factor in clinical practice when evaluating running mechanics.
Purpose: To identify the influence of BOG on peak hip adduction and peak contralateral pelvic drop in healthy, collegiate cross country runners at a range of speeds.
Methods: Whole body kinematics were recorded for 56 healthy runners (30 females) at 2.68, 3.35, and 4.47 m/s. The amount of variance in peak hip adduction and contralateral pelvic drop during stance explained by BOG was reported as the adjusted R^2 value using a linear regression model with significance at 0.05. Data across all speeds were included in the model with speed defined as a covariate to ensure validity. Sex was also included as a covariate due to its known effects on running mechanics.
Results: The final model used to predict peak hip adduction angle demonstrated an R^2 of 0.404 (p <0.001) with coefficients as follows: BOG at midstance (B = -0.491, p <0.001), sex (B = -1.69, p <0.001), speed (B = 0.7, p <0.001), and intercept (B = 12.240, p <0.001). This indicates a negative association between BOG and hip adduction, with a decrease in BOG demonstrating an increased hip adduction angle. An R^2 of 0.013 (p = 0.265) resulted from the model used to predict peak pelvic lateral drop with coefficients for BOG at midstance (B = 0.082, p = 0.436), sex (B = -0.242, p = 0.45), speed (B = -0.11, p =0.29), and intercept (B = -5.071, p <0.001).

Conclusion: When controlling for sex and running speed, BOG accounts for 40% of the variance in peak hip adduction, while only predicting <1% of the variance in contralateral peak pelvic drop. The increased peak hip adduction that accompanied a more narrow BOG is likely due to femoral adduction, as contralateral pelvic drop was minimally affected by BOG.

Physical Activity Modulates Blood Pressure Regulation During Controlled Low and High Salt Diets

Austin T. Robinson[1], Kamila U. Migdal[1], Matthew C. Babcock[1], Joseph C. Watso[1], Megan M. Wenner[1], Sean D. Stocker[2], William B. Farquhar, FACSM[1]. [1]*University of Delaware, Newark, DE.* [2]*University of Pittsburgh, Pittsburgh, PA.* (Sponsor: William B Farquhar, FACSM)

(No relevant relationships reported)

Purpose: Increased blood pressure (BP) reactivity and variability are predictive of future cardiovascular events. Excess dietary salt exaggerates neurally-mediated BP reactivity, and BP variability in salt-resistant rodents. Regular physical activity (PA) blunts BP reactivity in rodents. However, the interaction of salt and PA on neurovascular regulation has not been investigated in humans. Therefore, we sought to test the hypothesis that high habitual PA mitigates high dietary salt-induced increases in BP reactivity and BP variability in healthy, young adults. **Methods:** Nine participants (5F/4M, 27±2 yrs, BMI: 23.3±0.9 kg/m²) completed randomized, controlled 10-day diets of low (2.6 g/day), and high (18 g/day) salt. Beat-to-beat laboratory BP was measured via photoplethysmography on day 10 of each diet. BP reactivity was assessed as ΔBP (mmHg) during the final minute of a 2-min hand grip exercise at 40% maximal voluntary contraction compared to a preceding baseline. Average real variability (ARV) index was used to assess BP variability derived from 24-hour ambulatory BP monitoring. Habitual PA was assessed via accelerometry (Actigraph GT3X). Differences in high vs. low salt BP reactivity (ΔBP reactivity) and ambulatory BP variability (ΔBP ARV) were correlated against PA. Twenty four-hour urinary sodium excretion was measured. **Results:** There were no differences in 24-hr mean arterial BP on the high vs. low salt diet (82.9±2.1 vs. 79.8±2.4 mmHg; $p > 0.10$). Urinary Na+ excretion increased on the high vs. low salt diet (256.9±20.5 vs. 39.5±11.2 mmol/24 hours; $p < 0.05$). There was a trend for the high salt diet to augment systolic ($p = 0.08$), but not diastolic BP reactivity during hand grip exercise. Habitual PA was inversely correlated to Δ systolic BP reactivity (r = -0.74, $p = 0.03$), and there was a trend for an inverse correlation with Δ diastolic BP reactivity (r = -0.68, $p = 0.06$) during hand grip exercise. There was a trend for higher 24-hr systolic BP ARV on the high salt diet (10.6±0.8 vs. 8.9±0.6 mmHg; p = 0.09), but there was no correlation between PA with Δ systolic BP ARV (r = -0.29, $p = 0.48$) on the high vs. low salt diet. **Conclusion:** These preliminary data suggest that high habitual physical activity may offset some of the adverse neurovascular effects of high dietary salt in young, healthy, salt-resistant humans.

667   Board #2   May 30 3:15 PM - 5:15 PM

Particulate Matter Air Pollution and Vascular Function in Older Adults: A Natural Experiment

Jayson R. Gifford[1], Tyler Mangum[2], Joshua Weavil[2], Ashley Nelson[2], Joshua F. Lee[2], H. Jon Groot[2], Ryan Broxterman[2], Matthew Rossman[3], Russell Richardson[2]. [1]*Brigham Young University, Provo, UT.* [2]*University of Utah, Salt Lake City, UT.* [3]*University of Colorado: Boulder, Boulder, CO.*

(No relevant relationships reported)

PURPOSE: The risk of cardiovascular complications in the elderly increases with acute elevations in ambient, fine particulate matter air pollution ($PM_{2.5}$), and may be related to pollution-induced vascular dysfunction. Therefore, the purpose of this study was to utilize the large, episodic swings in ambient $PM_{2.5}$, typical of the Wasatch Front in Utah, as a natural experiment to determine the extent to which acute exposure to ambient $PM_{2.5}$ affects vascular function in healthy, older adults.
METHODS: Vascular function (flow-mediated dilation, FMD; passive-leg-movement-induced hyperemia, PLM), and pulmonary function were measured in 10 old subjects (70.5±2.3 years) during acute episodes of >120 hours of low (3.4±0.8 µg/m³) and

24-96 hours of high (50.0±1.2 µg/m³), naturally-occurring ambient $PM_{2.5}$ (Figures A and B). Markers of systemic inflammation were also assessed in venous blood during each visit.
RESULTS: Notably, high ambient $PM_{2.5}$ exposure was associated with a 34% reduction in vascular function assessed by FMD (Low $PM_{2.5}$: 8.9±1.0%; High $PM_{2.5}$: 5.9±1.0%; $P<0.05$; Figure C), and a 78% reduction in vascular function assessed by PLM (area under the curve: Low $PM_{2.5}$: 145±38 ml, High $PM_{2.5}$: 31±25 ml; $P<0.05$, Figure D). Additionally, acute exposure to high ambient $PM_{2.5}$ was accompanied by an increase in markers of systemic inflammation (*e.g.* Plasma C-Reactive Protein, Low $PM_{2.5}$: 872±143 ml, High $PM_{2.5}$: 1365±220 ng/ml; $P<0.05$), which may contribute to the decrease in vascular function. Interestingly, natural exposure to high levels of $PM_{2.5}$ did not significantly affect pulmonary function (FEV_1/FVC: Low $PM_{2.5}$: 74±2%; High $PM_{2.5}$: 72±2%; $P>0.05$).
CONCLUSIONS: Despite a lack of detectable changes in pulmonary function, acute, natural exposure to elevated ambient $PM_{2.5}$ results in markedly impaired vascular function in older adults, possibly a consequence of pollution-induced systemic inflammation.

* Significantly different from Low PM 2.5 (P<0.05)
# Significant main effect (P<0.05)

Skeletal Muscle Microvascular Permeability After Eccentric Contraction-Induced Muscle Injury: Novel In Vivo Imaging Using Two-Photon Laser Scanning Microscopy

Kazuki Hotta[1], Brad J. Behnke[2], Kazuto Masamoto[1], Rie Shimotsu[1], David C. Poole, FACSM[2], Yutaka Kano[1]. [1]*University of Electro-Communications, Tokyo, Japan.* [2]*Kansas State University College of Human Ecology, Manhattan, KS.* (Sponsor: David C. Poole, FACSM)

(No relevant relationships reported)

Within injured skeletal muscle the capillary bed plays a crucial role in leukocyte invasion through modulations of the endothelial integrity, associated with increased permeability. However, direct observation of altered microvascular permeability and compromised capillary integrity has not been technically feasible. Two-photon laser scanning microscopy (TPLSM) allows three-dimensional *in vivo* imaging that, given the depth of penetration and high resolution of TPLSM, will facilitate measurement of microvascular leakage. **PURPOSE:** We hypothesized that the regulation of capillary permeability *in vivo*, as assessed by real-time TPLSM, is temporally related to acute inflammatory and regenerative processes following muscle injury. **METHODS:** Tibialis anterior muscles of anesthetized male Wistar rats (n=57) were subjected to eccentric contractions (ECC) via electrical stimulation. The skeletal muscle microcirculation was imaged by an intravenously infused fluorescent dye (rhodamine b isothiocyanate dextran, molecular weight 70,000 Daltons) to assess microvascular permeability via TPLSM 1, 3 and 7 days after ECC. Immunohistochemistry on serial muscle sections was performed to determine the percentage of VEGF-A positive muscle fibers in the damaged muscle. **RESULTS:** Compared with non-ECC control, the volumetrically-determined interstitial leakage of fluorescent dye had increased significantly on days 1 and 3 post-ECC (5.1±1.4, 5.3±1.2 vs. 0.51±0.14 µm³x10⁶, $P<0.05$ respectively days 1 and 3 vs. control). However, by post-ECC day 7 interstitial leakage had returned to control values. Damaged muscle fibers were evident on days 1 and 3 (% damaged muscle fiber: 11.7±4.7, 48.4±12.4% vs. 0% $P<0.05$ respectively days 1 and 3 vs. control). Percentage of VEGF-A positive muscle fiber in damaged muscle fiber was significantly higher on days 1 and 3 compared to control (24.9±9.8, 39.3±16.7 vs. 0%, $P<0.05$ respectively days 1 and 3 vs. control). Regenerated

skeletal muscle fibers were found only at 7 days post-ECC. **CONCLUSION:** *In vivo* TPLSM imaging represents a powerful investigative technique for skeletal muscle microcirculatory research. Microvascular hyperpermeability is associated with ECC-induced muscle damage and increased VEGF expression.

Acute Ultraviolet Radiation Exposure Attenuates Nitric Oxide-Mediated Vasodilation in the Cutaneous Microvasculature

S. Tony Wolf, Anna E. Stanhewicz, Tyler B. Garner, Nina G. Jablonski, W. Larry Kenney, FACSM. *Pennsylvania State University, University Park, PA.* (Sponsor: W. Larry Kenney, FACSM)
(No relevant relationships reported)

The bioactive metabolite of folate, 5-methyltetrahydrofolate (5-MTHF), is degraded by ultraviolet radiation (UVR) *in vitro,* and UVR exposure to the skin may deplete bioavailable 5-MTHF in the exposed area. Adequate 5-MTHF is essential for full expression of nitric oxide (NO)-mediated vasodilation of the cutaneous microvasculature through its indirect role in enzymatic coupling of nitric oxide synthase (NOS). **Purpose:** To determine the acute effects of UVR exposure on NO-mediated vasodilation in the cutaneous microvasculature and the role of 5-MTHF on this response. We hypothesized that acute UVR exposure would attenuate NO-dependent vasodilation and that local delivery of 5-MTHF would augment NO-dependent vasodilation after UVR exposure. **Methods:** Two microdialysis fibers were placed in the ventral skin of both forearms in 11 healthy young adults (23 ± 4 y; 5M/6F) for local delivery of lactated Ringers (control) or 5 mM 5-MTHF. One arm was randomly chosen for exposure to 300 mJ/cm^2 UVR while the other served as a non-exposed control (CON). Red cell flux was measured at each site by laser-Doppler flowmetry (LDF). Following a baseline period, a standardized local heating ($42°C$) protocol was used to induce cutaneous vasodilation. Once a stable skin blood flow plateau was achieved, 15mM NG-nitro-L-arginine methyl ester (L-NAME) was perfused at all sites to inhibit NOS. Cutaneous vascular conductance was calculated (CVC = LDF/MAP) and expressed for each phase of the local heating response (initial peak, plateau, NO-mediated vasodilation) as a percentage of maximum (%CVC$_{max}$; 28mM sodium nitroprusside + $43°C$). **Results:** No differences were seen for %CVC$_{max}$ between UVR and CON for the initial peak ($p\geq0.51$) or heating plateau ($p\geq0.58$) across microdialysis sites. UVR exposure blunted NO-mediated dilation in the UVR exposed arm compared to CON (16.4 ± 12.1 vs $33.4\pm17.9\%$; $p=0.02$). Local delivery of 5-MTHF augmented NO-mediated vasodilation compared to the control site in the UVR exposed arm (36.4 ± 19.9 vs $16.4\pm12.1\%$; $p=0.005$). **Conclusion:** NO-mediated vasodilation is attenuated after acute UVR exposure, but is restored with local delivery of 5-MTHF. Acute UVR exposure may impair NO-mediated vasodilation through photodegradation of 5-MTHF.

No Sex Differences in Arterial Stiffness and Hemodynamics Response to Resistance Exercise in Older Individuals

Georgios Grigoriadis[1], Alexander J. Rosenberg[1], Sang Ouk Wee[2], Elizabeth C. Schroeder[1], Garett Griffith[1], Bo Fernhall, FACSM[1], Tracy Baynard, FACSM[1]. *[1]University of Illinois at Chicago, Chicago, IL. [2]California State University, San Bernardino, CA.*
(No relevant relationships reported)

Arterial stiffness (AS) contributes to high blood pressure and cardiovascular disease in both men and women. However, sex differences do exist in the incidences rates of stroke with aging, with older women having a greater risk. These sex differences in older individuals have not been fully explained and an acute hypertensive stimulus (e.g. resistance exercise (RE)) may provide a viable physiological stressor to elucidate potential differences. **PURPOSE:** To determine if sex differences exist for arterial stiffness following acute RE among older individuals. **METHODS:** Ten males (61 ± 6 yrs; 30.9 ± 4.4 kg/m^2) and 15 females (59 ± 6 yrs; 29.5 ± 6.3 kg/m^2) completed 3 sets of 10 reps of maximal isokinetic knee extension and flexion on a force dynamometer. Central AS was evaluated by pulse wave velocity (PWV), obtained from an automated ambulatory BP monitor at baseline, immediate and 30 min post-RE. Hemodynamic variables (cardiac output (Q), cardiac index (Qi), heart rate (HR), stroke volume (SV), mean arterial BP (MAP)), were also acquired from the brachial oscillometric BP waveforms. Local AS was determined by carotid measurements (β-stiffness index, pressure-strain elasticity modulus (Ep) and arterial compliance (AC)) using ultrasonography. **RESULTS:** See Table 1. PWV, Q, HR and MAP increased immediate post-RE similarly in both groups ($p<0.05$). However, females had an overall lower AC and Q compared to older males ($p<0.05$). **CONCLUSION:** No sex differences were observed in arterial stiffness following acute RE. Thus, the AS response to an acute RE bout did not provide insight regarding contributing factors as to why women are at a greater risk of cerebrovascular events.

	Group	Baseline	Immediate	30-min
PWV (m/s)*	Male	8.8 ± 0.9	9.6 ± 1.0	8.9 ± 0.8
	Female	8.5 ± 1.1	9.2 ± 1.1	8.5 ± 1.2
β-stiffness index	Male	10.9 ± 2.9	10.1 ± 2.6	11.2 ± 3.4
	Female	12.6 ± 2.5	12.1 ± 3.5	12.3 ± 2.1
Ep (kPa)	Male	141 ± 32	136 ± 33	147 ± 34
	Female	170 ± 42	168 ± 60	170 ± 30
AC (mm²/kPa)#	Male	0.63 ± 0.15	0.68 ± 0.19	0.60 ± 0.12
	Female	0.47 ± 0.09	0.51 ± 0.18	0.47 ± 0.10
Q (L/min)*#	Male	4.9 ± 0.8	5.9 ± 1.5	5.1 ± 0.6
	Female	4.5 ± 0.4	4.9 ± 0.8	4.7 ± 0.5

Moderate-to-Severe Sleep Apnea and Total Body Fat are Inversely Associated with Vascular Function Changes Following Exercise Training

Devon A. Dobrosielski[1], Christopher Papandreou[2], Susheel Patil[3], Hyunjeong Park[1]. *[1]Towson University, Towson, MD. [2]Rovira i Virgili University, Reus, Spain. [3]Johns Hopkins School of Medicine, Baltimore, MD.*
(No relevant relationships reported)

Obstructive sleep apnea (OSA) is associated with increased cardiovascular morbidity in middle-aged men due, in part, to impaired vascular function. Exercise confers cardioprotection by improving vascular health. Whether this beneficial effect is attenuated in the presence OSA is not known. **PURPOSE:** Examine the joint association of OSA severity and total body fat % with brachial artery flow mediated dilation (BAFMD) changes following exercise training in overweight men with and without OSA. **METHODS:** At baseline, all participants underwent overnight polysomnography to determine the presence of OSA, as defined by the apnea-hypopnea index (AHI). Total body fat was measured using dual energy X-ray absorptiometry. BAFMD was assessed using high- resolution ultrasonography before and upon completion of a 6-week (3 sessions/week; 1 hour/session) exercise training program. **RESULTS:** Five men with moderate to severe OSA (+OSA) and five men with no to mild OSA (*OSA) completed the study. Per study design, the AHI of the +OSA group was higher compared to the *OSA group (34 ± 12 events/hour vs. 8 ± 5 events/hour, p=0.009). While no baseline differences were observed between the groups in age (49 ± 6 years vs. 46 ± 9 years, p=0.528) or BMI (36.1 ± 6.2 kg/m^2 vs. 32.6 ± 3.8 kg/m^2, p=0.250), total body fat % was higher in the +OSA group (41 ± 3 % vs. 36 ± 3 %, p=0.009). Stepwise regression analysis revealed that an AHI above 15 events/hour and total body fat % above the median (joint category) [beta coefficient = -2.89, (95% CI -3.59 - -0.71), p=0.040] were significant and independent determinants of the change in BAFMD with exercise, after adjusting for baseline BAFMD, age and BMI. **CONCLUSION:** A combination of moderate-to-severe OSA and high total body fat % was inversely associated with the level of improvement in vascular function following exercise training.

Acute Influence of Caffeine on Arterial Stiffness and Central Blood Pressures Following Aerobic Exercise

Nicholas A. Carlini, Allison H. Steinbeck, Brittany Smith, Brandon Kistler, Bradley S. Fleenor, Matthew P. Harber, FACSM. *Ball State University, Muncie, IN.*
(No relevant relationships reported)

Caffeine ingestion alters blood pressure (BP), however, the interactive effect of caffeine and exercise on central BP is unknown. **PURPOSE:** Examine the acute influence of caffeine and moderate-intensity aerobic exercise on post-exercise

central BP and arterial stiffness. **METHODS:** Ten males (aged 55±5; range 31-71 years) completed two exercise trials after ingestion of caffeine (400 mg) or placebo. Peripheral (brachial) and central (aortic) BP were assessed via pulse wave analysis (PWA) and arterial stiffness via pulse wave velocity (PWV) obtained before and 30 min post-ingestion. Participants performed 40-min of cycling at 70% of HRmax using identical workloads between trials. PWA and PWV were collected again 10 and 30 min post-exercise. Data were analyzed via two-way ANOVA with repeated measures. **RESULTS:** Prior to exercise, compared to placebo, caffeine increased (P<0.05) brachial systolic blood pressure (bSBP) (+12mmHg), brachial diastolic blood pressure (bDBP) (+8mmHg), central systolic blood pressure (cSBP) (+11mmHg) and central diastolic blood pressure (cDBP) (+7mmHg). PWV was higher (0.75 vs. 0.22m/s) 30 minutes post caffeine ingestion, independent of trial (P<0.05) while there was a trend for an interaction (P=0.074), suggesting an increase in PWV with caffeine. Post-exercise, bSBP (-4.8 vs. -6.1mmHg) and PWV (-0.40 vs. -0.74m/s) were higher in caffeine (P<0.05), likely due to the influence of caffeine prior to exercise. cSBP (-5 vs. -6mmHg) and bDBP (-3.5 vs. -1.8mmHg) were lower after exercise, independent of trial (P<0.05) while bSBP (-4.8 vs. -6.1mmHg) and cDBP (-3.1 vs. -1.5mmHg) trended (P=0.07) to be lower after exercise, independent of trial. PWV (-0.11 vs. -0.06m/s) remained higher (P<0.05) after exercise in caffeine compared to placebo but was not influenced by exercise. Accordingly, AP (-2.7 vs. -1.1mmHg) and AIx (-5.5 vs. -1.2%) were lower (P<0.05) after exercise in placebo only. **CONCLUSION**: These findings suggest that the stimulatory effects of caffeine ingestion elevates central hemodynamics and arterial stiffness, which persists even after exercise, exerting a greater afterload on the heart.

Altered Vascular Function in Chronic Kidney Disease: Evidence from Passive Leg Movement

Elissa K. Katulka, Alexandra E. Hirt, Danielle L. Kirkman, David G. Edwards, Melissa A.H. Witman. *University of Delaware, Newark, DE.*
(No relevant relationships reported)

Chronic kidney disease (CKD) is an independent risk factor for the development of cardiovascular disease, with both diseases characterized by reduced nitric oxide (NO) bioavailability and vascular dysfunction. Passive leg movement (PLM) has previously been shown to produce NO-mediated hyperemia in the lower extremity, however this technique has not yet been utilized to assess vascular function in patients with CKD. **PURPOSE:** To assess vascular function in patients with CKD using PLM, in addition to the traditional flow-mediated dilation (FMD) technique. **METHODS:** Assessment of vascular function via PLM and FMD was performed on 12 patients (CKD, 67±3 yrs) and 12 healthy controls (CON, 59±2 yrs). Hemodynamics and artery diameters during PLM and FMD were measured utilizing ultrasound Doppler of the femoral and brachial arteries, respectively. **RESULTS:** Patients with CKD had reduced peak leg blood flow (LBF) (CKD, 384±39 vs. CON, 626±93 mL/min, p<0.05) and a reduced change in LBF from baseline to peak (ΔpeakLBF) (CKD, 153±27 vs. CON, 274±41 mL/min, p<0.05) during PLM compared to CON. Additionally, ΔpeakLBF was significantly correlated with kidney function as assessed by estimated glomerular filtration rate for all participants (r=0.53, p<0.05). As anticipated, FMD was also significantly attenuated in CKD patients compared to CON. **CONCLUSION:** Vascular function as assessed by PLM and FMD is attenuated in patients with CKD compared to controls, supporting a reduction in NO bioavailability in this chronic disease state. Additionally, PLM appears to be a novel and feasible approach to assess NO-mediated vascular function in CKD and is associated with kidney function.

Influence of Multiple Indices of Body Composition on Cardiometabolic Risk Factors in Adults

Lyndsey M. Hornbuckle[1], Robert Buresh, FACSM[2], Yuri Feito, FACSM[2], Cassie Williamson[2], Brian Kliszczewicz[2], Ayles Herrington[2], Corrine Ellis[3], Leah Tsui[3], Anna Schlupp[3], Kelsey Shepard[3], Stella Volpe, FACSM[3]. *[1]University of Tennessee, Knoxville, Knoxville, TN. [2]Kennesaw State University, Kennesaw, GA. [3]Drexel University, Philadelphia, PA.*
(No relevant relationships reported)

Body composition is an established predictor of cardiometabolic risk. Novel body composition variables may also predict risk and therefore, warrant further examination. **PURPOSE:** To assess the influence of fat to muscle ratio (FMR), percent body fat (%BF), and body mass index (BMI) on cardiometabolic risk factors in healthy adults. **METHODS:** Data were analyzed from 78 women (29.9 ± 13.5 years) and 45 men (25.0 ± 8.5 years). Height, weight, %BF (via dual-energy X-ray absorptiometry), resting blood pressure, and resting heart rate (RHR) were measured. BMI and mean arterial pressure (MAP) were calculated. Fasting total cholesterol (TC), high-density lipoprotein cholesterol (HDL), TC:HDL ratio, low-density lipoprotein cholesterol (LDL), triglycerides (TG), glycosylated hemoglobin (A1c), glucose (GLU), and insulin (INS) were measured. A 2-hour oral glucose tolerance test was conducted, from which 2-hour glucose (2HR-GLU) and 2-hour insulin (2HR-INS) were measured. Insulin sensitivity index (ISI) and homeostasis model assessment for insulin resistance (HOMA) were calculated. The influence of FMR [visceral fat area (cc) · fat free mass (kg)$^{-1}$], BMI (kg · m^{-2}), and %BF on markers of cardiometabolic risk was determined. **RESULTS:** Regression analysis showed that FMR was the strongest predictor of MAP, TC, TC:HDL ratio, LDL, TG, GLU, INS, and HOMA. %BF was the strongest predictor of RHR, 2HR-GLU, 2-HR INS, and ISI. BMI was the strongest predictor of HDL and A1c. One-way MANOVA (above- vs below-75th percentile) showed a significant multivariate (MAP, TG, HOMA) main effect for FMR. Wilks' Lambda = 0.628, F (4,96) = 14.24, p < 0.001, with univariate main effects for MAP (F=22.2, p < 0.001), TG (F = 8.39, p = 0.005), and HOMA (F = 16.27, p < 0.001). MANOVA also revealed a multivariate main effect for BMI (Wilks' Lambda = 0.695, F(4,96) = 10.55, p < 0.001), with univariate main effects for MAP (F = 18.7, p < 0.001) and HOMA (F = 19.5, p < 0.001). MANOVA showed a multivariate main effect for %BF (Wilks' Lambda = 0.770, F(4,96) = 7.17, p < 0.001), with univariate main effects for MAP (F = 13.8, p < 0.001) and HOMA (F = 10.6, p = 0.002). **CONCLUSION:** These data show FMR was a better predictor of several risk factors compared to %BF and BMI. This suggests that this method of calculating FMR may be effective for assessing cardiometabolic risk in adults.

Changes in Total and Regional Body Composition during the season in Division 1 Football Players

Tyler A. Bosch, Christiana Raymond-Pope, Donald R. Dengel, FACSM. *University of Minnesota, Minneapolis, MN.* (Sponsor: Donald R. Dengel, FACSM)
(No relevant relationships reported)

Purpose: The purpose of this study was to determine the association between changes in weight to changes in total and regional fat and lean mass in a group of division 1 football players.
Methods: A total of 78 players completed a pre-season (June) and Post-season (December) body composition scan using dual x-ray absorptiometry. Absolute and percent (%) changes in total and regional body composition were calculated. Linear regression was used to measure the association between change in weight and change in total lean (TLM) and total fat mass (TFM) for the entire sample and for each position. Linear regression was also used to analyzed the association between %change in TLM and TFM with %change in regional lean and fat mass.
Results: Position did not have a significant effect on the association between change in weight and change in TFM or TLM (p=0.171, p=0.172 respectively). However, change is weight was strongly associated with change in TFM for the entire group (slope $\pm$ SE = 0.8 $\pm$ 0.06, p <0.001 R^2=0.72). Conversely, change in weight was weakly associated with change in TLM for the entire group (slope $\pm$ SE = 0.2 $\pm$ 0.06, p <0.001 R^2=0.14).

Abstracts were prepared by the authors and printed as submitted.

Change in TLM was not significantly associated with change in TFM (slope$\pm$SE = -0.1$\pm$0.06, p=0.125, R^2=0.03). Regionally, the strongest association was between %change in TFM with %change in Android fat mass (1.62$\pm$0.08, p <0.001, R^2= 0.84). For lean mass, both %change in Trunk LM and Leg LM had similar associations with %change in TLM (R^2= 0.43 & 0.38, p<0.001 for both). When comparing each position separately, only RB (n=6) had a strong positive association between change in weight and change in TLM (R^2=0.82, p<-0.001), but, no association between change in weight and change in TFM (R^2=0.006, p=0.879).

Conclusion: These data suggest that changes in weight during a competitive football season are largely driven by changes in fat mass, except for potentially RB. The slopes of the relationship suggest that on average from every 1kg (2.2lbs) of weight increase there is 0.8 kg (1.8lbs) increase in TFM. Additionally, there a higher proportion of fat increase is distributed to the android or abdominal region. Given the relationship between increased fat mass with both reduced performance and injury risk, teams should focus on closely maintaining athlete weight during the season.

A Comparison of Preseason Body Composition and Phase Angle in NCAA Division I Female Athletes

Takudzwa A. Madzima, Svetlana Nepocatych, Daniel A. Baur, Kirtida Patel, Walter R. Bixby, FACSM. *Elon University, Elon, NC.*

(No relevant relationships reported)

Body composition has several implications for the overall health and performance of athletes. Phase angle, a marker of cellular integrity, nutritional status and distribution of intra- (ICW) and extracellular water (ECW) may indicate overtraining and poor nutrition. A phase angle less than 5° is used as a criterion of poor cellular integrity and nutritional status in non-athletic populations. However, limited phase angle, ICW and ECW data exists for collegiate athletes. **PURPOSE:** To evaluate the differences in measures of body composition between NCAA Division I female cross-country (XC), soccer (SOC) and basketball (BB) athletes. **METHODS:** Fifty female athletes (age: 19±1yrs; XC, n=19; SOC, n=19; BB, n=12) were assessed in the preseason. Body composition, including lean mass (LM), fat mass (FM), regional bone mineral density (BMD) of the lumbar spine (L1-L4), and hip (femur) were measured by DXA. Appendicular skeletal muscle adjusted by squared height (ASM index; kg/m^2), LM index (LMI; kg/m^2) and FM index (FMI; kg/m^2) were calculated to compare relative body composition. Bioelectric impedance analysis was used to assess phase angle, ICW (%) and ECW (%). ANOVAs were used to analyze the data. Significance was accepted at p<0.05. **RESULTS:** XC had significantly lower ASMI (6.83±0.5 vs. 7.42±0.5 and 8.07±0.9kg/m^2, p<0.001), FMI (3.85±1 vs. 6.04±2 and 6.07±0.9kg/m^2, p<0.001) and body fat % (18.5±5 vs. 25.5±5 and 27.4±9%, p=0.001) than SOC and BB. There were no differences in ASMI, FMI and body fat % between SOC and BB. LMI was significantly lower in XC (15.3±0.9kg/m^2) compared to SOC (16.2±0.9kg/m^2, p<0.001). XC had significantly greater ICW (58.8±2% vs. 54.3±2%, p<0.001) and lower ECW (41.2±2% vs. 45.7±2%, p<0.001) than BB. The average phase angle was 7.4±0.5° and did not differ between sports. BB had significantly greater lumber spine BMD (p<0.001), left femur BMD (p<0.001) and right femur BMD (p<0.001) than both XC and SOC. **CONCLUSIONS:** Our findings highlight the sport-specific differences in body composition measures that may inform strength and conditioning coaches and athletic trainers. Optimal body composition through quality nutrition and training programs improves performance, increases playing time, injury prevention and helps to assess overall health.

678   May 30 4:00 PM - 4:15 PM

Caffeine Consumption in Habitual Users Has No Impact on BIA-Derived Measurements of Body Composition

Cassie M. Williamson[1], Brett S. Nickerson[2], Emily E. Bechke[1], Cherilyn McLester[1], Brian M. Kliszczewicz[1]. *[1]Kennesaw State University, Kennesaw, GA. [2]5201 University Blvd, Laredo, TX.* (Sponsor: Mark Tillman, FACSM)

(No relevant relationships reported)

Bioelectrical impedance analysis (BIA) is often used to estimate total body water (TBW), intracellular body water (ICW), extracellular body water (ECW), and body fat percentage (BF%). A common restriction for BIA analysis is abstinence from caffeine 12-hours prior to testing. However, research has yet to determine whether the consumption of caffeine influences BIA testing results. **PURPOSE:** The purpose of this study was to determine if the consumption of caffeine influences BIA-derived BF% and body water values in habitual caffeine users. **METHODS:** 20 apparently healthy males (26.6 ± 4.1 years) identified as habitual caffeine consumers (≥ one 95mg serving per day ≥ four days per week) participated in this study. Participants came to the lab on three occasions, the first visit serving as the control (CON) with no supplementation. The remaining two visits were performed in a randomized double-blind, cross-over fashion. Participants consumed 200mg of dextrose (PLA) or caffeine (CAF) in capsule form. During each visit, seven multi-frequency BIA measurements

were conducted before (PRE) and after (15-min, 30-min, 45-min, 60-min, 75-min, 90-min) consumption. **RESULTS:** Repeated measures ANOVA revealed BF% for CAF was lower than the CON and PLA conditions at PRE and 15-min (p < 0.001, p = 0.004), but not statistically significant for the remaining time points (i.e. 30-, 45-, 60-, 75-, and 90-min). However, the effect size (ES) of the BF% differences were small. The CON, PLA and CAF conditions had higher PRE ICW values than their associated post time points (i.e., 15-, 30-, 45-, 60-, 75-, and 90-min). However, similar to BF%, the ES of the mean differences for ICW were all marginal. No other differences were observed. **CONCLUSION:** Caffeine consumption in habitual users produced trivial changes in TBW, ECW, ICW, and BF%. Therefore, the pre-testing guidelines for caffeine consumption may be too stringent in habitual caffeine consumers.

Regional Variations in Physical Fitness and Activity in Ecuadorian Adolescents

Cheryl A. Howe, FACSM[1], Sharon L. Casapulla[1], Jay Shubrook[2], Pablo Lopez[1], Mario J. Grijalva[1], Darlene Berryman[1], L Benelcazar[3]. *[1]Ohio University, ATHENS, OH. [2]Touro University, Vallejo, CA. [3]Pontifical Catholic University of Ecuador, Quito, Ecuador.*

(No relevant relationships reported)

As obesity rates are related to physical inactivity, and physical inactivity is positively related to economic status, it is important to assess the lifestyle habits of adolescents in countries, like Ecuador, who are undergoing significant economic growth. **PURPOSE**: Assessed the physical fitness (PF) and physical activity (PA) levels of adolescents from two different regions of Ecuador and their relationship with peer/familial influence on PF and PA. **METHODS**: Adolescents (N=407) were recruited from 4 schools: 2 from a suburb of Quito (n=217; Northern Sierra region) and 2 from the smaller town of Cariamanga (n=214; Southern Sierra region). Height (cm) and weight (kg) measurements were used to calculate BMI for weight classification. PF was estimate using a post-exercise heart rate following a 3-min step test. A questionnaire was used to assess PA habits (moderate-vigorous PA and sedentary behavior) and perceived peer/familial support for being physically active. T-Tests and ANOVAs assessed differences in outcome variables by sex, weight status and location. Person correlations assessed relationships among PF, PA habits, and perceived peer/familial influence. **RESULTS**: According to IOTF standards, 12.3% of the adolescents were classified as overweight or obese. Overall, PF level was 43.4±8.9 ml/kg/min, with males significantly higher than females (48.3±9.4 vs. 41.1±7.5 ml/kg/min) and Southern Sierra adolescents significantly higher than Northern Sierra (47.1±9.6 vs. 39.7±6.1 ml/kg/min) adolescents. Overweight adolescents had significantly lower PF levels compared to healthy and underweight adolescents **only** in Southern Sierra region (42.3±8.5 vs. 46.9±8.6 vs. 50.5±11.1 ml/kg/min; p<0.0001). Most adolescents reported participating in <60 min/day of moderate-vigorous PA (91.6%) and spending >2 hours/day in sedentary behaviors (79.9%). While perceived peer/familial influence did not correlate well with PF or PA levels (r=-0.18 to 0.20; adj. p>0.05), males perceived greater peer influence for PA participation than females, regardless of weight status or location. **CONCLUSIONS**: While adolescents of Southern Sierra had higher PF levels, these values were impacted by sex and weight status, but not by PA levels or perceived peer or family influence.

680   May 30 4:30 PM - 4:45 PM

Comparison of Ultrashort Versus Short High-Intensity Interval Training for Body Composition, Anaerobic, and Aerobic Performance

Masoud Moghaddam, Tyler W.D. Muddle, Carlos A. Estrada, Mitchel A. Magrini, Nathaniel D.M. Jenkins, Bert H. Jacobson, FACSM. *Oklahoma State University, Stillwater, OK.* (Sponsor: Bert H. Jacobson, FACSM)

(No relevant relationships reported)

PURPOSE: This study compared the effects of ultrashort (UH) versus short (SH) high intensity interval training (HIIT) in conjunction with functional training on body composition, anaerobic, and aerobic performance. **METHODS:** Thirty-four recreationally active participants were randomly assigned to SH (8 males and 9 females) and UH (8 males and 9 females) groups and completed 6 cycles of 6 exercises at ~90% of maximal heart rate (i.e. kettle bell snatches; step-up jumps; jumping jacks; front squat; burpees; high knees) 3 days a week for 4 weeks. SH was performed with 20s:10s work-to-rest ratio, and a 2-minute recovery within cycles, while UH was completed with 10s:5s work-to-rest ratio, and 1-minute recovery. Fat mass (FM), fat free mass (FFM), vastus lateralis cross sectional area (VL CSA), Wingate anaerobic capacity (i.e. peak power [PP] and anaerobic power [AP]), and aerobic fitness (i.e. VO$_{2max}$) were measured before and after the training interventions and analyzed with 2-way mixed factorial ANOVAs. **RESULTS:** FM did not significantly (p>0.05) change, however, both groups improved significantly (p<0.05) FFM (UH: 60.8 ± 15.0 to 61.5 ± 15.2 kg, SH: 54.3 ± 11.5 to 55.5 ± 11.0 kg), as well as VL CSA (UH = 24.8 ± 6.2 to 27.1 ± 6.3 cm, SH = 25.6 ± 5.1 to 27.9 ± 5.5 cm). Additionally, anaerobic

(UH: PP = 913 ± 305 to 1033 ± 300 W; AP = 11.5 ± 1.1 to 12.6 ± 1.1 W/kg, SH: PP = 839 ± 162 to 887 ± 181 W; AP = 11.8 ± 1.1 to 12.5 ± 1.2 W/kg) and aerobic capacity (UH: VO_{2max} = 35.8 ± 6.9 to 38.9 ± 6.1 ml/kg/min, SH: VO_{2max} = 39.7 ± 9.3 to 42.6 ± 9.1 ml/kg/min) significantly ($p<0.05$) increased in both groups. There were no significant (p>0.05) differences between groups. **CONCLUSION:** Current literature has shown a 20s:10s work-to-rest ratio to be the shortest, most effective HIIT protocol, as performed by the SH group. However, in the present study, the UH group improved FFM, VL CSA, anaerobic, and aerobic fitness in a similar manner to the SH group. These findings suggest that individuals may be able to achieve similar health benefits as the SH protocol, despite exercising for less total time by performing HIIT with a 10s:5s work-to-rest ratio.

23 Year Analysis Of Anthropometric Profiles And Long-Term Career Progression Of German Junior Female Rowers

Kay Winkert, Gunnar Treff, Werner Lormes, Katja Machus, Jürgen M. Steinacker, FACSM. *University Hospital Ulm, Ulm, Germany.*

(No relevant relationships reported)

Standing height (SH) and body mass (BM) are well established determinants of rowing performance, which therefore typically included in most talent identification programs. However, it remains unclear if anthropometric profiles allow for differentiation between subsequent career progression levels already in junior female rowers. **PURPOSE:** We aimed to evaluate the relationship between anthropometric profiles of adolescent junior female rowers and their long-term career progression level. We furthermore described their anthropometric profiles and calculated normative requirements associated with a successful career progression on elite level. **METHODS:** SH, BM and BM-index (BMI) of 399 female rowers (age 17.6 ± 0.58 years) of the German Junior National Team between 1991 and 2014 were retrospectively analyzed using ANOVA with Post-Hoc test. Rowers were grouped exclusively according to their highest long-term career progression level, categorized as participation in U19-, U23-, Senior-World Championships (WCh), or Olympic Games (OG). Normative anthropometric requirements were defined as interquartile range (IQR) of the OG-group. **RESULTS:** We found significant small effects between career progression level and SH (P = .009; η2 = 0.03), BMI (P = .004; η2 = 0.04). Rowers, who never competed higher than U23-WCh were significantly smaller than those who competed in Senior-WCh (-1.30%; P = .036) or OG (-1.34%; P = .049). Differences in BM were not significant (P = .115; η2 = 0.02). Significantly higher BMI was identified for rowers who remained on U19-level compared to those competing in Senior-WCh (+3.87%; P = .003) or OG (+3.28%; P = .039). The same was found for U23-WCh vs. Senior-WCh (+3.32%; P = .034). IQR of SH and BM was 178 - 184 cm and 68 - 73 kg. **CONCLUSIONS:** Advanced anthropometric characteristics partly mirror long-term career progression levels in female Junior National Team rowers, underlining the relevance of anthropometric data for talent identification and development. Interestingly, female rowers tending to a more athletic body type (lower BMI, BM at higher SH) reached higher career progression level, probably due to a better power to body mass ratio. As talent identification and development is multi-dimensional and partly inherently, anthropometric data should not used exclusively.

Telomere Length Of Middle-aged Sprinters And Endurance Runners: Relationships To Performance And Body Composition

HERBERT G. SIMÕES, CAIO V. SOUSA, LYSLEINE A. DEUS, SAMUEL S. AGUIAR, PATRICK A. SANTOS, LUCAS P. BASBOSA, HIGOR G. SOUSA, ÉRICA C. ROSA, ROSÂNGELA V. ANDRADE, THIAGO S. ROSA. *UNIVERSIDADE CATÓLICA DE BRASÍLIA, BRASÍLIA, Brazil.*

(No relevant relationships reported)

PURPOSE: The telomere length (TL) of middle aged master runners (RUN) (n = 23, 52.3 ± 8.6 yrs; 12 sprinters, SPT; 11 endurance runners, END) was compared to untrained controls (CON, n = 10; 43.7 ± 9.4 yrs), and the relationships between TL to both master athletes' performance and body composition were analyzed. **METHODS**: Participants had blood samples collected for biomolecular measures. Relative leucocyte telomere length (T/S) was measured through qPCR. ANOVA and unpaired t-tests were applied to compare TL between studied groups, and the Pearson's moment correlation was applied to verify relationships. **RESULTS**: The TL of all RUN (T/S = 1.24 ± 0.73) differ from CON (T/S = 0.515 ± 0.62) (p < 0.01), while the TL of SPT (T/S = 1.495 ± 0.85) trended to be longer than END (T/S = 0.954 ± 0.46) (p = 0.076) with a large effect size (d = 0.72). It was observed a significant correlation between TL and actual performance level as percentage of the current world record for RUN (r = 0.47, p < 0.01), and a negative correlation between TL and body fat for the entire sample (r = -0.447; p < 0.01). Furthermore, a negative correlation between TL and performance decline per decade was observed for the SPT (r = -0.651, p <

0.01). **CONCLUSIONS**: In conclusion, TL of studied master athletes was longer than their untrained peers, and seems to be not only a marker of health status, but also an indicator of sports longevity since both actual performance level, its decrease over years, and body composition were related to TL of studied sample.

Tumor Derived Factors Induce Muscle Mitochondria Hyperpolarization And Subsequent Superoxide Production

Megan E. Rosa-Caldwell, Jacob L. Brown, David E. Lee, Tyrone A. Washington, Nicholas P. Greene. *University of Arkansas, Fayetteville, AR.* (Sponsor: Dr. Stephen Crouse, FACSM)

(No relevant relationships reported)

Cancer associated muscle wasting (cancer cachexia) negatively affects the prognosis and treatment of cancer. Specifically, 20-40% of cancer deaths are attributable to cancer cachexia, however current treatments for cachexia are ineffective at reducing mortality. More so, it is currently postulated that once cachexia has developed, it may be impossible to halt its progression. Therefore, a more thorough understanding of the early mechanisms contributing to cachexia are necessary to develop effective therapeutics to halt cachexia before significant muscle loss occurs. Mitochondrial function is thought to largely mediate muscle health and may be a key contributor to the development of cachexia. **PURPOSE:** To examine the initial effects of tumor cell-derived factors on measures of mitochondrial function and subsequent cell proliferation. **METHODS:** C2C12 cells were treated with either CON media (1:1 ratio of DMEM to C2C12 conditioned media) or LLC media (1:1 ratio of DMEM to Lewis Lung Carcinoma conditioned media) for 4-72 hrs. Cells were then measured for mitochondrial polarization, superoxide production, and cell proliferation. Results were analyzed by blocked t-tests (CON v. LLC, blocked by experiment repeat). **RESULTS:** After 4 hrs of incubation with LLC media, cells had a ~12% greater mitochondrial polarization compared to CON (p=0.0002, Hedge's g effect size=1.08), with no difference in mitochondrial superoxide production (p=0.78, Hedge's g effect size= 0.10). After 24 hrs of incubation, mitochondrial polarization remained elevated by ~10% compared to CON (p=0.008, Hedge's g effect size =0.69) and mitochondrial superoxide production was increased ~12% compared to CON (p=0.009, Hedge's g effect size =0.99). However, LLC incubation for 24, 48 and 72 hrs did not alter cell proliferation (p=0.89, 0.13, and 0.45 respectively, Hedge's g effect size = 0.05, 0.53, and 0.27 respectively). **CONCLUSIONS:** Tumor-derived factors appear to have dramatic effects on muscle mitochondrial polarization and subsequent superoxide production. However, these alterations do not appear to affect muscle proliferative capacity.
This study was supported by The National Institutes of Health R15AR069913.

The Impact Of HSP72 On Metabolism And The Mitochondrial Response To Exercise In Female Mice

Amanda J. Lin[1], Zhenqi Zhou[1], Timothy M. Moore[2], Brian G. Drew[1], Vicente Ribas[1], Darren C. Henstridge[3], Mark A. Febbraio[4], Andrea Hevener[1]. [1]*University of California, Los Angeles, Los Angeles, CA.* [2]*University of Southern California, Los Angeles, CA.* [3]*Baker IDI Heart and Diabetes Institute, Melbourne, Australia.* [4]*Garvin Institute of Medical Research, Sydney, Australia.*

(No relevant relationships reported)

Regular exercise improves metabolic health in men and women; however, the molecular adaptations critical for delivering health benefit remain unclear. Heat shock protein (HSP)72 is one of the most highly induced proteins in muscle during exercise, and we have shown that muscle overexpression of HSP72 is protective against diet-induced metabolic dysfunction. By contrast, global deletion of HSP72 promoted glucose intolerance and insulin resistance paralleled by impairment in mitochondrial (mt) function and oxidative capacity. All aforementioned studies were conducted in male animals exclusively.

Abstracts were prepared by the authors and printed as submitted.

WEDNESDAY, MAY 30, 2018

PURPOSE: We studied the effects of HSP72 knockout (KO) on metabolism in female mice to determine whether sex plays a role in phenotypic outcome.
METHODS: We performed a standard metabolic phenotyping evaluation of WT and HSP72-KO female mice fed a normal chow diet (age 3 - 10 months). Additionally, to induce metabolic challenge, WT and HSP72-KO mice performed two exercise protocols. Protocol 1: Chronic voluntary wheel running for 30-days. Protocol 2: Acute treadmill running (90 min, 15 m/min, 5° incline). Comparisons of mean differences were by two-way ANOVA or t-test ($P<0.05$, *a priori*; values presented as mean ± SEM).
RESULTS: In contrast to male HSP72-KO mice, female KO animals were protected against aging-induced metabolic dysfunction and insulin resistance. Moreover, we observed no significant difference in grip strength, run time to exhaustion, latency to fall, or maximum running speed, between the genotypes. Although no differences in metabolic homeostasis or physical performance were detected between the genotypes of female mice, we did observe marked differences in expression of compensatory signaling nodes including transcription factors, the mt proteome, and mt fission-fusion-mitophagy dynamics in HSP72-KO compared with WT. Computational modeling and pathway analysis identified over 100 proteins differentially expressed between the genotypes. We found that ERα is strongly induced in muscle of female HSP72-KOs compared with WT, and we are currently testing whether ERα confers preservation of metabolic function in female vs. male HSP72-KOs.
CONCLUSIONS: Our findings show sex differences related to importance of HSP72 expression for the maintenance of metabolic health and exercise performance.

Mitochondrial Fusion Is Essential For Regulation Of Adult Skeletal Muscle Mass And Protein Synthesis

Graham R. McGinnis, Zachary D. Bush, Margaret B. Bell, Glenn C. Rowe. *University of Alabama at Birmingham, Birmingham, AL.*
(No relevant relationships reported)

Purpose: Mitochondrial dynamics and the function and health of skeletal muscle are inextricably linked. To preserve proper function, muscle mitochondria undergo constant remodeling through fission and fusion events. Mitochondrial fission is regulated by fission 1 (Fis1) and dynamin-related protein 1 (Drp1), while fusion is regulated by three GTPases; mitofusin 1 and 2 (Mfn1, Mfn2) and optic atrophy 1 (Opa1). However, the role of mitochondrial fusion in adult skeletal muscle mass regulation is not fully understood. We hypothesized that genetic disruption of mitochondrial fusion in adult skeletal muscle will impair muscle function and growth. **Methods:** We therefore developed and characterized adult inducible skeletal muscle specific Mfn1/2 double knockout mice (MFNDKO). Genetic deletion was induced in adult mice and confirmed by qPCR and western blot. Body/muscle size and composition was analyzed gravimetrically and by QMR. Muscle function was assessed by grip test. Interrogation of pathways regulating muscle mass, including atrophy and autophagy were performed by qPCR and western blotting. *In vivo* and *in vitro* protein synthesis rates were evaluated using a puromycin incorporation assay. **Results:** MFNDKO mice exhibited a progressive decrease in body weight (~20% lower than CON, respectively; p < 0.05). This reduction in body weight was associated with a decrease in lean mass, confirmed by QMR, gastrocnemius wet weight and cross sectional area (50% and 36% reduction, respectively; p < 0.05). Gene profiling of pathways that regulate muscle homeostasis revealed upregulation of *FBXO30, FBXO32, MT1* and *CTSL* (p < 0.05, all) suggesting an activation of muscle atrophy. Furthermore, muscles from MFNDKO mice revealed increased markers of autophagy with increased *p62* mRNA and increased LC3II/I and p62 protein levels. Protein synthesis rates were decreased *in vitro* and *in vivo* (14% and 75%; p < 0.05, respectively) in MFNDKO muscle. **Conclusions:** Taken together, these observations suggest that normal mitochondrial fusion is required for maintaining normal adult skeletal muscle mass.

Skeletal Muscle Mitochondrial Fusion is Required for Exercise Performance and Mitochondrial Oxidative Capacity

Glenn C. Rowe, Zachary D. Bush, Margaret B. Bell, Graham R. McGinnis. *University of Alabama at Birmingham, Birmingham, AL.*
(No relevant relationships reported)

PURPOSE: Endurance exercise has been shown to be a positive regulator of skeletal muscle metabolic function. Changes in mitochondrial dynamics (fusion and fission) have been shown to influence mitochondrial oxidative capacity. We therefore tested whether genetic disruption of mitofusins (Mfns) affected exercise performance in adult skeletal muscle.
METHODS: We generated adult inducible skeletal muscle-specific Mfn1 (iMS-Mfn1KO), Mfn2 (iMS-Mfn2KO) and Mfn1/2 knockout mice (iMS-MfnDKO). We assessed exercise capacity with a treadmill time to exhaustion stress test pre-deletion

and up to 8-weeks post-deletion. We measured individual electron transport chain (ETC) complex activity of both the subsarcolemmal (SS) and intermyofibrillar (IMF) mitochondria by high resolution spectroscopy. We also performed qPCR and western blotting analysis to measure the expression of ETC subunits.
RESULTS: Analysis of either the iMS-Mfn1KO or iMS-Mfn2KO did not reveal an effect on exercise capacity, suggesting a possible functional redundancy between the two Mfns. However, analysis of the iMS-MfnDKO animals revealed a progressive reduction (66% reduction; p <0.05) in time to exhaustion. The decrease in exercise capacity was associated with a reduction in ETC activity in both the SS and IMF mitochondrial fraction for Complex I (70% and 80% respectively; p <0.05) and Complex IV (60% and 80% respectively; p <0.05). Notably only the IMF fraction for Complex II and Complex V exhibited a significant reduction in activity (70% and 67% respectively; p <0.05), while Complex III was completely unaffected. These changes in enzymatic activity was associated with a decrease in protein expression of ETC subunits for Ndufb8 (86%; p <0.05) and MtCOI (50%; p <0.05). We did not observe any significant changes in mRNA expression of nuclear encoded ETC subunits, while mitochondrial encoded subunits (ND2, ND5, CYTb, COX2 and ATP6) were all reduced (77%; p <0.05). These data suggest that the decrease in exercise activity is the result of impaired ETC complex activity and expression.
CONCLUSION: Taken together these results suggest that mitochondrial fusion in adult skeletal muscle is required for normal exercise performance.

Human Muscle Fiber-Specific Responses of Mitochondrial Fusion Proteins to Sprint Interval and Moderate-Intensity Continuous Training

Lauren E. Skelly[1], Jenna B. Gillen[1], Barnaby P. Frankish[2], Florence E. Godkin[1], Mark A. Tarnopolsky[1], Robyn M. Murphy[2], Martin J. Gibala[1]. [1]*McMaster University, Hamilton, ON, Canada.* [2]*La Trobe University, Melbourne, Australia.* (Sponsor: Dr. Stuart Phillips, FACSM)
(No relevant relationships reported)

Mitochondrial dynamics, a process regulated by mitochondrial fission and fusion, is important for the maintenance of high quality mitochondria and healthy metabolic function. Low-volume sprint interval training (SIT) increases mitochondrial content to a similar extent as moderate-intensity continuous training (MICT); however, limited data are available regarding the effect of these diverse training approaches on mitochondrial dynamics proteins. Research has also relied primarily on whole muscle analyses which may mask fiber-type specific training adaptations.
PURPOSE: To examine changes in mixed whole muscle and fiber-type specific mitochondrial fusion protein abundance following 12 weeks of low-volume SIT and MICT.
METHODS: Sedentary adults performed 32 sessions of SIT (n=8) or MICT (n=9). SIT involved 3 x 20 sec 'all out' cycle sprints against 5% body mass (~500 W) interspersed with 2 min rest and MICT involved 45 min of continuous cycling at ~70% of maximal heart rate (~110 W). Biopsies (vastus lateralis) were obtained before training and 96 h after the final session. The protein contents of optic atrophy 1 (OPA1) and mitofusin 2 (MFN2) were measured in mixed muscle homogenates and pooled segments of type I and II fibers using Western blotting, normalized to total protein content within each sample.
RESULTS: Training increased the mixed whole muscle protein content of OPA1 [1.0 ± 0.3 to 1.5 ± 0.3 arbitrary units (AU)] and MFN2 (1.0 ± 0.2 to 1.1 ± 0.2 AU), with no differences between treatments (p < 0.05, main effect). OPA1 content increased after training (p < 0.05, main effect) in both type I (1.3 ± 0.6 to 1.9 ± 0.8 AU) and type II fibers (1.0 ± 0.4 to 1.4 ± 0.5 AU). MFN2 content increased after training in type I (1.4 ± 1.1 to 2.2 ± 1.5 AU, p = 0.03) but not type II fibers (1.9 ± 1.6 to 2.0 ± 1.1 AU; p = 0.73). Prior to training, OPA1 content was higher in type I versus type II fibers (1.3 ± 0.6 vs. 1.0 ± 0.4 AU, p < 0.01) but there were no fiber-type differences in MFN2 content.
CONCLUSIONS: Twelve weeks of low-volume SIT and MICT induces similar increases in mixed whole muscle and fiber-type specific mitochondrial fusion proteins. The potential of SIT to induce comparable skeletal muscle adaptations as MICT despite a reduced exercise volume may be related to a higher intensity per se and/or the intermittent contractile pattern.

689   May 30 4:30 PM - 4:45 PM

Exercise As An Intervention To Mitigate Mitochondrial Dysfunction And Impaired Glucose Tolerance Induced By Sleep-loss

Nicholas J. Saner, David J. Bishop, FACSM, Jonathan D. Bartlett. *Victoria University, Institute of Sport, Exercise and Active Living, Melbourne, Australia.* (Sponsor: David Bishop, FACSM)
(No relevant relationships reported)

Sleep-loss is emerging as an important risk factor for the development of impaired glucose tolerance, insulin resistance (IR) and, subsequently, type 2 diabetes mellitus. While the mechanisms underlying these changes remain to be fully elucidated, in some instances their development may be associated with reduced mitochondrial function. This suggests sleep-loss may also impair mitochondrial function, but this has not been investigated. Given the possible relationship between mitochondrial function and IR, exercise could be used as a strategy to counteract the detrimental physiological changes induced by sleep-loss; however, this has not been demonstrated. **Purpose:** To investigate the effect of sleep-loss, with or without exercise, on skeletal muscle mitochondrial function and glucose tolerance. **Methods:** Twenty healthy male participants were allocated into one of three experimental groups: a control group (CON, n=7) (8 h sleep opportunity for 5 nights), a sleep-restricted group (SR, n=7) (4 h sleep opportunity for 5 nights), and a sleep restricted and exercise group (SR+EX, n=6) (4 h sleep opportunity for 5 nights and 3 x high-intensity interval exercise (HIIE) sessions). The HIIE bouts consisted of 10 x 60-s intervals at 90% peak power, interspersed by 75 s of active recovery. Oral glucose tolerance tests (OGTT) and muscle biopsies were performed pre- and post-intervention. **Results:** Mean sleep duration per night for CON, SR, and SR+EX was 448 ± 25, 230 ± 13 and 237 ± 5 minutes, respectively. There was a significant reduction in mitochondrial respiratory function (O_2 flux - pmol/s/mg tissue) from pre- to post-intervention in the SR group (80 ± 16 vs 65 ± 24, p<0.05), but this remained unchanged in the CON (70 ± 5 vs 64 ± 12, p>0.05) and SR+EX (78 ± 20 vs 79 ± 28, p>0.05) group. OGTT total area under the curve increased post intervention in the SR group (692 ± 89 vs 832 ± 57 units, p<0.05), but remained unchanged in the CON (741 ± 202 vs 677 ± 184, p>0.05) and SR+EX (645 ± 51 vs 702 ± 83, p>0.05) group. **Conclusion:** Sleep-loss was associated with a reduction in mitochondrial respiratory function and a decrease in glucose tolerance. However, these changes were mitigated by performing HIIE, demonstrating exercise as a potent and cost-effective strategy to alleviate some of the negative metabolic effects of sleep loss.

Offspring of Mothers with Diabetes have Reduced Muscle Oxidative Capacity Measured by Near Infrared Spectroscopy

Brian A. Irving[1], Timothy D. Allerton[1], Guillaume Spielmann[1], Stefany Primeaux[2], Arnold Nelson, FACSM[1], Dennis Landin[1], Neil M. Johannsen[1]. *[1]Louisiana State University, Baton Rouge, LA. [2]LSU Health Science Center, Baton Rouge, LA.* (Sponsor: Arnold Nelson, FACSM)
(No relevant relationships reported)

Adult offspring of mothers with type 2 diabetes have been reported to have reduced skeletal muscle mitochondrial oxidative capacity (OXPHOS) using *in vivo* ^{31}P-Magnetic Resonance Spectroscopy (^{31}P-MRS). Near Infrared Spectroscopy (NIRS) also has the capability of measuring skeletal muscle OXPHOS, and provides indices of skeletal OXPHOS comparable to ^{31}P-MRS. Moreover, the cost of measuring skeletal muscle OXPHOS by NIRS is substantially less than by ^{31}P-MRS. **PURPOSE**: To determine whether NIRS could detect OXPHOS differences in adult offspring of mothers with type 2 diabetes (n=8) compared to controls (n=9). **METHODS**: Using continuous-wave NIRS (Artinis, Oxymon) coupled with transient arterial occlusions (~ 300 mm Hg, 5 on/5 off x 9, 10 on/10 off x 11), we measured muscle oxygen consumption (mVO_2) in the *vastus lateralis* following a 7 sec maximal isometric knee extension performed in the supine position. We express the mVO_2 as a percent per second (%/s), relative to an ischemic calibration. We fit the recovery mVO2 following the isometric contraction to an exponential curve using custom routines written in MATLAB by Terence Ryan to calculate the time constant (Tc) for the recovery of mVO_2, which is an index of mitochondrial OXPHOS. These routines also help correct for changes in blood volume that occur during the atrial occlusion. We also measured peak oxygen uptake (VO_2peak) using a standardized incremental exercise test with indirect calorimetry on a cycle ergometer. **RESULTS**: Age (21 ± 1 vs. 21 ± 2 y, p>0.05), BMI (24 ± 3 vs. 23 ± 2 kg/m^2, p>0.05), and VO_2peak (32 ± 4 vs. 32 ± 5 ml·kg^{-1}·min^{-1}, p>0.05) were similar between offspring and controls. In contrast, offspring had higher recovery Tc compared to controls (47 ± 24 vs. 28 ± 10 sec, p<0.05) suggestive of reduced OXPHOS. **CONCLUSIONS**: Our results support the use of NIRS to measure expected differences in skeletal muscle OXPHOS between offspring and controls. Of interest, we also found that the Tc measured in the offspring to have a greater degree of variability than controls suggesting the potential for prescribing therapeutic

Skeletal Muscle DNA Methylation Changes following Gastric Bypass in Women with Type 2 Diabetes

Matthew D. Barberio[1], G. Lynis Dohm[2], Walter J. Pories[2], Evan P. Nadler[1], Monica J. Hubal, FACSM[3]. *[1]Children's National Medical Center, Washington DC., DC. [2]East Carolina University, Greenville, NC. [3]George Washington University, Washington DC., DC.* (Sponsor: Monica Hubal, FACSM)
(No relevant relationships reported)

Purpose: Bariatric weight-loss surgery can resolve or ameliorate type 2 diabetes (T2D). The cellular and molecular adaptations driving this response remain largely unknown, but some evidence points to epigenetic changes in skeletal muscle following surgery. We assessed global skeletal muscle methylation patterns prior to and 1 year after Roux en Y gastric bypass surgery (RYGB) in women with and without T2D to determine if diabetes modifies the response of the skeletal muscle methylome to weight-loss surgery. **Methods**: Global vastus lateralis methylation profiles were generated via Illumina 450k Arrays pre- and 1 yr post-RYGB in black adult females (N=12) with (D; n = 6, age = 51 ± 6 yr, BMI = 53.0 ± 5.8 kg/m^2) and without (ND; n=6, 43 ± 6 yr, 51.0 ± 9.2 kg/m^2) T2D. Clinical values for insulin, glucose, and HOMA were measured at each time point. RM ANCOVA (group*time with age covariate) assessed changes in skeletal muscle methylation profiles in Partek Genomics Suite. Resultant methylation probes were filtered at p<0.001 and uploaded into Ingenuity Pathway Analysis for biological interoperation. **Results:** RYGB reduced BMI (P < 0.01; -62.6% ± 28.3) and HOMA (p = 0.01; -1.9 ± 2.4) 1 yr following surgery; with no differences between groups. ANCOVA detected interaction effects in 9016 methylation sites in 6059 known genes. Overall, 7541 methylation sites in 4557 genes were altered 1 yr following RYGB in ND as compared to 4056 methylation sites in 3245 genes in diabetics. Biological pathway analysis of genes with differential methylation in diabetics identified key metabolic signaling pathways such as AMPK Signaling (80 genes; p = 9.7×10^{-8}), PI3K/AKT Signaling (52 genes; p = 2.7×10^{-7}), and P70S6K Signaling (44 genes; 9.82×10^{-4}). Our analysis also identified hypomethylation in the promoter region of key metabolic genes IRS1 (-4.8% methylated following surgery), SLC2A4 (GLUT4; -2.8% to -3.9%), and GSK3 (-3.4%) following surgery. **Conclusion:** Skeletal muscle DNA methylation 1 year following RYGB suggest epigenetic changes in key metabolic signaling genes that are modified by diabetes. Changes in gene and protein expression of these genes have previously been demonstrated with improved glucose homeostasis. These data identify DNA methylation patterns that may play an important role in diabetes resolution following surgery.

Ankle Injury - Rugby Union (7-players-a-side)

Victor Lopez Jr[1], Eric F. Soto[1], Mario A. Ortega[1], Richard Ma[1], Answorth A. Allen[2]. *[1]Rugby Research and Injury Prevention Group, Inc, Hospital for Special Surgery, New York, NY. [2]Hospital for Special Surgery, New York, NY.* (Sponsor: Robert C. Cantu, FACSM)

(No relevant relationships reported)

HISTORY: A 22-year-old men's club Division I Rugby-7s winger, injured his right ankle post a simultaneous opposing two-player tackle. Tackler-one locked the ball carriers foot in place wrapping the lower leg, and tackler-two changed the direction of the upper body of the player which overcame ankle mortise stability and strength, inducing an ankle inversion. Post-tackle, injured player complained of pain and inability to bear weight. History noted, no ankle supports/brace or tape used, and no previous ankle injury/surgeries. **PHYSICAL EXAMINATION**: Sideline emergency services removed injured foot cleat, found ankle deformity, which was secured for transport. ED exam revealed patient with a medially deformed right foot. Exam noted localized pain and tenderness, post palpation on right ankle deformity and lower leg, plantar flexed and supinated. Mild swelling, no lacerations or open wounds noted. Patient's limited exam secondary to pain, however, reflected no decreased right sided lower extremity sensation, reflexes or strength. Patient was able to flex and extend toes despite extreme pain of deformed limb. Injured limb had a noted palpable dorsalis pedis and posterior tibialis pulse. **DIFFERENTIAL DIAGNOSIS**: 1. Subtalar joint subluxation/dislocation 2. Open sub-talar dislocation 3. Tibial-talar dislocation 4. Fractures of the ankle/foot **TEST AND RESULTS**: Ankle anterior/posterior radiographs: -right posteromedial peri-talar dislocation. Ankle lateral radiographs: -navicular dislocation laterally from talus -rotary subluxation of calcaneus medially from the talus -no associated fractures of the tibia/fibula including malleoli. **FINAL WORKING DIAGNOSIS**: Closed right posteromedial peri-talar dislocation without associated fracture. **TREATMENT AND OUTCOMES**: 1. Emergency. Clearly seen on radiograph. 2. Immediate ED conscious sedation closed-reduction, entailing injured knee flexion to relax gastrocnemius, with traction to heel/forefoot of injured ankle to reduce joint. 3. Short-leg cast post-reduction, PWB for 4 weeks. Rehabilitation post-cast removal, with ROM and heel/calf stretches, progressing to strengthening. FWB at 7 weeks post-injury and cleared for sport. 4. 3-month follow-up, FWB, 7° dorsi-flexion, 32° plantar-flexion, 14° inversion, and 10° eversion with no restrictions.

---

696   May 30 3:35 PM - 3:55 PM
Toe Injury - Dance

Julie Han, Andrea Stracciolini, Pierre d'Hemecourt. *Boston Children's Hospital, Boston, MA.*

(No relevant relationships reported)

HISTORY: A 21-year-old female college dancer presented with right great toe injury that occurred in February 2017 when she twisted the toe while pivoting then felt a pop and severe pain. Xrays at the ED were negative for fracture. She was able to continue dancing despite pain and had multiple episodes of re-injury. She was first evaluated in the Sports Medicine clinic in April 2017 after a recent episode of re-injury of first toe medial deviation while dancing with a pop sensation and swelling. Xrays were negative for fracture and she was diagnosed with a first MTP joint sprain treated with a walking boot for 1 month, dancing with buddy taping, and intrinsic foot exercises. By the end of May 2017, she reported near-full recovery with progression back into dancing until suffering the same injury while dancing with subsequent 1st MTP pain and instability.EXAM: Right foot: Normal alignment. No edema. Painful passive end-range 1st MTP joint flexion & extension. Significant laxity with 1st MTP joint varus stress, asymmetric compared to contralateral MTP joint. Discomfort but

no dorsal subluxation with 1st MTP joint drawer test. 5/5 great toe dorsiflexion & plantarflexion strength with discomfort. Lateral 1st MTP joint tenderness to palpation. Minimal fibular sesamoid tenderness to palpation. Intact distal sensation & dorsalis pedis pulse. DIFFERENTIAL DIAGNOSIS: 1. 1st MTP lateral capsule tear 2. 1st MTP lateral collateral ligament tear 3. Adductor hallucis brevis tear IMAGING: MRI right foot: Complete lateral collateral ligament tear of the first MTP joint at the metatarsal attachment. No bony avulsion, normal alignment, normal plantar plate. FINAL DIAGNOSIS: Tear of the first MTP lateral collateral ligament in a dancer with resultant joint instabilityOUTCOME:-Walking boot for 5-6 weeks, without dancing, and improvement of symptoms at follow-up in July 2017-Weaned out of boot, started physical therapy, progressed back into dancing with buddy taping-August 2017, noted 60% improvement of pain but continued 1st MTP joint instability-Referred to Orthopedic Surgeon Dr. Lyle Micheli for surgical opinion with consultation from Dr. William Hamilton, dance medicine expert in New York City-Per recommendations, she underwent two series of PRP injections of the LCL in August and October 2017, follow-up is pending

---

697   May 30 3:55 PM - 4:15 PM
Footloose

Julie Shelley. *University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

(No relevant relationships reported)

History:
A 27 year-old minor league baseball player presents to the ER with right ankle pain after sustaining an injury landing on first base. After hitting a ground ball, the player ran to first base and inverted his right ankle after stepping on the first baseman's foot. He had immediate pain and an obvious deformity in the right ankle. He was not able to ambulate due to pain. He was neurovascularly intact. There was no obvious skin puncture. The patient's right foot and ankle were immobilized on the field in a SAM splint, and the player was sent to the ER. He denied any previous injury to this ankle.
Physical Exam:
Examination of the right foot and ankle revealed an obvious deformity of right ankle without laceration or skin puncture. Patient was able to move all toes but unable to move the ankle due to pain. He was neurovascularly intact. Exam was limited due to pain.
Differential Diagnosis:
1. Subtalar Dislocation
2. Talonavicular Dislocation
3. Talus Fracture
4. Tibia Fracture
Test and Results:
Right ankle and foot x-rays: Closed dislocation of the medial subtalar joint and talonavicular joint without obvious fracture.
Final/Working Diagnosis:
Right Medial Subtalar dislocation, Talonavicular Dislocation, Talus Fracture
Discussion:
Consent was obtained, and the patient was taken to the OR for reduction under general anesthesia. After reduction of the right ankle, CT was performed which showed a successful reduction of the medial subtalar and talonavicular dislocations. The CT also revealed a nondisplaced fracture of the medial border of the talus. He was placed in a posterior splint and stirrup and made non-weightbearing. It was not determined why this relatively low impact mechanism caused such rare and significant injuries. Proper reduction was critical in this case to avoid future equinovarus deformity, ankylosis, or severe degenerative arthritis warranting further intervention.
Outcome:
The patient was unable to play baseball for the remainder of the season. However, due to his successful reduction, he did not require further interventional treatment. He was transitioned to a short leg walking boot after being non-weightbearing for 6 weeks and participated in a physical therapy program to regain strength and function of his right ankle. His roster status was changed from "disabled" to "active" 8 weeks after his injury.

---

698   May 30 4:15 PM - 4:35 PM
The Bare Necessities of Foot Pain-Running

Alex B. Behar. *University of Illinois at Chicago, Chicago, IL.* (Sponsor: Terry Nicola, FACSM)

(No relevant relationships reported)

HISTORY: 35 year old female presents with left dorsal foot pain beginning 2 weeks prior to presentation noticed at mile 10 of a half marathon. She is an established barefoot runner with no previous injuries. Denies trauma or mechanism of injury to the foot. The pain is 8/10, sharp, and intermittent. It is exacerbated by weight bearing and relieved by non-steroidal anti-inflammatories (NSAIDS) and ice. The pain returns once the medication or modality wears off. She eats a well balanced diet and takes a multi-vitamin daily. Her last menstrual period was 10 days prior to presentation and states

it is regular. Denies changes to her running technique or mileage. X-rays performed prior to presentation demonstrate no fracture or deformities. She denies back pain, weakness, or paresthesias.

PHYSICAL EXAMINATION: Inspection of foot and ankle demonstrates edema on dorsal aspect of left foot without ecchymosis. No pes planus or pes cavus is observed. Tenderness over the left dorsal proximal 2nd metatarsal head is present. Full active range of motion of the ankle, foot, and toes in all planes with pain at the 2nd metatarsal during toe extension and flexion. Sensation intact to light touch in all dermatomes. Strength is 5/5 in all myotomes. Reflexes are 2/4 at L4 and S1.

DIFFERENTIAL DIAGNOSIS: 1) Lisfranc injury 2) Metatarsal stress fracture 3) Forefoot sprain 4) tibialis anterior strain/enthesopathy **TEST AND RESULTS**: **Ultrasound**: Evaluation of 2nd metatarsal using a linear probe demonstrates disruption of periosteum with no subcutaneous edema or disruption of soft tissue. **X-ray:** No evidence of fracture with mild degenerative changes at first MTP joint. **MRI:** Second metatarsal stress reaction without visible fracture line **FINAL WORKING DIAGNOSIS**: Left distal 2nd metatarsal stress fracture in an established barefoot runner.

TREATMENT AND OUTCOMES: Patient is educated on stress fractures in barefoot runners. Continue ice and NSAID's for symptomatic pain control and inflammation. Recommend a short leg off loading boot to decrease stress on the forefoot. She should wean out of the boot and progress to a barefoot running program. Physical therapy to work on foot intrinsic, barefoot gait analysis, and ankle stabilizers. DEXA scan ordered for bone density evaluation. Consider ultrasound instead of MRI for future monitoring of stress fractures.

---

699   May 30 4:35 PM - 4:55 PM
Ankle Injury - Football

Sabrina P. Sawlani, Brian McCall. *Presence Resurrection Medical Center, Chicago, IL.* (Sponsor: Poonam Thaker, MD, FACSM)

(No relevant relationships reported)

HISTORY: A healthy Caucasian 12-year-old male presents with right ankle pain after slipping and twisting his ankle during a recreational football game at day camp. Hours after injury, he was seen by his PCP, who ordered plain films and referred him to orthopedic surgery for further evaluation.

PHYSICAL EXAMINATION: Examination in-office revealed mild swelling over the right lateral ankle with tenderness over the anterolateral tibia. Active range of motion was significantly decreased in all directions, and he was unable to bear weight on the right lower extremity. There was good peripheral perfusion, no open wounds or lacerations, and no erythema or ecchymoses.

DIFFERENTIAL DIAGNOSIS:
1. Lateral ankle sprain
2. Triplane fracture
3. Pediatric distal tibial fracture
4. Juvenile Tillaux ankle fracture
5. Incisural ankle fracture
6. Adolescent pilon fracture

TEST AND RESULTS:
XR Right Ankle 3+ Views: On AP view, the fracture is vertical through the epiphysis. On lateral view, the fracture extends posteriorly into the metaphysis.
CT Right Lower Extremity: Comminuted distal tibia fracture with intra-articular extension through posterior malleolus through metaphysis and 3 mm separation. Multiple fractures involving epiphysis. Approximately 3.5 mm separation anteriorly at fracture site. Nondisplaced fracture extending through medial malleolus. Tiny fracture fragment within tibiotalar joint space adjacent to fracture site.

FINAL WORKING DIAGNOSIS:
Triplane fracture of right distal tibia with intra-articular extension

TREATMENT AND OUTCOMES:
1. Open reduction internal fixation of the right distal tibia with intra-articular extension performed by orthopedic surgery under general anesthesia.
2. Intraoperative post-reduction ankle films demonstrated satisfactory alignment and position with postsurgical tissue changes of distal tibial metaphyseal and epiphyseal fractures.
3. 2-week postsurgical follow-up with repeat ankle films demonstrated the fracture to be anatomically reduced with hardware in optimal position. Physical exam had appropriate wound healing and excellent range of motion.
4. Toe-touch weight-bearing while in boot for 4 weeks post surgery.
5. Limited range of motion exercises out of boot during weeks 2 through 4 post surgery.
6. Weight-bearing initiated 4 weeks post surgery.

B-44   Clinical Case Slide - **Knee I**

Wednesday, May 30, 2018, 3:15 PM - 5:15 PM

Knees - Skiing

Anna R. King[1], Surein Theivakumar[1], Ramin R. Tabaddor[2]. *[1]New York University, NY, NY. [2]The Warren Alpert School of Medicine at Brown University, East Greenwich, RI.*

(No relevant relationships reported)

HISTORY:
A previously healthy 14-year-old female presents with left knee pain, stiffness, and swelling for one year after hearing a "pop" during a dance move. She is a competitive alpine skier and attends boarding school in Maine to pursue this. She was able to finish her skiing season, though continued to experience symptoms. MRI at that time showed effusion without associated ligamentous damage. Two weeks ago, her right knee began having similar symptoms. Her pain and stiffness in both knees are worse in the morning, after sitting for prolonged periods, and with stairs.

PHYSICAL EXAMINATION:
Patient has an antalgic gait pattern. The left knee has a tense effusion, with no soft tissue swelling, ecchymosis, or skin lesions. She has diffuse tenderness to palpation, especially along the medial femoral condyle. The right knee has a mild effusion and is not quite as tender. Both knees have full ROM, negative Lachman's and Anterior Drawer, and are stable to varus/valgus stress. She has full strength and sensation. Exam is also notable for left elbow fullness, warmth, and decreased extension by 10 degrees, as well as B/L Achilles tendon fullness without associated tenderness.

DIFFERNETIAL DX:
1. Inflammatory arthropathy
2. Synovial chondromatosis
3. Osteochondral defect
4. Lyme disease
5. Autoimmune process

TESTS / RESULTS:
-B/L knee XRs: no obvious abnormalities or defects.
-MRI left knee: large joint effusion with extensive tiny loose bodies (typical appearance of "rice bodies"). No meniscal, chondral, or ligamentous pathology.
-Lyme negative
-CRP and ESR elevated
- (+) ANA
-RF negative

FINAL / WORKING DX:
Juvenile Rheumatoid Arthritis (JRA)

TREATMENT & OUTCOMES:
-Strict activity modification, anti-inflammatories, ice, elevation, pediatric rheumatology referral, arthroscopic debridement of B/L knees with synovial biopsies.
-Rheumatology performed an intra-articular steroid injection of B/L knee joints, initiated DMARD therapy with Methotrexate, and referred for expedited ophthalmology evaluation.
-On post-op f/u, pathology findings were reviewed, which were consistent with JRA.
-At 1 month post-op debridement and 2 months s/p initiation of DMARDs, patient has no swelling or pain and is undergoing progressive return to full activities (including skiing) as tolerated under the guidance of her athletic trainer.

---

704   May 30 3:35 PM - 3:55 PM
Using Ultrasound To Diagnose Knee Pain

PATRICK CAREY. *Martin Army Community Hospital, FORT BENNING, GA.*

(No relevant relationships reported)

HISTORY:

16 year old male high school athlete was referred to sports medicine clinic with complaint of intermittent right knee pain exacerbated by cutting maneuvers. Pain began after feeling a strain and pop when pushing off a starting block in track season one year ago. Patient's mother stated that ice, compressions, use of hinged knee brace makes it better and working out without the knee brace makes it worse. The pain usually starts at the medial side of the knee and radiates to the lateral side and is associated with occasional buckling and locking. No change in character of pain after a course of physical therapy and relative rest during the summer. He just completed football season and is currently in middle of basketball season, participation has been limited at times due to pain.
.
PHYSICAL EXAM:
Right knee exam reveals skin intact with minimal effusion. ROM-0-130 degrees with no pain at extremes. +JLT medially-this is more on the condyle then the meniscus. Medial joint line pain with McMurray and Thessaly; however, no palpable click. 1A Lachman. Stable knee to varus and valgus stress at zero and 30 degrees of flexion. Negative Posterior drawer and sag sign. Sensation intact to light touch on all distributions distally. 2+ distal pulses.
DIFFERENTIAL DIAGNOSIS:
1. Osteochondritis dissicans
2. Osteochondral lesion
3. Meniscus tear
TEST AND RESULTS:
The initial diagnostic test available was the ultrasound. There had been no prior imaging.
A limited ultrasound of the RIGHT Knee showed + mild joint effusion and a step off in the lateral portion of the medial femoral condyle.
Impression: + effusion and chondral defect of the lateral portion of the medial femoral condyle.
FINAL/WORKING DIAGNOSIS:
1. osteochondritis dissicans on the lateral portion of the medial femoral condyle
TREATMENT AND OUTCOMES:
He was given instruction to remain non weight bearing using crutches for 8 weeks pending results of imaging to determine stability of lesion.

RIGHT KNEE MFC

705   **May 30 3:55 PM - 4:15 PM**

Knee Lesions - Treating The Athlete Not The Images

Spencer Kirk, Michael Ladewski. *Presence Resurrection Medical Center, Chicago, IL.*
(No relevant relationships reported)

HISTORY: A 33 year old male runner presented to clinic for evaluation of left knee pain. Pt has had intermittent pain since 14 years old when he was diagnosed with a left medial femoral condyle osteochondral defect. At that time he was a competitive runner and treated with 6 months of rest. He had nearly complete resolution of symptoms. He was able to resume competitive running throughout high school and college. He is currently extremely active with crossfit, marathons, and triathlons. He is seeking activity guidance in preparation for his first ironman triathlon. Current pain described as medial, sharp, 6/10, rarely present but felt after prolonged sitting or with weighted squats, associated difficulty fully extending knee, improves with manual manipulation.
PHYSICAL EXAMINATION: Gait: Normal appearance. Locks knee with heel strike of active phase of walking. Running gait without abnormality. Unable to perform left single leg squat.
Knee PROM: -10 to 140 degrees without subpatellar crepitance

Appearance: No effusion or ecchymosis
Patella: Tracks normally with negative apprehension and compression tests
Tenderness: Absent
Special Tests: Negative Valgus/Varus stress, Lachman's, McMurray's, Wilson's sign
DIFFERENTIAL DIAGNOSIS: 1. Osteochondral defect 2. Patellar Tendonitis 3. Patellofemoral Syndrome 4. Fat Pad Syndrome 5. Medial Plica
TEST AND RESULTS: Left knee MRI with 18.1 x 27.1 x 10.0mm osteochondral lesion of the medial femoral condyle with subchondral fluid consistent with Grade III lesion. Medial femoral condyle with bony edema and subchondral cyst. FINAL WORKING DIAGNOSIS: Osteochondral defect TREATMENT AND OUTCOMES: The worrisome appearance of the patient's MRI was discussed in detail. However, given the relatively benign physical exam and high functionality he was instructed to remain active and avoid surgical intervention as long as possible. He was advised that the traumatic nature of endurance running would likely lead to faster progression of the cartilage defect. Follow-up 6 months later, after completion of his triathlon, without change in symptoms. He remained extremely physically active but with a greater emphasis on swimming and biking.
This case exemplifies the importance of maintaining clinical perspective when treating individuals rather than the severity of their images.

---

706   **May 30 4:15 PM - 4:35 PM**

A Case of Bilateral Knee Pain in a Young Male Patient

Oluyemi Ajirotutu, Michael Fong. *Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA.*
(No relevant relationships reported)

HISTORY: A 34-year old male with hypertension reports bilateral knee pain for 6-7 months. He describes the pain as achy and in his anterior knees. The pain is worse in the morning and after being on his feet all day at work. He reports some associated swelling. There was no trauma to his knees. He denies pain in any other joints. His pain is not improved with non-steroidal anti-inflammatory drugs however is improved with oral steroids. There is no family history of autoimmune conditions or joint disease.
PHYSICAL EXAMINATION: Exam performed in sports medicine clinic revealed moderate effusions of bilateral knees, limited flexion of both right knee to 90 degrees and left knee to 110 degrees, negative testing in the patellofemoral compartment, and negative meniscal/ligamentous testing. He was neurovascularly intact.
DIFFERENTIAL DIAGNOSIS:
1. Gout
2. Rheumatoid Arthritis
3. Osteoarthritis
TEST AND RESULTS:
XR Bilateral Knees: Mild bony degenerative changes with slight bilateral medial femoral tibial compartments marginal sclerosis and possible slight joint space narrowing.
ESR 3, RF<10
Aspiration of bilateral knees: 50-60ml of clear yellow fluid removed from each knee. Synovial fluid analysis demonstrated hazy fluid that was possibly inflammatory and was negative for infection or crystals.
MRI Left Knee: Moderate-sized joint effusion with synovitis. Frond-like synovial thickening in the anterior midline of the femorotibial joint that may be related to pigmented villonodular synovitis. Complex tear of the body of the medial meniscus.
MRI Right Knee: Medium-sized joint effusion with evidence of synovitis and possible foci of gradient echo dephasing which may be seen in association with pigmented villonodular synovitis. Complex tear of anterior horn and body of medial meniscus. Partial thickness chondral fissuring in medial patellar facet. Mild medial and lateral femorotibial compartment chondromalacia.
FINAL/WORKING DIAGNOSIS: Pigmented Villonodular Synovitis of Bilateral Knees
TREATMENT AND OUTCOMES:
Knee joint aspiration with intra-articular steroid injection
Rest, ice, compression, elevation
Non-steroidal anti-inflammatory drugs
Physical therapy/home exercise program
Future arthroscopic synovectomy and post-operative radiation

---

707   **May 30 4:35 PM - 4:55 PM**

Opening Kickoff Knee Catastrophe in High School Football

Ryan Hunt. *Ohio Health, Columbus, OH.*
(No relevant relationships reported)

Knee Injury – Football
HISTORY
18-year-old senior high school football linebacker sustained a knee injury during the opening kickoff of the season. As he was pursuing the ball, his left leg planted and

hyperextended while being contacted by an opponent, producing forced valgus and lateral rotation. He immediately fell to the ground, required on field medical attention, and was unable to bear weight.

PHYSICAL EXAMINATION

Sideline examination occurred within 5 minutes. Left knee examination revealed a moderate effusion, normal patellar tracking, and no bony deformity. Neurovascular examination normal. Able to perform straight leg raise against light resistance. Active ROM limited to 60° flexion and lacked 10° extension. No bony tenderness. Ligamentous examination revealed a positive Lachman and valgus stress in 30 degrees of flexion. Unable to tolerate compression testing. Left hip and ankle examination normal. Contralateral knee normal.

DIFFERENTIAL DIAGNOSIS

1. Acute ACL tear
2. Acute MCL tear
3. Meniscus tear
4. Patellar dislocation
5. Tibial plateau fracture or contusion

INTERVAL COURSE

Office visit 7 days after injury. Arthrocentesis of the left knee returned 35 mL of blood. Initial treatment included use of crutches, ice, hinged-knee brace, and quadriceps rehab. MRI ordered, however study was delayed about 6 weeks due to gap in parent's insurance.

TESTS AND RESULTS

o Left Knee Radiographs: Normal

o Left Knee MRI:- Marrow contusion of medial, lateral compartments, fibular head, nondisplaced posterior tibial plateau fracture, subchondral impaction injury of lateral femoral condyle and lateral tibial plateau- ACL rupture, acute sprain of MCL, IT band, and LCL- Complex lateral meniscus tear, large fragment from posterior horn flipped anteriorly- Complex medial meniscus tear, vertically through posterior horn

FINAL DIAGNOSIS

Left knee acute ACL rupture, MCL sprain, medial and lateral meniscus tears, bone contusion

TREATMENT/COURSE

1. Referred to orthopedics, underwent arthroscopic ACL reconstruction with hamstring autograft, lateral meniscus repair, and partial medial meniscectomy 8 weeks after initial injury.
2. Significant discussion on post-op rehab and long-term activity modification.

---

708   May 30 4:55 PM - 5:15 PM

Unique Surgical Intervention for Patella Baja

Kevin MacIntyre, Christopher Mazoue, Andrea Taylor. *University of South Carolina, Columbia, SC.*
(No relevant relationships reported)

History: Patient is an active 41 year-old female (160 cm and 68 kg) who had a history of left, anterior knee pain with mechanical symptoms while playing tennis. Patient revealed a surgical history including: s/p partial lateral meniscectomy with lateral release, s/p lateral retinacula repair, manipulation under anesthesia (MUA), s/p open quadriceps tendon repair respectively, all within the last two years. Patient complained of continued pain, patella instability and functional deficits.

Physical Examination: Knee alignment and patella tracking was normal. She had 1+ joint effusion. She had significant restricted knee flexion (0-70 degrees). Ligament tests were stable. Neurovascular exam was normal.

Differential Diagnosis:

1. Patella tendon tendinopathy
2. Patellofemoral pain syndrome
3. Patella baja

Test and Results:

X-ray (February 2016): Insall-Salvati Ratio: 0.38; Blackburne-Peel Ratio: .31

MRI: Confirm patella baja; no patella tendon pathology; evidence of previous quadriceps tendon repair

CT: Confirm patella baja with no evidence of patella femoral syndrome

Post-op X-ray (February 2017): Insall-Salvati Ratio: 1.1; Blackburne-Peel Ratio: .98

Final Diagnosis: Patella baja with inadequate extensor mechanism

Treatment and Outcomes:

1. Surgical intervention included: left patella tendon Z-lengthening with patella tendon reconstruction with left hamstring autograft, left quadriceps tendon V-Y shortening and augmentation of medial patellofemoral retinaculum with a dermal graft.
2. Patient was fitted for a T-scope post-operatively with knee restricted to a maximum of 0-30 degrees of knee flexion for the first 2 weeks. The patient was restricted at 0-60 from weeks 2-4 then at 0-90 degrees from weeks 4-6.
3. At 6 weeks post-op, the patient had 65 degrees of active knee flexion.
4. Continued small improvements were present but by week 14 the patient only had 80 degrees of flexion.
5. An MUA was performed and within the first 4 weeks post-op and by October 2016, the patient had been discharged from physical therapy for meeting goals

and was going to the gym autonomously. The patient had 112 degrees of active knee flexion.

6. Patient and surgeon satisfaction were achieved, and patella positioning was maintained throughout the patient's recovery.

Unusual Cause of Postpartum Back Pain

Jacob Wessels. *Allina Health, St Paul, MN.* (Sponsor: Morteza Khodaee, FACSM)
(No relevant relationships reported)

HISTORY: A 27-year-old G5P0131 delivered an 1800g boy precipitously at 35 0/7 weeks. Her medical history was significant for gestational hypertension, hypothyroidism status post ablation, syphilis during pregnancy, and lumbar disc herniation. Twenty hours later she noted severe pain and inability to move her right lower extremity. She did have a fall or recent trauma. She had no numbness or tingling, normal bowel movements and urination. She did not have a fever, chills or any recent use of new medications.

PHYSICAL EXAMINATION:

Vital Signs: afebrile, other vital signs were unremarkable

Musculoskeletal: Normal back and hip appearance. Not warm. Tender over sacral ridge, right SI joint, piriformis area and thigh. Pain in the sacral/gluteal region worse with hip external and internal rotation (FABER and FADIR positive for pain). Back flexion and extension reproduced pain.

Neurological: Normal sensation and strength testing in lower right leg.

DIFFERENTIAL DIAGNOSIS:

1. Piriformis syndrome
2. Disc herniation
3. SI joint dysfunction
4. Gluteal muscle strain
5. Septic SI joint
6. Sciatica

TEST AND RESULTS:

Post Partum Day 4:

CRP 27 mg/dL, ESR 105 mm/hr

CT abdomen and pelvis:

No ileus or obstruction; normal postpartum uterus, no endometritis or retained products; central disc herniation at L4-5 and subtle effacement of left L5 nerve

Post Partum Day 8:

MRI Spine/Pelvis:

L4-5 disc space annular bulge, mild canal compromise and bilateral recess narrowing. Findings compatible with septic arthritis of the right sacroiliac joint with a small adjacent pericapsular and intramuscular fluid collection, worrisome for an abscess.

Post Partum Day 9:

CT guided aspiration:

Fluid culture positive Group B streptococcus

FINAL/WORKING DIAGNOSIS: right SI joint septic arthritis and iliopsoas abscess due to Group B streptococcus

TREATMENT AND OUTCOMES:

She was initially treated with physical therapy and pain medication. Failing improvement, labs and CT were obtained. CT was unrevealing and patient declined further imaging. After four days, she was agreeable to an MRI that revealed septic arthritis. She was initiated on broad-spectrum intravenous antibiotics and narrowed to ceftriaxone. She continued therapy and antibiotics for five weeks. Her CRP and ESR normalized and she followed up with primary care clinic and infectious disease.

WEDNESDAY, MAY 30, 2018

713   May 30 3:35 PM - 3:55 PM

A 37 Year Old Female Dance Instructor with Leg and Buttock Pain

John Franco, Cara Prideaux. *Mayo Clinic, Rochester, MN.*
(Sponsor: Dr. Karen Newcomer, FACSM)
(No relevant relationships reported)

HISTORY: A 37 year old female dance instructor with a history of stable multiple sclerosis presented with a 5 year history of left buttock and posterolateral thigh pain with radiation to the plantar surface of her foot that began during pregnancy. Pain was minimal at rest and aggravated by prolonged sitting and activities such as dancing, bicycling, and hiking. Pain progressed and now markedly limited activity. She reported tingling of the posterolateral calf and plantar surface of the foot. She denied weakness. Chiropractic care provided no relief. Previously obtained lumbar spine MRI was unremarkable and the patient completed 6 months of physical therapy without improvement.
PHYSICAL EXAMINATION: There was no appreciable deformity, malalignment, or rotation of the lumbar spine, hips, or knees. She walked with a non-antalgic gait, including normal heel and toe walking. Palpation of deep left gluteal muscles reproduced pain with radiation down the left lower limb. Range of motion of the lumbar spine and hips was grossly normal. Manual muscle testing of the lower limbs was normal. Passive hip flexion, abduction, and external rotation, as well as flexion, adduction, and internal rotation of the left hip reproduced pain. Remainder of provocative lumbar spine and hip maneuvers, including straight leg raise, were normal. She was neurovascularly intact.
DIFFERENTIAL DIAGNOSIS:
Chronic Piriformis Strain
Lumbosacral Radiculopathy
Hip Osteoarthritis
Multiple Sclerosis Flare
Sciatic, Tibial, or Peroneal Neuropathy
TEST AND RESULTS:
MRI Lumbosacral Plexus: 2.8 X 2.5 X 3.0 cm mass along the left sciatic nerve between the gluteus maximus and quadratus femoris with extension into the ischiofemoral space, consistent with cystic schwannoma
FINAL WORKING DIAGNOSIS: Left sciatic nerve tumor, concern for cystic schwannoma
TREATMENT AND OUTCOMES:
Neurosurgery evaluation
Underwent surgical resection of mass
16 weeks after surgery, reported 100% resolution of her symptoms

714   May 30 3:55 PM - 4:15 PM

Persistent Lower Back Pain In A Gaelic Footballer.

David Keohane. *Cork University Hospital, Cork, Ireland.*
(No relevant relationships reported)

History: A 27 year old, male, high-level, Gaelic Football and Hurling player presented to the Sports Medicine Clinic with a 3-year history of gradually deteriorating lower back pain rated 6/10. The pain was exacerbated by activity and improved by rest. He denied any history of trauma. He denied any radiation or radicular symptoms. Three years prior to presentation MRI had demonstrated a Scheuermann's kyphosis involving T12 with associated disc space narrowing at the T12-L1 level in addition to a transitional S1 vertebra.**Physical Exam**: Visual inspection was unremarkable. There was no pain on palpation over lumbar spine or paraspinal musculature. Lumbar flexion, extension and lateral side flexion were pain free and range of motion was within normal limits. Straight Leg Rise, Schobers and the Femoral Nerve Tension Test were normal. Examination of the hips revealed pain free but restricted internal and external rotation on the right but was otherwise normal. Neurovascular exam of lower limbs was normal.**Differential Diagnosis**: 1)Degenerative disc disease. 2)Lumber disc prolapse. 3)Spondylolisthesis. 4)Fracture of a lumbar vertebral body. 5)Hip pathology. 6)Inflammatory arthritis. 7)Seronegative spondyloarthropathy. 8)Infection.**Tests and**

Results: Bloods were analysed to out rule inflammation or infection. MRI lumbar-sacral spine demonstrated L2-L3 facet joint hypertrophy but no significant thecal sac or nerve root compression and no evidence of sacroiliitis. X-ray of right hip showed significant acetabular dysplagia with uncovering of the femoral head. MRI right hip revealed oedema and multiple small cysts in the right femoral head with remodelling and fragmentation, features consistent with avascular necrosis.**Final/Working Diagnosis:** Idiopathic Avascular Necrosis of the Femoral Head.**Treatment and Outcomes:** The patient was advised to abstain from training and competition. NSAIDs were prescribed for pain and Alendronate 70mg once weekly was initiated to inhibit osteoclastic activity and reduce the risk of femoral head collapse. The patient was referred for an orthopaedic opinion where options included, observation, femoral head core decompression, non-vascularized bone grafting and hip arthroplasty. The decision was ultimately made to pursue a conservative medical approach as outlined above.

Back Injury-Deadlift Weights

Amie Kim, Christopher Gentile, David Matherly, Ronald Alexander Horowitz. *Mount Sinai Icahn School of Medicine Beth Israel Medical Center, New York, NY.*
(No relevant relationships reported)

HISTORY: 35 year old transgender biologically female to male on 12-years high dose testosterone therapy presents with lower back pain for 2 weeks. He was deadlifting weights when noticed delayed left posterior thigh and calf pain. Pain was intermittently throbbing but responsive to acetaminophen. He went to an Urgent Care where a venous duplex was performed which was negative. He was diagnosed with paralumbar muscle strain, and cyclobenzaprine prescribed with little relief. One week later he presented to our emergency department with worsening pain and intermittent numbness in left foot and toes. He denies bladder or bowel changes. **PHYSICAL EXAMINATION:** Uncomfortable appearing. No bony lumbosacral tenderness. Tenderness to palpation left paralumbar muscles, left posterior thigh, calf. Active range of motion limited by pain including flexion/extension/lateral bend. Motor exam of nerve roots IP 4/5 Q 4/5 TA 4/5 EHL 4/5 GS 4/5 FHL 4/5. Sensory intact to light touch L2-S1. 2+ DP pulse. Gait antalgic and limited by pain. **DIFFERENTIAL DIAGNOSIS:** paralumbar strain, rhabdomyolysis, deep vein thrombosis, lumbar radiculopathy, conus medullaris, cauda equina syndrome **TEST AND RESULTS:** Serology including WBC, CPK and D-Dimer within normal values. Radiographs of pelvis / lumbosacral spine without findings. Calf venous duplex without acute thrombus. MRI lumbosacral spine with L4-L5 large left paracentral disc herniation displacing spinal canal with significant compression on the left S1 nerve root and thecal sac. Conus medullaris normal in signal. **FINAL WORKING DIAGNOSIS:** cauda equina syndrome **TREATMENT AND OUTCOMES:** Patient underwent emergent L5-S1 laminectomy with decompression of S1 nerve root, diskectomy with partial facetectomy. Discharged to outpatient therapy. Residual left lower extremity weakness, numbness, and perineal numbness treated with high dose methylprednisolone. Role of high dose testosterone in patient's presentation under evaluation.

Back Pain-hockey

Melanie Kennedy, Anastasia Fischer, FACSM, Reno Ravindran. *Nationwide Children's Hospital, Columbus, OH.*
(No relevant relationships reported)

HISTORY:
A 17 year old male hockey goalie presented with acute left low back pain with radiculopathy after falling on his left side making a save a few days prior. He was unable to continue participation. A non-contrast MRI of his lumbar spine was performed to evaluate for disk pathology/sacroiliac joint inflammation and was negative. He completed 8 weeks of physical therapy to address poor hamstring flexibility and core strengthening with minimal improvement. He attempted to return to hockey but it worsened his pain. At follow up visits, he now had increased bilateral ischial tuberosity pain, and inflexibility of bilateral hamstrings. Pelvic radiographs were negative. Case discussed with PMR for extreme inflexibility but patient elected to continue with therapy transitioning to functional rehabilitation with an athletic trainer. After a few weeks with functional rehab, he had worsening low back and was referred back to clinic. He endorsed alternating between left and right posterior glutes, SI joint pain, quad and calf achiness and occasional shooting pain down left leg to posterior knee. Additionally pain woke him at night; he had morning stiffness, unintentional weight loss and no significant improvement throughout his 13 weeks of therapy. He did have prior issues with back pain in previous years managed by his PCP. Further imaging and lab work were obtained.
PHYSICAL EXAM: Tender within bilateral SI joints and right iliac crest. Poor flexibility of bilateral hamstrings, full range of motion of low back but evidence of somatic dysfunction.
DIFFERENTIAL DIAGNOSIS:
1. Herniated lumbar disk
2. Sacroiliac Joint Dysfunction
3. Functional back pain
4. Muscular strain
5. Spondyloarthropathy
6. SI joint infection/ Osteomyelitis
7. Metastatic Cancer
8. Psychologic Illness
TEST AND RESULTS:
7/5: Lumbar radiographs: Normal
7/11: MRI lumbar spine: Subcentimeter synovial cyst but otherwise negative
9/12: Pelvic radiographs: Normal
10/16: Sacroiliac MRI with/without contrast: Bilateral sacroilitis
Laboratory 10/13: CBC. CMP, ESR, CRP: Unremarkable
FINAL/WORKING DIAGNOSIS: Enthesitis related arthritis
TREATMENT AND OUTCOMES:
1. Prescribed Naproxen twice a day
2. Care transitioned to Rheumatology
3. Additional lab work up
4. Started on methotrexate and anti-TNF therapy
5. Plans to return to hockey next season

B-58   Free Communication/Poster - **Body Composition**

Challenging The Testing Protocol Of The Bod Pod

Eric Shamus, PhD, DPT, Sarah Bengtson, DPT, Sierra Griffin, DPT, Ahmed Elokda, PhD, PT, Liza Malley, BS. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchell L. Cordova, FACSM)
(No relevant relationships reported)

The BOD POD uses air displacement plethysmography to determine an individual's body composition as percentages of fat mass and fat free mass. The BOD POD presents potential use in a clinical setting, but the feasibility is currently unknown. There were no studies found examining the consumption of fluids and pre-urination prior to body composition testing utilizing the BOD POD. **PURPOSE:** The objective was to determine if the BOD POD protocol, as set forth by Life Measurement, Inc., needs to be followed in its entirety to ensure validity of body composition results, where urination and fluid consumption prior to testing were both independently tested. **METHODS:** Thirty-two division 1 male (15) and female (17) soccer athletes were recruited for this research study. Male soccer players weighed 162.6 pounds ($\pm$ 19.03) and female soccer players weighed 133.8 pounds ($\pm$ 10.38). All athletes

were between 18 and 22 years old (Male $\pm$ 1.37 & Female $\pm$ 1.17). Four separate measurements of body composition were taken: pre-urination, standard LMI protocol test re-test, and consumption of water equal to 10% of their body weight in ounces. **RESULTS:** A Pearson product moment correlation between the second condition (post urination) and the third condition (post urination retest) signified a good to excellent relationship between the standard test and the retest conditions (0.977, p < .001). A MANOVA analysis was performed comparing pre-urination and post-urination test/retest indicated that not urinating prior to testing had no significant effect on body composition measurements (p > .05). Consumption of water did have a significant effect on the results of the body composition measurements. It was found that post water consumption, male participants' measurement of fat mass on average had a significant difference of 0.6% and female participants' fat mass measurements on average had a difference of 1.4%, p < .001). **CONCLUSION:** Results did not support the need to urinate prior to BOD POD testing while supporting the need to refrain from water consumption directly prior to testing.

Assessing The Impact Of Body Fat Percentage And Lean Mass On Wingate Performance

Robert T. Sanders[1], Andy Bosak[1], Matthew L. Sokoloski[2], Hannah E. Nelson[1], James Kelly[1], Jared Feister[1]. *[1]Liberty University, Lynchburg, VA. [2]Texas Woman's University, Denton, TX.* (Sponsor: Dr. James Schoffstall, FACSM)
(No relevant relationships reported)

The Wingate test is commonly utilized to assess the anaerobic power capabilities of athletes across various sporting disciplines. Although prior studies have assessed the impact that body composition values have on anaerobic performance in above averagely fit populations, it appears that no study has evaluated the relationship between body fat percentage (BF%), lean leg mass (LLM), and trunk lean mass (TLM) on Wingate performance in no less than averagely fit males. **PURPOSE:** To investigate the relationship between BF%, LLM, and TLM on Wingate performance in no less than averagely fit college-age males. **METHODS:** After having descriptive data recorded, 38 no less than averagely fit college-age males had their BF%, LLM, and TLM assessed via a bioelectrical impedance analyzer. BMI was also analyzed. Subjects participated in an 8 min dynamic warm-up on a leg cycle ergometer, followed by the completion of a maximal effort 30s sprint. Pearson Correlations were then performed between BF%, LLM, TLM, peak power (PP), and mean power (MP) with significant differences determined at p $\leq$ 0.05. **RESULTS:** High to moderately high positive correlations existed between PP and TLM (r = .834, p = .001), LLM (r = .773, p = .001), BMI (r = .657, p = .001) as well as between MP and TLM (r = .904, p = .001), LLM (r = .880, p = .001), and BMI (r = .619, p = .001). However, no relationship occurred between BF% and PP (r = -.064, p = .123) while a low negative relationship occurred between MP (r = -.234, p = .049) and BF%. **CONCLUSIONS:** TLM, LLM, and BMI appear to have a strong positive relationship with Wingate performance in no less than averagely fit males, while BF% appears to have little to no relationship with Wingate performance. Further research may be necessary in order to determine if fitness level, sport specificity, or a different type of body fat percentage measurement technique may play a factor when considering if BMI, BF%, LLM, and TLM has a relationship with Wingate performance.

742   Board #3   May 30 2:00 PM - 3:30 PM
Comparison Of A-mode And B-mode Ultrasound For Measurement Of Subcutaneous Fat

Dale R. Wagner, Trenton Judd, Joshua Gordon, Casey McPherson, Adrianna Robison. *Utah State University, Logan, UT.* (Sponsor: Edward Heath, FACSM)
(No relevant relationships reported)

With lower cost devices and technological advancements, ultrasound has been undergoing a resurgence as a method to measure subcutaneous adipose tissue. Amplitude (A-mode) ultrasound produces a spike at the interface between subcutaneous fat and muscle, while brightness (B-mode) ultrasound produces an image of the underlying tissues. **PURPOSE**: This study aimed to determine if a low-cost, low-resolution A-mode ultrasound designed specifically for body composition assessment could produce subcutaneous fat thickness measurements comparable to an expensive, high-resolution B-mode device. **METHODS**: Subcutaneous fat thickness was measured on 41 participants (21 female, 20 male; 29.6 ± 11.0 y; BMI 25.3 ± 5.1 kg/m²) at 7 sites (chest, subscapula, mid-axilla, triceps, abdomen, suprailiac, and thigh) with two devices: a 2.5 MHz A-mode ultrasound (BodyMetrix BX 2000), and a 12 MHz B-mode ultrasound (GE NextGen LOGIQ e R7). **RESULTS**: Pearson correlation coefficients between the two ultrasound devices exceeded 0.80 ($P < 0.001$) at all measurement sites. Mean differences in fat thickness were not significantly different between the devices ($P > 0.05$) with the exception of the triceps site ($P = 0.021$); however, the mean difference at this site (0.53 mm) was not clinically relevant. The variability between devices was greatest at the abdomen, the site with the greatest thicknesses. However, Bland-Altman plots revealed no systematic bias between

devices at any site. **CONCLUSIONS**: Given the strong relationships, insignificant mean differences, and lack of systematic bias, the low-cost, low-resolution A-mode ultrasound provides subcutaneous fat thickness measurements similar to the more expensive, high-resolution B-mode ultrasound.

743   Board #4   May 30 2:00 PM - 3:30 PM

Agreement in Fat and Muscle Estimation between Bioelectrical Impedance and Anthropometry in Youth Athletic Population

Enrique O. Prada, Aldo F. Longo, Néstor A. Lentini, Marcelo L. Cardey, Gustavo D. Aquilino. *CeNARD, Buenos Aires, Argentina.*

(No relevant relationships reported)

PURPOSE: The purpose of this research was to measure the level of agreement in the assessment of the body fat and muscle masses between an anthropometry-based model and the bioelectrical impedance analysis in youth athletes.
METHODS: A sample of 252 subjects was studied (137 boys and 115 girls). The participants covered an age range from 12.5 to 16.6 years (Body mass = 59.1 ± 9.8 kg, BMI = 21.2 ± 2.4 kg·m^{-2}; mean ± SD). Body composition was indirectly achieved by bioelectrical impedance analysis (BIA) and by the anthropometry-based model of De Rose and Guimaraes (1980) (DRG). DRG was updated using the simple regression equations of Withers *et al.* (1987, cited by Norton, 1996) to estimate body density, and Siri formula (1961) was then utilized to calculate the percentage of body fat. The mean values of the body fat and muscle masses given by the two methods were contrasted within each gender stratum, using the Student's *t*-test for correlated samples. The Bland-Altman analysis was employed to estimate 95% limits of agreement. Statistical significance was set at p<0.05.
RESULTS: The differences between DRG and BIA were statistically significant in both genders (p<0.001). In boys, the mean values were, respectively, 7.4 and 7.9 kg for the fat mass, and 28.9 and 31.0 kg for the muscle mass; the 95% limits of agreement were from -3.8 to 2.7 kg, and from -6.0 to 1.6 kg. In girls, the mean values were, respectively, 9.4 and 11.8 kg for the fat mass, and 22.4 and 23.3 kg for the muscle mass; the 95% limits of agreement were from -6.3 to 1.5 kg, and from -4.3 to 2.4 kg. The means for the variables expressed in percentage values were, in boys, 11.5 and 12.4 % for the fat mass, and 45.8 and 49.2 % for the muscle mass; the 95% limits of agreement were from -5.9 to 4.1 %, and from -8.9 to 2.1 %. And in girls, the means were 16.8 and 21.2 % for the fat mass, and 41.7 and 43.2 % for the muscle mass; the 95% limits of agreement were from -11.1 to 2.3 %, and from -7.2 to 4.1 %.
CONCLUSIONS: There was found a negative bias of DRG with respect to BIA for the two variables. In boys, the difference between methods was higher for the muscle mass, and in girls it was higher for the fat mass. The bias between DRG and BIA had a detrimental impact on the limits of agreement.

Normalization For Body Mass Affects The Correlation of Strength Tests To Speed And Agility Tests

Anthony Caterisano, FACSM[1], Mike Gentry[2]. *[1]Furman University, Greenville, SC. [2]Virginia Polytechnical Institution, Blacksburg, VA.*

(No relevant relationships reported)

Previous research has explored the correlation between strength tests and speed-agility tests among athletes with varying results. Much of this can be attributed to differences in reported results based on absolute strength test values versus those normalized to body mass (BM). **Purpose:** This study was to compare the correlation between absolute strength, speed, and agility test results to those normalized using body mass. **Methods**: Varsity Division I male football players (n = 327) were tested during several seasons. Tests for strength included one repetition maximum (1RM) back squat (BS), power clean (PC), and push jerk (PJ). Results were recorded as absolute values as well as normalized values, calculated by dividing each 1RM by the athlete's BM. Tests for speed and agility included 40-yard dash (40YD), 10-yard dash (10YD), 20-yard shuttle run (SR) and standing vertical jump (VJ). A Pearson Product-Moment Correlation analysis was used to determine significant correlations between tests. **Results:** Results are presented below, with the first table displaying the absolute values of the strength tests and the second table showing the normalized values:

	Shuttle Run	10-yd Dash	40-yd Dash	Vertical Jump
Push Jerk	.22*	.11*	.25*	- .08
Power Clean	.09	.02	.12*	.04
Back Squat	.16*	.05	.13*	.00

	Shuttle Run	10-yd Dash	40-yd Dash	Vertical Jump
Push Jerk / Body Mass	- .63*	- .60*	- .66*	.62*
Power Clean/ Body Mass	- .71*	- .64*	- .76*	.68*
Back Squat/ Body Mass	- .59*	- .57*	- .68*	.62*

*P≤0.05

Conclusions: The results suggest that the correlations between 1RM strength test, and speed-agility test results are affected by normalizing to BM. There is a stronger significant correlation between tests when 1RM strength test values are normalized to BM.

Ability of the LeanScreen App to Accurately Assess Body Composition

Kimberly L. Radtke, John P. Porcari, FACSM, Ray Marx, Richard Mikat, FACSM, Scott Doberstein, Abigail Ryskey, Carl Foster, FACSM. *University of Wisconsin - La Crosse, La Crosse, WI.* (Sponsor: John Porcari, FACSM)

(No relevant relationships reported)

Waist-to-hip ratio (WHR) and percent body fat (%BF) are commonly used to assess body composition in health and wellness settings. While there is only one commonly used method for measuring WHR, %BF can be determined many ways. However, the accuracy, cost, and ease of use of these methods vary greatly. The LeanScreen app is a new method designed to determine WHR and %BF using photographs. **Purpose:** This study was designed to assess the accuracy of the LeanScreen app to determine WHR and %BF against laboratory-validated methods. Eighty subjects (40 males; 40 females) participated in this study. Waist-to-hip ratio was manually measured and %BF was determined using the BOD POD. Photographs of each subject were taken from the front and back with the LeanScreen app according to the procedures demonstrated by the program software. **Results:** There was no significant difference in WHR between the LeanScreen app (.81 ± .078) and manual (.81 ± .087) WHR measurement (r=.83). Additionally, it was found that 73 subjects (91%) were within one standard deviation (0.08) of the mean. Overall, %BF was significantly underpredicted by the LeanScreen app compared to the BOD POD (20.2 ± 7.74 vs. 21.6 ± 8.77). Although there was a high correlation between the two methods (r=.82), only 35 subjects (44%) were within ± 3% of BOD POD derived %BF and there was a high degree of variability between methods (SEE=5.1). **Conclusion:** Based upon the results of this study, the LeanScreen app accurately determines WHR, but does not accurately determine %BF on an individual basis.

Validation of New Skinfold Prediction Equation Based on Dual-Energy X-Ray Absorptiometry for Women.

Jillian Barnas, MS, Stephen Ball, PhD. *University of Missouri - Columbia, Columbia, MO.* (Sponsor: Jill Kanaley, PhD, FACSM)

(No relevant relationships reported)

There is a high demand for affordable body composition assessments of body fat and fat free mass. Research has demonstrated that skinfold prediction equations recommended by the American College of Sports Medicine (ACSM) underestimate body fat percentage (%BF). **PURPOSE:** The purpose of this study was to validate an alternative equation for women created from dual energy x-ray absorptiometry (DXA). The DXA criterion (DC) equation is:
%BF= -6.40665 + 0.491946(S3SF) - 0.00126(S3SF)^2 + 0.12515(hip) + 0.06437(age); (S3SF = sum of triceps, suprailiac, thigh; hip = circumference in cm; age = years).
METHODS: Anthropometrics (skinfolds and circumferences) and a DXA scan were completed on 78 women (mean ± SD) [age: 28.0 ± 10.1 yr., height: 165.1 ± 5.9 cm, mass: 63.5 ± 10.5 kg., BMI: 23.2 ± 3.2 kg/m^2]. The three Jackson-Pollock skinfold prediction equations (JP7, JP3a, and JP3b) and the DC equation were compared to DXA %BF. **RESULTS:** Two-way ANOVA with repeated measures detected significant differences (p < 0.05) in the %BF with post hoc-comparisons revealing significant differences among JP7 (21.4 ± 5.8), JP3a (22.3 ± 5.9), and JP3b (22.7 ± 5.7) as compared to the DXA (26.6 ± 5.4). No significant difference existed between DC %BF (26.6 ± 5.9) and DXA %BF (26.6 ± 5.4) (p = 1.0) and the two assessments were highly correlated (R = 0.87). The standard error of the measurement for the DC equation was low (2.98%). **CONCLUSION:** The DC equation more accurately predicted %BF across a general population of women than the recommended ACSM equations. Practitioners should consider its use and exercise caution when using older equations since they may yield lower %BF compared to DXA.

747   Board #8   May 30 2:00 PM - 3:30 PM

Evaluation of Regional Body Composition in Able-Body and Wheelchair Basketball Teams

Judy R. Wilson, FACSM, Sara Kirk, Sarah Poydence. *University of Texas @ Arlington, Arlington, TX.*
(No relevant relationships reported)

BACKGROUND: The differences in maximum oxygen consumption (VO_{2max}) and peak oxygen consumption (VO_{2peak}) between able-bodied athletes and wheelchair athletes has been well documented. Another relationship that has been well established is that of body composition and aerobic or cardiovascular fitness (VO_2). **PURPOSE:** The purpose of this study was to evaluate the regional body composition, as measured by the dual energy x-ray absorptiometry (DXA), between the able-bodied (AB) men's and women's basketball teams and the men's and women's wheelchair (WC) basketball teams and its relationship to VO_2. **METHODS**: 7 WC athletes with a spinal cord injury (SCI, age 21.29 ± 2.29 yrs), 7 WC non-SCI athletes (NSCI, age 20.14 ± 2.14 yrs) and 28 AB athletes (age 19.43 ± 2.57 yrs) participated in the study. The subjects underwent exercise tests to determine VO_{2max} or VO_{2peak}. The AB teams performed the Bruce protocol using a Parvo metabolic cart while the WC teams used their wheelchairs attached to a treadmill using a Cosmed K4b2 portable metabolic machine. Body composition measures, total and regional percent body fat (%BF), were conducted using a GE-Lunar DXA. The regional measures (arms and legs) allowed body composition comparisons between AB and WC teams. SPSS 24 was used to run a linear regression to determine what percent of VO_2 could be attributed to %BF. **RESULTS**: DXA results were total (AB: 19.24 ± 16.06%; NSCI: 36.46 ± 14.34%; SCI: 31.70 ± 19.40%) and regional (AB: 20.40 ± 15.90%; NSCI: 25.67 ± 13.93%; SCI: 22.60 ± 14.70%). VO_{2max} results (AB 44.62 ± 14.98 ml/kg/min) and VO_{2peak} results (SCI: 25.80 ± 10.12 ml/kg/min; NSCI: 24.34 ± 5.51 ml/kg/min) were significantly different ($p < 0.05$). When evaluating WC users, specifically with a SCI, the R^2 value was 0.703 ($p = 0.018$) which showed this method does predict VO_{2max} significantly. When evaluating only the working limbs of the able body group, the R^2 value was 0.233 ($p = 0.009$). **CONCLUSION**: Significant differences were found among the 3 groups (AB, SCI, non-SCI) when evaluating total body fat. However, there were no significant differences when evaluating %BF of the working limb. This suggests that there may be more to the VO_{2max} differences seen between AB and WC athletes than just muscle size and that regional %BF of the working limb should be taken into account with SCI.

748   Board #9   May 30 2:00 PM - 3:30 PM

Effects Of Menstrual Cycle On Body Weight And Intracellular And Extracellular Fluid

Mikako Sakamaki-Sunaga, Kayoko Kamemoto, Mizuki Yamada, Tomoka Matsuda. *Nippon Sport Science University, Tokyo, Japan.*
(No relevant relationships reported)

Blood concentrations of ovarian hormones, such as estrogen and progesterone, change during each phase of the menstrual cycle. Ovarian hormones can have an effect on fluid retention. Therefore, it has been suggested that the body weight and body composition changes with different phases of the menstrual cycle. **PURPOSE**: The purpose of this study was to compare changes in body weight and intracellular and extracellular fluid levels during the menstrual cycle. **METHODS**: The subjects were eight women (age, 21.6 ± 1.1 y) with regular menstrual cycle who volunteered to participate in this study. Subjects performed 30 min of cycling at an intensity of 60% VO_2 peak at three time points during the menstrual cycle: follicular phase, FP; ovulation phase, OV; luteal phase, LP). Blood samples were collected at rest (0 min), immediately after the exercise (30 min), 30 min after the exercise (60 min), and 60 min after the exercise (90 min). The duration of each menstrual cycle phase was estimated by assessing the levels of ovarian hormones. Blood analyses of ovarian hormones (estradiol and progesterone), renin activity, and aldosterone were conducted. Intracellular fluid and extracellular fluid from each site (upper limb, lower limb, and trunk) were measured before and after exercise. **RESULTS**: Blood concentration of estradiol was greater during the OV and LP than during the FP at all time points (FP, 30.4 ± 12.3 pg/mL; OV, 186.6 ± 139.1 pg/mL; LP, 195.5 ± 118.0 pg/mL, $p < 0.05$). The body weight tended to greater in the LP when compared to the OV (FP, 57.8 ± 2.3 pg/mL; OV, 57.7 ± 2.4 kg; LP, 58.2 ± 2.2 kg, $p = 0.06$). The extracellular fluid from the trunk was significantly higher in the LP than in the FP and OV (FP, 5.49 ± 0.4 L; OV, 5.50 ± 0.4 L; LP, 5.55 ± 0.3 L, $p < 0.05$). A significant positive correlation was found between renin activity and progesterone levels (r = 0.632, $p < 0.05$). **CONCLUSIONS**: The increase in body weight during the LP was induced by an increase in body fluid volume. This study was supported by the JSPS KAKENHI Grant Number 26350768 and Ministry of Education, Culture, Sports, Science and Technology-Japan, Female Athlete Development and Support Project.

Body Fat Percent and Relative Intensity in Walking at 2.5 mph among University Students

Istvan Kovacs, Wenhao Liu, FACSM, Ethan E. Hull. *Slippery Rock University, Slippery Rock, PA.*
(No relevant relationships reported)

Purpose: To better understand the relationship between body composition and aerobic capacity, this study examined how body fat percent (%BF) would be related to heart rate (HR), maximal HR% (%HRmax) and HR reserve% (%HRR) when walking at 2.5 mph among university students. **Methods**: The three-site skinfold measure was administered to 176 university students (mean age: 20.82±1.49; 102 males and 74 females) in the US and converted to %BF using the conversion tables by Jackson et al. (1985). The ACSM %BF satisfactory ranges (2014, 10%-22%BF for men and 20%-32%BF for women) were used to divide participants into three %BF categories: Normal, Lean, and Obese. In addition, using HR monitors (Sigma PC26.14) resting HR (after lying on the floor for five minutes) was measured to calculate HRR, and HR at the end of a three-minute treadmill walking at 2.5 mph was also measured. One-way MANOVA was used to examine differences in HR, %HRmax, and %HRR at the end of the three-minute walking among the three %BF groups. **Results**: There were 90 participants in Normal, 64 in Lean, and 22 in Obese group. No age difference (p > .70) was found among the three %BF groups (Normal 20.71±.90, Lean 20.94±2.79, Obese 20.95±1.50). However, significant differences (p values ranged from .000 to .012) were observed in HR, %HRmax, and %HRR at the end of the three-minute walking at 2.5 mph among the three %BF groups. Specifically, significant differences were identified in HR in all the three pairwise comparisons: Lean (89.90±10.00) vs. Obese (104.77±10.32), Lean vs. Normal (98.39±11.10), and Normal vs. Obese; in %HRmax in all the three pairwise comparisons: Lean (45.18±5.14) vs. Obese (52.64±5.19), Lean vs. Normal (49.37±5.57), and Normal vs. Obese; and in %HRR between Lean (18.71±6.60) and Obese (24.39±6.69) and between Lean and Normal (22.06±6.61). **Conclusion**: Even walking at the threshold of moderate intensity (2.5 mph, a 3-MET activity), lean individuals demonstrate significantly lower HR, %HRmax, and %HRR than normal and obese individuals; and normal individuals show significantly lower HR and %HRmax than obese individuals. The %BF classified with ACSM %BF ranges has significant impact on relative intensity experienced among university students when walking at 2.5 mph.

Hyperhydration Acutely Increases Bioelectrical Impedance Analysis Body Fat Estimates

Evan L. Matthews, Marisa M. Maertens, Peter A. Hosick. *Montclair State University, Montclair, NJ.*
(No relevant relationships reported)

Bioelectrical impedance analysis (BIA) is a common and non-invasive method to evaluate body composition by measuring the electrical impedance of the body. Altering blood electrolyte concentration or blood volume may impact BIA measurements by directly influencing the electrical conductivity of the body. While dehydration and sweat induced electrolyte loss certainly impacts BIA, it is unclear how simultaneous hyperhydration and electrolyte loading effects BIA measurements. **PURPOSE:** To examine the effects of acute hyperhydration and salt loading on the impact of BIA derived body fat estimates. **METHODS:** Each participant ate a standardized meal followed by ≥4hr fast, prior to the experimental visit. Adequate hydration (urine SG ≤1.020) of each participant was confirmed prior to the start of the visit. Tanita TBF-300A BIA and a blood sample were performed at baseline and every 30min for 3hr following the consumption of 3.8 grams of table salt dissolved into 466mL of deionized water (sodium: 1500mg, 140mmol). All urine produced during the 3hr follow-up was collected to assess volume and electrolyte excretion. **RESULTS:** Seven healthy participants (3M/4W, 29±2 years, 67.0±4kg, urine SG 1.007±0.001, hemoglobin 13.7±0.2g/dL, hematocrit 45±1%, serum sodium 140.0±0.5mmol/L) were studied. Participants excreted 646±55mL of urine containing 17.1±6.8mmol of sodium during the 3hr follow-up period. Consumption of the salt water solution increased plasma volume 7.0±0.7% and serum sodium 1.3±0.4% with each statistically elevated above baseline during the time points ≥60min and ≥120min, respectfully (all $p<0.05$). Both body mass (+0.4±0.1kg) and BIA estimated body fat percentage (+0.6±0.2%) (both $p<0.05$) increased immediately and returned to baseline levels by 90min. Leg to leg electrical impedance was not affected by the consumption of the salt water beverage ($p=0.660$). **CONCLUSION:** This preliminary data suggests that when starting in a hydrated state, concurrent consumption of salt and water temporarily increases body mass causing an increase in body fat estimates. However, differences in temporal patterns suggest increased plasma volume with small elevations in electrolyte concentration does not directly affect body fat estimates when using bioelectrical impedance analysis.

751 Board #12 May 30 2:00 PM - 3:30 PM

Effects of a Six Week Weight Loss Challenge on Body Composition and Cardiovascular Health

Melissa A. Whidden, Jamie M. Blose, Jared M. James, Antonia L. Battaglino, Alexis N. Trumbetti, Anna K. Schade, Katie M. Cooper, Paul K. Stickles, Melissa A. Reed, Selen Razon. *West Chester University, West Chester, PA.* (Sponsor: Dr. W. Craig Stevens, FACSM)
(No relevant relationships reported)

Regular exercise and a healthy diet are associated with significant changes throughout the body including improved body composition and enhanced cardiovascular health. A local gym recruits individuals to participate in a six-week twenty pound weight loss challenge and provides participants with a structured diet and exercise plan. **PURPOSE:** The purpose of this study was to determine if a primarily weight loss driven program would also result in an improvement in body composition and enhance cardiovascular health. **METHODS:** Total weight, body fat, lean muscle mass, waist and hip circumference, resting metabolic rate (RMR), total cholesterol (TC), high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol, fasting plasma glucose (FPG), triglycerides (TG), resting blood pressure (BP), and resting heart rate (RHR) were assessed before and after the six-week program in thirty four sedentary adults (M_{age} =38.24, SD=9.93). Subjects were required to participate in a vigorous boot camp program a minimum of five days per week for fifty minutes and follow a structured diet plan. **RESULTS:** There was a significant decrease in total body weight following the six-week challenge (197.1 ± 7.76 lbs vs. 187.8 ± 7.16 lbs; P < 0.001). There was a decrease in body fat (38.6 ± 1.52% vs. 36.2 ± 1.52%; P < 0.001) as lean muscle mass increased (61.4 ± 1.52% vs. 63.8 ± 1.52%; P < 0.001). Participants successfully lost 1 inch off their waists and hips (P < 0.01). A significant decrease in TC (189.2 ± 6.81 mg/dL vs. 173.4 ± 6.65 mg/dL, P < 0.001) and LDL (115.0 ± 7.25 mg/dL vs. 107.0 ± 6.05 mg/dL, P < 0.05) were seen following the weight loss program. Unfortunately, neither RBP nor RHR were significantly altered by the program. **CONCLUSIONS:** These data suggest that this particular weight loss driven program is effective in significantly improving body composition and reducing TC and LDL. However, this program did not statistically improve resting metabolic rate or decrease resting cardiovascular measures. While this study emphasizes the health-related advantages of incorporating physical activity and a healthy diet into a sedentary lifestyle, further research can contribute to training specificity and the impact both cardiovascular and weight training have in junction with a structured weight loss program.

752 Board #13 May 30 2:00 PM - 3:30 PM

Evaluation Of Body Composition Measurements Obtained Using Whole-body Plethysmography

Timothy R. Macaulay, Conor D. Uhlir, E. Todd Schroeder, FACSM. *University of Southern California, Los Angeles, CA.* (Sponsor: E. Todd Schroeder, FACSM)
(No relevant relationships reported)

Purpose: Body composition assessments provide important health information, as excess body fat percentage (BFP) in relation to lean body mass can increase risk of cardiovascular disease and diabetes. While dual-energy x-ray absorptiometry (DXA) is a gold standard measurement of body composition, faster alternatives that do not expose participants to radiation, such as bioelectrical impedance (BIA), can promote awareness and be used to determine training efficacy. In this study, we compared body composition measurements obtained using whole-body plethysmography by the Airmetrix Whole-Body Self-Service Analyzer to those obtained via multifrequency BIA analysis and DXA scanning.
Methods: Twenty-six volunteers (17 female, 36.7 ± 12.3 years of age) were tested on two visits. On the first visit, body composition was assessed under fasted conditions by one Biospace InBody 770 analysis, one DXA scan (GE Lunar iDXA), and at least two Airmetrix tests. The second visit was performed at least 24 hours later, at a different time of day, and after the participant had consumed a meal. Body composition was assessed by one InBody analysis and at least two Airmetrix tests. For all tests, participants wore clothing that was tight and minimal with long hair tied up to minimize extra volume that may interfere with measurements. Shoes, keys, jewelry, and other accessories were removed.
Results: The Airmetrix system showed good precision, with a within-visit retest mean range of 0.04 lbs and 0.51% for weight and BFP, respectively. Although there were statistically significant absolute changes in weight and BFP between visits, there was no systematic direction and was therefore likely due to normal physiological fluctuation. Comparing devices, InBody and average Airmetrix BFP measurements were significantly lower than DXA BFP measurements for both visits (p<0.001). Although the Airmetrix system had slightly greater absolute mean percent error compared to InBody (18.8-19.4% vs. 16.8-17.1%, respectively), the difference in errors between devices was not statistically significant (p=0.067).

Conclusion: The Airmetrix system assess weight and BFP with good precision. Overall, the Airmetrix and InBody devices produce similar results, and both significantly underestimate BFP compared to DXA.

753 Board #14 May 30 2:00 PM - 3:30 PM

Large Exercise-induced Weight Loss on Fat Distribution and Metabolic Risk Factors in Young Obese Males

Jolene Lim[1], Govindasamy Balasekaran, FACSM[1], Melissa Mayo[1], Visvasuresh Victor Govindaswamy[2]. *[1]Nanyang Technological University, Singapore, Singapore. [2]Concordia University Chicago, Chicago, IL.* (Sponsor: Govindasamy Balasekaran, FACSM)
(No relevant relationships reported)

There has been a lack in research on the effects of large exercise-induced weight loss of more than 10 kg on fat distribution and metabolic profile of obese males. **PURPOSE:** To examine large exercise-induced weight loss on fat distribution and metabolic risk factors, and their improvements associated with coronary heart disease. **METHODS:** A total of 20 obese males (age: 19.3 ± 1.30 yrs) completed in the institutionalized regimented training (IRT) held over 16 weeks. Anthropometric, dual x-ray absorptiometry scan and resting metabolic rate (RMR) measurements were taken in the laboratory, while computerized tomography scan, fasting venous blood samples, and a 2-hour oral glucose tolerance test were completed at a local hospital. Daily activities and dietary habits were self-recorded over 2 weekdays and 1 weekend day. **RESULTS:** IRT resulted in an average weight loss of 13.4 ± 3.70 kg (p < 0.001), significantly reducing body fat percentage and body mass index (p < 0.001). There were significant reductions in total cholesterol (Pre: 4.79 ± 0.92 mmol.L[-1], Post: 4.12 ± 0.82 mmol.L[-1], p < 0.001), triglycerides (Pre: 1.19 ± 0.57 mmol.L[-1], Post: 0.74 ± 0.30 mmol.L[-1], p < 0.001), low density lipoprotein cholesterol (LDL-C) (Pre: 3.04 ± 0.83 mmol.L[-1], Post: 2.51 ± 0.74 mmol.L[-1], p < 0.001), Plasma Apolipoprotein (Apo) A-1 (Pre: 133.3 ± 13.1 mg.dL[-1], Post: 120.4 ± 14.5 mg.dL[-1], p < 0.001), Apo B (Pre: 88.1 ± 25.7 mg.dL[-1], Post: 70.1 ± 18.2 mg.dL[-1], p < 0.001), Total/high density lipoprotein cholesterol (HDL-C) (Pre: 4.00 ± 1.01, Post: 3.26 ± 0.81, p < 0.001), and LDL/HDL-C (Pre: 2.54 ± 0.82, Post: 2.00 ± 0.72, p < 0.001). A 45% decrease in the insulin area/glucose area ratio was compatible with an increase in insulin sensitivity. Daily RMR decreased by 138.0 ± 164 kcal.day[-1] (p < 0.05). RMR/Weight increased (Pre: 20.5 ± 3.30, Post: 21.9 ± 2.70, p < 0.01) while RMR/Fat free mass ratio decreased (Pre: 30.70 ± 4.5, Post: 29.10 ± 3.20, p < 0.05) after training. Reported total daily physical activity increased by 33%, which was associated with reductions in body weight (r = 0.39, p < 0.05). **CONCLUSION:** Large exercise-induced weight losses significantly reduced metabolic risk factors for disease and abdominal fat in young obese males. Therefore, large weight losses through exercise may be an effective strategy for maximizing health benefits to obese individuals.

754 Board #15 May 30 2:00 PM - 3:30 PM

Sport-Specific Changes to Bone and Lean Mass Proportionalities among College Athletes

Taylor Burlis[1], Elijah Farrales[1], Robert Taylor[1], Jerry L. Mayhew, 63501[1], William F. Brechue, FACSM[2], Laurel M. Wentz[3]. *[1]Truman State University, Kirksville, MO. [2]A. T. Still University, Kirksville, MO. [3]Appalachian State University, Boone, NC.*
(No relevant relationships reported)

Interest in the morphological characteristics of athletes has been growing in recent years. A Darwinian model suggests that some athletes may naturally gravitate to a sport based on their specific morphological characteristics. However, comparisons between male and female athletes in similar sports have not been fully explored. **PURPOSE**: To compare morphological distributions of regional bone mineral content (BMC) and lean mass (LM) between men and women athletes in comparable sports.
METHODS: NCAA Division-II male (n = 87) and female athletes (n = 60) in four sports [soccer (SOC), basketball (BB), cross-country (XC), and baseball/softball (BS)] were measured for regional BMC and LM using dual-energy X-ray absorptiometry (DXA). Inactive men (n = 23) and women (n = 27) served as a control group (CON). Ratio of BMC to LM for arms, legs, and trunk was calculated to indicate regional proportionalities.
RESULTS: Men were taller and heavier than women and had lower %fat (p<0.001). BB was taller (p<0.05) than other sports and CON. Men had significantly greater total LM/Ht (35.3 ± 4.4) than women (26.5 ± 2.6). LM/Ht was significantly greater in BS and BB than in XC, CON, and SOC which did not differ significantly among those groups. Sex x sport multivariate ANOVA revealed women had a greater arm BMC:LM than men (p<0.005) but total body, trunk, and legs BMC:LM were similar. Leg BMC:LM was greater in SOC (6.6 ± 0.5) and BB (6.5 ± 0.5) than in BS (6.1 ± 0.5), XC (6.4 ± 0.3), or CON (6.2 ± 0.7), which were not different. Trunk BMC:LM was significantly lower for XC (3.3 ± 0.2) and CON (3.5 ± 0.5) that for SOC (3.8 ± 0.4), BS (3.8 ± 0.5) and BB (3.9 ± 0.4. Total and arm BMC:LM was not significantly different among groups. Sex x sport interactions were not significant.

CONCLUSIONS: Sports and sport-specific training appears to impact LM and BMC accrual differently. Men and women athletes in sports that required more intense running and perhaps more weight lifting had greater legs BMC:LM than sports that apparently do not place the same degree of stress on bones and/or LM. The degree of stress on bones for the arms does not seem sufficient to differentiate among these sports or inactive individuals, but may be more related to differences in regional LM and specific strength training programs.

Body Fat Differences Between Skinfold, Impedance, And Dexa Measurements

Donna J. Terbizan, FACSM[1], Shannon David[1], Kyle J. Hackney[1], Sherri Stastny[1], Elizabeth Hilliard[1], Bryan Christensen[1], Yeong Rhee[1], Steven Mitchell[2]. [1]*North Dakota State University, Fargo, ND.* [2]*North Dakota State University and Sanford Health, Fargo, ND.*

(No relevant relationships reported)

Measurement of body fat can be performed using two, three, and four compartment models. Determining which technique to use in different populations is still being debated based on reliability, validity, ease of use, and subject safety. **PURPOSE:** To determine the differences between percent body fat measured by Dual X-ray Absorptiometry (DEXA), leg-to leg bioelectrical impedance, and 7-site skinfold techniques in college age students. **METHODS:** Students were recruited from undergraduate exercise science and dietetics classes, and graduate athletic training, exercise science, and nutrition classes. Sixty-one students (M age 21.7 ± 2.5 y, M wt. 71.1 ± 14.9 kg) (43 females (M age 21.3 ± 2.5y, M wt. 67.1 ± 13.4 kg), 18 males (M age 22.4 ± 2.2 y, M wt. 80.7 ± 14.3 kg) provided informed consent and completed the DEXA Screening Questionnaire, then had their body composition measured by the three different techniques. Subjects were asked to dress in t-shirts and shorts, and on the day of the appointment to do no vigorous physical activity, take no vitamin or mineral supplement, be well hydrated, not to eat 4-5 hours prior or consume alcohol or caffeine 24 hours prior. Females were screened for pregnancy. Once height and weight were measured, a 7-site skinfold measurement, a leg-to-leg electrical impedance measurement, and a whole body DEXA scan were performed. Comparisons between the techniques were done using repeated measures ANOVA, with Fisher's least significant differences post hoc test to determine differences. Significance was noted if $p<0.05$. **RESULTS:** Significant differences in percent body fat were noted between the three techniques ($p<0.0001$). DEXA ($26.7 \pm 7.5\%$) was significantly greater ($p<0.0001$) than both impedance ($24.9 \pm 7.5\%$) and skinfolds ($20.1 \pm 6.9\%$). Impedance was significantly greater ($p<0.0001$) than skinfolds and significantly lower ($p<0.0001$) than DEXA. Skinfolds were significantly lower ($p<0.0001$) than both DEXA and impedance. **CONCLUSION**: With the significant differences noted, care should be used when measuring and interpreting body fat composition.

Characterization Of Fat-free Mass Index And Body Fat Mass Index: Relationship To Strength Performance In Resistance-trained Females

Alexis A. Pihoker, Eric T. Trexler, Austin M. Peterjohn, Gregory L. Nuckols, Malia N.M. Blue, Katie R. Hirsch, Kara C. Anderson, Abbie E. Smith-Ryan, FACSM. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)

(No relevant relationships reported)

Fat free mass index (FFMI) and body fat mass index (BFMI) are valuable tools to compare body composition in individuals that differ in height. Currently there are no published ranges for FFMI or BFMI in trained females. **PURPOSE**: To characterize FFMI and BFMI in resistance trained females. A secondary aim evaluated the relationship between FFMI, BFMI, and lean mass (LM) with strength performance in females with normal, overweight, and obese body mass index (BMI). **METHODS**: Forty-seven resistance-trained females (Mean $\pm$ SD; Age: 20.4 ± 2.2 yrs; Height: 165.4 ± 6.0 cm; Weight: 66.7 ± 11.0 kg) participated in the study. Body composition was determined using dual energy X-ray absorptiometry (DEXA) and used to calculate FFMI. FFMI (kg/m^2) was calculated by dividing the sum of lean mass (kg) and bone mineral content (kg) by height (m) squared. BFMI (kg/m^2) was calculated by dividing fat mass (kg) by height (m) squared. Performance was evaluated by one repetition maximum testing on the leg and bench press (LP1RM and BP1RM, respectively). Participants were stratified by BMI classification (normal (18.5-25 kg/m^2), overweight (25-30 kg/m^2), and obese (>30 kg/m^2)). **RESULTS**: Average FFMI in this sample was 16.7 ± 2.2 kg/m^2, with a range of 13.3-25.5 kg/m^2. Average BFMI was 7.5 ± 2.2 kg/m^2, with a range of 4.8-15.2 kg/m^2. In females with a normal BMI (n=33), FFMI and LM were both significantly correlated with LP1RM (R=0.873, p<0.001; R=0.779, p<0.001) and BP1RM (R=0.838, p<0.001, and R=0.791, p<0.001), respectively. For the overweight cohort (n=9), FFMI and LM were significantly correlated with LP1RM

(R=0.730, p=0.025; R=0.747, p=0.021) and BP1RM (R=0.883, p=0.002; R=0.757, p=0.018). In the obese cohort (n=5), FFMI neared significance for both LP1RM (R=0.846, p=0.071) and BP1RM (R=0.862, p=0.060); LM was not significantly correlated with LP1RM (R=0.845; p=0.072) or BP1RM (R=0.666, p=0.219). BFMI was not significantly related to performance for any BMI cohort (p>0.05). **CONCLUSIONS**: FFMI may be an adequate predictor of strength performance across all BMI ranges. LM was also significantly correlated with performance in both normal and overweight BMI cohorts, indicating that height may not be a moderating factor in this population.

Body Composition Varies by Position in Female NCAA Division 1 Lacrosse Players

Jessica S. Siplon, James M. Smoliga, FACSM. *High Point University, High Point, NC.*

(No relevant relationships reported)

There is limited scientific literature on women's lacrosse players, especially for body composition measurements. Understanding the relationship between body fat percentages and player position can benefit both the team and individual players. **PURPOSE**: To determine if body composition in female NCAA Division I lacrosse players differs between player position. **METHODS**: 58 female NCAA D1 lacrosse players underwent whole body DEXA scans. Height and body mass of each player were measured on a stadiometer before each scan. A linear mixed effects model was used to determine whether body fat percentage differed by player position. Position was entered as a fixed factor, and height and body mass were included as covariates into the full factorial model **RESULTS**: The final model demonstrated significant main effects for position (p=0.015), body mass (p=0.001), height (p=0.001), and the interaction between position and body mass (p=0.009). Post-hoc analyses revealed attack ($30.8 \pm 4.2\%$) had significantly greater body fat than defense ($29.8 \pm 3.3\%$, p=0.021) and midfield ($28.5 \pm 3.9\%$, p=0.045). There were no other statistically significant differences in body between positions. Attack (61.8 ± 7.7 kg) had a statically significant lower body mass than goalies (76.0 ± 4.1kg, p=0.012). Midfielders (60.4 ± 14.8kg) had a significantly lower body mass than defense (67.3 ± 6.2kg, p=0.044) and goalies (p=0.007). **CONCLUSIONS**: Positions differed in mean body composition, with the attack position having the greatest body fat percentage. Body mass was also significantly different by position. It was unexpected that the attack position had a greater body fat percentage, despite having one of the lower mean weights (although only statistically less than goalies). There were few data points for goalies (n=4), which may have limited statistical power. It is a limitation that these data are from one university team across multiple seasons. The style of play for this team influences aerobic demand and may differ from that of other teams. Because there is limited data on body composition in women's lacrosse, further comparisons across other teams is needed.

Does the Body Composition of Collegiate Male Lacrosse Players Differ by Position?

Abigail Goldburt, James M. Smoliga, FACSM. *High Point University, High Point, NC.*

(No relevant relationships reported)

There are distinct roles for each playing position in men's lacrosse, which often results in apparent anthropometric differences between playing positions. However, little research has examined whether body composition, namely body fat percentage, differs by playing position. **PURPOSE**: To determine whether or not the body composition of collegiate male lacrosse players differs across playing positions. **METHODS**: 71 NCAA Division I competitive male lacrosse players (age 18-23y) participated in the study. Athletes underwent a whole body dual energy x-ray absorptiometry (DEXA) scan to measure whole body lean and fat mass. Total body fat percentage was then computed. A linear mixed effects model was used to determine whether body fat percentage differed by playing position. Playing position was entered as a fixed factor, and height and body mass were included as covariates into the full factorial model. **RESULTS**: Mean $\pm$ standard deviations were: height 180.5 ± 6.6cm, body mass 84.3 ± 8.2kg, and body fat percentage $18.2 \pm 3.5\%$. Body fat percentage did not differ by position (main effect: p=0.318; attack: $18.9 \pm 4.4\%$, midfield: $18.2 \pm 3.7\%$, defense: $18.3 \pm 2.8\%$, goal: $17.0 \pm 2.5\%$). However, body fat percentage was dependent upon height (p<0.001) and body mass (p<0.001). Further analysis revealed no significant differences across playing positions for height (p=0.087; attack: 177.3 ± 3.9cm, midfield: 180.2 ± 6.6cm, defense: 183.4 ± 6.8cm, goal: 179.4 ± 6.9cm) or total body mass (p=0.072; attack: 79.6 ± 8.2kg, midfield: 85.0 ± 8.5kg, defense: 86.9 ± 6.6kg, goal: 81.2 ± 8.0kg). **CONCLUSIONS**: Although not statistically significant, there were trends for height and body mass to differ between positions. It is possible that there was insufficient

statistical power to detect position-specific differences between these parameters. This data might be slightly skewed because the sample included more midfielders (n=34) than attack (n=11), defense (n=19), or goal (n=7) players. Nonetheless, no clear position-specific trends were observed for body fat percentage. However, statistically significant covariates indicate that heavier and shorter players tended to have greater body fat percentages. Further research is needed to determine if body composition differs between lacrosse players across a larger cohort from multiple teams.

Effects of an Acute Strength and Conditioning Bout on Dual Energy X-ray Absorptiometry Results

Jason R. Lytle, Steve E. Martin, John S. Green, FACSM, Stephen F. Crouse, FACSM. *Texas A&M, College Station, TX.*
(Sponsor: Stephen F. Crouse, FACSM)
(No relevant relationships reported)

Dual Energy X-ray Absorptiometry (DXA) scans to assess body composition have become increasingly popular, especially in athletic populations. Acute factors, such as hydration status and food intake have been shown to alter DXA results (Tinsley, MSSE 2016). It is currently not known if prior strength and conditioning bouts may alter fat mass, lean mass, and bone density results. **PURPOSE:** To determine if a strength and conditioning (S&C) bout, similar to what athletes regularly engage in, will alter the fat mass, lean mass, and bone content results of a DXA scan. **METHODS:** Fourteen strength-trained subjects (10 men, 4 women, age 24 ± 2 yrs, height 176.7 ± 8.1 cm, weight 88.8 ± 14.7 kg) who were enrolled in an athletic strength and conditioning course volunteered to participate in this study. Each subject underwent two DXA scans on the same day. The first scan was performed prior to the S&C bout. The second scan was completed within 45 minutes after completion of the S&C bout. Participants were instructed to consume their normal, free living breakfast prior to scan one. A food and water log was distributed during the informed consent process and was maintained by the participants for 24 hours prior to all DXA scans. Nutritional information was analyzed via a commercial nutrition software for macronutrients, micronutrients, and hydration status. All DXA scans were performed and analyzed by the same trained technician. After the first scan, subjects were instructed to avoid all food intake until completion of the second scan. Subjects were encouraged to drink water ad libitum during the S&C bout from individually assigned 1-liter bottles; the volume consumed during the bout was measured by weight. **RESULTS:** No significant difference was found (correlated t-test $\alpha = 0.05$) on any of the body composition measures between pre and post DXA body composition measurements after a S&C bout (changes pre to post: fat mass 46.5-46.0 kg, lean mass 64.8-64.9 kg, bone content 3.3-3.3 kg). **CONCLUSION:** Based on the results of the present study, S&C bouts do not need to be considered to ensure accuracy when performing DXA scans. The physiological changes that occur in response to a single S&C bout do not affect body composition analysis of DXA scans.

The Effect of Pretest Instructions and Between Day Test-Retest Reliability of Air Displacement Plethysmography

Emily Dunston, Shelby Chriest, Sayer Avena, Katrina Taylor, Annika Vahk. *Eastern Washington University, Cheney, WA.*
(Sponsor: Wendy Repovich, FACSM)
(No relevant relationships reported)

Air displacement plethysmography (ADP) is considered a valid estimate of body composition. However, pretest instructions are often not followed by the general population which is imperative for tracking body composition via multiple testing sessions. **PURPOSE**: To determine the reliability of ADP measurements with and without pretest instructions both between days and on the same day. **METHODS**: Participants (n=19; 14 females, 5 males, age 20.8±1.4 years, weight 69.2±12.5 kg) completed four testing sessions across two days. ADP testing on day one occurred in the morning (T1) and afternoon (T2) and 48-hours later another morning (T3) and afternoon (T4) test were completed. For T1, participants were not provided with pretest instructions and were asked to maintain normal activities. Standard pretest instructions were provided for all subsequent visits. At each session, a standard ADP measurement was completed with participants wearing manufacturer-approved clothing and lab-issued swim cap. Data were analyzed using paired samples t-tests to determine the effect of pretest instructions and Pearson correlations to determine test-retest reliability with an alpha level set at 0.05. **RESULTS**: Pretest instructions did not change body volume (BV; T1 66.3±12.4 vs. T2 66.2±12.4 L; p=0.33) or body fat (BF; T1 23.4±6.9 vs. T2 23.6±7.1 %; p=0.54) across same day measures. However, differences were detected for BV (T1 66.3±12.4 vs. T3 65.7±12.2 L; p<0.01) and BF (T1 23.4±6.9 vs. T3 22.7±7.3%; p=0.04) for measures completed on different days. Test-retest reliability for BV and BF was high across different days (r≥0.97, p<0.01). **CONCLUSIONS**: Pretest instructions did not change ADP measures on the same day, suggesting they may not be necessary to attain measurements within standard error of

estimate for ADP. However, differences were found between scores across different days, although these were also within ADP standard error. Between day test-retest reliability was high for BV measurements and BF estimations, with greater variability noted in BF. Future research would be important to ascertain how varying amounts of food and fluid consumption, as well as participation in exercise prior to testing can affect the reliability of ADP measures. Quantifying these factors may provide insight on threshold measures to follow.

Relationship Between Sarcopenia Classification Methods, Relative Fat Mass, and Skeletal Muscle Mass

Kassi Meacham, A. Page Glave, John P. Yakel, Mary L. Williams, Jennifer J. Didier. *Sam Houston State University, Huntsville, TX.*
(No relevant relationships reported)

Sarcopenia has been identified using muscle mass normalized by height squared (SMIh), similar to BMI, and by total mass(SMIm). As there is not a single agreed-upon definition, it is important to examine the relationships between the various methods of defining sarcopenia, body fat percentage (BFP), and skeletal muscle mass (SMM). **PURPOSE:** The purpose of this study was to examine the relationships between skeletal muscle index (SMI) normalized for SMIh, SMIm, BFP, and SMM. **METHODS:** Participants (n = 62, 42 F, 20 M; 26.4 +/- 8.3 yrs) were tested using bioelectrical impedance analysis (BIA). The BIA provided information on fat mass, fat-free mass, BFP, and SMM. Skeletal muscle mass index (SMI) was calculated by dividing SMM (kg) by height squared (m^2) (SMIh) and by dividing SMM (kg) by total mass (kg) (SMIm). Data were analyzed using standard spreadsheet and statistical analysis software. Pearson product-moment correlations were calculated using statistical analysis software. Significance was set at $p < .01$ to control for the number of tests. **RESULTS:** There were significant correlations between SMIm and SMIh ($r = 0.49$, $p = 0.00$), SMIm and BFP ($r = -0.93$, $p = 0.00$), SMM and SMIm ($r = 0.50$, $p = 0.00$), SMM and SMIh ($r= 0.95$, $p = 0.00$). The correlation between SMIh and BFP was not significant ($r = -0.20$, $p = .11$). **CONCLUSIONS:** It is important to look at both muscle mass and body fat. Both methods of identifying sarcopenia should be used as using a single method gives an incomplete picture. Ideally body fat percentage and both methods of determining sarcopenia would be used to account for individuals of differing leanness.

A Comparison Of Methods Used To Determine Percent Body Fat And Minimum Wrestling Weight

Paul T. Cutrufello[1], Andrew C. Venezia[1], Michael J. Landram[1], Curt B. Dixon, FACSM[2]. *[1]The University of Scranton, Scranton, PA. [2]Lock Haven University, Lock Haven, PA.*
(No relevant relationships reported)

The accurate measurement of percent body fat (%BF) is important in the determination of a wrestler's minimum wrestling weight (MWW) under the National Collegiate Athletic Association (NCAA) Wrestling Weight Management Program (WMP). Currently, skinfold measurements (SF), air displacement plethysmography (ADP), and hydrostatic weighing are the only approved methods of assessing body composition for the WMP. While dual energy x-ray absorptiometry (DXA) is considered a criterion method and type-A ultrasound (US) may serve as an alternative method, to our knowledge, no previous study has examined DXA or US in the determination of a wrestler's MWW. **PURPOSE**: To compare %BF and MWW determined using SF, ADP, US, and DXA. **METHODS**: Twenty-three college-aged men (21.1±0.8 yrs) participated. As per NCAA WMP guidelines, participants reported to the lab in a euhydrated state (Urine specific gravity/Usg<1.020). %BF was estimated using SF, ADP, DXA, and US and the wrestlers' MWW was calculated for each assessment method. **RESULTS**: Body mass and Usg values were 83.2±13.2 kg and 1.005 ± 0.004, respectively. There was a significant difference between methods for both %BF (p<0.001) and MWW (p<0.001). %BF values (SF=15.7±5.2%; ADP=18.1±6.4%; DXA=21.2±6.2%; US=15.2±5.2%) and MWW (SF=73.3±8.4kg; ADP=71.1±7.5kg; DXA=68.5±8.2kg; US=73.8±8.9kg) were significantly different between all methods except SF and US (p=0.594 and p=0.586, respectively). When comparing the MWW determined by DXA to those determined by SF, the use of DXA would have allowed 57% of participants to reach one weight class lower and an additional 30% of participants to reach two weight classes lower. Compared to ADP, DXA would have allowed 48% of participants to reach one weight class lower and an additional 9% of participants to reach two weight classes lower. **CONCLUSION:** These data indicate that US may provide an alternative to the SF procedure when determining the MWW of a wrestler. However, when compared with two WMP-approved methods of assessment, DXA would permit approximately 57% (ADP) to 87% (SF) of wrestlers the opportunity to certify at a lower weight class. Given these preliminary

findings, future research should further examine if the currently approved methods of assessment during the NCAA WMP put a wrestler at a disadvantage by restricting weight loss.

Comparison of Methods Assessing Body Composition in Young Adults

Maura L. Jegerski, Baruch Vainshelboim, Gabrielle M. Brennan, Henry Piascik, Sara D. Dieterich, Patricia Fitzgerald, Stephen LoRusso, Kristofer S. Wisniewski. *Saint Francis University, Loretto, PA.*

(No relevant relationships reported)

Maura L. Jegerski, Baruch Vainshelboim, Gabrielle M. Brennan, Henry Piascik, Sara D. Dieterich, Patricia Fitzgerald, Stephen LoRusso, Kristofer S. Wisniewski, Saint Francis University, Loretto, PA.
Previous studies have shown that bioelectrical impedance analysis (BIA) is a simple and reliable noninvasive way to measure body composition. However, the results differ in accuracy compared to other methods. **Purpose:** To compare the validity of different BIA devices against the Bod Pod (BP) for estimating percent body fat (%BF) and lean body mass (LBM) in young adults. **Methods:** Eighty-seven subjects (45 males, 42 females) aged 20.3 ± 1.6 years with BMI 25.1 ± 5.2 kg m^{-2} were assessed for %BF and LBM using BodPod, Tanita TBF-300A [both Athletic (TA) and Standard (TS) modes], and InBody770 (InB) in counterbalanced order in one session. Subjects followed the most stringent pre-testing instructions outlined for the InB. Pearson's correlations and Repeated measures ANOVAs were utilized. **Results:** Results for each method (mean ± SD) and correlations are displayed in Table 1. ANOVA showed TA significantly underestimated (p<0.001), and TS significantly overestimated (p<0.001) %BF compared to BP. There was no significant difference between BP and InB (p=0.701) %BF. ANOVA showed TA significantly overestimated (p<0.001) LBM, and the LBM from TS (p=0.197) and InB (p=0.825) were not significantly different from BP. **Conclusions:** The results show that each method is strongly correlated with the BP. However, there were significant differences between Tanita scale values and the BP. Therefore, BIA devices using both hand and feet sensors and multiple frequencies may be more accurate at estimating body composition than devices using feet and one frequency only.

	%BF	Correlation with BP (%BF)	LBM (kg)	Correlation with BP (LBM)
BP	21.1 ± 11.3		59.8 ± 14.2	
TA	18.3 ± 9.9	r=0.922, p<0.001	62.6 ± 14.8	r=0.928, p<0.001
TS	22.5 ± 9.3	r=0.925, p<0.001	59.0 ± 12.9	r=0.921, p<0.001
InB	21.3 ± 10.9	r=0.932, p<0.001	59.9 ± 14.4	r=0.956, p<0.001

Table 1. Comparison of Body Composition Methods

Lifestyle Behaviors and Body Composition in Young Adults

Stephen LoRusso, Gabrielle M. Brennan, Henry Piascik Piascik, Sara D. Dieterich, Maura L. Jegerski, Kristofer S. Wisniewski, Baruch Vainshelboim, Patricia I. Fitzgerald. *Saint Francis University, Loretto, PA.*

(No relevant relationships reported)

Physical inactivity, prolonged sitting and poor body composition are established cardio- metabolic risk factors. However, their association in young adults has not been well characterized. **PURPOSE:** To assess the association between physical activity, sitting time and body composition in young adults. **METHODS:** Ninety-four participants (20.2 ± 1.6 years, 46 men, 48 women) were assessed for weekly physical activity (PA), average daily sitting time (Global Physical Activity Questionnaire) (ST) and body composition measurements (BodPod). Pearson correlation and t-tests were performed. **RESULTS:** Means are: ST (M: 5.7 ± 2.7 hours/day, F: 6.8 ± 2.8 hours/day, p=0.059), PA (M: 10,977.6 ± 11,068.3 MET-min/week, F: 7,181.9 ± 4,481 MET-min/week, p=0.043), %Fat (M: 15.2 ± 9.2 %, F: 27.4 ± 9.9 %, p=0.000), and LBM (M: 69.9 ± 10.5 kg, F: 47.7 ± 5.7 kg, p=0.000). Sitting time was mildly correlated with body composition measurements, but not with PA in the total sample (Table 1). In subgroup analysis of men and women separately, the correlation between ST and LBM and %Fat were significant only among women (LBM: r=-0.478, p=0.001, %Fat: r=0.309, p=0.047). PA mildly correlated with LBM, but not with %Fat. No correlation between physical activity and body composition measurements was observed in the subgroup analysis. **CONCLUSION:** Prolonged sitting time is associated with higher %Fat and lower LBM in young women, suggesting a negative impact on body composition. Higher physical activity levels are associated with higher LBM in both genders, but were not associated with ST or %Fat. These results support the independent association between physical activity, sitting time and body composition, and their importance in evaluation of lifestyle behaviors for primary cardio-metabolic disease prevention.

Table 1.

	Sitting Time (hours/day)	Lean Body Mass (kg)	%Fat	Physical Activity (MET-min/week)
Sitting Time (hours/day)	1	r= -0.300 p= 0.006*	r= 0.310 p= 0.005*	r= -0.033 p= 0.767
LBM (kg)	r= -0.300 p= 0.006*	1	r= -0.365 p= 0.001*	r= 0.276 p= 0.011*
%Fat	r= 0.310 p= 0.005*	r= -0.365 p= 0.001*	1	r= -0.162 p= 0.143
Physical Activity (MET-min/week)	r= -0.033 p= 0.767	r= 0.276 p= 0.011*	r= -0.162 p= 0.143	1

Validation Of The Inbody 770 For The Assessment Of Percent Body Fat In Young Adults

Joseph L. Andreacci, FACSM[1], Vncenzo Nocera[1], Chelsea Wenrich[1], Andrea J. Fradkin, FACSM[1], Curt B. Dixon, FACSM[2]. *[1]Bloomsburg University, Bloomsburg, PA. [2]Lock Haven University, Lock Haven, PA.*

(No relevant relationships reported)

Multi-frequency bioelectrical impedance analysis (MFBIA) is a rapid, non-invasive, and relatively inexpensive method of assessing body composition that has been suggested as an alternative to laboratory methods including dual energy X-ray absorptiometry (DXA) and hydrostatic weighing. **PURPOSE**: To determine the accuracy of a commercially-available MFBIA analyzer for the assessment of percent body fat (%BF) in young adults.
METHODS: Three hundred eighty-four (209 women; 175 men) subjects volunteered to participate in this study (age = 20.8 ± 2.1 years). %BF was assessed using MFBIA (InBody 770, Biospace Co.) and DXA (GE Lunar Prodigy) within the same visit. **RESULTS**: When compared to DXA, MFBIA significantly (p<0.001) underestimated %BF (men = 16.8 ± 6.5% *vs.* 19.4 ± 8.0%; women= 28.8 ± 7.8% *vs.* 32.7 ± 8.3%). Linear regression analyses revealed significant correlations (men = 0.92, women = 0.93; *p*<0.001) and standard error of estimate values (men = 3.2%; women = 3.1%) rated as 'very good' between methods. However, Bland-Altman plots revealed a weak bias for %BF (*r* = 0.36, *p*<0.001) and a large percentage of the subjects (women = 53%, men = 41%) were outside the ± 3.5% minimally acceptable standard for accuracy. **CONCLUSIONS**: When compared to DXA, the InBody 770 underestimated %BF by greater than 3.5% in approximately half of the subjects tested in this study. Given this consistent underestimation, we recommend interpreting the %BF values produced by the InBody 770 with caution.

Association between Segmental Lean Body Mass and Muscular Strength

Joshua D. Graham. *Saint Francis University, Loretto, PA.*

(No relevant relationships reported)

Previous studies have shown lean body mass (LBM) is positively correlated with muscle strength in older and younger individuals. Studies have also shown a strong correlation between grip strength when muscle mass is adjusted for height. However, previous studies have not looked into young adults. **Purpose:** The purpose of this study was to examine the relationship between segmental LBM and various measures of muscular strength in healthy young adults. **Methods:** 48 subjects (23 females, 25 males) aged 20.4 ± 1.9 years underwent bioelectrical impedance analysis using the InBody770 to determine total LBM, legs LBM (sum of both legs), right arm LBM, left arm LBM, and arms LBM (sum of both arms). Strength tests included 1RM bench press, 1RM leg press, maximal voluntary contraction (MVC) handgrip, and MVC deadlift. Standard 1RM protocols were used to assess 1RM for bench press and leg press. Maximal handgrip scores were measured for each arm independently and added together for the summed handgrip strength. MVC deadlift was measured using a Baseline Back, Legs, and Chest Dynamometer. **Results:** Correlation analyses showed a moderate correlation between total LBM and MVC deadlift (r = 0.557, p < 0.001), legs LBM and 1RM leg press (r = 0.520, p < 0.001), right arm LBM and right handgrip strength (r = 0.428, p < 0.001), left arm LBM and left arm handgrip strength (r = 0.425, p < 0.001), and arms LBM and summed handgrip strength (r = 0.441, p < 0.001). A

strong correlation was observed between arms LBM and 1RM bench press (r = 0.763, p < 0.001). **Conclusion:** **S**egmental LBM assessed using the InBody770 showed a moderate-to-strong correlation with various measures of muscular strength. The findings suggest segmental LBM may play a significant role in overall body strength and arm LBM may have a significant role in 1RM bench press.

767 Board #28 May 30 2:00 PM - 3:30 PM

Alphabet Soup: BMI, WC, ADP - What Measures Provide Adequate Estimates Of Obesity In Aging Adults?

Amy L. Morgan, FACSM[1], Mary-Jon Ludy[1], Edward T. Kelley[1], Sarah G. Kearney[1], Matt Laurent[2]. *[1]Bowling Green State University, Bowling Green, OH. [2]Tarleton State University, Stephenville, TX.*

(No relevant relationships reported)

It is well accepted that body fat increases with aging, and that obesity contributes to a number of negative health concerns. Clinically, body mass index (BMI) and waist circumference (WC) are the preferred measures for a quick estimate of adiposity, but it is not clear if these measures are accurate estimates in aging individuals. **PURPOSE:** The purpose was to investigate if BMI or waist circumference (WC) are adequate measures of adiposity in those aged 50 and older. **METHODS:** Participants were 38 men (60±7.7 years) and 62 women (57±7.3 years) who reported to the laboratory on one occasion. BMI was calculated using height and weight (kg/m²). WC was measured using a Gulick tape at two anatomical points; narrowest waist (WCN) and the umbilicus (WCU). Percent fat was analyzed via air-displacement plethysmography (ADP; Bod Pod, COSMED) and bioelectrical impedance (BIA; InBody 230, Biospace Inc). ADP was used as the criterion measure of body composition. Correlations were calculated to examine relationships between all measures (of weight related health risk and body composition). Sensitivity and specificity analyses were conducted to classify participants into categories (true positive, true negative, false positive, and false negative) to assess if WC and BMI provide correct categorization when compared to body composition by ADP. **RESULTS:** Correlations indicated moderate to strong relationships between ADP and WCN (r=0.408), WCU (r=0.527), BMI (r=0.565), and BIA (r=0.888, p<0.05 for all). For the measures of WC, sensitivity was considerably higher for WCU (All=70%, W=86.2%, M=47.6%) than WCN (All=46% all, W=58.6%, M=28.6%). For BMI, sensitivity was slightly higher in women (86.2%) than men (81.0%). **CONCLUSION:** These results suggest that, in addition to being easy to measure in the clinical setting, BMI and WC are also adequate indicators of obesity in adults aged 50 and over. Training and standardization of WC measurement techniques are warranted, since WCU was more strongly correlated with ADP than WCN, suggesting that the optimal site for WC measurement is the umbilicus.

---

768 Board #29 May 30 2:00 PM - 3:30 PM

Validity of Ultrasound and Skinfolds for the Measurement of Body Composition in Collegiate Basketball Players

Jeremy T. Barnes[1], Jason D. Wagganer[1], Jeremy P. Loenneke[2], William M. Miller[2]. *[1]Southeast Missouri State University, Cape Girardeau, MO. [2]University of Mississippi, University, MS.*

(No relevant relationships reported)

Body composition (BC) is a frequently assessed component of health-related fitness. Many different field methods are used to measure BC including bioelectrical impedance analysis and skinfolds (SKF). Recently, a portable computer based ultrasound (US) system has become commercially available for estimating BC. **PURPOSE:** The purpose of this study was to determine the validity of a portable computer based US system and skinfolds (SKF) for estimating percent body fat (%fat) in male collegiate basketball players. **METHODS:** Participants' %fat was estimated using US (3 site) and SKF (3 site), then compared to dual-energy X-ray absorptiometry (DXA), which served as the criterion estimate. Participants were 50 male collegiate basketball players [age = 20 (1) yrs., height = 1.89 (0.08) m., body mass = 87.9 (10.9) kg, and BMI = 24.5 (2.3) kg/m²]. The ethnicity of the participants was 41 African Americans and 9 Caucasians. All participants were tested in the hydrated state [1.014 (0.009), Urine Specific Gravity]. The validity of the US and SKF %fat estimates was based on the evaluation of each method versus the criterion value from the DXA by calculating the mean, SD, coefficient of determination (r²), and standard error of estimate (SEE) from linear regression analysis. To assess the average deviation of individual scores from the line of identity, total error (TE) was calculated for each field method. Paired sample t-tests determined pair-wise differences between measurements using an alpha level of <0.05. **RESULTS:** The mean %fat results were as follows: US = 12.5 (4.0), SKF = 9.2 (4.5) and the DXA = 12.5 (5.1). %fat differences [mean (95% CI)] were observed between DXA and SKF [3.3 (2.5, 4.1), p=0.001] but not between DXA and US [-0.04 (-1.4, 1.4), p=0.951]. The r² values were 0.159 for US and 0.699 for SKF; SEE values for %fat were 4.7 for US and 2.8 for SKF; and total error (TE) values for %fat were 5.03 for US and 4.36 for SKF. **CONCLUSIONS:** In this study, neither the US nor SKF estimates provided a valid assessment of %fat. When

compared to the criterion (DXA), both SKF and US produced TE values outside of the acceptable range of 4%. Relative to the DXA, neither estimate can be recommended for estimating %fat in collegiate basketball players.

769 Board #30 May 30 2:00 PM - 3:30 PM

Efficacy Of Ketogenic Diet On Body Composition During Resistance Training In Trained Men.

Vargas Salvador[1], Ramón Romance[2], Jorge L. Petro[3], Diego A. Bonilla[4], Ismeal Galancho[5], Sergio Espinar[6], Rick B. Kreider, FACSM[7], Javier Benitez-Porres[2]. *[1]EADE-University of Wales, Málaga, Spain. [2]University of Malaga, Málaga, Spain. [3]University of Córdoba, Málaga, Spain. [4]University, Bogotá, Bogota, Colombia. [5]Better by Science, Málaga, Spain. [6]BetterbyScience, Málaga, Spain. [7]Texas A & M University, Málaga, Spain.* (Sponsor: Richard Bruce Kreider, FACSM)

(No relevant relationships reported)

Nowadays, ketogenic diet (KD) is widely used in body aesthetics for changing body composition, even though there is a lack of research regarding to the possible benefits on muscle hypertrophy.**PURPOSE**: The purpose of this study was to evaluate the efficacy of an 8-week KD during energy surplus and a resistance training protocol on muscle hypertrophy in trained men. **METHODS**: 24 healthy men (age 30 ± 4.7 years; weight 76.7 ± 8.2 kg; height 174.3 ± 19.7 cm; > 2 years of consecutive training experience) performed an 8-week resistance training (RT) program with similar hypertrophy training variables. Participants were randomly assigned to either a KD (10:20:70, n=9), or a non-ketogenic diet (55:20:25, n=10, NKD), or a control group (n=5, CG) in hypercaloric condition (39 kcal · kg⁻¹ · d⁻¹). Body composition changes were measured by dual energy X-ray absorptiometry (DXA) before and after each nutritional intervention and training program in all participants. Compliance with the ketosis state was monitored by measuring urinary ketones weekly. Statistical evaluations to determine significant differences between groups and substantive significance were performed with paired t-test, where critical α was $p<0.05$, and Cohen's d effect size (ES), respectively. **RESULTS**: There was a significant reduction in fat mass (Δ= -10.4%, p =0.030, ES = 0.46) and abdominal visceral adiposity in KD (Δ= -16.3%, p =0.008; ES = 0.84); while no significant changes were observed in the NKD and CG groups. Muscle mass significantly increased after 8 weeks of RT program in the NKD group only (Δ=+2.1%, p <0.01, ES = 0.31). **CONCLUSIONS**: Our results suggest that KD can be helpful for decreasing abdominal visceral adiposity and fat mass, but not to increase muscle mass during positive energy balance in men undergoing RT. This study shows the relevance of macronutrient manipulation in RT programs, in order to improve body composition parameters focusing on training goals (fat reduction and/or increase of muscle mass) in trained men. Supported by University of Málaga (Campus of International Excellence Andalucía Tech).

Bioelectrical Impedance Analysis Versus Dual-Energy X-ray Absorptiometry Body Fat Percentage Measurements in Collegiate Basketball Players

Michelle L. Otte. *Southeast Missouri State University, Cape Girardeau, MO.* (Sponsor: Joe Pujol, FACSM)

(No relevant relationships reported)

Body composition (BC) is an important component of health-related fitness and is also related to athletic performance. There are many quick, cost efficient, accessible, and user-friendly ways to assess BC. Field measurement methods, including body mass index, waist circumference, skinfolds, and bioelectrical impedance analysis (BIA). Criterion methods for measuring BC, which are more expensive and generally less accessible, include techniques like dual-energy X-ray absorptiometry (DXA). DXA is commonly used to assess body fat percentage (BF%) (i.e., fat vs. lean mass) in clinical settings due to its standard deviation (±2-4%). The manufacturer of the Direct Segmental Multi-frequency InBody230 BIA, which uses eight separate contact points with two electrical frequencies, claims a similar BF% accuracy range to DXA. **PURPOSE:** To assess the reliability of the InBody230 BIA to DXA BF% values in college-aged, male basketball players. **METHODS:** Participants were 72 male collegiate basketball players (age=20.51±1.32 yr; wt=89.35±10.68 kg; ht=183.96±5.97 cm; BMI=27.50±3.02 kg/m²). The participants had BF% assessed, in the early morning, using the InBody230 BIA in the standing position followed by a total-body DXA scan which served as the criterion value. **RESULTS:** A paired samples t test revealed a significant difference in BF% between the InBody230 (31.22±14.64) and DXA (20.55±6.13) (p<0.001). **CONCLUSIONS:** While the two modes of BF% were significantly different, the standard deviation (SD) (i.e., reliability) of the InBody230 BIA was more than double the DXA. This SD difference is supported by past research using athletes of similar age and BMI. However, research finding significant differences between modes with lower SD values have utilized varying sample sizes of non-athletes, including both genders and children. Future research needs to be conducted comparing the InBody230 BIA to DXA using various populations to assess the InBody230 manufacturer accuracy claim of (98±3-5%).

771   Board #32   May 30 2:00 PM - 3:30 PM

Anthropometric and Performance Statistics Comparisons in Baseball Batters: A Longitudinal Study

Vishak Vinod[1], Thejasvi Reddy Anantasagar[2], Richard A. Karasch[2], James G. Disch[2], Zacharias Papadakis[2]. *[1]University of Houston, Houston, TX. [2]Rice University, Houston, TX.* (Sponsor: Peter W. Grandjean, FACSM)
(No relevant relationships reported)

Appropriate stature and adequate somatotype is believed to be some of the most important prerequisites for sports participation and success. In baseball, there is scarce evidence on players' anthropometric profiles, such as body weight (BW), body height (BH), and body fat % (BF%) and their association with baseball performance statistics (PS) which has led to form anecdotally based beliefs. **PURPOSE**: To compare BW, BH, and BF% and selected baseball-specific PS, such as batting average % (b/avg%), slugging % (slg%), and on-base % (ob%) in NCAA Division I batters; to examine the relationship between BW, BH, BF% and baseball-specific PS. **METHODS:** During a 5-year period, 232 collegiate batters (age 19.7 ± 1.3 yr; weight 87.9 ± 7.7 kg) were assessed for body weight (BW), body height (BH), and body fat % (BF%). Batters' respective specific-baseball PS were collected with regards to b/avg%, slg%, ob%. BW, BH, BF%, and PS were normalized to z-scores. Missing data were estimated from least squares prediction from non-missing variables. Forward multiple stepwise regression was used to evaluate the relative impact of BW, BH, and BF% on PS (JMP® Pro 13). **RESULTS:** From the selected anthropometric variables, only BF% is significantly negative correlated with both b/avg% (r=-0.19, p=0.0043) and slg% (r=-0.17, p=0.0103). Slg% was selected as the independent variable with the highest goodness of fit significantly correlating with BF% (p=0.0007) and BW (p=0.0151) with adjusted R^2=0.04. **CONCLUSIONS:** The results indicate that leaner batters have higher b/avg% and slg%. BF% and BW appeared to provide the greatest predictive power of slg%. Slg% is a measure of the batting productivity of a hitter and only 4% of this productivity can be explained by anthropometric variables, such as BF% and BW. The common anecdotal belief that heavier players are better batters, no matter their motor skill abilities, is not justified from the results of this study. Practitioners want to improve their batters' hitting productivity. Therefore, they may need to focus on other factors than anthropometrics, for instance agility, speed, power, and lower-body performance.

772   Board #33   May 30 2:00 PM - 3:30 PM

Comparison of Overall and Segmental Body Composition in Collegiate Track Athletes Using BIA and DXA

Dustin W. Davis[1], Matthew J. Garver[1], Molly A. Jennings[1], Brian J. Hughes[1], Steve Burns[1], Taylor K. Dinyer[2], Alex Rickard[1], Justin L. Colf[1], Laura A. Wilson[1], Jenna L. Carducci[1], Anna L. Blazer[1]. *[1]University of Central Missouri, Warrensburg, MO. [2]University of Kentucky, Lexington, KY.*
(No relevant relationships reported)

Anthropometric and body composition measurements can offer insight into athletes' health as well as assist in developing training or diet regimens to enhance competitive potential. Valid and reliable assessments of these measures are vital. **PURPOSE**: The purpose of this analysis was to compare overall and segmental body composition data of collegiate track athletes using bioelectrical impedance analysis (BIA) and dual energy X-ray absorptiometry (DXA). **METHODS**: Participants visited the Human Performance Laboratory once for measurement of anthropometric data (ht via stadiometer) and body composition assessment by BIA (via InBody 570) and DXA (via GE Healthcare Lunar Prodigy Advance). Contraindications were addressed and jewelry was removed prior to testing. Athletes were instructed to remove their socks; thereafter, they followed verbal instructions provided by the InBody 570. Body weight (lbs.) determined by the InBody 570 was converted to kilograms (kg) and used in the DXA analysis, for consistency. Relative body fat (%BF) and regional lean mass in the arms (ArmsLean), legs (LegsLean), and trunk (TrunkLean) (kg) were compared between methods, by sex, using paired-samples t-tests. **RESULTS (females)**: Twenty-four females (age: 19.6±1.0 yr, ht: 168.8±7.9 cm, and wt: 65.0±13.7 kg) volunteered for testing. There were statistical differences (ordered by BIA and DXA) for %BF [19.8±6.4 vs. 25.0±7.9%, p < 0.0001] and TrunkLean [22.10±3.72 vs. 21.11±2.42 kg, p = 0.038]. No statistical differences were found for ArmsLean [5.18±1.23 vs. 5.03±0.92 kg, p = 0.163] or LegsLean [15.73±2.33 vs. 16.32±2.35 kg, p =0.070]. **RESULTS (males)**: Thirty males (age: 20.5±1.9 yr, ht: 179.9±5.7 cm, and wt: 80.2±16.8 kg) volunteered for testing. There was a statistical difference (ordered by BIA and DXA) for ArmsLean [8.02±1.54 vs. 8.65±2.17 kg, p = 0.026], while %BF was at the statistical cut-point [11.2±4.7 vs. 13.0±6.7%, p = 0.05]. No statistical differences were found for LegsLean [21.23±2.53 vs. 22.31±4.95 kg, p = 0.115] or TrunkLean [30.36±4.42 vs. 29.87±3.65 kg, p = 0.231]. **CONCLUSIONS**: Clearly, differences exist in the estimation of overall and segmental body composition depending on the method utilized. If pre-post or serial evaluations are to occur, switching assessment methods would not be appropriate.

Longitudinal Changes In Skinfold Thicknesses In Relation To Body Fat Changes Assessed with DXA

Juan R. Lopez-Taylor, Roberto Gabriel Gonzalez-Mendoza, Alejandro Gaytan-Gonzalez, Juan Antonio Jimenez-Alvarado, Marisol Villegas-Balcazar, Edtna Elvira Jauregui-Ulloa, Francisco Torres-Naranjo. *Universidad de Guadalajara, Guadalajara, Mexico.*
(No relevant relationships reported)

The assessment of skinfold thicknesses is a widespread anthropometric technique to evaluate body composition. However, little is known about the relation between the changes through time in body fat assessed with only skinfolds compared with DXA. **PURPOSE**: To determine the relation between changes in body fat through time assessed with DXA and the changes of skinfold thicknesses. **METHODS**: We analyzed the data for 66 professional male soccer players. Subjects' body composition was evaluated two times with a time difference of one to five years between them. Ten skinfold thicknesses (10SKF, triceps, subscapular, biceps, chest, mid-axilla, iliac crest, supraspinal, abdomen, thigh, calf) were evaluated by anthropometry, and body fat (BF) by a DXA scanning (Hologic QDR4500). The changes between evaluation 1 and 2 were calculated for both 10SKF and BF for every subject. Then the determination coefficient (assuming a zero intercept), slope and SEE for the slope were calculated, where the changes in 10SKF predicted the changes in BF. We also calculated the changes in BF related to initial BF (CBF= [BF evaluation 1 - BF evaluation 2]/ BF evaluation 1). The mean ±SD, [min-max] is reported. **RESULTS**: The 10SKF (in mm) at evaluations one and two were 84 ± 31 and 89 ± 27 respectively (Δ 5 ± 22 [-57 to 74]). The BF (in kg) at evaluation one and two were 10 ± 3 and 11 ± 3 (Δ 1 ± 2 [-6 to 8]). The %BF at evaluation one and two were 14 ± 3 and 15 ± 3 (Δ 1 ± 3 [-7 to 9]). The CBF (expressed as percentage) was 14 ± 25 (-40 to 92). There were a strong relationship between the changes in skinfold thicknesses and the changes in absolute and relative BF, but the best estimation was observed with Δ%10SKF - %CBF. **CONCLUSIONS**: The changes in BF (kg, % and CBF) were well estimated with the changes in 10SKF and %10SKF through time. The Δ%10SKF had a ≈1% of change for every 1% in %CBF, which is an easier relationship to remember. However these changes had an error estimate threshold to overcome for increasing the chance to assess a significant change.

Table 1. Determination coefficient and slope for skinfold thicknesses and body fat changes			
	R^2	Slope	SEE
Δ10SKF - ΔBF	0.81	y=0.11x	0.93
Δ%10SKF - ΔBF	0.78	y=0.08x	1.16
Δ10SKF - %CBF	0.66	y=1.11x	11.95
Δ%10SKF - %CBF	0.80	y=0.94x	10.44
Δ10SKF - Δ%BF	0.78	y=0.11x	1.19
Δ%10SKF - Δ%BF	0.76	y=0.09x	1.36

Δ10SKF: Changes in the sum of 10 skinfolds (mm).
Δ%10SKF: Percentage of changes in the sum of 10 skinfolds.
ΔBF: Changes in body fat (kg).
%CBF: Percentage of changes in body fat relative to the initial body fat.
Δ%BF: Changes in body fat percentage.

Hydration and Electrolyte Status of Brazilian Olympic Athletes

Franz H. Burini, Rafael Rezende, Pedro Rodstein, Thalles Messora, Roberto C. Burini, FACSM. *UNESP Medical School, Botucatu, Brazil.* (Sponsor: Roberto C Burini, FACSM)
(No relevant relationships reported)

Weight based sports categories induces detrimental behaviors on health and perfomance. Dehydration and nutritional deficiencies may lead to acute and chronic risks, deteriorating fitness level and health integrity. **Purpose:** The purpose of this study was to evaluate hydration and electrolyte status of elite athletes of Judo and Boxing fron the Olympic National Team. **Methods:** Blood samples were taken from 27 Boxing and Judo elite athletes (18 males and 9 females; 26.4±3.7years) pre and post maximal specific protocol (3x3 minutes round/1minute interval for Boxing and 5 minutes of Handori for Judo) for hydration and eletrolyte status: Osmolality (Osmol), Haematocrit (Ht), Sodium (Na⁺), Potassium (K⁺) and Calcium (Ca⁺⁺) levels. **Results:** Before tests were performed, 100% of the athletes would be considered dehydrated: Osmol 304±62mOsmol.kg⁻¹ (Normal range: 285-295mOsmol.kg⁻¹) and Ht 45.9±6.1%. Sodium, Potassium and Calcium values were 143,3±12.7mmol.L⁻¹; 6,4±1.6mmol.L⁻¹; 9,9±2.3mg.dL⁻¹. After specific sport protocol, Osmol, Ht, Na⁺, K⁺ and Ca⁺⁺ levels were 302.4±73mOsmol.kg⁻¹, 44,7±3.2%, 142,4±14.6mmol.L⁻¹, 6,1±1.1mmol.L⁻¹ and 10,1±3.3mg.dL⁻¹. **Conclusions:** Weight based category sports athletes should focused

on acquiring ideal body weight on a long-term period to avoid dehydration and others short-period strategies that may lead to detrimental aspects of physical fitness and health risks. Re-Hydration must be guided by electrolyte status to avoid major risks issues such as cardic arrhythmias, hyponatremia and aedema. These strategies should be encourage by coaches leagues and federations worlwide.

Injury Monitoring and Player Education, a Survey of Current Practices in Irish Amateur Rugby Union

Caithriona A. Yeomans, Thomas M. Comyns, Roisin Cahalan, Giles D. Warrington, FACSM, Andrew J. Harrison, Kevin Hayes, Mark Lyons, Mark J. Campbell, Ian C. Kenny. *University of Limerick, Limerick, Ireland.* (Sponsor: Dr. Giles D Warrington, FACSM)
(No relevant relationships reported)

Rugby Union is one of the most played and watched collision sports worldwide, with high injury incidences widely reported in the literature. Participation rates in Rugby Union are rising with increasing popularity, particularly in Ireland with 224 amateur clubs and approximately 190,400 players currently registered. Internationally, the Irish men's team is currently ranked in the top five in the world. **PURPOSE**: To evaluate injury monitoring and player education practices in Irish amateur Rugby Union. **METHODS**: A survey was designed and distributed to coaches and medical staff of 58 clubs. These clubs represent the highest level of amateur Rugby Union in Ireland. The survey consisted of 27 questions, with five sections: 1) Club demographics, 2) Monitoring, 3) Education, 4) Staffing and 5) Injuries. **RESULTS**: Forty-nine clubs responded to the survey. Five surveys were incomplete and excluded from analysis. The overall response rate was 75.9% representing current practices of 4,843 amateur players (mean 110±57 players per club). Injuries were monitored in 91% of clubs, with medical staff recording data in 75% of cases, using paper records (52.5%), Excel spreadsheets (37.5%) or online resources (7.5%). Training load was monitored in 36% of clubs mainly by the strength and conditioning coach (37.5%). All clubs operated return to play protocols, with 64% for all injuries and 36% for concussion only. Twenty-three% conducted pre-season concussion screening and 82% educated players on concussion. Seventy-one% educated players about injury prevention. **CONCLUSIONS**: Injury monitoring is crucial in collision sports such as Rugby Union, where injury risk is substantial. While comprehensive monitoring systems are prevalent in professional sport, injury monitoring is often infrequent and inconsistent in amateur settings. In order to minimize injury risk, it is the duty of care of governing bodies to implement monitoring systems in both amateur and professional cohorts. In Ireland, 91% of clubs monitor injuries by various means. The implementation of a centralized monitoring system in Irish amateur Rugby would allow injury trends to be effectively tracked and used to guide evidence-based injury prevention strategies. **Funding:** The Irish Rugby Injury Surveillance Project is funded by the Irish Rugby Football Union**.**

Optimal Cooling Periods For Rugby League In Hot/ humid Conditions

Grant Lynch, Connor Graham, Timothy English, Ollie Jay, FACSM. *University of Sydney, Sydney, Australia.* (Sponsor: Dr Ollie Jay, FACSM)
(No relevant relationships reported)

PURPOSE: The current extreme heat policy for the National Rugby League (NRL) recommends 1-min cooling breaks mid-way through each half to permit greater fluid ingestion as the primary strategy to mitigate heat stress. The present study aims to assess the effectiveness of the current policy relative to an extended halftime break for mitigating thermal strain.**METHODS**: Six trained males (age: 24±4 y, height: 177±11 cm, weight: 90.8±14.2 kg) undertook four counterbalanced experimental trials in a climate chamber simulating hot/humid conditions (36.5±0.4°C, 51±2% RH), consisting of 80 min of intermittent running on a treadmill matching the demands of a professional rugby league game. Participants completed a regular game (RG) with a 12-min half-time break, an extended (20-min) half-time break (EH), a regular game with a 1-min (R1C) cooling break and an extended game with a 1-min cooling break (E1C) 20 mins into each half. Change in core temperature (ΔT_c), change in thermal sensation (TS) and whole-body sweat rate (WBSR) were measured. **RESULTS:** End-trial ΔTc were RG: 1.90±0.14°C, R1C: 1.75±0.52°C, EH: 1.70±0.18°C, E1C: 1.68±0.36°C, with the ΔTc from the start to end of halftime reported as: RG: 1.11±0.20°C, R1C: 1.09±0.36°C, EH: 0.97±0.15°C, E1C: 1.00±0.23°C. The length

---

of in-play break duration (i.e. 1-min or 3-min) had no influence on rise in core temperature by the end of the first half (p=0.88) or the second half (p=0.66). However, there was a greater reduction in core temperature during EH compared to RG (p=0.05). This blunted rise in core temperature with EH persisted to the end of exercise with lower end-trial values in EH compared to RG (p=0.02). TS was also cooler at end-trial after EH (p=0.02) with no additive effect of in-play breaks (p=0.96). There were no differences (p=0.40) in WBSR between trials (RG: 1.25±0.25 L/h, R1C: 1.17±0.19 L/h, EH: 1.19±0.18 L/h, E1C: 1.23±0.25 L/h). **CONCLUSIONS**: Preliminary data indicate that extending halftime from 12 to 20 min in Rugby League is effective at reducing thermal strain whereas in-play cooling breaks of up to 3 minutes may not provide any additional benefit. These findings may also be applicable to all field based team sports (e.g. American football, soccer and Australian football (AFL)).**FUNDING:** This research was funded by the National Rugby League (NRL), Australia

777   Board #38   May 30 2:00 PM - 3:30 PM

Wearable Sensors to Quantify Performance and Fatigue during Tournament Competition among Elite Developmental Ice Hockey Players

Ken Martel, Andrea Workman, Davor Stojanov, Stephen J. McGregor. *Eastern Michigan University, Ypsilanti, MI.* (Sponsor: Andrew R. Coggan, Ph.D., FASCM, FACSM)
(No relevant relationships reported)

At the highest performance levels of ice hockey (e.g. senior/professional), rules govern the number of successive competition days and prevent multiple competitions on a single day. Yet, some youth leagues run weekend showcase events that include multiple competitions per day. It is generally assumed that multiple competitions per day and several competitions over multiple days will impart excessive fatigue and impair performance, but there is no evidence directly related to ice hockey. **PURPOSE**: Use player-worn sensors (PWS) to compare accelerations (ACC) and heart rate (HR) over 4 games in 3 days among elite youth ice hockey players in order to establish changes in cardiovascular stress and physical exertion associated with fatigue. **METHODS**: 33 elite, youth ice hockey players in two age categories (18U: N=17, 18.2 yrs ± .92 & 16U: N=16, 16.4 yrs ± 1.1) on two teams in a league showcase consented to procedures approved by the EMU-HSRC. Bioharness-3 (Zephyr, MD) recorded HR and ACC at 1 Hz over the 4 games (G1-G4) in the 3- day event. Peak ACC across multiple time frames (10, 15, 20, 30,··· 90, sec and 2, 2.5, 3, 5, 10, ···, 45 min) were quantified and analyzed and HR was quantified and used in conjunction with ACC to determine exertion profiles for each on-ice session. MANOVAs for peak ACC and HR at each time point across G1 -G4 with Bonferoni *post hocs* and multiple games per day (M1, M2) for magnitude and time as main effects were performed using SPSS 23.0 (IBM, NY; α=0.05). **RESULTS**: HR (bpm) decreased G1 v G4 at 3 (187.5 ± 2.8 v 176.1 ± 2.8), 5 (178.7 ± 3.0 v 165.7 ± 3.0), 10 (170.4 ± 3.1 v 157.6 ± 3.1), 15 (167.1 ±3.0 v 153.3 ± 2.9) and 20 min (164.3 ± 3.0 v 150.5 ± 2.9)(p<.05). In addition, HR also decreased G1 v G3 for 10 (170.4 ± 3.1 v 158.5 ± 3.0), 15 (167.1 ±3.0 v 154.5 ± 2.9) and 20 min (164.3 ± 3.0 v 152.4 ± 2.9)(p<.05), although ACC were not different. Peak ACC (g's) were lower for M2 vs M1 at 60 (0.632 ± 0.012 v 0.592 ± 0.012), 90 (0.551 ± 0.01 v 0.520 ± 0.01), 120 (0.495 ± 0.009 v 0.469 ± 0.009) and 180 sec (0.412 ± 0.009 v 0.386 ± 0.009)(p<.05). **CONCLUSIONS**: The decline in HR, but not ACC across games over 3 days indicates a cardiovascular adaptation as opposed to overt fatigue. On the other hand, the reduced ACC from 60 - 180 sec between games 1 and 2 in a day indicate reduced shift capacity and an overall decline in performance indicative of fatigue during the second contest.

Movement Deficiencies in Division II Male Football Athletes as it Relates to Class and Position

Taylor A. Taraski, Jenny A. Martinez, Christopher C. Winter, Jeremy E. Glaser, Brandon M. Fjerstad, Jeremy L. Knous. *Saginaw Valley State University, University Center, MI.*
(No relevant relationships reported)

The NCAA Division II Student-Athlete population may be subject to numerous mobility and stability deficiencies as it relates to sport and training requirements. Deficiencies must first be identified prior to prescription of sport performance training modalities. **PURPOSE:** Identify movement deficiencies in Division II male football athletes and investigate differences among specified groups. **METHODS:** Forty-three athletes (weight 103.1 ± 19.9 kg, height 183.3 ± 6.6 cm) underwent 11 screening exercises assessing deficiencies in 15 evaluation areas. Data was collected by trained evaluators who scored athletes on a pass/fail system with failure defined as compromised mobility or stability during exercises. Scores were compiled into evaluation areas determining deficiencies. For analysis, athletes were dichotomized into Upperclassmen (UC) n = 22 and Lowerclassmen (LC) n = 21 and stratified into position groups: Skill (n = 15), Big Skill (n = 15), and Bigs (n = 13). Descriptive statistics and comparative analysis, T-Test and ANOVA, were performed using SPSS (version 22.0) with significance set at p ≤ 0.05. **RESULTS:** All athletes displayed deficiencies, but comparative analysis identified significant differences between UC

---

and LC in lower body strength (UC = 1.9 ± 1.4, LC = 3.1 ± 0.9; F = 11.9, p = 0.001) and single leg strength (UC = 3.8 ± 1.9, LC = 5.1 ± 1.2; F = 6.5, p = 0.02). Within position groups, Bigs (6.9 ± 1.7; 13.2 ± 2.8; 2.6 ± 0.5, 1.9 ± 0.9) presented greater deficiencies in posterior chain (F = 6.4, p = 0.004), core stability (F = 5.4, p = 0.01), hip girdle endurance (F = 3.6, p = 0.04) and posterior shoulder girdle strength (F = 3.6, p = 0.04) compared to Skill (3.7 ± 2.7, p = 0.001; 9.9 ± 3.3, p = 0.01; 1.8 ± 0.9, p = 0.01; 1.3 ± 0.9, p = 0.06) and Big Skill (4.3 ± 2.9, p = 0.01; 10.0 ± 2.8, p = 0.01; 1.8 ± 0.9, p = 0.37; 1.1 ± 0.8, p = 0.01). **CONCLUSION:** Identification of individual and group deficiencies allows for utilization of targeted training protocols with the goal of enhancing overall performance.

779　　Board #40　　　　　　　May 30 2:00 PM - 3:30 PM

Physical Demands of NCAA Division I Hockey Training and Competition Using Microtechnology

Bryce V. Murphy, Donald R. Dengel, FACSM, Julian Wolfson, Calvin C. Dietz, Corey S. Petersen, Tyler A. Bosch. *University of Minnesota, Minneapolis, MN.* (Sponsor: Donald R Dengel, FACSM)

(No relevant relationships reported)

PURPOSE: Wearable technology has gained popularity to measure external workloads during practices and games in sport. Most often a tri-axial accelerometer, combined with a magnetometer and gyroscope measures directional movement in three planes of motion. This study investigated the external loads of collegiate hockey practices and games by period. **METHODS:** External workload (i.e. Player Load™ [PL]) and workload intensity, PL per minute (PL/m), were measured in 18 NCAA Division I Hockey athletes [11 forwards (FWD) and 7 defenders (DEF)] using OptimEye S5 monitoring devices (Catapult Sports, Melbourne, Australia) during the 2016-2017 season. Measurements were recorded during games and practices. Linear mixed effects models with random intercepts for player and date were used to test the effect of position on each variable. Effect sizes were calculated to determine the magnitude of differences between groups. **RESULTS:** The PL for Period (PD) 1 was 2.27 PL higher than PD 3 (95% CI: 0.61, 3.93; p = 0.007; d = 0.48). The PL/m for PD 1 was 0.13 PL/m higher than PD 2 (95% CI: 0.09, 0.17; p < 0.001). The PL/m for PD 1 was 0.18 PL/m higher than PD 3 (95% CI: 0.14, 0.23; p < 0.001). The PL/m for PD 2 was 0.05 PL/m higher than PD 3 (95% CI: 0.01, 0.10; p = 0.0147). There were no differences within PD by position (p = 0.198). The PL for practices was 19.43 PL lower than games (95% CI: -35.19, -3.69; p = 0.018). The PL/m for practices was 0.28 PL/m higher than games (95% CI: 0.20, 0.36; p < 0.001; d = 0.9). The PL for FWD was 29.2 PL higher than DEF during practice (95% CI: 12.6, 45.8; p = 0.003; d = 1.65). There were no differences in PL between FWD and DEF during games (p = 0.167). The PL/m for FWD was 0.36 PL/m higher than DEF across practice and games (95% CI: 0.18, 0.55; p = 0.002). **CONCLUSION:** Within this study we observed: 1) player workload intensity decreasing as the game progresses; 2) higher PL/m for practice compared to games; and 3) higher PL for FWD compared to DEF during practice. However, these differences are relatively small in absolute terms and may not be meaningful considering individual variation between players. Playing time, penalties, and minor injuries may affect positional averages throughout the course of a game. Future studies should examine the effect of individual variation within and between weeks and by drill type.

780　　Board #41　　　　　　　May 30 2:00 PM - 3:30 PM

Physical Skills of Teen Student-Athletes of Combat Sports: A Comparative and Correlational Analysis

Aldo F. Longo, Gustavo D. Aquilino, Marcelo L. Cardey, Néstor A. Lentini, Enrique O. Prada. *CeNARD, Buenos Aires, Argentina.*

(No relevant relationships reported)

PURPOSE: To analyze comparatively the performances of elementary and high school athletes of combat sports in a set of tests of conditional abilities. **METHODS**: Data from 518 male and female teenagers who took part in inter-provincial competitions of Judo, Taekwondo and Wrestling were studied (age range: 11.9 to 14.9 years). A battery of field tests was carried out: Handgrip strength (HAST), Abalakov, Countermovement and Squat jumps (ABJ, CMJ and SQJ), 0-10 m Sprint acceleration (0-10SA) and Sit and reach flexibility (SARF). Pearson's r was used to test correlations among the physical skills. ANCOVA models were run to evaluate the performances in HAST, ABJ, 0-10SA and SARF, which included Gender, Sport and their interaction, and Age as a covariate. Feasible weighted least squares was applied on HAST and ABJ, to account for heteroscedasticity. *Post hoc* Tukey-Kramer tests were conducted for multiple comparisons. The statistical significance level was fixed at p<0.05. **RESULTS**: The correlations were high among the jumps (0.82 to 0.91; p<0.001), and from moderate to marked among HAST, 0-10AS and any of the jumps (0.50 to 0.65; p<0.001). SARF showed very low correlations (0.05 to 0.15; 0.0007≤p≤0.25). The interaction term was not statistically significant in the models analyzed. Gender was a significant factor in the four models, and Sport was significant in the models for ABJ

and SARF. Boys exhibited higher performances than girls in HAST, ABJ and 0-10SA, and lower in SARF. *Post hoc* comparisons between sports revealed that judokas and taekwondists had higher values than wrestlers in ABJ, and that taekwondists had higher values than wrestlers in SARF. In boys, the mean responses of HAST (kgf), ABJ (cm), 0-10SA (m·s^{-2}) and SARF (cm) were 28.8, 31.7, 4.7 and 5.1 for judokas; 28.0, 32.8, 4.7 and 5.7 for taekwondists; and 27.0, 29.9, 4.7 and 3.0 for wrestlers. And in girls, the mean responses were, respectively, 23.9, 25.4, 4.1 and 9.4; 23.6, 25.3, 4.0 and 10.8; and 23.6, 23.6, 4.0 and 8.2.
CONCLUSIONS: Flexibility evidenced the lowest associations with the rest of the physical skills. The differences between boys and girls appeared to remain constant across sports. Averaged over both genders, martial arts athletes showed higher performances in ABJ, and taekwondists revealed to be more flexible than wrestlers.

781　　Board #42　　　　　　　May 30 2:00 PM - 3:30 PM

Differences in Velocity Output in the Back Squat, Bench Press, and Deadlift Among Collegiate Hockey Players

Chris Pitsikoulis, Chad Trudo, Josh Kieffer, Ryan Goochey, Josue Argueta, Guillermo Blano. *Aurora University, Aurora, IL.*

(No relevant relationships reported)

Resistance-training loads are commonly assigned as a percentage of an individual's one-repetition maximum (1-RM). Unfortunately, repetition maximums do not account for an athlete's current state of readiness (training state). The use of velocity-based training (VBT) provides objective data about training state, and is an effective and reliable method of examining an athlete's movement efficiency. Currently, there is insufficient evidence regarding velocity profiles of exercises that are body-weight dependent (BWD) such as the free-weight back squat (BS) and deadlift (DL) compared to non-body-weight dependent (NBWD) such as the barbell bench-press (BP). **PURPOSE**: To determine velocity profiles for the BS, BP and DL in Division III collegiate male hockey players. **METHODS**: Fourteen Division III male collegiate hockey players, (age 21.3 ± 1.5 years; height 181.2 ± 5.0 cm; mass 88.6 ± 8.8kg) completed this study. Prior to velocity testing, body composition via air displacement plethysmography (BodPod) and one repetition maximum (1RM) for the BS, BP, and DL were measured. On separate days, subjects performed nine repetitions each of the BS, BP and DL (10, 20, 30, 40, 50, 60, 70, 80, and 90% of their 1RM). Average velocity was measured with a Tendo Power Analyzer (Tendo Sports Machines, Slovak Republic). A repeated measures ANOVA was used to investigate the impact of exercise on mean velocity (alpha level of p ≤ 0.05). **RESULTS**: Subject anthropometric measurements included: BMI (26.95 ± 2.0 kg/m^2) and percent body fat (17.12 ± 3.4 %). 1-RMs for the BS, BP, and DL were 146.0 ± 13.1 kg, 103.7 ± 15.3 kg, and 156.84 ± 14.9 kg), respectively. A significant exercise x %1-RM interaction was found (p < .05). Mean velocity for the BP was significantly greater at 10%, 20% and 30% of 1-RM compared to the BS and DL and 90% compared to the DL (p <.017). There were no significant differences in mean velocity between the BS and DL. **CONCLUSIONS**: The BS and DL, BWD exercises, demonstrated significantly slower average velocities at various levels of %1-RM compared to the BP, a NBWD exercise. While the differences were not seen throughout the entire range of %1-RM, practitioners should account for body-mass when using VBT with BWD exercises.

Evaluation Of The Health And Physical Fitness And Factors Influencing Retention Of Scholastic Sports Officials In The Sport Of American Football

Aaron T. Hall[1], Cody E. Morris[2], Stacey Forsythe[2], Tricia Jordan[2], Mark A. Schafer[2], Teresa L. Wiczynki[2], Paula Upright[2]. [1]*Trevecca Nazarene University, Nashville, TN.* [2]*Western Kentucky University, Bowling Green, KY.* (Sponsor: Scott Lyons, FACSM)

(No relevant relationships reported)

PURPOSE: As the competitive level and skill level of the athletes increases, so does the demand and elevation in expectation of that official's performance. There is currently a dearth of information and data as it relates to the official's capacity and ability to perform their job. The purpose of this study was to evaluate the health and physical fitness status as well as job satisfaction of officials in the sport of American football. **METHODS**: Eighteen National Federation of High Schools certified officials in the sport of American football participated in the study. Participants completed an Adult Health History Questionnaire to risk classify for cardiovascular disease (CVD) according to American College of Sports Medicine (ACSM) standards (ACSM, 2017). Also, each participant completed a Minnesota Satisfaction Questionnaire (1977) related to their current officiating responsibilities. In addition, each participant had body mass index (BMI) assessed using standard scales.

WEDNESDAY, MAY 30, 2018

RESULTS: Descriptive statistics showed that the mean age of the participants was 47.7 ± 13.2 years old with a mean BMI of 29.0 ± 5.0 kg/m². 50.0% of participants were classified as High Risk for CVD, 27.8% Moderate Risk, and 16.7% Low Risk. A significant correlation was found between age and total sports officiated ($r = -.505$, $p = 0.046$) and while the correlation between BMI and extrinsic satisfaction ($r = -.493$, $p = 0.062$) was not significant, it did imply a moderate correlation. A one-way ANOVA exhibited a significant difference between ACSM risk classification and the number of sports officiated ($p = 0.044$). A post-hoc Tukey test indicates that individuals who are High Risk officiate significantly more sports ($p = 0.046$) than those who are Moderate Risk. However, High Risk was not significantly different from Low Risk and Low Risk was not significantly different from Moderate Risk ($p > 0.05$).
CONCLUSIONS: Based on the results of the current study, it appears that the data can confirm that as officials get older they tend to drop out of officiating. In addition, a large degree of officials (77.8%) were considered either Moderate or High Risk for CVD, implying that the physiological stress that officiating typically entails could place these individuals at an increased risk of experiencing a cardiovascular event.

Hydration Status in Division III Female Hockey Players Prior to Competition

Anthony Clapp, Danielle Heitkamp. *Augsburg University, Minneapolis, MN.* (Sponsor: John L. Walker, FACSM)
(No relevant relationships reported)

Voluminous sweating and collegiate athletes share an association, especially during competition. The accountability is on the athlete to arrive to the venue euhydrated and it is paramount for optimal performance. For the collegiate hockey player it has been reported that improper hydration will most likely cause headaches, dry mouth, sluggishness, malaise, and reduced performance. **PURPOSE:** To elucidate the hydration status in a group of DIII collegiate female hockey players prior to competition. **METHODS:** Sixteen intercollegiate athletes from a NCAA Division III Women's Hockey team (age = 19.9 ± 0.7 yrs, height = 168.7 ± 8.2 cm, mass = 62.6 ± 9.1 kg) participated in this investigation. During an eight week span over two seasons, 16 skaters randomly provided a sample moments before competition. Urine samples were collected in a sterile 4oz specimen container and measured with a pen refractometer (ATAGO model 3749-E04) to determine urine Standard Gravity (SG). Data were analyzed using a one sample t-test against established optimal hydration levels at or below 1.020 SG. **RESULTS:** Mean(x) SG score was 1.0239 ± 0.0027 ($p < 0.05$). Three out of sixteen subjects met the criteria of the 1.020 SG or lower number. Thirteen measured between 1.022 and 1.031. **CONCLUSION:** This reveals a significant difference above the population standards and indicates that the majority of athletes were slightly dehydrated in that, only 16.7% were properly hydrated by SG guidelines. Thus, revealing that the typical DIII female hockey player is not adequately hydrated prior to competition and would benefit from additional guidance and preparation.

This Study Provides Quantification Of Positional Physical Demands Of Selected Positions

Bert H. Jacobson, FACSM. *oklahoma state university, Stillwater, OK.*
(No relevant relationships reported)

Global positioning tracking comparisons of selected NCAA Division I football player positions during conference games
Bert H. Jacobson FACSM, Garrett E. Bayliff, Masoud Moghaddam, Carlos A. Estrada
Applied Neuromuscular Physiology Laboratory, Oklahoma State University, Stillwater, OK
Global positioning (GPS) tracking of Division I (DI) football players is a relatively new method of assessing total distance covered, velocities and accelerations during practices and games.
PURPOSE: To compare differences in distance traveled, maximum velocity, high accelerations, among DI football players during competition. **METHODS:** NCAA DI football players (N=21) wore GPSs monitors during four randomly assigned conference games to track selected variables of each athlete. Athletes were grouped by playing position; skilled = wider receiver (WR) and defensive back (DB) and line = offensive linemen (OL) and defensive linemen (DL). Dependent variables included total distance covered (m), maximum velocity m·s⁻¹), and high acceleration (>3ms⁻²) distances. Oneway ANOVAs were used to compare differences among groups and Newman-Keuls post hoc tests to determine location of significant differences. **RESULTS:** For total distance, DBs traveled significantly ($p<0.05$) further than WR and OL, but not DL. There was no significant differences between DL and any other positions. DBs and WR had significantly greater maximum velocities than OL and DL and DL had significantly greater velocity than OL. There was no significant difference between DBs and WRs. For high acceleration, DBs had significantly greater distance than all other groups. WRs had greater distance than DL and OL. No difference was found between OL and DL. **CONCLUSION**: This study provides quantification of

physical demands of selected DI football positions by determining that defensive player traveled further than offensive players did and that skilled players noted greater velocity and acceleration distances than linemen. Fatigue is related to duration and exertion, which is also associated with potential injury. With factual data regarding these variables, it may be possible to avoid over-reaching, hence reducing injury susceptibility.

Relationship between Body Composition, Cardiorespiratory Fitness, and Position in DII Collegiate Male Rugby Union Players

Edward K. Smith, David Q. Thomas, FACSM, Daniel J. Dodd, Dale D. Brown, FACSM, Kelly R. Laurson, Tyler R. Langosch, Jonathan C. Grimwood, Nathan P. Fillers. *Illinois State University, Normal, IL.* (Sponsor: David Q. Thomas, FACSM)
(No relevant relationships reported)

Different aspects of body composition such as fat-mass (FM), fat-free mass (FFM), percentage of body fat (BFP), and body mass (BM) have been identified as affecting cardiorespiratory fitness ($VO2_{max}$) in children and young adults. In the sport of rugby union, different positions have been found to benefit from different body compositions based on their roles. Forwards have been found to have greater FM, FFM, BFP, and BM than backs. **PURPOSE:** To determine if FM, FFM, BFP, and BM had any relationship with $VO2_{max}$ among positional groups in collegiate male rugby union players. **METHODS:** Twenty-nine participants (20.34 ± 1.52 years) agreed to perform a 20m multi-stage shuttle-run until volitional failure with the aim of estimating their $VO2_{max}$. FM, FFM, BFP, and BM, were estimated through air-displacement plethysmography via a BODPOD. Players were split into 2 groups based on their general position (forwards, n=16 and backs, n=13). **RESULTS:** An independent samples t-test comparing FM, FFM, BFP, BM, $VO2_{max}$, between forwards and backs revealed that the forwards had a significantly higher BM ($t(27) = 5.64$, $p < .001$), FM ($t(27) = 2.69$, $p < .05$), and FFM ($t(27) = 4.9$, $p < .001$). A Pearson correlation coefficient was calculated for the relationships between estimated $VO2_{max}$ and FM, FFM, BFP, and BM for each positional group. Strong negative relationships were found between $VO2_{max}$ and FM ($r(14) = -.767$, $p = .001$), BFP ($r(14) = -.740$, $p = .001$), and BM ($r(14) = -.699$, $p = .003$) in the forwards. As for the backs, no significant relationships were found between $VO2_{max}$ and FM, FFM, BFP, or BM.
CONCLUSION: The higher amounts of FM, FFM, and BM in forwards likely benefits them during play as they spend a large amount of time in contact with the opposition. However, the increased amount of FM, BFP, and BM may negatively affect the forwards' cardiorespiratory fitness as they are required to move a heavier amount of mass.

Longitudinal Observation Of Cardiac Adaptation In Junior Rugby Players Using Echocardiography

Kazuo Oguri[1], Kosho Kasuga[2], Takahiro Nakano[3], Tomoaki Sakai[3]. *[1]Gifu shotoku Gakuen University, Gifu, Japan. [2]Gifu University, Gifu, Japan. [3]Nagoya Gakuin University, Aichi, Japan.* (Sponsor: Kiyoji Tanaka, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study is to conduct a 3-year longitudinal study of cardiac adaptation in junior and senior high school athletes who play rugby with echocardiography in an effort to examine how continuous practice of rugby during the growth period affects ventricular volume expansion and ventricular septum thickening.
METHODS: Subjects were 34 male junior high and 79 senior high school rugby players with top-level game power. Subjects engaged in rugby-related training approximately 3 hours a day, 6 days a week continuously for 3 years. We measured height, body weight, blood pressure and took electrocardiogram and echocardiography measurements once a year for 3 consecutive years in these subjects. Echocardiography measurements were taken by portable ultrasonic measurement apparatus on B mode to measure left ventricular end-diastolic dimension (LVDd) and posterior left ventricle wall thickness (PWT). As a substitute for the control group, we estimated predicted values for each subject based on their height to make a cross-sectional comparison with the actual measured values.
RESULTS: A cross-sectional comparison of LVDd and PWT measured in junior high schoolers exhibited a significant increase between the 1st and 2nd grade (equivalent of American 7th and 8th grades, respectively) ($p<0.01$). A cross-sectional comparison of the predicted and actual LVDd values for each year of junior high school revealed a significant difference in 2nd year students ($p<0.01$). In contrast, there was a significant difference between predicted and actual PWT values in the 2nd and 3rd (equivalent of American 9th) grade students ($p<0.05$). In senior high schoolers, LVDd increased significantly between the 1st and 2nd grade as well as between the 2nd and 3rd grade, and PWT increased significantly between the 1st and 2nd grade ($p<0.01$). In senior high school, there was a significant difference between actual and predicted values of

LVDd and PWT in all three grades (p<0.01). **CONCLUSIONS**: Continuous practice of rugby in junior and senior high school was associated with marked expansion of left ventricular volume and thickening of the left ventricular septum.

Characteristics of Female Collegiate Ice Hockey Players

Jessica Moon. *Lindenwood University Belleville, Belleville, IL.* (Sponsor: Chad M. Kerksick, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of this research is to examine the physical characteristics and fitness levels of ACHA Division 1 collegiate female hockey players by examining data collected from various fitness tests including vertical jump, anaerobic step test, the Cooper Run test, anaerobic cycling (Wingate) and body composition testing (BodPod). **METHODS:** Twelve ACHA female hockey players visited the lab on three separate visits to complete the three day testing protocol. On the initial visit, percent body fat was assessed using the BodPod (BP). Also height as well as weight, blood pressure, age, sit and reach, vertical jump (using the Vertec), and anaerobic power output through the anaerobic step test were assessed. On day two, the athletes performed a 1.5 mile aerobic run (Cooper Run Test). On day three, an anaerobic cycling test (Wingate) was performed. **RESULTS:** Percent body fat as assessed by BP (29.7 ± 8.2; range: 19.6-43.3%), height (162.3 ± 6.2; 150-170cm), weight (70.6 ± 12.1; 50.1-95.2 kg), resting systolic blood pressure (119 ± 5; 110-130 mmHg), resting diastolic blood pressure (77 ± 6; 68-88 mmHg), age (21.3 ± 4.2; 18-34 years), sit and reach (32.5 ± 6.4; 23-41.5 cm), vertical jump (18.7 ± 3.1; 13.25-23.5 inches), anaerobic step test (46.5 ± 12.6; 31-74 steps; mean power 254 ± 72; 624-1295 watts), aerobic capacity (VO_2 max) as assessed by the Cooper Run Test (46.6 ± 10.3; 33-65.4 ml^{-1}*kg^{-1}*min). The Wingate mean power was (3743 ± 981; 4965-8057 Watts) and total repetitions were (45.7 ± 4.7; 38-53 repetitions). **CONCLUSION:** These tests present a unique fitness profile for an understudied group of athletes. This profile can be useful for coaches, players and trainers within this sport, ACHA Div.1 Women's Ice Hockey.

Comparison Of Heart Rate, Speed, And Sprints Performed By A Division I College Female Field Hockey Team Using Game Data

Jane A. Groetsch, Ashley N. Triplett, James M. Pivarnik, FACSM. *Michigan State University, East Lansing, MI.* (Sponsor: James M. Pivarnik, FACSM)

(No relevant relationships reported)

Heart rate (HR) monitoring, GPS tracking, and accelerometry are new techniques for evaluating players' activity levels during competition. Results from live tracking can help the coaches with practice schedules and game strategies. To date, there are few data available from these tracking modalities within NCAA varsity women's field hockey. **PURPOSE:** Our purpose was to determine descriptive information related to players' game performance, and analyze the results by player position. **METHODS:** A team HR monitoring system was used to evaluate in-game HR responses and movement patterns of women field hockey players from a single NCAA Division I team. Players were divided into 3 groups based on position (back, midfielder, forward). Data were collected and averaged among 15 women who played in 3 games, and 95% confidence intervals were computed. HR max was determined through a continuous graded treadmill test with increases in intensity every 2 min. Given that field hockey is fast-paced game, variables of interest in this preliminary investigation included time spent at HRzone 4 (80-90%HRmax) and HRzone 5 (>90%HRmax), maximum speed achieved, and number of sprints performed. **RESULTS:** On average, players spent 31.3% of game time in HRzone 4 and 49.2% in HRzone 5. Differences were seen according to player position as backs spent less time in HRzone 4 (22%) compared to midfielders (34.9%) and forwards (37.1%); P<0.05. In contrast, forwards spent less time in HRzone 5 (35.6%) compared to backs (57.6%) and midfielders (54.5%); P<0.05. Midfielders spent significantly more time >80%HRmax (89.4%) compared to forwards (72.7%); P<0.05. Max sprint speed was not statistically significant by position, midfielders (435±56.2 m/min), backs (401±42.2 m/min) and forwards (393±31.9 m/min). Backs engaged in fewer sprints (0.4±0.08 sprints/min) compared to midfielders (0.7±0.27 sprints/min) and forwards (0.6±.58 sprints/min); P<0.05. **CONCLUSIONS:** Heart rate data show clearly that field hockey is played under very intense aerobic conditions, with high burst interval runs being performed throughout the competition. Our data suggest that backs achieve their HR values using less short bursts and likely, more constant movement, while overall aerobic intensity (according to HR response) appears greatest among the midfielders.

Validity & Reliability Of A New Hockey-Specific Test In Elite Ice Hockey Players

Richard M. Storie[1], Jason S. Grindstaff[1], David C. Good[2], Dennis G. O'Connell, FACSM[3]. [1]*Cumberland University, Lebanon, TN.* [2]*Nashville Hockey Club, LLC, Nashville, TN.* [3]*Hardin Simmons University, Abilene, TX.*

(No relevant relationships reported)

A valid and reliable method of assessing hockey-specific physiological performance is warranted as elite hockey players compete for scholarships and professional contracts. The Hockey-Specific Test (HST) is an on-ice, position-specific assessment that integrates competition specific, multi-planar movement patterns and is generalizable to hockey players at the highest level of competition. Generalizability in the use of published on-ice tests is problematic due to small sample sizes and the use of recreational youth and non-elite players. More importantly, they don't include hockey-specific movement patterns (e.g., turns, deceleration, skating backward). **PURPOSE:** The purpose of this study was to determine the validity and reliability of the new assessment. **METHODS:** 54 male players (National Hockey League = 16; American Hockey League = 23; Under 17 USA National Team = 15) gave informed consent and minor assent to participate in both the HST and a 30-second Wingate Test (WAnT) with a resistance of 0.075 kg/kg body weight. The HST consists of 6 on-ice trials interspersed with 30-seconds active rest. All players wore full gear and carried a stick. Measurements included 15 m peak acceleration (m/s^2), 166 m total trial speed (m/s), percentage of age-predicted maximum heart rate (APMHR$_\%$), and post-exercise blood lactate (BLA$_{post}$) as markers of maximal effort and physiological capacities. **RESULTS:** A strong correlation exists between WAnT peak power and HST trial speed ($r = .765, p < 0.001$) and 15 m acceleration ($r = .716, p < 0.001$) in elite players, demonstrating construct validity. Intra-class correlation coefficients (*ICC*) for all participants verified within and between trial reliability for 15 m acceleration, $F(50) = 0.67, p < 0.001$ and trial speed, $F(50) = 0.85, p < 0.001$. Multinomial logistic regression for predicting WAnT peak power (w) from results of the HST = 27.98 - (18.05 x trial 1 time) + (11.04 x weight) + (25.69 x age). Adjusted peak power, APMHR$_\%$, and BLA$_{post}$ were 1023±108, *SEE* = 26±6; 89.3±3.6 and 91.2±4.5; 10.6±2.0 and 11.2±1.7 for the WAnT and HST, respectively. These values coincide with a test that sufficiently taxes the glycolytic energy pathway. **CONCLUSION:** The HST appears to be a valid and reliable test for determination of physiological performance in elite hockey players.

790   Board #51   May 30 2:00 PM - 3:30 PM

Updating the Skating Multistage Aerobic Test for VO_2max Prediction Including Skating Economy in Ice-Hockey Players

Alain S. Comtois[1], Maxime Allisse[2], Luc Léger[3], Hung Tien Bui[4], Mario Leone[4]. [1]*University of Quebec in Montreal, Montreal, QC, Canada.* [2]*University of Littoral Côte d'Opale, Dunkerque, France.* [3]*University of Montreal, Montreal, QC, Canada.* [4]*University of Quebec in Chicoutimi, Chicoutimi, QC, Canada.*

(No relevant relationships reported)

Purpose: In ice hockey, the aerobic metabolism is responsible for up to 30% of total energy expenditure and thus, is considered as an important performance factor. Recently, a number of field tests, including the Skating Multistage Aerobic Test (SMAT) have been developed to predict VO_2max in hockey players. When it was developed, the SMAT determined energy expenditure using the retro-extrapolation of the O_2 recovery curve at time 0 method. With the development of portable metabolic analyzers, it would be relevant to update the VO_2 values using this more precise device. In addition, the SMAT, like most field tests, assumes that participants who reach a given stage have the same oxygen cost, which is not usually true. Thus, the objectives of this research are to update the VO_2 values during the SMAT using a portable breath-by-breath metabolic analyzer and to propose a simple index of skating economy to improve the prediction of O_2 uptake. **Methods:** Twenty-six elite hockey players (age 15.8±1.3 years) participated in this study. The oxygen uptake was assessed using a portable metabolic analyzer (K4b2) during an on-ice intermittent maximal multistage shuttle skate test. During the test, participants had to skate back and forth over a distance of 45m at a velocity dictated by an audible signal. The initial skating velocity was set to 3.5m·s^{-1} and at each stage, speed increased by 0.2m·s^{-1}. In order to develop an index of skating economy (SSI = # Strides · Body Mass^{-1}), the number of skating strides was compiled for each stage of the test. **Results:** The SMAT enabled the prediction of the VO_2max (ml·kg^{-1}·min^{-1}) from the maximal velocity (m·s^{-1}) and the SSI (at Stage 4, which corresponds to 4.1m·s^{-1}) using the following regression equation: VO_2max = 13.86·(maximal velocity)+(3.23·SSI)-19.95 (r=0.95, SEE=1.96). **Conclusion:** This research allowed for the update of the oxygen uptake values of the SMAT test and proposed a simple measure of skating efficiency for a more accurate evaluation of VO_2max in elite hockey players. By comparing the highest and lowest observed SSI scores in our sample for a given stage, it was noted that the VO_2 values

---

Abstracts were prepared by the authors and printed as submitted.

can vary by up to 5 (ml·kg^{-1}·min^{-1}). Our results suggest that movement economy should be included in the prediction of VO$_2$max in field tests requiring high technical skills in order to improve prediction accuracy.

791　Board #52　May 30 2:00 PM - 3:30 PM

Do Metrics Between Back-to-Back National Hockey League Away Games Indicate a Presence of Fatigue?

Anthony B. Ciccone, Joseph P. Weir, FACSM. *University of Kansas, Lawrence, KS.* (Sponsor: Dr. Joseph Weir, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of this investigation was to estimate the fatigue caused by game one of a set of back-to-back games (away) as indicated by play-by-play metrics. **METHODS**: The R package, nhlscrapr, was used to acquire the 2015-2016 National Hockey League play-by-play database. First, the database was filtered for all regular-season, full-strength events with no pulled goalies. Next, all back-to-back games were identified and coded as being either away-away, home-home, home-away, and away-home. Only away-away back-to-back games were analyzed. Finally, the data were filtered so each back-to-back team had a frequency count for games one and two of the following variables: goals for, goals against, shots on goal for, shots on goal against, missed shots for, missed shots against, shots for blocked, shots against blocked, hits for, penalties against, and penalties for. All metrics were analyzed using mixed models, with random effects for team and fixed effects for game number. Goals, penalties, and blocked shot models were fit using Poisson distributions, and all other models were fit using Gaussian distributions. Alpha was set at 0.05. **RESULTS**: 186 away-away pairs of games were identified; teams had anywhere from 1 to 10 pairs. There was a significant effect of game number on goals for (game 1=1.8±1.3; game 2=1.5±1.2; p=0.035), shots against (game 1=20.8±5.5; game 2=22.0±6.2; p=0.04), and missed shots against (game 1=8.9±3.7; game 2=9.9±4.0; p=0.011). There was no significant effect of game number on goals against (game 1=1.8±1.2; game 2=1.7±1.3; p=0.46), shots on goal for (game 1=20.8±6.0; game 2=19.9±5.5; p=0.14), missed shots for (game 1=8.8±3.6; game 2=8.8±3.7; p=0.95), shots for blocked (game 1=10.9±4.5; game 2=11.4±4.7; p=0.13), shots against blocked (game 1=10.4±4.2; game 2=10.5±4.7; p=0.92), penalties against (game 1=2.9±1.5; game 2=2.8±1.4; p=0.86), penalties for (game 1=2.8±1.5; game 2=2.6±1.5; p=0.10), and hits for (game 1: 21.4±8.9; game 2 20.7±7.6; p=0.31). **CONCLUSIONS**: Hit data indicates that physicality is likely not as affected by game 1 fatigue. However, teams give up a greater number of total shot attempts in game 2's and score fewer goals in game 2's. Thus, game 1 fatigue may result in lower-quality shots for and generally poorer defensive play by skaters.

792　Board #53　May 30 2:00 PM - 3:30 PM

Comparison of Muscular Strength and Reactive Strength Index between Football Linemen and Backs

Katie L. Eichholz[1], Taylor Manes[1], Jerry L. Mayhew[1], William F. Brechue, FACSM[2], J Bryan Mann[3]. *[1]Truman State University, Kirksville, MO. [2]A. T. Still University of Health Sciences, Kirksville, MO. [3]University of Missouri, Columbia, MO.*

(No relevant relationships reported)

Ability to generate force quickly is a primary evaluation protocol for assessing athletic potential. Jumping indices have become major indicators of potential or judging training improvement. However, there is limited information concerning these indices for college football players. **PURPOSE:** To compare two forms of reactive strength index (RSI) between college football linemen and backs. **METHODS:** Linemen (n = 11) and backs (n = 12) from an NCAA D-II program were tested for one-repetition maximum (1RM) squat (SQ), paused squat jump (SJ) and drop-jump vertical jump (DVJ) determined from reach height. Flight time during SJ and ground contact time (GCT) were measured using an automated contact mat. Each player performed 3 trials of each jump. Relative 1RM SQ was expressed allometrically (SQ/kg$^{0.67}$). RSI was calculated as a ratio of DVJ to GCT (RSI-1) and Ft/GCT (RSI-2). Data were analyzed with ANOVA and significance was accepted with p<0.05. **RESULTS:** Linemen were significantly taller (186.7 ± 3.6 cm) and heavier (117.3 ± 15.7 kg) than backs (180.1 ± 6.0 cm and 90.1 ± 5.3 kg, respectively). 1RM SQ was greater in linemen (200.0 ± 26.7 kg) than backs (182.7 ± 28.4 kg), but relative SQ was similar (linemen: 8.20 ± 1.05; backs: 8.99 ± 1.32). Reliability for GCT (ICC = 0.922), Ft (ICC = 0.990), DVJ (ICC = 0.960), and SJ (ICC = 0.991) was high. RSI-1 (2.12 ± 0.52) was greater than RSI-2 (2.04 ± 0.54), although they were highly correlated (r = 0.93). RSI-1 and RSI-2 were greater in backs (2.33 ± 0.38 and 2.42 ± 0.46, respectively) than in linemen (1.67 ± 0.49 and 1.91 ± 0.48, respectively) with large effect sizes (ES = 1.52 and 1.07, respectively). Relative SQ was moderately correlated with RSI-1 (r = 0.63) and RSI-2 (r = 0.59), but there was no relationship with 1RM SQ (r = 0.06 and 0.13, respectively). RSI-1 and 1RM SQ correctly classified 80% of linemen and 85% of backs to the proper position. **CONCLUSION:** Ratios utilizing contact time appear more effective at evaluating reactive strength than measurements of strength or simple jump performance (jump height). The relationship between relative strength and

---

reactive jumps suggests that players who have greater relative strength can move more effectively in reactive situations which may more accurately identify performance potential in college football players.

793　Board #54　May 30 2:00 PM - 3:30 PM

Effect Of Rapid Weight Loss On Strength In Mma Fighters

João Carlos A. Bueno[1], Ragami C. Alves[1], Marcelo Saldanha Aoki[2], Brad J. Schoenfeld, FACSM[3], Alan C. Utter, FACSM[4], Steven R. McAnulty, FACSM[5], Tácito Pessoa de Souza Junior, FACSM[1]. *[1]Universidade Federal do Paraná, Curitiba, Brazil. [2]Universidade de São Paulo, São Paulo, Brazil. [3]CUNY Lehman College Bronx,, NY, NY. [4]Texas Woman's University,, Dentron TX, TX. [5]Appalachian State University,, Boone, NC, NC.* (Sponsor: Steven R. McAnulty, FACSM)

(No relevant relationships reported)

PURPOSE: The aim of this study was to verify the effect of the rapid weight loss (RWL) induced by the restriction of fluids at different moments on the manual grip strength in mixed martial art (MMA) athletes. **METHODS**: Twenty-seven male amateur MMA athletes (age 24.0 ± 5.3 years, height 175 ± 8.2 cm, body mass 76.0 ± 14.66 kg) and twenty-three women (age 19,0 ± 6,9 years; height 164,0 ± 6,1 cm; body mass 66,0 ± 6,70 kg) participated in this study. All athletes had BM, handgrip strength, and hydration status assessed at baseline (10 days before the onset of RWL), the official match weigh-in, and again 24 h later (match time). **RESULTS**: A repeated measures ANOVA showed for men and women, basal body weight (male: 75,0 ± 2,0; female: 66,1 ± 6,7) was significantly higher than at the time of weighing (male: 65,2 ± 2.1; woman: 56,9 ± 4,9) and match time (male: 68,5 ± 2,1, female: 59,6 ± 6,1). Density for males was higher at baseline (1.039 ± 0.1) compared to 24 h later (1.018 ± 0.1). However, women presented a difference in density for the three moments (baseline: 1,040 ± 0,2 > 1,030 ± 1,0 > 1,017 ± 0,1). In the handgrip for men it was evidenced difference between baseline (44,2 ± 13,8) and weighing (40,3 ± 17,7); however for women not found difference. **CONCLUSIONS**: Rapid weight loss showed to reduce significantly manual grip strength. In addition, was observed that this technique leads the athlete to dehydration. This would possibly interfere in a negative way in the performance of the athletes. In this way, the subjective criterion of a supposed advantage in the reduction and supercompensation of the weight must be well planned so that there is no deleterious effect on the performance and health of the athlete.

Changes In Elite Canadian Collegiate Hockey Player'S Body Compositions And Physiologic Tests Across Playing Careers

Nathan Chiarlitti, Patrick Delisle-Houde, Ryan RE Reid, Alex Sirois, Cory Kennedy, Ross E. Andersen, FACSM. *McGill University, Montreal, QC, Canada.* (Sponsor: Ross Andersen, FACSM)

(No relevant relationships reported)

The combined athletic and academic demands place a significant burden on collegiate hockey players. Numerous cross-sectional studies have been conducted with professional hockey players assessing body composition and skeletal fitness; yet, no research has investigated the longitudinal physiologic changes among elite collegiate athletes. **PURPOSE**: To examine changes in body composition and physiologic tests across a player's collegiate hockey career. **METHODS:** Over three seasons, six elite male Canadian university hockey players (age = 21.35 ± .28 years, weight = 84.53 ± 7.26 kg , height = 179.48 ± 7.60 cm, body fat percentage = 15.55 ± 1.68% at baseline) participated in the study at the beginning of their hockey seasons. All participants underwent physical testing (as outlined in the 2016 NHL combine) and a day after testing, one total body dual energy x-ray absorptiometry (DXA) scan to measure body composition. **RESULTS:** A repeated measures ANOVA was used to track body composition and physiologic performance variables over a three-year period. Players gained body weight (1.66 ± 1.96 kg), total body fat percentage (2.83 ± 1.91%), visceral adiposity (.16 ± .15 kg), upper fat mass (1.57 ± 1.20 kg), and lower fat mass (.52 ± .36 kg) (p < .05 for all comparisons). Total and regional lean tissue mass stayed relatively constant throughout their careers. There were no significant changes in agility scores, left grip strength, long jump distance or impulse generated in the vertical jump as all of these assessments stayed relatively consistent throughout the seasons. As players progressed through their careers, they achieved significantly more bench press repetitions, pull-ups, and had higher Wingate peak power scores (p < .05 for all comparisons). **CONCLUSIONS:** Pilot findings suggest that as players progress through their collegiate hockey careers, they gain weight, total and regional body fat, and are typically stronger in respects to some fitness tests. With this knowledge, strength and conditioning coaches can work in tandem with food scientists

and nutritionists to optimize meal plans in an effort to prevent weight and adipose tissue gain which may enhance on-ice play and player health across their three-year university careers.

The Association Among Body Composition, Explosive Leg Power and Aerobic Capacity in Male Varsity Hockey Players

Sebastien Beauregard[1], Nathan A. Chiarlitti[1], Patrick Delisle-Houde[2], Ryan E. Reid[1], Ross E. Andersen[1]. [1]*Mcgill University, Montreal, QC, Canada.* [2]*Mcgill University, bromont, QC, Canada.* (Sponsor: Ross Andersen, FACSM)
(No relevant relationships reported)

The Association Among Body Composition, Explosive Leg Power and Aerobic Capacity in Male Varsity Hockey Players.
Author Block: Sebastien Beauregard, Nathan A. Chiarlitti, Patrick Delisle-Houde, Ryan E. Reid, Ross E. Andersen, FACSM. *McGill University, Montreal, QC, Canada.* (Sponsor: Ross E Andersen, FACSM)
Abstract:
Fitness testing and body composition assessments in sports are ubiquitous and rapidly becoming an indispensible resource for strength and conditioning coaches. Previous research has shown that higher amounts of lean tissue mass have been associated with increased power outputs and lower levels of body fat percentage have been associated with improved aerobic fitness. **PURPOSE:** To examine the relationship between body composition and lower body power and aerobic fitness in elite collegiate hockey players. **METHODS:** Sixteen elite male Canadian university hockey players (age = 22.194 ± 0.99 years, weight = 85.74 ± 5.80 kg, height = 182.25 ± 6.67 cm), participated in the study at the beginning of their hockey season. All participants completed the long jump and the beep-test and a day after testing, one total body dual energy x-ray absorptiometry scan to measure body composition. Simple linear regression was used to explore the relationship between body fat percentage, visceral adipose tissue, and abdominal adipose tissue with aerobic fitness evaluations and leg lean with lower body power. **RESULTS:** On average body fat percentage was 16.6 ± 3.0%, fat mass 13.7 ± 2.8 kg, abdominal adipose tissue 0.9 ± 0.3 kg, leg lean mass 23.8 ± 1.97 kg, long jump 2.67 ± 0.16 m, beep test 12.8 ± 1.32 min. Visceral adipose tissue explained 24.5% of the variance in the test of aerobic fitness (p .05), while other adiposity measures were non-significant. Body fat percentage and lower lean mass did not significantly contribute to aerobic fitness and lower body power respectively (all p > .05). **CONCLUSIONS:** Despite a lack of inter-relationships among field tests and body composition, these variables should remain part a test battery to allow strength and conditioning coaches to better tailor training programs for elite hockey players. Keywords: body composition, hockey, Fitness testing

Comparison Of Direct And Indirect Vo$_{2max}$ Test In Mexican College Football Players.

Pedro G. Morales-Corral[1], Elfega Sámano-Pérez[1], Dulce E. Morales-Elizondo[1], Fernando A. Ochoa-Ahmed[1], Rosalinda Sepúlveda-Sepúlveda[2]. [1]*UANL, Monterrey, Mexico.* [2]*Harvard University, Cambridge, MA.*
(No relevant relationships reported)

Football is considered an anaerobic sport, therefore anaerobic evaluations are usually the main tests performed. Nonetheless, due to the number of plays and the duration of the game, the evaluation of the aerobic system through the measurement of the maximum oxygen consumption (VO$_{2max}$), becomes an important variable in the sport performance. The direct evaluation of the VO$_{2max}$ can be expensive due to the equipment and special laboratory conditions needed to perform it. Normally, most Mexican coaches perform indirect estimation of the VO$_{2max}$, through field test. **PURPOSE**: To determine direct VO$_{2max}$ of a sample of a Mexican College football team and compare the measurements with two different indirect methods. **METHODS**: Twenty voluntary Mexican College football players participated in the study. Informed consents were signed. Athletes were divided according to their play position into two groups: Lineman (LM) and No-Lineman (NL). Direct VO$_{2max}$ was measured through open-circuit spirometry by indirect calorimetry during a maximal graduated exercise test, using the Bruce protocol. The first indirect measurement (FIM) was performed using the Bruce protocol equation [VO$_{2max}$ (mL . kg^{-1} . min^{-1}) = 14.8 - 1.379 (time in min) + 0.451 (time^2) - 0.012 (time^3)] for a maximal graduated exercise test. The second indirect measurement (SIM) was taken using the ACSM´s running metabolic equation [VO$_{2max}$ (mL . kg^{-1} . min^{-1}) = 0.2 (speed) + 0.9 (speed) (fractional grade) + 3.5)] in the 1.5-mile run test. VO$_{2max}$ comparisons were made using Sperman´s correlation coefficient test. **RESULTS: :** LM´s direct VO$_{2max}$ (34.77 ± 10.41 mL . kg^{-1} . min^{-1}) was lower than NL´s direct VO$_{2max}$ (46.82 ± 4.41 mL . kg^{-1} . min^{-1}). Regarding, FIM of LM (32.56 ± 7.67 mL . kg^{-1} . min^{-1}) and SIM of LM (36.87 ± 5.18 mL . kg^{-1} . min^{-1}) both of them were lower than FIM of NL (42.56 ± 3.74 mL . kg^{-1} . min^{-1}) and

SIM of NL (45.96 ± 4.84 mL . kg^{-1} . min^{-1}). Correlations between direct VO$_{2max}$ and indirect VO$_{2max}$ were as follows: LM´s FIM= 0.79 (p<0.05), LM´s SIM= 0.63 (p<0.05), NL´s FIM= 0.78 (p<0.05) and NL´s SIM 0.73 (p<0.05).
CONCLUSIONS: Indirect measurements of VO$_{2max}$ can be used reliably to determine Mexican College football player's aerobic capacity when it is not possible or feasible to measure VO$_{2max}$ direct.

Relationship between Acceleration Profiles and Game Statistics among Members of a National U18 Ice-Hockey Team

Khristian Burke, Devon J. Erps, Davor Stojanov, Dakota J. Burke, Andrea Workman, Kenneth Martel, Stephen J. McGregor. *Eastern Michigan University, Ypsilanti, MI.*
(No relevant relationships reported)

The use of player-worn sensors (PWS) has become increasingly common in team sports. We have previously shown a relationship between PWS metrics during on-ice sessions and laboratory measures in ice hockey. It is not clear, though, if metrics derived from PWS are indicative of player performance in terms of performance results based metrics (e.g. goals, assists, etc.). **PURPOSE: :** To determine if on-ice measures obtained from PWS relate to player in-game statistics: plus/minus, goals, assists, or shots on goal.
METHODS: 19 members of the US National Team Development Program ice hockey team (17.5+.21 y, 1.82+0.8 m, 83.1+7.6 kg) consented to procedures approved by the EMU-HSRC. Zephyr Bioharness-3 (Zephyr, MD) PWS measured triaxial accelerations and heart rate for games. Data was downloaded to Omnisense (Zephyr, MD) and exported to database for mean maximal acceleration (MMA) determination. MMA from 10 - 90 sec at 10 sec intervals and from 2 - 60 min were calculated and used to determine relationships to game statistics. Game statistical data for each player for 10 games was obtained from USA Hockey, including plus/minus, goals, assists and shots on net. Pearson product correlations for game statistics and linear stepwise regressions were performed for game statistics vs. MMA using SPSS 22.0 (IBM, NY; α=.05).
RESULTS: Goals were correlated with shots (r = .35; p<.01), while plus/minus was correlated to goals (r = .24; p<.01) and shots (.14; p<.05). Linear regressions showed that goals were significantly related to 3 min MMA (β= .139; p =.02). Assists were related to 2 min (β= .135), 30 min (β= -.37), and 60 min (β= .226) MMA (p<.05). Shots were related to 3 min MMA ((β= .135; p<.05). No variables were accepted into the regression for plus/minus vs MMA.
CONCLUSIONS: Some metrics derived from PWS during on-ice sessions are related to game performance statistics. In particular, 2 and 3 min MMA would be indicative of a combination of anaerobic and aerobic energy system contributions and appear important for all scoring metrics.

Lowest Perceived Exertion In The Late Morning Due To Effects Of The Endogenous Circadian System

Saurabh S. Thosar, Maya X. Herzig, Sally A. Roberts, Alec M. Berman, Noal A. Clemons, Andrew W. McHill, Nicole P. Bowles, Miki Morimoto, Matthew P. Butler, Jonathan S. Emens, Steven A. Shea. *Oregon Health & Science University, Portland, OR.*
Reported Relationships: S.S. Thosar: *Salary; NIH F32 award.*

INTRODUCTION
There are daily variations in the rate of perceived exertion (RPE) during exercise, with lower RPE in the beginning of the night as compared to the early morning. Whether these variations are caused by effects of the internal circadian system or daily variations in the environment or behavioral patterns is not known. It is important to determine whether the endogenous circadian system affects RPE as this could influence sports performance when athletes experience prior jetlag.
METHODS
10 healthy adults (6 females, aged 52±2years [mean ± SEM]) participated in a protocol in dim light where all behaviors, including exercise, meals and sleep periods were evenly spread across the circadian cycle. After a normal night of sleep and baseline testing, participants underwent ten recurring 'behavioral cycles' of 2-h 40-min sleep opportunities and 2-h 40-min of standardized waking episodes. Approximately one hour after each sleep episode, participants performed cycle-ergometer exercise for 15-min at 50% predicted maximal heart rate (Karvonen's formula). The speed and resistance were identical across each cycling bout. Participants rated their exertion

using Borg RPE scale after 3, 8 and 13 minutes of exercise. Salivary melatonin was used as the circadian phase marker ($0°$ = the dim-light melatonin onset). RPE data were normalized within each participant (Z-scored), sorted into $60°$ (~4 h) circadian phase bins and compared across phases using repeated-measures ANOVA.
RESULTS
The circadian system significantly affected RPE, with lowest RPE in the late morning (circadian phase $210°$, ≈10:45 AM) and highest RPE during the biological night ($90°$ ≈3:45 AM).
CONCLUSION
We have uncovered an endogenous circadian effect on RPE with least perceived exertion in the late morning. This finding leads to the intriguing possibility of shifting the circadian phase of athletes (e.g. with bright light) to maximize performance, and has great relevance to athletes who experience jet lag.

Time Perception, Pacing And Exercise: Intensity Distorts The Perception Of Time
Andrew M. Edwards, Alister McCormick. *Plymouth Marjon University, Plymouth, United Kingdom.*
(No relevant relationships reported)

Currently there are no data examining the impact of exercise on the perception of time which is surprising as optimal competitive performance is dependent on accurate pacing using knowledge of time elapsed. **PURPOSE:** The purpose of this study was to examine whether or not differential, self-selected exercise intensities influenced the perception of time elapsed during both short duration and endurance exercise. Specifically, the experiment tested the hypothesis of whether maximal exercise distorts the perception of time. **METHODS:** With institutional ethics approval, 12 recreationally active adult participants (f=7, m=5) undertook both 30s Wingate cycles and 20min (1200s) rowing ergometer bouts as short and long duration self-paced exercise trials, in each of three conditions on separate occasions: 1) light exertion: RPE 11, 2)heavy exertion: RPE 15, 3) maximal exertion: RPE 20. Participants were unaware of exercise duration and were required to verbally indicate when they perceived (subjective time) 1) 25%, 2) 50%, 3) 75% and 4) 100% of each bout's measured (chronological) time had elapsed. **RESULTS:** In response to the Wingate task, there was no difference between durations of subjective time at the 25%, nor at the 50% interval. However, at the 75% and 100% intervals, the estimate for the RPE 20 condition was shortest (P<0.01). In response to rowing, there were no differences at the 25% interval, but there was some evidence that the RPE 20 condition was perceived shorter at 50%. At 75% and 100%, the RPE 20 condition was perceived to be shorter than both RPE 15 (P=0.04) and RPE 11 (P=0.008) conditions. **CONCLUSION:** This study is the first to empirically demonstrate that exercise intensity distorts time perception, particularly during maximal exercise. Consequently external feedback of chronological time may be an important factor for athletes undertaking maximal effort tasks or competitions.

Establishment of a Non-Exercise Questionnaire Using Physical Activity Exertion Perception to Predict Maximal Oxygen Uptake in Adults
Emily W. Flanagan, Craig P. Flanagan, Graham D. Salmun, Vanessa Lara, Wesley N. Smith. *University of Miami, Coral Gables, FL.* (Sponsor: Arlette Perry, FACSM)
(No relevant relationships reported)

Maximal oxygen uptake (VO_2max) is an important diagnostic variable for health and fitness status. ACSM has published several sub-maximal VO_2max prediction equations. Non-exercise VO_2max prediction equations currently exist, often requiring

variables obtained by a fitness professional. The equation published by Uth *et. al* (USOP) is often used to predict VO_2max from age and RHR measures. No validated models incorporate perceived exertion of physical activities. Non-exercise predictions of VO_2max may provide a quick, valuable alternative to sub-maximal assessments for healthcare providers in order to stratify disease risk and prescribe aerobic exercise. **Purpose**: The purpose of the study was to explore the efficacy of a non-exercise VO_2max assessment using a combination of perception of activities, body mass index (BMI), gender, and age. **Methods**: Twenty-seven subjects (ages 19-49) performed a maximal graded exercise test (GXT) and the Forestry Step Test (FST). Subject anthropometrics were assessed and all subjects completed a questionnaire in which perceived exertion was estimated for 15 well known physical activities. VO_2max estimations were derived from each of the activity items by dividing the metabolic equivalent by the percentage of perceived exertion. The USOP prediction of VO_2max used both RHR and the Tanaka MHR equation. Data was entered into a statistical software package where five activity items with the highest correlation to GXT VO_2max were used in a linear regression model to create a prediction model (PEQ). This was then compared to both the FST and USOP prediction equations. **Results**: Mean GXT VO_2max were 48.50 ± 1.74 ml/kg/min^{-1}. PEQ correlated most strongly with GXT ($F_{(8,18)}=6.159$, r=0.856, p=.001), followed by FST ($F_{(1,25)}=28.635$, r=.0731, p<0.001) and USOP ($F_{(1,25)}=8.575$, r=0.505, p=0.007). A model using age, gender, and BMI alone yielded a Pearson correlation of 0.791. **Conclusion**: The inclusion of exertion perception in VO_2max prediction models may strengthen the validity of non-exercise estimations. Future research should elucidate the most predictive activity items across populations. Given their ability to be self-administered, VO_2max prediction surveys can provide valuable information to large populations where traditional evaluation methods are impractical to perform.

Perceived Exertion As A Monitoring Strategy During Crossfit®: Useful Or Useless?
Derek Crawford, Nicholas Drake, Michael Carper. *Pittsburg State University, Pittsburg, KS.*
(No relevant relationships reported)

Perceived Exertion as a Monitoring Strategy during CrossFit®: Useful or Useless?
Facing harsh criticism of potentially causing injury, CrossFit® (CF) may benefit from the inclusion of appropriate monitoring strategies. Rate of perceived exertion (RPE) is a monitoring strategy commonly used for both quantification and modulation of workloads during exercise and sports training. Despite its widespread use in CF investigations, the validity of RPE as a monitoring strategy in CF training remains untested. **PURPOSE:** To assess the utility of RPE as a monitoring strategy during CF training. **METHODS:** Six males (height, 182.8±8.6 cm; weight, 84.3±12.4 kg; and age, 25.0±5.4 years) participated in three weeks (5 days/week) of CF training. Following each training session, RPE, workout duration (Dura), and immediate post-exercise heart rate (THR) were recorded. Dura and THR were used to quantify the workload (WL) for each session. Means for RPE, Dura, THR, and WL were calculated for week 1 and week 3 of training. The Profile of Mood States (POMS) questionnaire was administered pre-week 1 and post-week 3. A repeated measures MANOVA with Tukey post-hoc adjustments was used to assess differences in training session variables between weeks 1 and 3. Linear regression of mean RPE and WL were compared between weeks 1 and 3. POMS outcomes were compared between weeks 1 and 3 using magnitude-based inferences of each subscales' minimum clinically important difference (MCID). **RESULTS:** There are increases in mean session THR (%Δ=+6.2%; F=1.19, p=0.324), Dura (%Δ=+17.3%; F=4.55, p=0.086), and WL (%Δ=+23.9%; F=8.14, p=0.036) from week 1 to 3. In contrast, mean session RPE decreased (%Δ=-4.9%; F=1.42, p=0.183) between these weeks. RPE was a better predictor of WL during week 3 compared to week 1 (week 1: r=0.364, R^2=13.5%, p=0.048; week 3: r=0.614, R^2=37.7%, p=0.001; ΔR^2=+24.2%). For POMS outcomes, total mood disturbance (2.69 foldΔ; 87.6% likelihood), tension-anxiety (3.13 foldΔ; 90.7% likelihood), and vigor-activity (3.25 foldΔ; 94.9% likelihood) subscales most likely highlight meaningful negative changes. **CONCLUSION:** RPE has the potential to be a useful monitoring strategy for incorporation into CF training. Questions still remain as to whether or not RPE is sensitive enough to detect early signs of overreaching during CF training.

Effect Of Progressive Fatigue On Session Rpe
Carl Foster, FACSM, William Sustercich, Keegan Edgerton, Richard P. Mikat, FACSM, Matthew Andre, John P. Porcari, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*
(No relevant relationships reported)

Introduction: The Session Rating of Perceived Exertion (sRPE) is an accepted surrogate measure of exercise intensity. The purpose of this study was to examine the effect of progressive fatigue from heavier than normal training on sRPE. **Methods**: Twelve moderately fit college age students completed 30-min or 60-min interval

workouts on a cycle ergometer, with the sequence of sessions designed to test the hypothesis that sRPE for a given exercise bout would increase with progressive fatigue, whether from a longer bout, or from successive days of harder than usual bouts. The workouts were Monday through Thursday for two weeks. The first week was three 30-min sessions (e.g. normal training) followed by a 60-min session (30-min session repeated 2x) (e.g. heavier than usual training). The second week was three 60-min sessions followed by a 30-min session. sRPE was measured 30-min post exercise, and RPE and HLa were measured at 10 min intervals during exercise. **Results**: The 30-min sessions in week 1 had sRPE that was significantly less than the 60-min session $(4.3\pm1.7, 4.3\pm1.4, 4.5\pm1.7 \& 5.3\pm1.8)$. During week 2 the 60-min sessions became progressively harder, before the recovery 30-min session on day 4 $(5.3\pm1.4, 5.9\pm1.6, 6.0\pm2.1 \& 4.5\pm1.6)$. The mean RPE/HLa during the exercise bouts, a potential index of glycogen depletion mediated fatigue, followed a relatively constant course in week 1 $(0.7\pm0.2, 0.9\pm0.4, 0.8\pm0.4 \& 0.9\pm0.4)$ and an increasing course in week 2 $(0.8\pm0.4, 0.9\pm0.4, 1.0\pm0.4 \& 0.9\pm0.4)$. **Conclusion**: The results suggest that in addition to being a surrogate of exercise intensity, sRPE reflects accumulated fatigue during periods of increased training.

Perceptions of Employers of Personal Trainers: A Pilot Survey

Marla Jones, William Russell, Justin Kraft, FACSM, Kenneth G. Kriewitz, Tiffany Domon, Cassidy Chappell. *Missouri Western State University, Saint Joseph, MO.* (Sponsor: Justin Kraft, FACSM)
(No relevant relationships reported)

The American College of Sports Medicine (ACSM) developed its certified personal trainer (CPT) exam based on a job task analysis (JTA) of a trainer's day-to-day job-related tasks. To competently perform the duties of a personal trainer, one should possess certain knowledge, skill, and abilities (KSAs) identified by the JTA. **PURPOSE**: The purpose of this study was to determine employer perceptions of the importance of various KSAs identified by ACSM's JTA. **METHODS**: A 42 item survey was developed based on ACSM's 153 KSAs and also included questions regarding demographics and hiring preferences. Selection of KSAs was based on their generalizability to personal trainers working in various settings. Employers were asked to use a 1-5 Likert scale (1= not important and 5 = very important) to rank their perception of how important it is for personal trainers to possess the KSAs. The survey was distributed online and in person to approximately 80 employers. A total of 20 surveys were completed and returned. The KSAs in the survey were divided into the eight ACSM categories. Qualtrics was used to determine mean responses to each of the survey items and provided frequency data for demographics and hiring preferences. **RESULTS**: Overall mean for each category and KSA was determined. The category with the highest overall mean (4.63) was Safety, Injury Prevention, and Emergency Procedures. The category with the lowest overall mean (4.24) was Human Behavior and Counseling. The KSA with the highest overall mean (4.76) was the ability to modify exercises based on age and physical condition (1.7.29). The KSA with the lowest overall mean (3.65) was the ability to determine training heart rate (1.7.25). Only 50% of respondents stated that personal trainers should possess a degree in Exercise Science or a related field. Sixty-five percent stated personal trainers should be certified through a nationally recognized certifying agency. The top two preferred certifying agencies were ACSM and NSCA. **CONCLUSIONS**: Employers are most concerned with knowledge and abilities related to safety, injury prevention, and emergency procedures and least concerned with knowledge and skills associated with behavior change and counseling. Respondents emphasized professional certification over a degree in Exercise Science or related field when hiring.

Relationship between Self-Regulation of Perceive Exertion and Heart Rate using Games Concept Approach

Peggy Boey[1], Govindasamy Balasekaran, FACSM[1], Visvasuresh Victor Govindaswamy[2], Yew Cheo Ng[1], Jolene Lim[1]. *[1]Nanyang Technological University, Singapore, Singapore. [2]Concordia University Chicago, Chicago, IL.*
(No relevant relationships reported)

There is a lack of research on the use of OMNI Rate of Perceived Exertion (RPE) scale with Heart Rate (HR) during Physical Education (PE) lessons. **PURPOSE**:To examine the relationship between OMNI RPE scale and HR on primary school children in Singapore using the Games Concept Approach (GCA) of teaching during PE lessons. **METHOD**: A total of 18 healthy subjects, 9 boys (age: 10 ± 0.00 yrs, height: 138 ± 5.94cm, weight: 34.56 ± 7.30kg) and 9 girls (age: 10 ± 0.50 yrs, height: 135 ± 8.00cm, weight: 33 ± 10.45kg) were randomly separated into experimental (EG) and control group (CG) with 9 subjects each. The intervention was conducted over 6 weeks, each lasting 45 minutes. Every session comprised of a warm up, modified game (MG) and cool down. The MG was conducted using GCA for the EG and skills based approach

(SA) for the CG. HR and RPE were recorded every 15 minutes of each session. Parental consent was obtained and orientation procedures on the use of OMNI RPE scale were administered prior to intervention. Self-regulation of RPE by subjects was at RPE 1-3 for both warm up and cool down, and RPE 4-6 for the MG. A 1.6km fitness run test was conducted pre- and post- intervention to assess their aerobic fitness. Physical activity was kept constant throughout the intervention by a physical activity questionnaire, verbal emphasis and monitoring. **RESULTS**: HR values were significantly different during MG (EG: 159.03 ± 12.22beats.min[-1], CG: 129.99 ± 17.23beats.min[-1], p = 0.001). Percentage of HR_{max} was higher in EG (75.73%) than CG (61.9%). No significant difference was observed between the RPE values during the MG for both groups (EG: 4.30 ± 1.16, CG: 3.73 ± 1.72, p = 0.426). Significant difference was observed between EG and CG in the pre- (EG: 693.67 ± 98.03sec, CG: 817.11 ± 92.98sec, p = 0.015) and post- (EG: 614.89 ± 74.18sec, CG: 712.00 ± 68.51sec, p = 0.011) 1.6km run timings. **CONCLUSION**: Improvement in aerobic fitness was reflected in the 1.6km post-test results for EG and CG. HR recorded from EG was slightly higher than 50-70% of HR_{max} but range of RPE during MG was kept consistent within the ventilatory breakpoint of RPE 4-6, which suggests their ability to self-regulate within the safe intensity. The GCA approach is recommended to PE teachers for students to work at a higher HR to achieve aerobic fitness while having fun utilizing motor skills.

Comparison of Borg Rpe and CR-10 Scales in Incremental Exercise

Reese A. Glover[1], Blaine E. Arney[1], Cristina Cortis[2], Jos J. de Koning, FACSM[3], Andrea Fusco[2], Salvador Jaime[1], Richard Mikat, FACSM[1], John P. Porcari, FACSM[1], Teun van Erp[3], Carl Foster, FACSM[1]. *[1]University of Wisconsin-La Crosse, La Crosse, WI. [2]University of Cassino and Lazio Meridionale, Cassino, Italy. [3]Vrije Universiteit-Amsterdam, Amsterdam, Netherlands.*
(No relevant relationships reported)

The Borg Rating of Perceived Exertion (RPE) and Category Ratio (CR-10) scales are the most well-known and frequently used scales for quantifying subjective intensity during exercise. However, limited data exists comparing the intra-individual correlations among the Borg RPE and CR-10 scales. **PURPOSE:** To evaluate the intra-individual variability between the Borg RPE and CR-10 scales during incremental exercise. **METHODS:** 5 males (20.4±1.14 years) and 5 females (22.0±0.71 years) completed two graded exercise tests (GXTs) on an electronically-braked cycle ergometer with a 48-hour interval in between. Each GXT included 2-minute stages with increments of 25 Watts/stage to volitional fatigue. Heart rate (HR), oxygen consumption (VO_2) and power output (PO) were measured. Subjective responses were recorded at the end of each stage using Borg RPE and CR-10 scales with a randomized order between the GXTs. Pearson's correlation with 95% Coefficient Intervals (95% CI) was used to examine the relationship between the Borg RPE and CR-10 scales. **RESULTS:** Maximal values during GXT were: VO_2max = 48.0±8.13 ml/kg/min, HRmax = 191.0±6.65 bpm; Peak PO = 238.1±56.83 Watts; RPEmax = 18.7±0.95; CR-10max = 9.1±1.28). There was a significant (p<0.0001) and very strong correlation coefficient (r=0.94, 95% CI: 0.91-0.96). **CONCLUSION:** Results from this study showed that the Borg RPE and CR-10 scales are related in a highly regular and predictable way.

Self-Confidence is Positively Related to Rating of Perceived Exertion During a Maximal Squat Test

Colby A. Sousa[1], Michael H. Haischer[1], Daniel M. Cooke[1], Joseph P. Carzoli[1], Amber M. Shipherd[2], Trevor K. Johnson[1], Edward P. Davis[1], Dan J. Belcher[1], Robert F. Zoeller[1], Michael Whitehurst, FACSM[1], Michael C. Zourdos[1]. [1]*Florida Atlantic University, Boca Raton, FL.* [2]*Texas A&M University-Kingsville, Kingsville, TX.*

(No relevant relationships reported)

Often, rating of perceived exertion (RPE) is assessed during a one-repetition maximum (1RM) strength test to validate that a true 1RM has been reached. Recently, data have indicated variance in reported RPE at 1RM across individuals. However, it is not known what accounts for this variation. Two proposed traits which may affect an individual's RPEs are self-confidence and acute anxiety. **PURPOSE**: Therefore, the purpose of this investigation was to examine the relationship between self-confidence, somatic anxiety, and cognitive anxiety with RPE at a 1RM in the back squat. **METHODS**: Fifty-eight resistance-trained males (n=41) and females (n=17) (age: 23±3yrs; body mass: 80.64±16.49 kg) completed the Revised Competitive State Anxiety Inventory-2 (CSAI-2) questionnaire prior to performing a 1RM back squat. Additionally, participants completed a perceived self-efficacy (PSE) questionnaire in which participants stated what they believed they were 100%, 75%, and 50% confident they could squat for a 1RM. Next, following a 5-minute dynamic warm-up, subjects completed a validated 1RM back squat protocol. At all 1RM attempts subjects recorded an RPE value using the repetitions in reserve (RIR)-based RPE scale. Pearson's product moment correlations were then utilized to determine the relationship between the self-confidence, somatic, and cognitive anxiety subscales of the CSAI-2 with RPE at 1RM. **RESULTS**: Self-confidence was positively and significantly related to RPE at 1RM (r=0.26, p=0.05). However, neither somatic anxiety (r=0.01, p=0.97) nor cognitive anxiety (r=0.19, p=0.16) were significantly related to RPE at 1RM. **CONCLUSIONS**: These results indicate that increased self-confidence is associated with higher reported RPE during a 1RM squat test, while heightened anxiety does not alter the perceptual response during a maximal strength test. It is possible that those with high self-confidence chose higher loads and reached a true 1RM accounting for the high RPE.

Effects of Performance Foam on Perceived Exertion and Recovery in High-Intensity Functional Exercise

Justin M. Goins, Toni M. Torres-McGehee, Tim Bailey, Samantha Weber, Jacob Kay. *University of South Carolina, Columbia, SC.*

Reported Relationships: J.M. Goins: *Contracted Research - Including Principle Investigator; Funded by Avadim Technology - C0-PI Toni M. Torres-McGehee.*

Performance foam, when used as an adjunct to training, may positively affect thresholds within the muscle allowing for more intense training, longer training sessions, possible muscle recovery, and a decrease in delayed onset muscle soreness symptoms. **PURPOSE:** To evaluate the effectiveness of a performance foam on perceived exertion and self-reported recovery on performance in adults participating in a high-intense functional exercise program. **METHODS:** Thirty adults (age: 31.2 ± 8.1; males: n = 12, 176.9 ± 6.2 cm, 89.5 ± 15.1 kg; females: 164.7 ± 7.1 cm, 69.9 ± 11.1 kg) participated in a randomized counter-balanced and double blind trial over a 2-week period. Randomized experimental conditions (ExCon) consisted of performance foam (PF) or placebo (P) foam. Participants completed 5 workouts each week and applied either PF or P to the primary muscles used before and after each daily workout and before going to bed. Rating of perceived exertion (RPE) was assessed after each workout, and self-reported recovery was assessed using the perceived recovery scale (PRS) the following day. Four repeated measure ANOVAs examined differences in PRS and RPE between experimental conditions (PF and P) for all participants and across gender. **RESULTS:** A main effect was revealed for **RPE** and ExCon (F_1=4615.2, P < 0.01, n²=0.99) for all participants. Interactions existed between days (P ≤ 0.01) with no interaction found between ExCon and days. A main effect was revealed for **PRS** and ExCon (F_1=1624.6, P ≤ 0.01, n²=0.98) for all participants with no interactions between days and ExCon and days. Across gender, a main effect was revealed for **RPE** and ExCon (F_1=4279.9.8, P < 0.01, n²=0.99) with no interactions between days and ExCon and days. Similarly, a main effect was found for **PRS** and ExCon (F_1=1579.8, P < 0.01, n²=0.98) with no interactions between days and ExCon and days. **CONCLUSIONS:** RPE declined at the end of 5-day regimen using PF compared to P and participants' average PRS was higher throughout the week using the PF compared to P. Participants felt more recovered from the previous workout when using PF and felt as if they were not exerting as much effort the following workout. The decrease in RPE allows for one to continue exercising longer at the same intensity or increase their intensity levels, leading to a greater improvement in training results.

808   Board #69   May 30 2:00 PM - 3:30 PM
Comparison Of HR And RPE During Self-selected And Prescribed Exercise Bouts In College Students

Ashley Ewald, Nicholas Boer, Kara Hamilton. *University of Tennessee at Chattanooga, Chattanooga, TN.*

(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if there were differences in heart rate (HR) and ratings of perceived exertion (RPE) between self-selected and calculated exercise intensities. **METHODS:** Subjects (n=47) were instructed to complete moderate (M) and vigorous (V) intensity exercise bouts for 20 minutes each on a treadmill ergometer. Subjects selected M and V speed and grade, and kept intensity constant throughout each bout. Subjects next completed a graded maximal exercise test using one of five Boer treadmill protocols. Finally, subjects completed exercise bouts at 60% and 80% of their calculated VO_2 reserve for 20 minutes. HR (Polar FT1) and RPE (OMNI scale) were collected at minute 2 and 20 of each bout. A repeated measures ANOVA was completed with Bonferroni post hoc comparisons to evaluate differences between corresponding intensities (Mx60% and Vx80%) by time and between minute 2 and 20 for each bout. **RESULTS:** There were no statistically significant differences (p>0.05) for HR between M and 60% (2min: 126.3±25.8 and 134.2±27.8; 20min: 142.5±31.2 and 161.7±5.8, respectively) or between V and 80% (2min: 154.1±28.1 and 153.6±28.6; 20min: 179.8±26.9 and 184.7±24.6, respectively) There were no statistically significant differences (p>0.05) for RPE between M and 60% (2min: 2.9±2.7 and 1.9±1.1; 20min: 4.3±2.8 and 4.8±1.8, respectively) or between V and 80% (2min: 4.3±2.1 and 3.1±1.6; 20min: 7.2±1.8 and 7.8±1.5, respectively). HR and RPE increased significantly from minute 2 to 20 during each bout (p<0.0001). **CONCLUSION:** HR and RPE did not differ between self-selected and calculated exercise bouts, but drifted significantly within all sessions. While subjects showed aptitude at selecting proper intensities, caution must be used when prescribing exercise based on HR or RPE.

Effect of Spotters on State Anxiety and Self Confidence During Maximal Squatting Among Male High School Athletes

Drew Rykert[1], Abigail Larson[1], Chad Harris, FACSM[2], Kent J. Adams, FACSM[3], Mark DeBeliso, FACSM[1]. [1]*Southern Utah University, Cedar City, UT.* [2]*Metropolitan State University of Denver, Denver, CO.* [3]*California State University Monterey Bay, Seaside, CA.* (Sponsor: Mark DeBeliso, FACSM)

(No relevant relationships reported)

The ideal performance state is manifested by optimal psychological and physiological efficiency. The effects of anxiety and self-confidence have been shown to alter psychological and physiological efficiency and hence performance. **PURPOSE:** This study attempted to identify the state anxiety and self-confidence of high school athletes just prior to a one repetition maximum (1-RM) back squat and determine if the number of spotters affects an athlete's level of state anxiety and/or self-confidence. **METHODS:** Male high school athletes (10th and 11th grades) were randomly separated into two experimental groups who performed the 1-RM back squat (BSQ) with either 1 spotter (1SG: n=52) or 3 spotters (3SG: n=54). Following a dynamic warm-up period and several progressive BSQ warm-up sets, and just prior to attempts at a 1-RM BSQ, the participants completed the revised Competitive State Anxiety Inventory-2 (CSAI-2R). The CSAI-2R included the number of spotters (1 or 3) that would be present during the subsequent 1-RM BSQ attempts. The CSAI-2R is a17-question instrument with three subscales (self-confidence, somatic anxiety, and cognitive anxiety). The subscale scores were compared between the 1SG and 3SG with an independent t-test (alpha≤0.05). **RESULTS:** Competitive State Anxiety Inventory-2 scores were 1SG (self-confidence=30.2±6.1, somatic anxiety=17.0±4.7, and cognitive anxiety=20.1±5.6) and 3SG (self-confidence=28.4±6.8, somatic anxiety=16.5±5.1, and cognitive anxiety=19.0±5.7). None of the subscales (self-confidence, somatic anxiety, and cognitive anxiety) were significantly different between the 1SG and 3SG experimental groups (p>0.05). **CONCLUSION:** Within the parameters of this study, the number of spotters present during the execution of the 1-RM BSQ had no practical or statistical impact on self-confidence, somatic anxiety, and cognitive anxiety. Coaches and athletes could use this information in the training environment in order to make best use of personnel (assigned to spotting tasks), physical resources (ex. squat racks), and time management.

Comparing Training Load and Intensity Perceptions Between Female Distance Runners and Their Coach

Lawrence W. Judge[1], Beau M. Links[2], Andrew Mullally[2], Mark King[2], Zachary Waterson[2], David M. Bellar[3]. [1]Ball State University, Muncie, IN. [2]Fort Wayne Medical Education Program, Ft. Wayne, IN. [3]University of Louisiana at Lafayette, Lafayette, LA. (Sponsor: Matthew Harber, FACSM)

(No relevant relationships reported)

The ability of athletes and coaches to adapt training in order to improve athletic performance and prevent injuries is the cornerstone of modern sports medicine. Overtraining syndrome occurs when training consistently occurs at or above lactate threshold without appropriate recovery. It is critical that the coach's perceptions of effort and intensity of training are similar to what the athlete experiences. **PURPOSE:** The purpose of this study was to evaluate the training regimen fidelity and quantify training load and intensity in female division I collegiate distance runners. **METHODS:** An observational descriptive longitudinal design was utilized. The duration of the data collection was 14 weeks. The subjects were six collegiate female track and field distance athletes (≥18yrs of age) who ran >800 meter events. Baseline pre-training heart rate and blood lactate levels were recorded during a custom six stage treadmill test. Blood lactate, duration, rate of perceived exertion (RPE), average heart rate for each training session and hours slept nightly were recorded. **RESULTS:** Average training intensity (duration x RPE) over the course of the competitive season as prescribed was 159.56. The mean value was 144.5 and results ranged from 126.21 to 156.62. Coach intended training load (duration x blood lactate average) was 170.75; athletes ranged 73.25 to 140.66; mean = 109.36. Hours of sleep averaged 7.8 the day before a meet and 7.3 the day after. Easy training days (intended RPE of 1.5 out of a possible 10) showed a discernible difference with actual RPE higher than the target value (mean 3.4 ±1.2, range 2.7- 4.26). Intermediate training days (intended RPE of 4.3) had a lower RPE than target with a mean of 3.9 ±1.6 (range 3.0 - 4.8). Hard training days (intended RPE of 8.16) showed the most marked difference from target with a mean of 6.24 ±1.4 (range 4.94 - 7.25). **CONCLUSIONS:** Similar to male athletes, female athletes perceived easier workouts as more difficult and harder workouts as easier than their coaches intended. Average training intensity and training load (duration x blood lactate average) were measurably less than their coach intended. The combination of poor adherence to their coach's training regimen and potentially inadequate recovery may be some of the etiologies for increased overuse injuries in female athletes.

Rating Of Perceived Exertion In The Squat Until Muscle Failure Versus Non-failure In Women

Wanderson Divino Nilo dos Santos[1], Carlos Alexendre Vieira[1], Ronyson Camilo Soares[1], João Felipe Mota[1], Alcides Corrêa de Morais Junior[1], Martim Bottaro[2], Paulo Gentil[1]. [1]Federal University of Goias, Goiânia, Brazil. [2]University of Brasília, Brasília, Brazil.

(No relevant relationships reported)

PURPOSE: The objective of this study was to compare the rating of perceived exertion (RPE) and the volume of repetitions in women performing the parallel squat in the Smith machine in two different situations, repetitions until failure or non-failure. **METHODS**: A randomized, crossover trial was performed, involving twelve women (24.93 ± 5.04 years, 59.29 ± 11.28 kg) with previous experience in strength training (4.5 ± 4.23 years). Participants were randomized to either muscle failure (MF) or non-muscle failure (NF) groups. The RPE (OMNI-RES 0-10) and the total volume of session repetitions in the MF and NF situations in the parallel squat in the Smith Machine were evaluated. The protocol consisted of: 4 sets of 10 RM (determined by the 10 RM test), with 2 min rest interval between sets, at the highest intentional movement speed, until muscle failure or until loss of 20% of the median propulsive velocity (MPV). All participants performed the two methodologies with interval of two to three days of rest. Movement velocity control was provided by the linear transducer T-Force® System (Ergotech, Spain). Descriptive analyzes were given by mean and standard deviation, using repeated measures ANOVA (2:4) with Tukey post hoc and independent t test for the total volume of repetitions. **RESULTS**: A higher RPE was observed in the MF versus NF (1 set: 9.67 ± 0.78a vs 5.91 ± 1.68c; 2 set: 10a vs 6.75 ± 1.86bc; 3 set: 10a vs 7.33 ± 1.72bc, 4 set: 8.08 ± 1.16b, p <0.0001), respectively. No differences were observed between the total volume of repetitions (MF vs NF: 26.25 ± 3.47 vs 24.5 ± 3.65, respectively, p = 0.19). **CONCLUSIONS**: In women, performing the parallel squat on the Smith Machine, at the highest intentional speed, until 20% drop in MPV produced similar total volume of repetitions and lower RPE when compared to its execution until muscle failure.

B-61   Free Communication/Poster - **Blood Flow**

Effects of High-Intensity Interval Training on Plasma Volume

William B. Trimble, II, Jerita Mitchell, Olivia D. Hocevar, Tyron'E Hawkins, Robert R. Kraemer, FACSM. *Southeastern Louisiana University, Hammond, LA.* (Sponsor: Dr. Robert R Kraemer, FACSM, FACSM)

(No relevant relationships reported)

High-intensity interval training (HIIT) has been shown to be an effective form of training to improve aerobic fitness. Plasma volume shift has the potential to contribute to acute fatigue via temporary reduction of blood volume. There is a lack of data regarding the acute effects of HIIT on plasma volume shifts over the course of an HIIT protocol. **PURPOSE:** The purpose of the study was to determine the effects of a bout of HIIT on changes in plasma volume during and after the protocol. **METHODS:** Eight participants (1 female, 7 males) completed a preliminary session to collect anthropometric data and determine cardiorespiratory fitness, followed by an experimental session. During the experimental session, a modified Tabata HIIT protocol on a cycle ergometer was completed: six 15-second sprints at maximum effort against a resistance proportional to lean body mass with two minutes of active recovery between sprints. Hematocrit was determined using a microhematocrit method and hemoglobin was determined using a hemoglobin meter. Plasma volume shifts were determined using hematocrit and hemoglobin concentrations. **RESULTS:** A repeated measures ANOVA was used to determine changes in oxygen consumption (VO_2), mean arterial pressure (MAP), heart rate (HR), and minute ventilation (V_E); t-tests were used for post-hoc analysis. Additionally, shifts in plasma volume were compared using a paired T-test. A significant ($P < 0.05$) change from pre- to mid-HIIT occurred for HR (80.625±4.52 to 173.50±3.78 b/min), VE (26.75±2.87 to 69.85±6.95 L/min), VO2 (11.68±1.45 to 27.49±3.59 ml/kg/min), MAP (93.08±1.65 to 122.75±2.86 mmHg), and plasma volume shift (-12.28±2.14%) with significantly ($P < 0.05$) greater changes in HR from mid- to post-exercise (173.50±3.78 to 181.00±3.15 b/min) but not VE, VO2, MAP or plasma volume shift (-2.69±1.85%). **CONCLUSION:** Findings revealed that 13 min of HIIT increases cardiorespiratory stress and results in large plasma volume reductions from pre- to mid-exercise with smaller reductions from mid- to post-exercise. These acute reductions in plasma volume are similar to reductions that have been reported after running a marathon.

Cardiovascular Responses to Blood Flow Restriction and Very Low Load Resistance Exercise in the Upper Body

J Grant Mouser, Kevin T. Mattocks, Scott J. Dankel, Samuel L. Buckner, Matthew B. Jessee, Zachary W. Bell, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

Blood flow restriction (BFR) applied as a percentage of arterial occlusion pressure (AOP) combined with low load resistance exercise in the upper body elicits a cardiovascular response that, compared to high-load resistance exercise, appears dependent upon the load as well as the cuff pressure. The response to very low load resistance exercise (15% 1RM) combined with BFR is unknown. **PURPOSE:** To investigate the cardiovascular and hemodynamic responses to very low load resistance exercise combined with BFR, and compare these to high load resistance exercise in the upper body. **METHODS:** Sixty-six (50% men) participants (18-35 yrs) were recruited and, following 1RM testing, were randomly assigned to either high load (HL) at 70% 1RM or very low load at 15% 1RM. Very low-load conditions were no restriction (VLL0), 40% AOP (VLL40), or 80% AOP (VLL80) applied using a 5cm cuff. Four sets of unilateral biceps curls were performed to failure or 90 repetitions, whichever occurred first. Blood pressure (SBP/DBP) was taken before and after. Ultrasound measures of blood flow (BF) were taken at rest, following Set 2, and 1 minute after exercise. Repeated measures ANOVA tests were performed to determine whether differences occurred across time and condition. Results presented as mean (SD). **RESULTS:** Participants were 1.72 (0.1) m tall, weighed 72.0 (13.8) kg, with a 1RM of 15.9 (7.4) kg, and AOP of 103 (73) mmHg. There were no interactions for SBP ($p = 0.416$), DBP ($p = 0.414$), but an interaction existed for BF ($p < 0.0005$). Main effects of time found that SBP [change of 10 (10) mmHg] and DBP [change of 6 (13) mmHg] increased. BF increased following Set 2 in all conditions except for VLL80 (p=0.129), which remained similar to pre until 1 minute post deflation [change of 378 (256) ml·min[-1]]. Following set 2, BF was similar between VLL0 [547 (244) ml·min[-1]] and HL [465 (269) ml·min[-1]]; both were greater than VLL40 [365 (189) ml·min[-1]]

WEDNESDAY, MAY 30, 2018

and VLL80 [128 (75) ml·min^{-1}]. At 1 minute post, there were no differences in BF between VLL0: 438 (227), VLL40: 470 (248), VLL80: 464 (290), and HL: 364 (239) ml·min^{-1}. **CONCLUSIONS**: The hemodynamic response to very low load resistance exercise combined with BFR at different pressures is similar to high load resistance exercise when performed in the upper body, although the BF response differs per the cuff pressure.

Novel Gene Variant Associated with Exercise Pressor Reflex Responsiveness

Nathan Garvin, John Hayes, David Vandenbergh, James A. Pawelczyk, FACSM. *Pennsylvania State University, University Park, PA.* (Sponsor: James A Pawelczyk, FACSM)

(No relevant relationships reported)

PURPOSE: Activation of thinly myelinated and unmyelinated afferents innervating contracting skeletal muscle elicits the exercise pressor reflex. We hypothesized that single nucleotide polymorphisms (SNPs) of genes encoding ionotropic and metabotropic receptors commonly found on skeletal muscle afferents might account for part of the typical variation in blood pressure responses to exercise. **METHODS**: 101 healthy, college age, men and women of European ancestry participated. Multivariate modeling of the mean arterial pressure response to post-exercise circulatory arrest following 3-min of static handgrip exercise (30% of maximum) was used to stratify subjects into quartiles. Subjects from the highest (N=33) and lowest (N=25) quartiles provided buccal mucosa cells. DNA was extracted, amplified, and analyzed for common (minor allele frequency >20%), non-synonymous SNPs of genes with functional associations to autonomic disorders. We evaluated selected variants of the TRP (N=18), ASIC (N=3) and P2X (N=4) receptor families (real-time PCR, custom OpenArray™) and used contingency table analysis to compare the frequency of homozygotes and trait allele carriers between the two groups. **RESULTS**: Trait allele carriers of rs8065080, a T-to-C missense mutation of TRPV1, were more frequent in the high response group (73% vs 48%, P<0.1). Frequencies of all other SNPs did not differ between groups. **CONCLUSIONS**: Data from this pilot investigation suggest that intra-subject variation in mean arterial pressure during post-exercise circulatory arrest may associate with SNPs of genes putatively linked to the metabolic component of the exercise pressor reflex. Additional work is warranted to confirm these observations and explore the mechanistic role of TRP channels in exercise pressor reflex responsiveness. Supported in part by the Huck Institutes of the Life Sciences and the College of Health and Human Development.

Acute Hemodynamic Response to Very Low Load Resistance Exercise With or Without Blood Flow Restriction

Kevin T. Mattocks, J Grant Mouser, Matthew B. Jessee, Scott J. Dankel, Samuel L. Buckner, Zachary W. Bell, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

Although lifting a load at 30% one-repetition maximum (1RM) to failure elicits an increase in muscle size similar to high load resistance exercise, it is unknown if an individual can reach failure when lifting loads <20% 1RM. Applying blood flow restriction (BFR) can cause blood flow to be artificially reduced which may help create an environment necessary to induce fatigue when exercising with a load <20% 1RM. **PURPOSE**: To determine changes in blood pressure and blood flow following exercise with and without different levels of BFR (based on arterial occlusion pressure (AOP)) while using a very low load (15% 1RM) and compare those changes with high load (70% 1RM) exercise. **METHODS**: Sixty-nine participants were randomized into one of four conditions: 1) 15% 1RM, no BFR (15/0), 2) 15% 1RM, 40% AOP (15/40), 3) 15% 1RM, 80% AOP (15/80), and 4) 70% 1RM, no BFR (70/0). Following 1RM testing in one leg (randomized) and 10 min of seated rest, resting blood flow of the exercising limb was measured at the posterior tibial artery followed by blood pressure. AOP was determined using a 10cm wide cuff in the BFR conditions. Participants then exercised for 4 sets to failure (up to 90 repetitions) with 30 (15% 1RM) or 90 (70% 1RM) seconds of rest. Blood flow and blood pressure [Systolic (SBP), Diastolic (DBP)] were measured immediately after exercise. A repeated measures ANOVA with a between subject factor of group was used to determine differences between groups. Significance was set at p ≤ 0.05 and data presented as mean (SD). **RESULTS**: There was an interaction for SBP. There were no differences between groups at pre (p=0.874) or post (p=0.064) and all conditions increased from Pre-Post [overall average change of 15 (10) mmHg]. However, the 15/80 condition [125 (14) mmHg] tended to have lower SBP values than the 15/0 [138 (14) mmHg] and 70/0 [136 (14) mmHg] conditions. There was no interaction for DBP (p=0.485) or blood flow (p=0.088) but there were main effects of time with an increase from Pre to Post [DBP: 3 (5) mmHg;

blood flow: 3 (13) ml·min^{-1}]. **CONCLUSIONS**: Very low load exercise to failure with or without BFR induces a similar hemodynamic response (i.e. blood flow and blood pressure) compared to high load resistance exercise. This suggests that applying BFR does not augment the cardiovascular response over that observed with traditional resistance exercise.

Comparison of Exercise-induce Endothelial Shear Stress Between Poiseuille'S Law and Womersley'S Approximation

Francisco J. Morales[1], Brycen J. Ratcliffe[2], Caleb D. Harrison[2], Evan J. Bockover[2], Sierra Crowe[2], Colin R. Carriker[3], Alvaro N. Gurovich, FACSM[1]. *[1]The University of Texas at El Paso, El Paso, TX. [2]Indiana State University, Terre Haute, IN. [3]High Point University, High Point, NC.*

(No relevant relationships reported)

Purpose
Endothelial dysfunction is the first step for the development of atherosclerosis, and one protective regulatory mechanism is exercise-induced endothelial shear stress (ESS). To quantify ESS, most clinical studies employ Poiseuille's law rather than Womersley's approximation, although Poiseuille's law underestimate the dynamic properties of blood flow. The aim of this study is to compare ESS calculated by Poiseuille's law to EES estimated by Womersley's approximation during exercise.

Methodology
Twelve young healthy subjects (age 13-31, 10 males and 2 females) were recruited to perform two exercise tests on a cycle ergometer. The first test was a maximal incremental test to establish the workloads for the next test, according to lactate levels. The second one, performed at least 48 hours after the first exercise test, was a three 5-minute workload steady-state test at lactate levels of 0-2, 2-4, and >4 mmol/L. Blood flow patterns of the brachial artery were recorded via Doppler ultrasound. For Poiseuille's law ESS was determined during anterograde and retrograde blood flows using $ESS=\mu*SR$ and $SR=2*V/D$, where μ is blood viscosity, SR is shear rate, V is peak systolic or diastolic blood flow velocities, and D is artery diameter. For Womersley's approximation $ESS=\mu*SR$ and $SR=2K*V/D$ were used, where K is a complex factor dependent on Womersley parameter (α), and $\alpha=(D/2)*(\omega/(\mu/\rho))^{1/2}$, where ω is the angular frequency of the flow pulsation ($\omega=freq*2\pi$), and ρ is blood density. Statistical analysis included paired t test to compare ESS from both estimations.

Results
EES was significantly higher for Womersley's approximation in comparison to Poisueille's law at rest and during all exercise intensities for anterograde flow (basal: 34.7±5.8 vs. 13.1±2.6 dynes/cm^2; 0-2 mmol/L: 41.1±13.7 vs. 15.3±4.8 dynes/cm^2; 2-4 mmol/L: 44.1±17.2 vs. 16.5±7.2 dynes/cm^2; >4 mmol/L: 57.0±21.6 vs. 21.0±8.0 dynes/cm^2; all p<0.05) and retrograde flow (basal: 6.9±3.9 vs. 3.1±1.5 dynes/cm^2; 0-2 mmol/L: 11.5±5.6 dynes/cm^2 vs. 4.3±2.0 dynes/cm^2; 2-4 mmol/L: 17.4±9.2 vs. 6.4±.5 dynes/cm^2; >4 mmol/L: 19.6±8.4 vs. 7.2±3.0 dynes/cm^2, all p<0.05).

Conclusion
Exercise-induced ESS is underestimated by Poiseuille's law. Womersley's approximation might be a better approach to estimate ESS in resting conditions and during exercise.

Influence of High-Intensity Exercise on Aortic Stiffness and Femoral Artery Shear Patterns

Jacob P. DeBlois[1], Wesley K. Lefferts[1], Kevin S. Heffernan[1], Bo Fernhall, FACSM[2]. *[1]Syracuse University, Syracuse, NY. [2]University of Illinois Chicago, Chicago, IL.* (Sponsor: Bo Fernhall, FACSM)

(No relevant relationships reported)

Influence of High-Intensity Exercise on Aortic Stiffness and Femoral Artery Shear Patterns
Jacob P. DeBlois, Wesley K. Lefferts, Kevin S. Heffernan. Syracuse University, Syracuse, NY
Aortic stiffness is linked to atherogenic retrograde and oscillatory shear patterns in peripheral arteries. High-intensity exercise may increase aortic stiffness. Whether such acute changes in aortic stiffness detrimentally affect peripheral shear patterns remains unknown. **PURPOSE:** Determine if acute changes in aortic stiffness negatively influences superficial femoral artery (SFA) shear rates (SR) and stiffness following high-intensity cycling. **METHODS:** 20 adults (27±5 yrs; 10 women) underwent arterial assessment at baseline (BL), after a 5-min time control period (TC), and following a 30-sec bike sprint against 7% body mass (POST). Aortic stiffness was measured using carotid-femoral pulse wave velocity (cfPWV). SFA diameter, blood velocity, and stiffness (β stiffness and Young's elastic modulus, ϵ) were measured via Doppler ultrasound. Diameters and blood velocities were used to determine SFA antegrade and retrograde SR as well as the oscillatory shear index (OSI). **RESULTS:**

BL and TC were not different for any measures (*p*>0.05). cfPWV increased POST compared with BL and TC (*p*≤0.01). SFA retrograde SR and OSI were reduced POST compared with BL and TC (*p*≤0.001). SFA stiffness was unchanged by exercise (*p*≥0.06). The change in cfPWV from pre-exercise to POST was not associated with changes in retrograde SR (r = 0.03, *p*=0.90), OSI (r = 0.13, *p*=0.58), β (r = 0.07, *p*=0.78), or ε (r = 0.08, *p*=0.73). **CONCLUSION:** Acute high-intensity exercise increases aortic stiffness while concomitantly reducing oscillatory shear in the SFA. High-intensity exercise-mediated increases in aortic stiffness appear independent from downstream atherogenic shear patterns in the exercised vasculature.

Table 1. Arterial stiffness and shear patterns before and after high-intensity cycling exercise.

	Baseline	Time Control	Post
Stiffness Measures			
Aortic cfPWV (m·s⁻¹)	5.8 ± 0.6	5.7 ± 0.6	6.8 ± 1.3†
SFA β Stiffness (aU)	11.2 ± 2.8	13.6 ± 6.0	13.8 ± 4.6
SFA ε (kPa)	135.1 ± 7.8	157.0 ± 19.9	168.5 ± 12.7
Shear Patterns			
Primary Antegrade Shear Rate (s⁻¹)	216.1 ± 68.7	200 ± 58.7	255.4 ± 55.5†
Retrograde Shear Rate (s⁻¹)	88.4 ± 30.4	89.9 ± 25.5	41.2 ± 25.9*
Secondary Antegrade Shear Rate (s⁻¹)	43.9 ± 8.8	42.1 ± 7.8	47.4 ± 36.1
Oscillatory Shear Index	0.25 ± 0.05	0.27 ± 0.04	0.11 ± 0.08*
cfPWV, carotid-femoral pulse wave velocity; SFA, superficial femoral artery; †Significantly different from pre-exercise (p<0.05); *Significantly different from pre-exercise (p≤0.001).

Acute Resistance Exercise Effects on Blood Flow in Resistance-Trained Versus Untrained Individuals

Alaina Glasgow, Kathryn Geither, Jason C. Parks, Erica M. Marshall, Leslie Sensibello, Yu Lun Tai, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*
(No relevant relationships reported)

Data suggests that an acute bout of resistance exercise (ARE) increases forearm blood flow (FBF) and vasodilatory capacity compared to rest. However, the effects of training status on FBF and vasodilatory capacity at rest and during recovery from ARE are uncertain. PURPOSE: To compare the effects of resistance exercise training status on measures of vascular function at rest and recovery from ARE. METHODS: Fifteen resistance-trained (RT) individuals, and seven untrained (UT) individuals volunteered to participate. Measurements were taken after a 10min supine rest and 20min after ARE, or a control. Venous occlusion plethysmography was used to measure FBF and vasodilatory capacity, with 5min of occlusion (220mmHg) to induce reactive hyperemia. Area under the curve (AUC) was utilized to determine differences in blood flow. The ARE consisted of 3 sets of 10 repetitions at 75% 1-repetition maximum (1RM) on the leg press, leg curl, leg extension, lat pulldown, and chest press, with 2min of rest between sets and exercises. A 2x2x2 repeated measures ANOVA was used to evaluate group (RT, UT) across condition (ARE, control) and time (rest, recovery). If the ANOVA was significant, t-tests were used for post-hoc comparisons. RESULTS: Groups were similar (p>0.05) for age, height, and BMI, but not for weight (RT: 74.5±13.0kg; UT: 61.9±10.8kg, p=0.04). The 1RMs for chest press, leg curl, leg press, and lat pulldown were significantly different between groups (p<0.05), but not for leg extension (p=0.26). The total volume of exercise for the ARE was similar between groups (p=0.10). There were no significant (p>0.05) group differences at rest for FBF or vasodilatory capacity. There were no significant (p>0.05) 3-way interactions for FBF or vasodilatory capacity. There was a significant condition by time interaction for FBF (RT: rest: 2.9±1.1ml/100ml of tissue/min, recovery: 8.9±4.0ml/100ml of tissue/min; UT: rest: 3.1±1.1ml/100ml of tissue/min, recovery: 8.9±2.9ml/100ml of tissue/min; p<0.001) and AUC (RT: rest: 56.8±20.2units, recovery: 139.0±66.5units; UT: rest: 53.8±20.2units, recovery: 116.6±25.1units; p<0.001). CONCLUSION: These data demonstrate that acute resistance exercise significantly increases forearm blood flow and vasodilatory capacity regardless of training status. <!--EndFragment-->

Chronic Effects Of Replacing Workplace Sitting With Upright Activities On Human Popliteal Artery Shear Rate

Diego J. Arguello[1], Alvin Morton, III[2], Gregory Cloutier[1], Dinesh John[1]. *¹Northeastern University, Boston, MA. ²University of Tennessee Knoxville, Knoxville, TN.*
(No relevant relationships reported)

Previous work has shown that a single bout (i.e, 10 min- 3hrs.) of static upright posture decreases lower-limb arterial peak shear rate (PSR). **Purpose**: To examine if long-term replacement of workplace sitting with short (10-30 min) intermittent standing and/or stepping bouts results in PSR adaptations in the popliteal artery. **Methods**: Sixty-six sedentary (SED) overweight office workers (mean ± SD: age= 45.3 ± 12.3 years, BMI= 32.4 ± 5.8 kg/m²) were cluster randomized to a sitting control (C), a sit-to-stand desk (D), or a treadmill desk (T) group. Popliteal artery PSR was calculated from Poiseuille's Law as 4 x (mean blood velocity/internal diameter) using Doppler ultrasonography at baseline (B), and after 3 (M3), 6 (M6) and 12 months (M12). Daily SED, stand, and step time was measured over 7 days at each time-point with an ActivPal. Change (Δ) in PSR and physical behavior (PB) within groups across measurement time points were evaluated using mixed linear models (p<0.05). The PSR model was adjusted for demographics (age, gender, race, ethnicity) and systolic blood pressure, and PB models were adjusted for demographics, avg. daily monitor wear-time and total wear-days. **Results**: Between B and M3, both the D and T groups significantly reduced SED time [T: mean ± SD of Δ for daily proportion=-17.0% ± 3.2%; D: mean ± SD of Δ for daily proportion= -8.5% ± 3.0], and increased stand time [T: mean ± SD for Δ for daily proportion= 14.9% ± 3.3%; D: mean ± SD for Δ for daily proportion= 6.7% ± 3.1%]. Neither D nor T groups significantly increased step time. Changes in PB (B to M3) for D and T returned to baseline levels by M6. In conjunction with the PB change (B to M3), popliteal PSR decreased significantly between B and M6 in group D (mean Δ (95% CI)= -307.1 s⁻¹ (-478.4 to -135.7) and T [mean Δ (95% CI), p: -210.0 s⁻¹ (-378.3 to -41.7)]. These changes were sustained to M12. **Conclusions**: A few months of increasing workplace standing using workstation-based strategies may yield chronic reductions in PSR that extend beyond the duration of the PB change. Given the greater likelihood of atherosclerotic lesions developing in vasculature with low shear stress, increasing workplace standing may have a negative atherogenic effect. Further studies are needed to see if replacing sitting with stepping, rather than standing, increases shear rate.

Inferior Vena Cava Diameter Reductions Precede Changes in Traditional Vital Signs during Simulated Blood Loss

Morgan C. O'Leary, Zachary J. Schlader, Michael W. Schaake, James R. Sackett, Howard Lin, Erika St. James, Penelope C. Lema, Brian M. Clemency, Blair D. Johnson. *University at Buffalo, Buffalo, NY.* (Sponsor: David Hostler, FACSM)
(No relevant relationships reported)

Hemorrhage is a leading cause of trauma deaths. Many of these deaths could be prevented with early detection and appropriate treatment. Traditional vital signs such as heart rate (HR) and mean arterial pressure (MAP) can remain relatively normal despite the central hypovolemia that occurs during blood loss. Ultrasound measurements of the inferior vena cava diameter (IVCD) have been used clinically as gross indicators of central hypovolemia. However, it is not known if reductions in IVCD occur prior to changes in traditional vital signs during blood loss in humans. **PURPOSE**: To test the hypothesis that reductions in IVCD occur prior to changes in traditional vital signs during central hypovolemia. **METHODS**: Blood loss was stimulated using lower body negative pressure (LBNP) in fourteen healthy men (22±2 years). Pressure within the LBNP chamber was reduced by 10 mmHg every four minutes until the pressure reached -80 mmHg or subjects experienced pre-syncopal signs. Sagittal view images of maximum and minimum IVCD were obtained using B-mode ultrasonography between minutes two and four of each stage. The mean HR (ECG), MAP, pulse pressure (PP) and stroke volume (SV) (photoplethysmography) were obtained during the last minute of each stage. **RESULTS**: Maximum IVCD was lower than baseline (1.5±0.4 cm) at -20 mmHg (1.0±0.3 cm, P<0.01) and throughout LBNP (P<0.01). Minimum IVCD was lower than baseline (0.9±0.3 cm) at -20 mmHg (0.5±0.3 cm, P<0.01) and throughout LBNP (P<0.01). HR was only higher than baseline (70±16 bpm) at the final stage of LBNP (94±19 bpm, p<0.01). MAP was only lower than baseline (91±7 mmHg) at the final stage of LBNP (78±17 mmHg, p<0.0001). PP was lower than baseline (62±5 mmHg) starting at -40 mmHg (53±9 mmHg, P=0.03) and throughout LBNP (P<0.03). SV was lower than baseline (93±28 ml) starting at -50 mmHg (65±14 ml, P=0.01) and throughout LBNP (P<0.01). **CONCLUSIONS**: Reductions in maximum and minimum IVCD preceded changes in tradition vital signs during graded simulated blood loss. IVCD may be a useful tool to identify blood loss and guide treatment in patients prior to the development of vital sign abnormalities.

Abstracts were prepared by the authors and printed as submitted.

Calf Venous Compliance in College Age Male Smokers and Non-smokers

Juliane P. Wallace, FACSM, Jocelyn Rothschild-Frey. *Southern Illinois University, Carbondale, IL.*

(No relevant relationships reported)

Smoking causes endothelial damage and autonomic dysfunction which leads to decreases in arterial compliance. Similar to changes in arterial compliance with fitness and aging, calf venous compliance improves with higher fitness and declines with increasing age. While previous studies have compared smokers and non-smokers for changes in arterial wall properties, no research to date has investigated the impact of smoking on limb venous compliance. **PURPOSE**: To determine the calf venous compliance differences in college age smokers (S) versus non-smokers (NS). **METHODS**: 7 S's (2-12 years of smoking; mean of 4 pack years; age = 22 ± 4 yrs; mass = 83.7 ± 18.4 kg; ht = 181.1 ± 9.5 cm; BMI = 25.4 ± 4.4 kg/m²; calf volume = 2485.4 ± 482.1 ml; VO_2 max = 34.3 ± 7.8 ml/kg/min) and 7 NS's (age = 23 ± 2 yrs; mass = 76.6 ± 5.8 kg; ht = 176.2 ± 4.7 cm; BMI = 24.7 ± 2.0 kg/m2; calf volume = 2242.1 ± 450.8 ml; VO_2 max = 38.0 ± 4.1 ml/kg/min) volunteered for this project. Participants underwent anthropometric assessment, a graded exercise test, and assessment of calf venous compliance. Utilizing venous occlusion plethysmography, calf pressure-volume relations was determined using the quadratic regression equation [Δ limb volume) = $\beta_0 + \beta_1$*(cuff pressure) + β_2*(cuff pressure)²]. Calf venous compliance was calculated as the first derivative of the pressure-volume relation during cuff pressure reduction [Compliance = $\beta_1 + (2 * \beta_2 *$ cuff pressure)]. Differences in anthropometric, fitness, and compliance variables between S & NS were analyzed with a simple ANOVA. **RESULTS**: There were no significant differences between S & NS in anthropometric variables or fitness except the smokers were significantly higher in body fat % ($19.2 \pm 6.5\%$ vs. nonsmokers at $12.3 \pm 2.7\%$). There were no significant differences between S & NS in calf volume or compliance [S; Δ volume = $0.8093 \pm 1.401 + 1.0184 \pm 0.06123$ * (cuff pressure) - 0.0010 ± 0.00082* (cuff pressure)² vs. NS; Δ volume = $.0874 \pm 1.39718 + 0.1211 \pm 0.06413 - 0.0011 \pm 0.00069$ (cuff pressure)²]. **CONCLUSIONS**: College age male smokers have similar calf venous compliance to non-smokers. It is likely that the chronic effects of smoking that would alter the vessel wall and subsequently decrease venous compliance have not had enough time to influence venous wall structure in men in their early 20's.

Combined Effects Of Heat And Altitude Exposure On Cutaneous Microvasculature Responses During Submaximal Exercise

Katherine M. Mitchell, Nisha Charkoudian, FACSM, Beau R. Yurkevicius, Karleigh E. Bradbury, Adam J. Luippold, Robert W. Kenefick, FACSM. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

(No relevant relationships reported)

Exposure to hot environments augments cutaneous vasodilation during exercise, whereas exposure to hypoxia can have both direct vasodilator and indirect (reflex) vasoconstrictor influences in the skin. PURPOSE: To test the hypothesis that hypobaric hypoxia will have a modulating effect on forearm cutaneous circulation during steady state (SS) exercise in the heat. METHODS: Seven participants (2 F, 5 M) completed 30 min of SS exercise on a cycle ergometer at 50% of respective VO_{2peak} during four separate environmental conditions, 1) Sea Level Thermoneutral (SLTN; 250 meters (m), 20°C, 30-50% RH), 2) Sea Level Hot (SLH; 250 m, 35°C, 30% RH), 3) Altitude thermoneutral (ATN; 3,000 m, 20°C, 30-50% RH), and 4) Altitude Hot (AH; 3,000 m, 35°C, 30% RH). Skin blood flow was recorded using laser-Doppler flowmetry on the ventral forearm. SS cutaneous vascular conductance (CVC = laser-Doppler flow/mean arterial pressure; %max) was calculated as the average of min 20-25 during exercise. After exercise, participants completed 30 min of local warming (42°C) of the skin for calculation of maximal CVC. A one-way repeated measures ANOVA was performed comparing %max CVC during SS exercise across the four conditions. RESULTS: AH CVC ($63\pm31\%$) and SLH CVC ($52\pm19\%$) were significantly higher than both SLTN CVC ($20\pm9\%$, P < 0.001) and ATN CVC ($25\pm12\%$, P < 0.05), but were not different from each other (P > 0.05). CONCLUSION: As expected, ambient heat increased CVC during exercise; counter to our hypothesis, hypoxia appeared to have no net effect on CVC. Any potential local effects of hypoxia to cause additional cutaneous vasodilation during SS exercise may have been offset by simultaneous hypoxia-mediated activation of sympathetic vasoconstrictor nerves. Disclaimer: Authors views are not official U.S. Army or DoD Policy.

The Effects Of Cuff Width On Hemodynamics In The Legs During Blood Flow Restriction

Scott J. Dankel, J Grant Mouser, Kevin T. Mattocks, Matthew B. Jessee, Samuel L. Buckner, Takashi Abe, Jeremy P. Loenneke. *The University of Mississippi, University, MS.*

(No relevant relationships reported)

Blood flow restriction allows individuals to exercise with low loads while producing similar increases in muscle size as high load resistance training. It has been suggested that the pressure should be made relative to the individual (as a percentage of their arterial occlusion pressure), but it remains unknown if a given pressure results in a similar reduction in blood flow, and further, whether this differs based on the width of the cuff being applied. **PURPOSE**: To examine hemodynamic responses to various relative pressures in the supine position using two commonly used cuffs (10 cm and 12 cm). **METHODS**: Participants (men=17, women=14) came to the laboratory for two visits. One cuff (10 cm or 12 cm) was randomly applied to the right proximal thigh for each visit and arterial occlusion pressure was measured. Ultrasound measures of blood flow, mean blood velocity, peak blood velocity, and artery diameter were taken from the posterior tibial artery at rest and during the application of 10% increments of the arterial occlusion pressure. A repeated measures ANOVA was used to examine differences across conditions. **RESULTS**: There was no significant interaction or overall difference between the 10 cm and 12 cm cuff relating to blood flow [-0.501 (7.9) ml•min⁻¹, p = 0.728], mean blood velocity [-0.168 (1.7) cm•sec⁻¹, p = 0.590], peak blood velocity [0.586 (11.7) cm•sec⁻¹, p = 0.783], or artery diameter [0.003 (0.02) cm, p = 0.476]. There was a main effect of pressure for blood flow (p < 0.05), mean blood velocity (p < 0.05), peak blood velocity (p < 0.05), and artery diameter (p < 0.05), with each decreasing with increasing pressures. Peak blood velocity increased until 60% of arterial occlusion pressure before decreasing with increased pressure. The 80% and 90% arterial occlusion pressures reduced blood flow by 69.4% and 79.3% respectively when collapsed across the 10 cm and 12 cm cuffs. No other pressures differed significantly between the relative applied pressure and amount of blood flow restricted. **CONCLUSIONS**: Provided relative pressures are applied, cuff width appears to have little to no effect on the blood flow response at rest. Importantly, relative pressures may not indicate the magnitude of blood flow being reduced (e.g. 80% arterial occlusion may not reduce 80% of blood flow), particularly at higher arterial occlusion pressures.

Manipulation of Retrograde Shear in the Superficial Femoral Artery in Recreationally Active & Exercise-Trained Men

Patricia Pagan Lassalle, Adam J. Palamar, Jacob P. DeBlois, Wesley K. Lefferts, Kevin S. Heffernan. *Syracuse University, Syracuse, NY.* (Sponsor: Bo Fernhall, FACSM)

(No relevant relationships reported)

Retrograde shear stress increases with age and contributes to atherosclerosis. Habitual exercise has been shown to ameliorate the effects of age on cardiovascular disease possibly due to favorable vascular remodeling and reductions in retrograde shear. **PURPOSE:** Examine whether the vascular remodelling from habitual exercise training affects retrograde shear at rest and during a manipulation designed to alter shear (lower limb compression) in young adults. **METHODS:** Doppler ultrasound was used to measure superficial femoral artery (SFA) diameter and retrograde shear rate in 11 exercise-trained men (Division I track athletes; 20 ± 3 years of age, body mass index 21 ± 2 kg·m⁻²) and 18 recreationally active controls (23 ± 5 years of age, body mass index 23 ± 2 kg·m⁻²). Measures were made at rest and during a shear manipulation: inflation of a pneumatic cuff applied to the calf to 5 mmHg (sham) and 60 mmHg (experimental) in a randomized order. **RESULTS:** All results are displayed in Table 1. SFA diameter was larger in exercise-trained men versus controls ($P < 0.05$). Retrograde shear was similar between the exercise-trained men and controls at baseline and during the sham condition ($P > 0.05$). Exercise-trained men had lower retrograde shear during the experimental condition ($P < 0.05$). Group differences during the experimental condition remained after co-varying for resting retrograde shear and body mass index ($P < 0.05$). **CONCLUSION:** Manipulation of retrograde shear using lower limb compression reveals differences in shear patterns not detected at rest. Exercise-trained men have a more optimal, anti-atherosclerotic shear pattern (i.e. less retrograde shear) in comparison to recreationally active men.

Table 1. SFA diameter and shear at rest and during lower limb compression.

Various Cuff Pressures During Blood Flow Restriction Exercise on Blood Flow During and After Exercise

Tyler J. Singer. *Kent State University, Kent, OH.*
(No relevant relationships reported)

Title: Various Cuff Pressures During Blood Flow Restriction Exercise on Blood Flow During and After Exercise
**
Blood flow restricted (BFR) exercise has emerged as an intervention that increases muscle size and strength during low intensity resistance training. Although the cuff pressures prescribed for this intervention are typically based on pressures required to occlude blood flow at rest, the impact on blood flow during and after exercise is unclear. **PURPOSE:** To determine how various cuff pressures impact blood flow and tissue perfusion during and post exercise. **METHODS:** Seven healthy male participants completed four sets of a knee extension exercise (30 reps per set at 30% of max torque, 15 minutes recovery between sets). Four different cuff pressures were used during each set (0%, 60%, 80%, and 100% of arterial occlusion pressure). Doppler ultrasound was used to measure superficial femoral blood flow and NIRS was used to measure tissue saturation index, oxygenated and deoxygenated hemoglobin at rest, during and post exercise. EMG was also recorded for the vastus lateralis during exercise. **RESULTS:** Blood flow during exercise decreased as cuff pressure increased however there was still blood flow during exercise at 100% AOP. Tissue saturation showed greatest decrease during the100% occlusion trial (62± 5, 39± 5; p=. 001) followed by 80% (62±8, 40±8; p=. 001), 60% (63±12, 45±12; p=. 012), and the control (66±9, 52±9; p=. 019). Deoxygenated hemoglobin increased the most at 100% occlusion (2.0±7, 31±7; p=. 001) followed by 80% (1.1±7, 27±7; p=. 002), 60% (-0.7±14, 15±14; p=. .029) and the control (-5.0±8, 11±8; p=. 02). Oxygenated hemoglobin decreased the most in the 100% condition (5.0±12, -14±12; p=. 002) followed by 80% (6.0±14,-12±14;p=.007), 60% (7.0±15, -9.0±15;p=.023) and the control (4.0±11, -7.0±11;p=.014). There was no difference in total hemoglobin during those time points. EMG showed the largest change in the 100% condition (10±9,23±9;p=.002) compared to the control followed by 80% (9±14,19±14;p=.002) and 60% (18±13,23±13;p=.03). **CONCLUSION:** This data suggests that during dynamic exercise 100% of AOP still allows some blood flow and tissue perfusion during and post exercise but it still results in the greatest fatigue compared to lower cuff pressures.

The Effects of Upper- and Lower-body Blood Flow Restriction Exercise on Vascular Function

Leslie Sensibello, Yu Lun Tai, Erica M. Marshall, Alaina Glasgow, Kathryn Geither, Jason C. Parks, Ramon Oliveira, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*
(No relevant relationships reported)

Previous studies indicate acute resistance exercise (ARE) improves vascular function, primarily forearm blood flow (FBF) and vasodilatory capacity. However, the effects of acute upper- and lower-body RE with and without blood flow restriction (BFR) on vascular function are unknown. **PURPOSE**: To determine the differences between UB and LB ARE with and without BFR on vascular function in resistance-trained individuals. **METHODS**: Twelve individuals were assessed on a one-repetition maximum (1RM) for the UB on the lat pulldown and chest press, and for the LB knee extension and knee flexion. Vascular function was assessed using venous occlusion plethysmography with five minutes of occlusion at 220mmHg to induce reactive hyperemia. Forearm blood flow and area under the curve (AUC) were assessed at Rest, and during recovery at 15 (R15) and 45 (R45) min. The BFR protocol consisted of 4 sets of 30, 15, 15,

and 15 repetitions at 30% of 1RM. BFR was applied at a pressure of 40% of arterial occlusion pressure during each exercise, and was released for 2min between exercises. For the non-BFR protocol, participants performed 4 sets of 8 repetitions at 70% 1RM. A 2x2x3 repeated measures ANOVA was used to examine the effects of condition (BFR, non-BFR) and group (UB, LB) by time (Rest, R15, R45) on vascular function. **RESULTS**: There were no 3-way interactions for any variable, and no effect of condition. There was a significant (p=0.001) group by time interaction for FBF (UB: Rest: 2.8±1.2ml/100ml/min; R15: 9.3±4.5ml/100ml/min; R45: 5.3±2.7ml/100ml/min; LB: Rest: 3.3±2.0ml/100ml/min, R15: 4.3±2.5ml/100ml/min, R45: 4.2±2.2ml/100ml/min) such that FBF was elevated at R15 compared to Rest, and was higher after UB than LB at R15. There was also a significant (p=0.02) group by time interaction for AUC (UB: Rest: 65.1±21.6ml/100ml/min, R15: 144.7±50.2ml/100ml/min; R45: 91.0±27.8ml/100ml/min; LB: Rest: 61.9±10.3ml/100ml/min; R15: 113.1±32.4ml/100ml/min, R45: 88.6±32.3ml/100ml/min) such that it was augmented at R15 and R45 compared to Rest, with greater augmentation at R15 after UB compared to LB. **CONCLUSIONS**: While there were no differences between BFR and non-BFR, our data demonstrate that acute upper-body resistance exercise has a greater effect than acute lower-body resistance exercise on forearm blood flow and vasodilatory capacity.

Examining Peripheral Hemodynamics During Handgrip Exercise in Varsity Rowers

Kevin Decker, Austin Hogwood, Jennifer Weggen, Ruhi Maniyar, Ashley Darling, Austin Michael, Ryan Garten. *Virginia Commonwealth University, Richmond, VA.*
(No relevant relationships reported)

PURPOSE: This study sought to examine the impact of upper arm aerobic training on peripheral hemodynamics during exercise. **METHODS**: Seven young male trained rowers (20±1 yrs) and seven male recreationally active controls (24±1 yrs) with no history of upper limb aerobic training were recruited for this study. Subjects performed three minute bouts of progressive rhythmic handgrip exercise (4, 8, and 12 kg). Brachial artery diameter and velocity (Doppler ultrasound), heart rate (ECG), and blood pressure (Tango M2) were continually measured at rest and during each workload. **RESULTS**: Resting values for brachial artery diameter, blood flow, mean arterial pressure, and heart rate were not different between rowers and controls (p>0.05). During exercise, the rowers reported significantly reduced brachial artery blood flow [4 kg (146 vs 243 ml/min); 8 kg (249 vs 417 ml/min); 12 kg (356 v 536 ml/min) p<0.05] and shear rate [4 kg (289 v 470 s^{-1}); 8 kg (439 v 720 s^{-1}); 12 kg (478 v 797 s^{-1}) p<0.05] across all workloads when compared to controls. Brachial artery dilation, when normalized for shear rate, was significantly greater in rowers than controls during 8 and 12 kg workloads (p<0.05). Exercising heart rate and mean arterial pressure were not different between groups (p>0.05). **CONCLUSIONS**: The results from this study revealed rowers have improved vasoreactivity to a given shear rate stimulus when compared to untrained controls. These findings suggest that upper limb aerobic training results in improved efficiency of blood flow regulation during exercise.

Muscle Oxygenation and Metabolic Regulations During Low and Moderate Intensity Exercise with Blood Flow Restriction

HYEJUNG HWANG, Sahiro Mizuno, Nobukazu Kasai, Chihiro Kojima, Daichi Sumi, Nanako Hayashi, Kazushige Goto. *Ritsumeikan University, Shiga, Japan.*
(No relevant relationships reported)

A number of studies have shown that low-intensity exercise with blood flow restriction (BFR) increases oxygen uptake and heart rate during exercise compared to normal exercise without BFR. However, it is currently unknown about the influence of moderate-intensity exercise with BFR on systemic and peripheral metabolic regulations.
Purpose : To investigate the effect of endurance exercise with BFR under either low (25% of VO$_2$max) or moderate (40% of VO$_2$max) intensities on muscle oxygenation, energy metabolism and endocrine responses.
Methods : Ten male subjects conducted three trials on different days (with a cross over design). All subjects performed three different trials consisting of moderate intensity (40% of VO$_2$max) exercise without BFR (NORMAL) or with BFR (MOD) and low intensity (25% of VO$_2$max) exercise with BFR (LOW). The exercise was designed as a 15 min of pedaling exercise. During the exercise in MOD and LOW, 2 min of cuff pressure (160mmHg) was applied repeatedly for proximal cites of both legs followed by 1 min of release. Muscle oxygenation for vastus lateralis muscle was evaluated using near-infrared spectroscopy (NIRS). Respiratory and venous blood samples were also collected during exercise.
Results : The oxygen consumption (VO$_2$) did not differ significantly between NORMAL and MOD, but LOW revealed significantly lower VO$_2$. Carbohydrate

Abstracts were prepared by the authors and printed as submitted.

oxidation rate was significantly elevated in MOD (Mean±SD, 25.6 ± 8.6 mg/kg/min), with no difference between NORMAL and LOW (10.6 ± 4.8 and 8.7 ± 2.8). There were no significant differences among three trials for blood glucose and serum growth hormone levels. Blood lactate and serum cortisol levels were significantly higher in MOD than those in the other two trials. Oxyhemoglobin (oxy-Hb) for vastus lateralis muscle was significantly lower in MOD than the other two trials. In addition, deoxyhemoglobin (deoxy-Hb) was significantly increased in both MOD and LOW (vs. NORMAL), and MOD showed highest value of total hemoglobin among three trials. **Conclusion :** Moderate intensity (40% of VO_2max) exercise with BFR caused profound elevations of deoxy-Hb with lower oxy-Hb and augmented carbohydrate oxidation. Furthermore, carbohydrate oxidation during low-intensity (25% of VO_2max) exercise with BFR was similar moderate intensity exercise without BFR.

Usefulness Of Two-Dimensional Echo Strain In Evaluation Of Cardiac Function In Elite Athletes

Benedetta Tosi, Beatrice Leone, Loira Toncelli, Giorgio Galanti, FACSM. *University of Florence, Florence, Italy.*

(No relevant relationships reported)

Purpose: Cardiovascular adaptation to sport training is influenced by many factors, including the intensity and the kind of sport practiced. The "Morganroth hypothesis" asserted that a static exercise characterized by a pressure load and dynamic (isotonic) exercise which involves a volume load to the heart lead to different myocardial adaptation patterns. More recent studies revisited this hypothesis, showing that left ventricular (LV) remodelling observed in both resistance and endurance trained athletes, presented similar aspects. Although morphological modifications secondary to exercise have been largely studied, less is known on myocardial systolic function in LV remodeling patterns in different elite athletes. Two-dimensional strain analysis allows a complete study of the contractile function in different myocardial regions of interest in left and right ventricle. In this study we aim to underline possible differences in contractile myocardial function with strain analysis in two groups of elite athletes, trained with different loads and playing different sports (football and cyclism). **Methods**: We enrolled 47 male athletes: 23 football players and 24 cyclists, belonging to same football or cyclism team (mean age in both groups 18±3 years old). The athletes were evaluated with echocardiography at the beginning of the sports season. We assessed LV contractile function using speckle-tracking echocardiographic global longitudinal strain (GLS) and global circumferential strain (GCS). We also analysed right ventricular function by strain echocardiography. **Results:** Cyclists showed a significantly augmented indexed LV mass and TAPSE. No significant differences were found in GLS data between the two groups (23.4±0.02 in football players and 24.1±0.02 in cyclists), whereas a significantly higher GCS was found in cyclists compared to football players (31.2±0.04 and 27.2±0.05 respectively, p< 0.005). The cyclist group showed a significant increase in right ventricular strain compared to football players (26.3±0.04 and 23.2±0.04, respectively, p< 0.05). **Conclusions**: Our preliminary data suggest that a dynamic exercise, which involves a volume load, like cyclism, lead to a sensible increase in systolic function in elite athletes especially in right ventricle contractility.

830   Board #91   May 30 3:30 PM - 5:00 PM

HR, %HRmax, %HRR, SPM In Moderate-Intensity Walking Among University Students By Sex And Resting HR

Wenhao Liu, FACSM, Istvan Kovacs, Ethan E. Hull. *Slippery Rock University, Slippery Rock, PA.*

(No relevant relationships reported)

PURPOSE: This study was intended to examine how heart rate (HR), maximal HR% (%HRmax), HR reserve% (%HRR), and steps per minute (SPM) would be related to sex and resting HR (HRrest) when walking at 2.5 mph among university students. **METHODS**: HRrest was measured after lying on the floor for five minutes to 186 university students (mean ages: 20.97±1.24; 108 males, 78 females) in the US. Males and females were divided into three equal-size groups respectively based on the ranking of the HRrest: low HRrest (LR), medium HRrest (MR), and high HRrest (HR). In addition, participants walked on treadmills for three minutes wearing HR monitors (Sigma PC26.14) and pedometers (Yamax SW-200), and HR and steps were recorded at the end of the walking. The HR, %HRmax, %HRR, and SPM in walking at 2.5 mph and the HRrest were compared between sexes and among the three HRrest groups for males and females separately with one-way MANOVA.

RESULTS: While no difference was found in age between sexes (p > .05), significant differences (p values: .00 to .01) were identified between sexes in HR (M, 92.36±10.77 vs. F, 102.61±11.34), %HRmax (M, 46.42±5.49 vs F, 51.49±5.72), %HRR (M, 20.07±6.82 vs. F, 23.06±6.86), and SPM (M, 98.24±9.53 vs. 105.89±9.12) in walking at 2.5 mph, and in HRrest (M, 65.48±9.46 vs. F, 73.47±11.68). As for the three HRrest groups, significant differences were found in all the three pairwise comparisons for males (p values: .00 to .01) in walking HR (LR 85.89±9.01, MR 96.61±8.15, HR 100.80±9.43), in walking %HRmax (LR 43.07±4.65, MR 46.56±4.07, HR 50.75±4.77), and in HRrest (LR 55.78±4.73, MR 65.11±2.44, HR 75.83±6.30); and for females as well (all pairwise p values < .01) in walking HR (LR 93.12±9.18, MR 103.6±8.76, HR 111.04±8.27), in walking %HRmax (LR 46.68±4.61, MR 52.07±4.43, HR 55.69±4.19), and in HRrest (LR 60.84±5.13, MR 72.81±3.48, HR 86.77±5.96). No differences were found in age or other variables among the HRrest groups for either sex.

CONCLUSIONS: Sex is closely related to HR, %HRmax, %HRR and SPM in walking at 2.5 mph and to HRrest as well with males having significant advantage over females. When comparisons are made among the HRrest groups, both male and female university students with lower HRrest have significantly lower HR and %HRmax in walking at 2.5 mph than those with higher HRrest.

Passive Heat Stress Attenuates the Rise in Blood Pressure During Face Cooling

Muhamed M. Mcbryde, Morgan C. O'Leary, James R. Sackett, Zachary J. Schlader, Blair D. Johnson. *University at Buffalo, Buffalo, NY.* (Sponsor: Dave Hostler, FACSM)

(No relevant relationships reported)

The rise in mean arterial pressure (MAP) during the cold pressor test is attenuated by passive heat stress (HS). However, it is not known if HS attenuates the rise in MAP during face cooling (FC). **PURPOSE:** Test the hypothesis that HS attenuates the rise in MAP during FC. **METHODS:** FC was performed on ten healthy subjects (23±2years, 1 woman) during thermoneutral (TN) conditions and during HS induced by a water perfused suit. Subjects rested supine for 10 min while 34°C water was perfused through the suits. Then a 0°C bag of water was placed on the forehead, eyes, and cheeks for 15 min (FC). Subjects were then given 10 min to recover from FC before 50°C water was circulated through the suit until intestinal temperature (telemetry pill) was 1.0°C greater than TN. Five min of data were collected before FC was repeated. Heart rate (ECG), MAP (photoplethysmography), and forearm skin blood flow (SkBF; laser Doppler) were continuously collected. Forearm cutaneous vascular resistance (CVR) was calculated. Face pain (0 = no pain, 10 = worst pain imaginable) was obtained immediately after FC. Change from TN and HS baseline data were analyzed across 1 min intervals for the first 3 min and every 3 min thereafter during FC. **RESULTS:** Baseline HR (71±14 vs. 93±17 bpm) and SkBF (22±14 PU vs. 127 ± 35 PU) were greater and MAP (88±14 vs. 81±6 mmHg) and CVR (4.9±1.8 vs. 0.7±0.3 mmHg/PU) were lower during HS (P<0.05 for all). FC caused a greater decrease in HR during HS (largest difference at 12 min of FC: -7±3 vs. -15±11bpm, P=0.02). FC caused a greater increase in MAP during TN (largest difference at 6 min of FC: 20±10 vs. 1±6 mmHg; P<0.01). FC did not change SkBF across time (P=0.31) nor was there a difference between TN and HS (P=0.61). FC caused a greater increase in CVR during TN (largest difference at 6 min of FC: 1.4±1.2 vs. 0.0 ± 0.0 mmHg/PU; P<0.01). Face pain was not different between trials (TN: 6±3 vs. HS: 4±3; P=0.06). **CONCLUSION:** Passive HS attenuates the rise in MAP during FC. The impaired ability to increase CVR appears to contribute to the attenuated rise in MAP during HS with FC.

Alcohol and Cardiovascular Health: Acute Alterations Versus Chronic Adaptations

Jennica Harrison[1], Grace L. Naylor[1], J. Mark VanNess[1], Michelle M. Amaral[1], Greg Roberts[2], Jonathan M. Saxe[2], Lewis E. Jacobson[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.*

(No relevant relationships reported)

Alcohol abuse is a risk factor for disease but moderate use may be beneficial. Mechanisms for this contrast remain speculative. Differences may be explained by acute alterations rather than chronic adaptations. **PURPOSE:** To compare cardiovascular health markers in patients with and without a history of heavy drinking, and patients who are currently intoxicated. **METHODS:** Health outcomes of patients treated at a U.S. hospital were analyzed; 2,033 were sober, 273 tested positive for alcohol, and 131 reported a history of alcohol abuse. Dependent variables were systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), hemoglobin, oximetry, and disease incidence. Independent variables were age, sex, anthropometry, and use of alcohol. Independent-samples t tests and chi-square tests evaluated differences between patients with and without a history of alcohol abuse. Linear and logistic regressions tested the effects of alcohol on dependent variables. **RESULTS:**

Among sober patients, each year of age predicted 0.3 mmHg higher SBP (p<0.001) but no change in DBP (p=0.137). Across the total sample, current intoxication predicted 8.6 mmHg lower SBP (p<0.001), 8.7 bpm higher HR (p<0.001), and 1.0 g/dL higher hemoglobin (p<0.001). Linear regression found patients who tested positive for alcohol to have 4.6 mmHg lower SBP (p=0.002; 95% CI: -7.6 to -1.6) holding confounders constant. Among sober patients, a history of alcohol abuse associated with an elevated HR (p=0.001), lower pulse pressure (p=0.002), lower oximetry (p=0.018), and a trend for reduced SBP (p=0.056) with no difference in DBP (p=0.404). Linear regression found a history of alcohol abuse to lower pulse pressure (p=0.009) and oxygen saturation (p=0.012) and raise HR (p<0.001). Among sober patients, a history of alcohol abuse did not affect the odds of having a myocardial infarction (p=0.805), congestive heart failure (p=0.712), peripheral vascular disease (p=0.997), stroke (p=0.691), diabetes (p=0.107), or dementia (p=0.905); it did associate with a 15-fold increase in the odds of cirrhosis (p<0.001). **CONCLUSIONS:** Sober patients with a history of alcohol abuse mimic the cardiovascular profile of intoxicated patients. This suggests that both short and long-term alcohol ingestion may confer modest cardiovascular benefits.

Cardiac Structure-function And Aerobic Capacity In Individuals With A Competitive Sports History

Nicholas A. Wasinger, Zachary Headman, Brent W. Lambson, Ty M. Fulmer, Tatyana V. Kondrashova, William F. Brechue, FACSM. *A.T. Still University, Kirksville, MO.* (Sponsor: William F. Brechue, Ph.D., FACSM)

(No relevant relationships reported)

Athletes (A) conduct intense physical training to attain peak performance. Intense training is associated with cardiac remodeling and electrical abnormalities. Although certain ECG abnormalities are considered benign, these changes have been linked to sudden cardiac death in A. **PURPOSE:** to investigate cardiac structure-function and electrocardiographic changes relative to aerobic capacity (Vo₂max). **METHODS:** A cross-section of individuals consented for this university IRB approved study. The population consisted of controls (C; n=21; high school sports (n=8 women, 9 men) or active, no organized sports (n=3 women, 1 man)), college A (CA, completed career <3 years ago; n=9, 5 women, 4 men), and A (presently competing, n=22, 6 women, 16 men). Measurements included anthropometric assessment (DEXA), resting 12-lead ECG, and graded exercise test (GXT) with echocardiography/Doppler ultrasound performed before and following the GXT. An incremental treadmill GXT was conducted (6 mph) to Vo₂max with respiratory gas measurements (open-flow, indirect calorimetry). **RESULTS:** CA and A had greater fat-free mass, but bone density was greater in A. While resting heart rate was lower in A and CA, blood pressure, stroke volume (A=87±19 ml; CA=83±23 ml; C=77±18 ml) and cardiac output (A=4.8±1.3 $L·min^{-1}$, CA=5.2±1.5 $L·min^{-1}$; C=4.8±1.3 $L·min^{-1}$) were similar among groups. Left ventricular (LV) end-diastolic dimension and posterior and septal wall thickness provided evidence of cardiac remodeling (eccentric hypertrophy-EH, concentric hypertrophy-CH, concentric remodeling-CR) in C (EH n=3, CR n=4), CA (EH n=1, CR n=2), and A (EH n=2, CH n=1, CR n=4). Overall, ECG analysis showed PVC's (n=3), LV hypertrophy voltage criteria (n=10), peaked T-waves (n=7), J-waves (n=4), U-waves (n=5), wandering pacemaker (n=4), early repolarization (n=5), short PR (n=1), Wenckebach (n=1), small Q waves (n=13). Vo₂max (C=44.7±9.8 $ml·kg^{-1}·min^{-1}$; CA=44.7±8.2 $ml·kg^{-1}·min^{-1}$, A=49.9±9.3 $ml·kg^{-1}·min^{-1}$) and maximal heart rate (C=187±91 $b·min^{-1}$; CA=194±7 $b·min^{-1}$, A=187±9 $b·min^{-1}$ were not different. **CONCLUSION:** Given similar, moderate levels of Vo₂max and cardiac function, presence of cardiac remodeling and ECG abnormalities among each group raises questions regarding the genesis of these changes relative to training history.

Free-Weight Resistance Exercise Versus Weight Machines on Pulse Wave Reflection

Kathryn Geither, Leslie Sensibello, Jason C. Parks, Erica M. Marshall, Yu Lun Tai, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*

(No relevant relationships reported)

Acute resistance exercise (ARE) has a large effect on pulse wave reflection, but the data are limited when examining these responses after free-weight (FW) versus weight-machine (WM) exercises. **PURPOSE:** To evaluate alterations in pulse wave reflection after FW exercise compared to WM exercise in resistance-trained individuals. **METHODS:** Individuals volunteered to participate in either FW (n=25) or WM (n=16) resistance exercises. Data were collected at rest, and 10-15min after ARE. The FW group completed 3 sets of 10 repetitions at 75% 1-repetition maximum (1RM) on the squat, bench press and deadlift, while the WM group completed 3 sets of 10 repetitions at 75%1RM on the leg press, lat pulldown, leg extension, chest press, and the leg curl. A 2x2x2 analysis of covariance (ANCOVA) was used to analyze the effects of group (FW, WM) across condition (ARE, control) and time (rest, recovery) with workload as a covariate. **RESULTS:** The groups were similar for anthropometrics

(p>0.05), but differed in years spent training (FW: 7±4 yrs; WM: 4±2 yrs, p=0.0001). There were no differences at rest for any measures of pulse wave reflection. Neither group nor condition had an effect on brachial or aortic blood pressure. There was a significant 3-way interaction for heart rate (FW: rest: 59±8bpm, recovery: 88±13bpm; WM: rest: 65±9bpm, recovery: 89±13bpm, p=0.04) such that it was augmented during recovery from resistance exercise in the FW group compared to the WM group. There were also significant 3-way interactions for the augmentation index (FW: rest: 116±8.4%, recovery:121.2±9.5%; WM: rest: 116.8±8.4%, recovery: 113.7±5.5%, p=0.006), augmentation pressure (FW: rest: 5.0±2.9mmHg, recovery: 8.4±5.9mmHg; WM: rest: 4.3±4.0mmHg, recovery: 3.8±3.6mmHg, p=0.029), and the augmentation index normalized at 75bpm (FW: rest: 4.9±8.1%, recovery: 24.1±14.5%; WM: rest: 8.7±12.3%, recovery: 16.8±8.2%, p=0.015) such that they were increased in the FW group compared to the WM group during recovery from ARE, which differed from the control. **CONCLUSION:** These data demonstrate that recovery from free-weight resistance exercises has significant effects on pulse wave reflection that supersede those of weight machine resistance exercises in resistance-trained individuals, despite no differences in brachial or aortic blood pressures.

Accuracy of a Smartphone Application to Measure Heart Rate Variability in Adult Females

Clayton Nicks, Kate Early, Brian Tyo. *Columbus State University, Columbus, GA.*

(No relevant relationships reported)

Heart rate variability (HRV), a non-invasive measurement of the autonomic nervous system, has been associated with incidence of diseased states to overtraining in athletes. HRV monitoring has become popular due to the ease of measurement with a number of commercially available devices. **PURPOSE:** The purpose of the study was to determine the accuracy of a smartphone app (APP) to measure resting HRV versus a commercially available bio-harness (BH). **METHODS:** Forty-seven females (age = 23.5 ± 4.4 y; height = 1.6 ± .05 m; mass = 73.8 ± 18.5 kg) volunteered to participate in the study. After arriving in the laboratory, participants rested in a supine position for 20 minutes. A BH was used to measure indices of HRV during a five-minute interval while the APP was used during the last 3 minutes. Time measurements included R-R interval (NN), standard deviation of the NN intervals (SDNN), root mean square of the successive differences (RMSSD), and percent of NN intervals over 50 ms (pNN50). **RESULTS:** There were no significant differences between the BH and APP with respect to NN (883.1 ± 126.1 vs 894.3 ± 129.8 ms; *p* = .12), SDNN (72.9 ± 29.9 vs 71.8 ± 29.9 ms; *p* = .77), and pNN50 (38.8 ± 21.9 vs. 40.8 ± 20.6 %, *p* = .24). HRM and APP RMSSD were significantly different (66.8 ± 33.0 vs 74.4 ± 30.1 ms; *p* = .014). Significant correlations were observed between BH and APP for all variables: NN, r = .93, *p* < .001, SEE = 48.8 ms; SDNN, r = .61, *p* < .001, SEE = 23.9 ms; RMSSD, r = .79, *p* < .001, SEE = 18.5 ms; and pNN50, r = .86, *p* < .001, SEE = 10.6%. **CONCLUSIONS:** The APP provided an accurate assessment of HRV when compared to the BH in the supine position. Moderate to strong correlations were observed for all indices of HRV with no statistical differences between the variables with the exception of RMSSD. The APP could provide an economical, valid method of measuring HRV in adult females.

Effects of AMPK α2 Gene Deficiency on Exercise Induced Cardiac Hypertrophy in Mice

Xin Xu[1], Xuedong Shang[2], Jing Jing[1], Guo Lu[1]. *[1]Shanghai University of Sport, Shanghai, China. [2]National Research Institute of Sports Medicine, Beijing, China.*

(No relevant relationships reported)

PURPOSE: The purpose of this study is to explore the role of AMPK α2 in exercise induced cardiac hypertrophy by using AMPKα2 knock out mice and treadmill running model.**METHODS:** AMPK α2 knock out(KO)and wild type (WT) mice were randomly divided into four groups as wild type control (WT+Ctr, n=6),wild type exercise (WT+EX, n=12), AMPK α2 KO control (KO+Ctr, n=6) and AMPKα2 KO exercise (KO+EX, n=12). WT+EX and KO+EX group mice were applied to treadmill running for 7 weeks at 20m/min for 90 minutes to induce cardiac hypertrophy. Cardiac fibrosis and myocyte size was evaluated by Sirius red staining and WGA staining separately. The protein expression in heart tissue was analyzed by Western blots. **RESULTS:** 1. AMPKα2 gene deficiency had no effect on ratio of heart weight to body weight (HW/BW, mg/g, 3.89±0.22 vs 3.77±0.13, p>0.05) and cardiomyocyte cross section area (CSA, um2 , 220±36 vs 229±27, p>0.05) under control condition. After 7 weeks exercise training, WT+EX and KO+EX group mice had greater HW/BW (4.34±0.19, 4.52±0.21) and cardiomyocyte CSA (306±27, 355±11) as compared to their control mice (p<0.05), and KO+EX group were significant higher than WT+EX group(p<0.05).2. There were no significant difference on cardiac fibrosis among four groups (p>0.05).3. Seven weeks exercise training significantly increased cardiac tissue

AMPKα and p-ACC protein expression in both WT+EX and KO+EX as compared to their control groups(p<0.05), while AMPKα2 protein expression only significant increase in WT+EX as compared with WT+Ctr group. 4. Seven weeks exercise training significantly increased cardiac tissue p-Akt protein expression in both WT+EX and KO+EX as compared to their control groups (p<0.05), and in KO+EX was significant decrease as compared with in WT+EX group (p<0.05). **CONCLUSIONS**: 1.Seven weeks treadmill running could induce cardiac hypertrophy in mice with increased heart weight and myocyte size. 2.AMPKα2 gene deficiency significantly amplified exercise induced cardiac hypertrophy in mice.3.Seven weeks treadmill running induced cardiac hypertrophy was not founded with cardiac fibrosis.4.AMPKα2 might play some important role in exercise induced cardiac hypertrophy through Akt signal pathway.

Validation Of The Non-invasive Assessment Of Cardiac Output Via The Closed-circuit Acetylene Rebreathing Technique

Dean Palmer, Ashley Hardin, Justin Lawley, Satyam Sarma, Michinari Hieda, Benjamin Levine, FACSM. *IEEM, Dallas, TX.* (Sponsor: Benjamin D. Levine, FACSM)
(No relevant relationships reported)

Accurate assessment of cardiac output (Qc) is critical to the diagnosis and management of various cardiac disease states; however, the clinical standards of direct Fick and thermodilution (THD) are invasive. Non-invasive alternatives, such as acetylene rebreathing (RB), warrant validation. **PURPOSE:** Validate the non-invasive, closed-circuit acetylene rebreathing (RB) technique for measuring Qc. **METHODS:** Acetylene is an inert, soluble gas that enters the blood stream via pulmonary diffusion but, does not bind to hemoglobin and thus its concentration decreases during rebreathing at a rate proportional to Qc**.** We retrospectively analyzed 10 clinical studies and all available cardiopulmonary exercise stress tests performed in our laboratory that included RB and either direct Fick or THD. Studies included healthy individuals and patients with clinical disease (mostly HFpEF). For accuracy and precision analyses, simultaneous Qc measurements were obtained under normo-, hypo-, and hypervolemic conditions, as well as submaximal and maximal exercise. **RESULTS:** A total of 3,198 measurements in 519 patients were analyzed (mean age 59 years, 48% women). The RB method was more precise than THD in healthy subjects with nearly half the typical error (TE)=0.34 l/min, Pearson r=0.92, and coefficient of variation (CV)=7.2% vs THD TE=0.67, r=0.70, and CV=13.2%. In healthy subjects during supine rest and upright exercise, RB correlated well with THD (supine r=0.84, TE=1.02; exercise r=0.82, TE=2.36). In patients with clinical disease during supine rest, RB correlated well with THD (r=0.85, TE=1.43). Sensitivity analyses showed the agreement of the RB method was similar to, or better than, THD compared to direct Fick in healthy adults (RB rest r=0.85 and TE=0.84, RB exercise r=0.87 and TE=2.39; THD rest r=0.72 and TE=1.11; THD exercise r=0.73 and TE=2.87). Additionally, RB had an excellent correlation with direct Fick in patients with clinical disease during upright exercise (r=0.89, TE=1.14). **CONCLUSION:** The acetylene rebreathing method is much more precise than, and as accurate as, the THD method in a variety of patients and under a range of conditions. These data support the clinical use of RB derived Qc.

Holter Ecg In Sports People: 20 Years Of Monitoring

Riccardo Ariani, Alessio Bartoletti, Giorgio Galanti. *University of Florence, Florence, Italy.*
(No relevant relationships reported)

Purpose: Arrhythmias are a common finding in the population that practices sports activity and sometimes their clinical interpretation is not easy. Thus, we aimed to analyze and follow up the recordings in a group of subjects who underwent a 24-hour or weekly Holter ECG monitoring to assess the presence of arrhythmias in a large cohort of sportsmen.
Methods: Since April 1997 to April 2017, 6172 unselected and consecutive subjects (35±22 years) were enrolled. Revision analysis was performed by Holter Analysis System (Spacelabs Healthcare, LLC, California) on a sample of 10903 Holter ECG registrations, focusing on the ECG features, such as arrhythmias (origin, number, complexity), conduction delays and channellopathies. We then divided the population with follow ups by sex and into three age groups to follow the trend of arrhythmias (age<18; age=18-35; age>35).
Results: The subjects were 68,6% male and 31,4% female. The 27,8% of them (n=1716) had a semiannual or yearly Holter ECG follow-up, composing the 58,7% of the total amount of recordings. AV blocks were found 13,1% recordings (mainly AVB I and II-degree type 1) and other blocks in the 3,2%. Ventricular pre-excitation was recorded in 3,2% cases, whereas channellopathies in the 0,4% (BS or LQTS). Supraventricular arrhythmia was found in the 80% of recordings (<100 ectopic beats in 24h=76,0%), while ventricular arrhythmia in the 69,3% of exams (<100 ectopic beats in 24h=62,3%).

Conclusions: In the Holter recordings examined, we found that there was a clear prevalence of arrhythmias (91,4%) compared to conduction delays (16,3%) and channellopathies (0,4%). Analyzing in detail the features of the arrhythmias we observed that the 41,5% of the population of the study had more than 100 ectopic beats/24h and more than one fourth of the subjects had complex supraventricular (28,0%) or ventricular (23,9%) arrhythmias. Analyzing the follow ups, we found that older athletes had higher complexity and prevalence of arrhythmias, whereas younger people had higher frequency of arrhythmias in the 24h recordings. Arrhythmic peaks in each of the three age groups were found respectively at 14±2 years, 24±4,5 years and 58±11,1 yrs. These findings lead us to say that in sports population arrhythmias are a common event and they are often compatible with sports practice.

The Effects Of High Intensity Interval Training On Heart Rate Variability In Physically Inactive Adults

Abdullah B. Alansare[1], Elward K. Alford[1], Sukho Lee[2], Tommie Church[1], Hyun Chul Jung[1]. *[1]The University of Louisiana at Monroe, Monroe, LA. [2]Texas A&M University-San Antonio, San Antonio, TX.*
(No relevant relationships reported)

High intensity interval training (HIIT) is a type of exercise that involves repeated intense exercise with active or passive recovery. Heart rate variability (HRV) analysis has been widely used to measure cardio-autonomic functions. **PURPOSE**: The purpose of this study was to examine the effects of HIIT on heart rate variability (HRV) in physically inactive adults. **METHODS**: This study was conducted with a randomized and controlled design. Thirteen physically inactive male adults (27.5 ± 3.80 years) were randomly assigned to HIIT (N = 7) or moderate intensity continuous training (MICT, N = 6). The HIIT program consisted of 20 min of interval training with work to rest ratio (10/50 sec) at 90% HR$_{peak}$ while the MICT program consisted of 40 min of continuous training at 60-75% HR$_{peak}$. Both groups completed 8 sessions of cycle training over a period of two weeks. Height, body weight, blood pressure, and body composition were measured. HRV was measured for 20 minutes in sitting position with Actiwave-Cardio (CamNtech, UK). Time domain (R-R interval, IBI, RMSSD) and frequency domain (high frequency, low frequency, and LF/HF ratio) variables were analyzed by actiwave analyzer. A natural logarithmic transformation of all frequency domain variables was performed to meet the assumptions of parametric statistical analysis. Rrepeated measures ANOVAs were applied to analyze interaction effects on HRV variables and the significant level was set at .05. **RESULTS**: Significant time effects on R-R interval (F = 8.437, p < 0.05) and IBI (F = 9.611, p < 0.05) were observed with both HIIT and MICT groups decreasing over time. lnLF/HF ratio was significantly decreased in the HIIT group while the MICT group did not change (F = 4.875, p < 0.05). **CONCLUSIONS**: The present study suggests that the HIIT program improves sympathovagal (lnLF/HF ratio) activity following only 8 sessions of HIIT. Health professionals or fitness trainers could consider this time efficient exercise program (HIIT) for improving cardio-autonomic function in adults who are physically inactive.

Autonomic Modulation in Response to Three Different Autonomic Reflex Tests in Women with Fibromyalgia

J. Derek Kingsley, FACSM, Kathryn Geither, Alaina Glasgow, Erica M. Marshall, Jason C. Parks, Leslie Sensibello, Yu Lun Tai. *Kent State University, Kent, OH.*
(No relevant relationships reported)

PURPOSE: To evaluate autonomic modulation in response to three different autonomic stressors, including isometric handgrip with post-exercise circulatory occlusion (IHG/PECO), the cold pressor test (CPT) and head-up tilt (HUT) in women with Fibromyalgia (FM) compared to healthy controls (HC). **METHODS:** Participants previously diagnosed with FM (n=37) and HC (n=25) were randomly assigned to an autonomic test. Baseline ECG recordings were completed during 5 minutes of seated (IHG/PECO and CPT) and supine rest (HUT). For IHG/PECO, participants completed 2 minutes of IHG at 30% maximal voluntary contraction followed by 2 minutes of PECO. For the CPT, circulated cold water hand immersion (10C) lasted for 2 minutes. For HUT, participants completed 5 minutes of 70-degree head-up tilt followed by 5 minutes of supine recovery. Heart rate variability measures included normalized low-frequency (LFnu) and normalized high-frequency (HFnu) powers as markers of sympathetic and parasympathetic modulation, respectively. A 2 x 3 repeated measures ANOVA was used to compare the effects of group (FM and HC) across time for IHG/PECO (rest, IHG, and PECO) and HUT (rest, HUT, and recovery). A separate 2 x 2 repeated measures ANOVA was used to compared of group (FM and HC) across time for the CPT (rest and CPT). Paired t-tests were used for post-hoc testing if the ANOVA was significant. **RESULTS:** Age, weight and height were similar (p>0.05) between groups. There were no significant differences between groups at rest for any measure of autonomic modulation. There were no changes in autonomic modulation in response to the IHG/PECO in either group. For the CPT, there were significant main

effects of time for LFnu (Rest: 42.5±20.9%; CPT: 61.1±20.6%, p=0.003) and for HFnu (Rest: 50.4±26.8; CPT: 37.3±20.0, p=0.03) such that they increased and decreased, respectively, during the CPT. During the HUT, there were significant group by time interactions (p=0.041) such that LFnu increased (FM: 136%; HC: 64.3%) and HFnu decreased (FM: 51.0%; HC: 24.0%). Measures of autonomic modulation during the recovery from the HUT were similar between groups. **CONCLUSION:** These data suggest that perhaps the hypotensive stress elicited by HUT is a stronger predictor of autonomic dysfunction then either IHG/PECO or the CPT in women with FM.

Heart Rate Variability Response To Altitude Exposure In College-aged Students In Nepal

Alex Claiborne, Helaine M. Alessio, FACSM, Mark Walsh, Eric Slattery, Arden McMath, Byran Smucker. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
(No relevant relationships reported)

Altitude places a burden on cardiovascular homeostasis, and heart rate variability (HRV) may serve as a biomarker for altitude stress. PURPOSE: HRV was studied at different altitudes in college-aged students of varying fitness levels, trekking in Nepal. METHODS: 10 min resting HRV data and heart rate (HR) were measured in college aged students (n=17,9F age=20±1.7yrs, BMI 23±3kg•m2) at 300m in Oxford Ohio,1900m, and 4500m above sea level in Nepal. 1 min average oxygen saturation (pO2) was measured at 4500m via fingertip pulse oximetry. Root-mean-squared of the successive differences (RMSSD ms), percent of successive R-R intervals varying>50ms (pNN50), and Poincare-plot SD1(ms) and SD2(ms) describe time variation between adjacent R-wave-to-R-wave intervals. Low-Frequency and High-Frequency Power Spectral Analysis (LFP,HFP), which describe the balance of sympathetic and parasympathetic drive to the heart, were other HRV variables of interest. RESULTS: RMSSD and pNN50 were highly correlated (r=0.90). Most HRV variables responded similarly to altitude, decreasing at 1900m and partially returning towards baseline as the trek continued to 4500m. Initial graphical analysis revealed an apparent relationship between log(RMSSD) and heart rate at 1900m and 4500m, though the relationship was less pronounced at 300m. Linear mixed effects modeling of log(RMSSD) provided evidence of a fairly strong interaction between altitude and HR (p=0.005 for 1900m vs. 300m; p=0.002 for 4500m vs. 300m). This model predicts that for lower HR (e.g. 75 bpm) RMSSD increases as a function of altitude, while at median (82.5 bpm) and higher (90 bpm) HR, RMSSD is lower at 1900m than at the other two altitudes. Oxygen saturation mean was 87±3 at 4500m. CONCLUSIONS: Evidence of a substantial altitude by HR interaction on log(RMSSD) suggest that HRV is sensitive to an altitude stressor, but also that subjects with lower resting heart rates at altitude presented with more favorable HRV.

Ageing Alters Right Ventricular But Not Left Ventricular Myocardial Mechanics

Glenn Stewart[1], Bruce Johnson[1], Bryce Balmain[2], Kenji Shino[2], Akira Yamada[2], Norman Morris[2], Jonathan Chan[3], Surendran Sabapathy[2]. *[1]Mayo Clinic, Rochester, MN. [2]Griffith University, Gold Coast, Australia. [3]The Prince Charles Hospital, Brisbane, Australia.*
(No relevant relationships reported)

Introduction: Ageing is associated with a progressive stiffening of the pulmonary vasculature that causes an increase in pulmonary vascular resistance and a decrease in compliance. It remains unclear if right ventricular myocardial mechanics adapt in response to age-related remodeling in the pulmonary vasculature. **Purpose:** Accordingly, this study examined global and transmural longitudinal myocardial tissue deformation (strain) in a cohort of healthy young and middle-aged men to characterize age-related changes in myocardial tissue mechanics. **Methods:** Two-dimensional echocardiography was used to measure left (LV) and right (RV) ventricular strain in 10 young men (YM; Age: 27 ± 2yr, BMI: 23.2 ± 2.4m²) and 10 middle aged men (MAM; Age: 61 ± 7yr, BMI: 25.9 ± 3.2m²). A transmural strain gradient was calculated as the difference between endocardial and epicardial strain as an index of regional non-uniformity. **Results:** Systemic blood pressure was similar in young and middle aged men (YM: 118 ± 4mmHg vs MAM: 122 ± 4mmHg, p > 0.05), while echocardiographic estimates of pulmonary blood pressure via the tricuspid regurgitation pressure gradient were greater in middle aged men (YM: 17 ± 4mmHg vs MAM: 25 ± 6mmHg, p < 0.05). LV and RV dimensions were similar (p > 0.05) in young (LV EDV: 118 ± 19mL; RV EDA: 18.3 ± 2.2cm²) and middle aged men (LV EDV: 118 ± 17mL; RV EDA: 17.3 ± 3.8cm²). LV global longitudinal strain (YM: -17.5 ± 1.0% vs MAM: -18.0 ± 1.0%, p > 0.05) was similar in young and middle aged men, while RV global longitudinal strain (YM: -27.3 ± 1.8% vs MAM: -22.5 ± 1.7%, p<0.01) was lower in middle aged men. LV transmural strain gradient (YM: -4.6 ± 0.4% vs MAM: -4.6 ± 0.4%, p > 0.05) was similar in young and middle aged men, while RV transmural strain gradient (YM: -1.1 ± 0.4% vs MAM: -5.5 ± 0.5%, p<0.01) was higher in middle aged men. **Conclusion:** Ageing was associated with global and regional alterations in RV myocardial

mechanics, while LV function was unaltered. Specifically, ageing resulted in a decrease in RV global strain and an increase in transmural non-uniformity (i.e., increased transmural strain gradient). Differences in LV and RV myocardial architecture and age-related changes in the pulmonary vasculature are possible explanations for opposing LV and RV functional remodeling in response to ageing.

Risk Factors of Hypertension Among Different Adult Groups in the Tujia-nationality Settlement of China

Xiaoli Liu[1], Xiangrong Shi, Male, FACSM[2]. *[1]Hubei University for Nationalities, Enshi, China. [2]UNTHSC, Fort Worth, TX.*
(No relevant relationships reported)

PURPOSE: Hypertension as a well-known major independent risk factor for cardiovascular disease and stroke has had great impact on health outcomes. However, few studies focus on the different risk factors of hypertension among various age groups in the Tujia-Nationality settlement of China. The study aimed to investigate the different risk factors of hypertension among different adult groups in this area. **METHODS:** Demographics questionnaires and fitness tests were utilized to identify the risk factors of hypertension among different adult groups in the years 2010 and 2014 in China's southwest province of Hubei. **RESULTS:** Of the 5,646 individuals aged 20-69 years (age=42.7±13.7 years) people, 1,219 were classified as hypertensive, giving an overall prevalence of hypertension of 21.6%. The prevalence of hypertension was 13.5% in 2010, before doubling to 29.0% by 2014. For all age groups, testing time (i.e., 2014) and overweight/obesity were significant factors associated with hypertension. In addition, the risk factors for the young adult group (31.9±7.2 yr, n = 2039?) included age, gender (men>women), lower level of education, and lower cardiorespiratory function (CRF), with ORs of 1.214 (CI, 1.116-1.320), 0.365 (CI, 0.285-0.466), 0.720 (CI, 0.625-0.829), and 0.603 (CI, 0.498-0.731), respectively, and for the middle-aged group (51.7±4.3 yr, n = 1795), included Tujia nationality, white collar workers, and lower CRF, with ORs of 1.076 (CI, 1.056-1.095), 1.612 (CI, 1.390-1.871), and 0.780 (0.631-0.963), respectively. **CONCLUSIONS:** The prevalence of hypertension increased dramatically in this area during 2010-2014. BMI was the common risk factor of hypertension in all adult groups. For both young and middle-aged adults, low CRF was a common risk factor associated with hypertension.

Risk of Cardiovascular Disease in American Firefighters: An Intervention is Warranted

Nicholas B. Zachmeier, Hyosung Han, Alexis C. King, J. Mark VanNess, Cynthia Villalobos, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
(No relevant relationships reported)

Cardiovascular disease (CVD) is the most common cause of job-related mortality among firefighters in the United States. Although age, family history, and work environments cannot be controlled, other predictors are modifiable. If solutions are to be implemented, it is important to know which health parameters are responsible for the elevated CVD risk in this population. **PURPOSE:** To examine the cardiovascular health of California firefighters. **METHODS:** We measured physiological CVD risk factors in 35 firefighters from Northern California. Assessments were age, anthropometry, blood lipids, blood pressure, and blood glucose. Risk factors were summed according to the American College of Sports Medicine guidelines. We evaluated the frequency of individual risk factors and used regression analyses (logistic, negative binomial, and linear as appropriate) to test the effect of age on risk. **RESULTS:** Firefighters were 33.5 ± 11.8 years old, had a body mass index (BMI) of 26.6 ± 3.4, body fat percent (BF%) of 21.2 ± 6.0%, waist circumference (WC) of 90.3 ± 10.4 cm, and waist-hip ratio of 0.87 ± 0.10. Systolic blood pressure (SBP) was 122.5 ± 8.0 mmHg, diastolic pressure (DBP) was 78.1 ± 10.3 mmHg, fasted blood glucose (FBG) was 98.5 ± 14.3 mg/dL, LDLs were 128.9 ± 40.1 mg/dL, HDLs were 31.6 ± 12.5 mg/dL, triglycerides were 116.8 ± 90.3, and the average number of risk factors was 1.8 ± 1.2. There were 32 firefighters (91.4%) with ≥ 1 risk. The proportion of at-risk firefighters for each variable was: lipid profile (77.1%), obesity (65.7%), FBG (37.1%), blood pressure (34.3%), and age (14.3%). Most of the lipid profile was met by low HDLs (65.7% of all firefighters). Age was a significant predictor of BMI (p=0.001), BF% (p=0.003), WC (p=0.001), and waist-hip ratio (p=0.047), but not SBP (p=0.553), DBP (p=0.590), FBG (p=0.961), HDLs (p=0.369), LDLs (p=0.593), or triglycerides (p=0.688). Increased age significantly predicted an increased number of CVD risk factors (p=0.003). **CONCLUSION:** As firefighters advanced in age, they experienced elevations in CVD risk, mostly as a consequence of increasing adiposity. Weight loss interventions aimed at improving lipid profile, blood glucose, and blood pressure may help reduce job-related CVD mortality in American firefighters.

Effectiveness of Three-Dimensional Echocardiography for Asian Postural Orthostatic Tachycardia Syndrome during Exercise Therapy

Takahiro Uechi[1], Tomoya Suda[1], Kazukuni Hirabuki[1], Noritaka Hata[1], Yuki Sano[1], Ai Hirasawa[2], Takeaki Matsuda[1], Shigeki Shibata[1]. [1]*Kyorin University School of Medicine, Mitaka, Japan.* [2]*Kyorin University, Mitaka, Japan.* (Sponsor: Shigehiko Ogoh, FACSM)
(No relevant relationships reported)

PURPOSE: Postural tachycardia syndrome (POTS) is a form of chronic orthostatic intolerance characterized by an excessive increase in heart rate in the absence of orthostatic hypotension. It is known that women are more likely to suffer from this disorder with 5:1 female to male ratio. Previous studies have reported that POTS is characterized by reduced stroke volume (SV) caused by reduced left ventricular (LV) mass due to cardiac atrophy. Moreover, previous studies indicated that exercise training for POTS patients improved their symptoms and increased LV mass and SV. In the clinical setting, magnetic resonance imaging (MRI) is widely accepted as the gold standard to quantify LV mass and SV. However, probably because it is too expensive to perform MRI very frequently, there have been few studies that intermittently evaluate LV mass and SV changes over exercise therapy. Recent development of three-dimensional transthoracic echocardiography (3D-TTE) may enable us to accurately measure LV mass and SV. The primary purpose of this study was to assess LV mass and SV changes in an Asian POTS patient over exercise therapy by using 3D-TTE. **METHODS:** We diagnosed a 27-years-old Asian woman as POTS in Kyorin University Hospital. We prescribed exercise therapy in which she trained 3 times per week for 30 minutes per session by using a recumbent bike with target heart rate equivalent to 60% of maximum (130-140bpm). We performed 3D-TTE (EPIC 7C, Philips)and analyzed LV mass and SV by using 3D speckle-tracking software (Analysis 3.1, TomTec) before and every 3 months after exercise training. **RESULTS:** Her symptom started to gradually improve 3 months after exercise training. LV mass and SV gradually increased during exercise training; LV mass was 90g, 98g and 114g, and SV was 39.3ml, 48.5ml, and 43.6ml before exercise, 3 and 6 months after exercise training, respectively. **CONCLUSIONS:** We revealed that exercise training for an Asian POTS patient improved her symptom and increases in LV mass and SV were able to be assessed by using 3D-TTE, indicating the effectiveness of 3D-TTE to assess LV mass and SV for POTS patients.

Left Ventricular Hypertrophy: New Indexation With Body Cell Mass

Gabriele Mascherini, Cristian Petri, Giorgio Galanti. *University of Florence, Florence, Italy.*
(No relevant relationships reported)

Purpose Cardiac adaptation to intense physical training is determined by many factors. Eliminate the fat mass from the indexing of left ventricular parameters seems to better explain some heart modifications, characterizing the so-called "athlete's heart". Fat free mass also contains the extracellular mass which does not represent a metabolically active compartment. The aim of this study is to verify a new left ventricular indexation with the metabolically active tissue of the body as body cell mass in elite athletes. **Methods** 18 females (F) were matched with 18 elite male (M) soccer players (F=26.2±2.4 yrs, M=26.9±2.5 years; p=NS). An accurate body composition analysis (skinfold and bioimpedance) and an echocardiography were performed. **Results** Greater relationship were found between left ventricular mass and body cell (r=0.827, r^2=0.684, p<0.001) compared to fat free mass (r=0.822, r^2=0.676, p<0.001). Differences in body composition were confirmed (hip circumference/height: F=0.55±0.03, M=0.52±0.02, p<0.01; fat mass index: F= 3.7±0.7 kg/m², M=2.4±0.4 kg/m², p<0.001), no difference were found in extra cellular mass index (F=7.1±1.2 kg/m², M=7.6±0.4 kg/m²; p=NS). There are no differences in systo-diastolic parameters between sexes. Left ventricular dimension show higher values in males also with body cell indexation (F=126.62±16.08 g/m², M=142.87±13.48 g/m² ; p<0.001). **Conclusions** Analyzing body composition in three compartments appears a solution that physiologically can explain some aspects of the athlete's heart. These results could be considered a preliminary data in order to create a new indexation.

847   Board #108   May 30 3:30 PM - 5:00 PM

Parasympathetic Modulation At Rest, During Exercise And Recovery From Maximal Exercise, In Boys And Men

Justin Guilkey[1], Brandon Dykstra[2], Jennifer Erichsen[3], Eric Heidorn[2], Anthony D. Mahon[2]. [1]*Coastal Carolina University, Conway, SC.* [2]*Ball State University, Muncie, IN.* [3]*South Carolina School of Medicine, Columbia, SC.*
(No relevant relationships reported)

PURPOSE: Assess heart rate variability (HRV) to examine the parasympathetic nervous system (PNS) response from rest to light- (LIE) to moderate-intensity exercise (MIE) and recovery from maximal exercise in pre- (n = 10; maturity offset (MO) = -3.0 ± 1.2 yrs; age = 10.1 ± 1.9 yrs), mid- (n = 9; MO = -0.1 ± 0.6 yrs; age = 13.7 ± 1.0 yrs), and post-pubertal (n = 10; MO = 1.9 ± 0.6 yrs; age = 15.6 ± 1.2 yrs) boys and men (n = 10; age = 24.1 ± 2.0 yrs). **METHODS**: Subjects completed seated rest, LIE (50% HR$_{max}$) and MIE (65% HR$_{max}$). Intensity was then ramped to elicit maximal HR, followed by a 25-min seated recovery. HRV (root mean square of successive differences [RMSSD] and high-frequency power [HF]) was assessed during the last 3 min of rest, LIE and MIE and 3-min epochs ending at 10, 15, 20 and 25 min in recovery. RMSSD and HF were natural log transformed (ln) due to non-normal distribution. Significance was established if p ≤ 0.05. **RESULTS**: In each group, lnRMSSD and lnHF were similar at rest and decreased from rest to LIE to MIE. During LIE, lnRMSSD was greater in pre (3.4 ± 0.3 ms) than men (2.8 ± 0.5 ms) but similar to mid (3.1 ± 0.5 ms) and post (3.0 ± 0.5 ms). During MIE, lnRMSSD was similar between groups (pre = 2.1 ± 0.4 ms; mid = 1.9 ± 0.5 ms; post = 1.7 ± 0.5 ms; men = 1.8 ± 0.6 ms). Pre had greater lnHF than men during LIE (5.4 ± 0.7 ms² vs 4.0 ± 0.9 ms²) and MIE (2.8 ± 1.0 ms² vs 1.4 ± 1.0 ms²), but similar to mid (LIE = 4.8 ± 1.2 ms²; MIE = 2.3 ± 1.7 ms²) and post (LIE = 4.9 ± 0.9 ms²; MIE = 2.2 ± 0.8 ms²) at each intensity. In recovery, groups increased lnRMSSD from 10 (pre = 3.2 ± 0.8 ms; mid = 2.4 ± 0.6 ms; post = 1.8 ± 0.8 ms; men = 1.9 ± 0.5 ms) to 25 min (pre = 3.8 ± 0.6 ms; mid = 3.4 ± 0.6 ms; post = 2.8 ± 0.8 ms; men = 2.7 ± 0.8 ms). For lnHF, all groups increased from 10 (pre = 4.9 ± 1.8 ms²; mid = 3.4 ± 1.2 ms²; post = 2.2 ± 1.8 ms²) to 25 min (pre = 6.5 ± 1.3 ms²; mid = 5.6 ± 1.5 ms²; post = 4.1 ± 1.7 ms²), except men (2.5 ± 1.0 ms² vs 3.9 ± 1.6 ms²; p = 0.09). At all points, lnRMSSD and lnHF were greater in pre compared to post and men. Also, mid and post had different lnRMSSD at 15 min (2.9 ± 0.7 ms vs 2.0 ± 0.7 ms) and lnHF at 20 min (5.5 ± 1.4 ms² vs 3.7 ± 1.2 ms²). **CONCLUSIONS**: The primary findings were PNS withdrawal was reduced in pre-pubertal boys than men during LIE and MIE (HF only). Otherwise, MO did not affect PNS response from rest to MIE. Throughout recovery, PNS reactivation was greater in pre-pubertal boys compared to post-pubertal boys and men.

Link Between Left Ventricle Mass And Body Composition In Young Male And Female Athletes

Giorgio Galanti, Cristian Petri, Gabriele Mascherini. *University of Florence, Florence, Italy.*
(No relevant relationships reported)

Purpose Competitive sports induce gradual cardiac adaptations in young athletes. During growth, changes occur in their body composition. The purpose of this study is to provide the left ventricular parameters indexed for body composition during young athletes' growth. **Methods** 220 young athletes, 110 females and 110 males aged from 8 to 19 years old were enrolled. An accurate body composition analysis (skinfold and bioimpedance) and echocardiography were performed. The left ventricular parameters were then indexed to the body surface area formula with the data related to body composition (fat-free mass and body cellular mass). **Results** The left ventricular and body composition parameters increased continuously during growth and no differences between the sexes were found before puberty. Higher fat mass was found in females from 12 years old (Fat Mass Index: Female=4.8±1.8kg/m2, Male=3.6±0.9 kg/m2; p<0.05). Cardiac differences started at 13 years old, with a greater left ventricular mass in males (Female=128.7±23.7 g, Male=110.9±20.2 g; p<0.05). The indexing of the left ventricle to the body composition parameters increased the age of onset of these cardiological differences to 14 years old with fat-free mass (Female=91.8±18.7 g/m2, Male=105.0±19.5 g/m2; p<0.05), or to 15 years old with body cell mass (Female=124.3±17.9 g/m2, Male=145.8±28.5 g/m2; p<0.05). **Conclusions** Differences between the sexes appear to start after puberty. The above indexing was used in order to normalize the differences between the sexes according to body composition. This study reports the reference values for age and gender of the left ventricular parameters indexed for metabolically active mass.

Sex Differences In Aortic Stiffness, 24-hour Blood Pressure, And Cardiac Deformation In Marathon Runners

Jacqueline A. Augustine[1], Wesley K. Lefferts[1], Jacob P. DeBlois[1], Tiago V. Barreira[1], Kan Liu[2], Beth A. Taylor[3], Kevin S. Heffernan[1]. [1]*Syracuse University, Syracuse, NY.* [2]*SUNY Upstate Medical University, Syracuse, NY.* [3]*University of Connecticut, Storrs, CT.* (Sponsor: Bo Fernhall, FACSM)

(No relevant relationships reported)

Endurance exercise reduces risk for cardiovascular disease. Excessive endurance exercise may be detrimental to cardiovascular health. Interestingly, these detrimental cardiac adaptations may be more prevalent in male marathoners. Sex differences in the effect of marathons on cardiac function may be related to differences in aortic stiffness and blood pressure (BP). **PURPOSE:** 1) Examine sex differences in aortic stiffness, BP and cardiac function; 2) Explore associations between aortic stiffness, BP and cardiac function in marathoners. **METHODS:** Sixteen experienced marathoners had peak aerobic capacity, aortic stiffness, BP and cardiac function measured on 3 separate days. Aortic stiffness was measured as carotid-femoral Pulse-Wave Velocity (cfPWV) obtained using applanation tonometry. An ambulatory oscillometric blood pressure cuff was used to measure 24-hr systolic blood pressure (BP). Cardiac function was measured using 3-dimensional deformation echocardiography (3DE). Left ventricular (LV), longitudinal, circumferential, area, and radial strain were used as indices of cardiac function. **RESULTS:** cfPWV and 24-hr aortic BP were higher and 3DE longitudinal and area strain were lower in males compared to females (p<0.05). cfPWV was associated with longitudinal (r=0.58, p=0.04), circumferential (r=0.71, p=0.01), area (r=0.66, p=0.01), and radial strain (r= -0.66, p=0.02). **CONCLUSION:** Among marathoners, males have higher aortic stiffness, BP and lower cardiac function when compared to females. Higher aortic stiffness may be associated with lower cardiac function in experienced marathoners.

Influence of Cuff Pressure on Cardiovascular Responses to Knee Extension Exercise with Blood Flow Restriction

Sarah G. Kearney[1], Tyler Singer[1], Jon Stavres[1], Steven J. Elmer[2], Matt A. Kilgas[2], John McDaniel[1]. [1]*Kent State University, Kent, OH.* [2]*Michigan Technological University, Houghton, MI.*

(No relevant relationships reported)

Blood flow restriction (BFR) exercise is a growing exercise modality in which blood flow to the muscle is occluded during low intensity exercise. Recent reports indicate that BFR training leads to increase muscle strength and hypertrophy, however the acute cardiovascular responses to BFR exercise are not as clear. **PURPOSE:** The purpose of this study is to examine the effects of various occlusion pressures on cardiac output (CO), mean arterial pressure (MAP), and heart rate (HR) before, during and post exercise. **METHODS:** Eight healthy male participants completed 4 sets of knee extension exercises. Participants performed 30 repetitions per set at 20% max torque with 15 minutes of recovery between each set. Four different cuff pressures were administered with each set (0%, 60%, 80% and 100% of arterial occlusion pressure). CO, MAP, and HR were analyzed across 5 time points: baseline, after cuff inflation (prior to exercise), last five seconds of exercise, 30 seconds post exercise (prior to cuff deflation), and two minutes post cuff deflation. **RESULTS:** Repeated measures

ANOVA indicated a main effect of time point (p<0.001) and cuff pressure (p=0.018) on HR as well as a significant interaction (p<0.001). HR at the end of exercise was 97±22, 128±27, 135±24, and 148±24 bpm for 0%, 60%, 80% and 100% respectively. The 0% condition was significantly different than the other three occlusion pressures as well as 60% being different than 100%. There was a significant main effect of time point (p>0.001) on CO in that it was greatest during exercise, however there was no main effect of cuff pressure (p=0.805). Finally, MAP also significantly increased with exercise (p>0.001) but there was no main effect of cuff pressure (p=0.058). **CONCLUSION:** During BFR knee extension exercise greater cuff pressure resulted in greater HR response despite the fact that external workload was the same. This is likely due to the accumulation of metabolic by-products in the limb and greater exercise-pressor reflex with blood flow occlusion.

Does UK Cardiac Rehabilitation Provide An Effective Stimulus For Change?

Said Ibeggazene[1], Chelsea Moore[2], Michelle Swainson[2], Theocharis Ispoglou[2], Costas Tsakirides[2], Karen Birch, FACSM[1]. [1]*University of Leeds, Leeds, United Kingdom.* [2]*Leeds Beckett University, Leeds, United Kingdom.* (Sponsor: Professor Karen Birch, FACSM)

(No relevant relationships reported)

Purpose: The efficacy of cardiac rehabilitation (CR) in reducing mortality and rehospitalizations has been questioned. UK CR typically consists of 6 weeks biweekly circuit-type exercise at 40-70% of heart rate (HR) reserve (HRR). This study aims to characterise the exercise performed in UK CR and explore relationships between exercise dose and changes in physiological variables.
Methods: 48 patients (35 M/13 F 33-80 y) were recruited following referral to local outpatient CR. HR was recorded continuously during exercise sessions throughout the programme (Table 1). Assessments of incremental shuttle walk test distance (ISWD), blood pressure (BP), brachial artery flow-mediated dilatation (FMD), carotid artery compliance, and habitual physical activity (PA) were measured prior to and following CR completion.
Results: ISWD increased following CR (439 ± 116 m vs 632 ± 213 m, p < 0.001) and was strongly associated with the change in peak HR achieved between tests (r = 0.56, p < 0.001), baseline ISWD (r = 0.51, p < 0.001) and age (r = -0.51, p = 0.001). Spending >1 min above 55% HRR at the start and middle of the programme was associated with greater change in ISWD (χ2 = 3.9, p = 0.047; χ2 = 4.7, p = 0.03). Time spent exercising > 55% HRR increased between the start and end (8.4 ± 14.1 vs 11.5 ± 14.7 min, p = 0.02) but not the middle and end of the programme (11.9 ± 13.6 vs 11.5 ± 14.7 min, p = 0.87). PA, body mass, diastolic BP, FMD and arterial compliance were unchanged following CR (p > 0.05). Systolic BP decreased following CR (129 ± 20 vs 124 ± 20 mmHg, p = 0.01), and correlated only with the volume of light activity performed at baseline and following CR (r = 0.34, p = 0.04 & r = 0.41, p = 0.03).
Conclusion: Patients in current UK CR may not accumulate sufficient exercise time above 55% HRR to drive health gain. Large improvements in ISWD do not reflect the lack of change in PA, FMD and arterial compliance. Strategies to increase the dose and progression of time spent above 55% HRR are needed to enhance UK CR effectiveness.

Table 1: % of participants achieving a total of 8 min above threshold			
HRR threshold	Start (n=44)	Mid (n=40)	End(n=39)
40%	66	77	74
50%	41	60	54
55%	27	42	38
60%	27	22	36
65%	23	22	31
70%	9	20	18

852 Board #113 May 30 3:30 PM - 5:00 PM

Changes in Functional Capacity and Hemodynamic Responses in Costa Rican Cardiac Rehabilitation Patients

Felipe Araya-Ramirez[1], José Moncada-Jiménez[2], Peter W. Grandjean, FACSM[3]. [1]National University of Costa Rica, Heredia, Costa Rica. [2]University of Costa Rica, San José, Costa Rica. [3]Baylor University, Waco, TX. (Sponsor: Peter W. Grandjean, FACSM)

(No relevant relationships reported)

PURPOSE: To examine changes in walking distance and hemodynamic responses (HED) following a 12-week exercise-based CR program in Costa Rican cardiac patients. **METHODS**: Six-min walking distance (6MWD) and HED variables - systolic blood pressure (SBP), diastolic blood pressure (DBP), post-6MWD heart rate (FHR), post-6MWD recovery heart rate (REC), post-6MWD SBP (PSBP), and post-6MWD DBP (PDBP) were measured before and after CR in three-hundred and eleven (237 males and 74 females) patients (age = 57.7 ± 13 yr.). Using age as a covariate, two by two (gender x measurement) ANCOVAs determined differences in 6MWD and HED variables. Pre-to-post CR intervention changes (Δ) in 6MWD and HED variables were correlated to the number of CR exercise sessions attended by age-quartile (Q_n) within genders. **RESULTS**: Patients underwent 33.0 ± 5.1 CR sessions. Males walked a longer distance than females (males = 493.5 ± 5.6 vs. females = 429.0 ± 9.9 m; $p \leq 0.001$) from pre-to-post CR program (males pre = 429.3 ± 6.2 vs. post = 557.6 ± 5.8 m, $p \leq 0.001$; females pre = 374.9 ± 11.2 vs. post = 483.2 ± 10.3 m, $p \leq 0.001$). Both genders reduced DBP following the CR program (males pre = 67.01 ± 0.7 vs. post = 65.6 ± 0.5 mmHg, $p = 0.034$; females pre = 69.2 ± 1.2 vs. post = 65.0 ± 1.0 mmHg, $p = 0.001$), and increased FHR following a 6MWD test after the CR program (males pre = 97.7 ± 1.2 vs. post = 112.7 ± 1.4 bpm, $p \leq 0.001$; females pre = 100.7 ± 2.1 vs. post = 110.2 ± 2.5 bpm, $p \leq 0.001$). Males increased SBP immediately after 6MWD test (pre = 122.8 ± 1.3 vs. post = 133.6 ± 1.3 mmHg; $p \leq 0.001$). Significant correlations between CR sessions completed were found in males in Q_1 (age ≤ 49.9 yr.) for ΔDBP ($r = -0.328$; $p = 0.013$), Q_2 (age 50 to 59.9 yr.) for ΔFHR ($r = 0.407$; $p = 0.001$), ΔREC ($r = 0.286$; $p = 0.030$), and Q_4 (age ≥ 67 yr.) for ΔREC ($r = -0.310$; $p = 0.016$), but none for males in Q_3 (age 59 to 66.9 yr.). For females in Q_4 (age ≥ 67 yr.), significant correlations were found between CR sessions and ΔDBP ($r = 0.474$; $p = 0.040$) and Δpost-6MWD SBP ($r = 0.510$; $p = 0.022$). No significant correlations were found between CR sessions on Q_1 (age ≤ 51.9 yr.), Q_2 (age ≤ 52 to 59.4 yr.), Q_3 (age ≤ 59.5 to 66.9 yr.) for 6MWD or any HED variable. **CONCLUSION**: Both men and women improved functional capacity as observed in the 6MWD and HED variable adaptations to exercise following a 12-week CR program.

853 Board #114 May 30 3:30 PM - 5:00 PM

Comparison of Outcomes Related to Dietary Behavioral Changes in Phase II Cardiac Rehabilitation

Jillian N. Turek[1], Nathan J. Boehlke[1], Teresa M. Corbisiero[1], Caitlin M. Stackpool[1], Allison B. Haverkate[1], Mary S. Meyers[2], Cynthia A. Oster[1]. [1]Porter Adventist Hospital/Centura Health, Denver, CO. [2]Centura Health, Denver, CO.

(No relevant relationships reported)

PURPOSE: Study aim was to compare pre and post dietary survey scores and waist circumference measurements of Phase II Cardiac Rehabilitation (CR) participants receiving an individual, one-hour dietary counseling session from a registered dietitian (RD). **METHODS:** A retrospective comparative design was used to compare 104 Phase II CR program participants who completed ≥ 12 sessions between May 2015 and August 2017 at a hospital-based nationally certified CR program. The Rate Your Plate (RYP) (target score ≥ 58), a general dietary assessment survey of usual eating habits prior to cardiac event, was administered to all participants during the initial session and two sessions prior to program discharge. Individual dietary scores were compared among participants receiving and not receiving a one-hour dietary counseling session. A medical record review was conducted to collect completed dietary survey scores, attendance of dietary session, waist circumference, gender, and age. ANOVA, paired T-tests and generalized linear model were used for analysis. **RESULTS:** 104 participants completed a pre and post RYP survey. Seventy-three males (mean age = 66.4 years) and 31 females (mean age = 66.9 years) participated. 78 participants met with the dietitian and 26 declined. Mean dietary scores for all participants significantly increased post program (mean pre = 54.8, mean post = 60.2; p<.001). Participants meeting with the RD significantly increased their RYP scores (mean pre = 54.4, mean post = 60.2, p<0.001). There was no correlation between dietary score and waist circumference. **CONCLUSION:** Preliminary data suggest CR participants meeting with a RD are more likely to improve dietary scores. There may be gender differences, but a larger female sample size is needed to further explore these differences. In previous studies, dietitian services are associated with improved diet related patient outcomes. Weight management intervention for male patients with waist circumference > 40 inches and > 35 inches in women supports a multidisciplinary approach in CR programs to achieve overall cardiovascular risk reduction.

854 Board #115 May 30 3:30 PM - 5:00 PM

Influence of Metabolic Syndrome on Response to Cardiac Rehabilitation

Lynn Gerber, Samuel Powers, Carey Escheik, Jillian Kallman Price, Patrick Austin, Carla Porter, Henry Tran, Marianne Sherman, Zobair Younossi, Zobair Younossi. Inova Health System, Falls Church, VA. (Sponsor: Walter Frontera, FACSM)

(No relevant relationships reported)

Metabolic syndrome (MS) and its hepatic manifestation non-alcoholic fatty liver disease (NAFLD), are independently associated with cardiovascular disease. The metabolic impact of these conditions may influence exercise tolerance and response to exercise interventions. This is relevant to patients undergoing cardiac rehabilitation (CR) who are expected to have high prevalence for MS and NAFLD. We compared performance measures and self-reports from patients receiving CR with/without MS to investigate whether those with MS had different baseline characteristics and CR outcomes.
Methods: We assessed the independent associations between MS, having met 3 criteria, exercise performance measures (peak METs), anthropometrics and self-reports (PROs) for patients pre and post CR. PROs included DASI METs (activity), CESD (depressive symptoms), COOP (motivation/well being). Anonymized data were collected from a CR registry; and an IRB approved protocol for personal health data from hospital medical records. We used parametric and non-parametric tests.
Results: 181 participants, 132 males, mean age 62, 76 STEMI, 91 had MS. Baseline means: BMI = 29, peak METs = 3.4, DASI = 7, CESD = 8, COOP = 19. At baseline, peak METs were significantly lower in those with MS as compared to non-MS patients (adjusted for age and gender, p=.003). For every unit increase in initial peak METs, the probability of having MS decreases by 64% (OR= 0.36, p =.001. Age (r=-.4), COOP(r=-.42), DASI(r=.37), diabetes (OR 4.3) and female gender (OR = 5.36, p <.001) were associated with lower baseline peak METs. The change in peak METs following CR was not significantly different between the two groups. Significant increases in peak METs were associated with number of sessions attended (r .27, p<0.01) and DASI (r=.4, p <.001. High initial COOP (r -.34, p<.001) and older age (r -.4, p<.001) were associated with less increase in peak METs.
Conclusion: Patients with MS receiving CR have lower peak METs and higher BMI at baseline than those without. PROs are not significantly different between groups. MS is not a risk factor for improvement in peak METs. Improvement in peak METs post CR is independently associated with the number of sessions attended and with increased daily activity (DASI). Clearly, program adherence is essential for improved exercise performance.

855 Board #116 May 30 3:30 PM - 5:00 PM

Enablers, Barriers, And Intervention Strategies For Maintaining Exercise Following Cardiac Rehabilitation

Carmen C. Cuthbertson, Molly S. Miller, Sydney A. Jones, Joseph C. Engeda, Kelly R. Evenson, FACSM. University of North Carolina at Chapel Hill, Chapel Hill, NC.

(No relevant relationships reported)

PURPOSE: A significant proportion of cardiac rehabilitation (CR) patients decline or cease regular exercise following the structured CR program. The purpose of this qualitative study was to identify barriers, enablers, and intervention strategies to maintain exercise post CR.
METHODS: We conducted five focus groups (3 to 5 participants in each group) in three North Carolina locations in 2017 with 22 current CR participants. Participants also completed a brief survey. Focus groups were transcribed verbatim and double coded, analyzed, and reconstructed to identify overarching themes using ATLAS.ti software.
RESULTS: Focus group participants were referred to CR after experiencing a myocardial infarction (36%), coronary artery bypass grafting surgery (36%), stents (9%), angina (5%), and heart failure (5%). Over half of participants were male (55%), the mean age was 72 years (standard deviation=7 years), and 82% were retired. Potential barriers to continuing exercise post CR included lack of motivation to exercise, lack of financial resources to stay active, health conditions, loss of group social support, and not enjoying exercise. Potential enablers to continuing exercise post CR included continued contact with CR staff after finishing the CR program, extending the number of weeks of CR, returning for a check-in CR session after discharge, having an exercise plan after finishing CR, and receiving social support from family and friends. The focus group discussion asked participants about their interest in using an activity tracker during and following CR. Most participants were positive about using activity trackers; however, some expressed concern about the complexity of using the tracker. In questions about specific activity tracker features, most participants expressed favorable views about tracking step counts, but had mixed views about sharing their tracking information with peers. Participants were asked about introducing peer support from CR alumni and this feature received positive feedback. **CONCLUSION**: These findings can be used to design interventions that help CR participants maintain exercise following CR.

Functional Capacity And Cardiac Self-efficacy Measures Are Associated With Health Literacy In Cardiac Rehabilitation

James Kostra[1], Kelly Allsup[2], Amanda Delligatti[2], Andrew Althouse[1], Ross Arena, FACSM[3], Daniel Forman[1]. *[1]University of Pittsburgh, Pittsburgh, PA. [2]Va Pittsburgh, Pittsburgh, PA. [3]University of Chicago, Chicago, IL.* (Sponsor: Ross Arena, FACSM)
(No relevant relationships reported)

PURPOSE: Health literacy (HL) defines the degree to which individuals can obtain, process, and understand basic health information and services needed to make proper health decisions. Low HL (LHL) is associated with reduced adherence to exercise, medications, healthy nutrition, and low utilization of preventive health services. Cardiac Rehabilitation (CR) is a secondary prevention program that improves functional capacity and risk factor profile, leading to improved health status. The purpose of the present study is to assess the how the effectiveness of CR, as measured by functional capacity and cardiac self-efficacy (CSE), may differ between patients with LHL and high HL (HHL) who attend CR.
METHODS: In a quality improvement project, we evaluated the impact of LHL versus HHL on change in functional capacity and CSE measures. HL of patients enrolling in CR was evaluated by the REALM-SF. HL was divided into two groups: LHL was less than 9th grade reading level and HHL was greater than 9th grade reading level. We assessed changes in functional capacity by six-minute walk distance (6MWD) in relation to scores from the 13 question CSE scale that measures controlling and maintaining cardiac symptoms.
RESULTS: 134 patients that completed CR were assessed: 42 LHL and 92 HHL. LHL patients had lower baseline 6MWD and CSE scores compared to HHL patients (**Table 1**). There were clinically significant gains in 6MWD (>30 m) and statistically significant improvements for CSE in both groups (**Table 1**). Additionally, LHL and HHL patients both had significant correlations between 6MWD and CSE (**Table 2**).

Table 1	Pre		Post		Change		P-Value (P) (PRE vs POST)		P
	LHL	HHL	LHL	HHL	LHL	HHL	LHL	HHL	(BETWEEN GROUPS)
6MWD (m)	272 ± 92	333 ± 86	326 ± 94	384 ± 93	54 ± 48	47 ±59	<0.001	<0.001	0.47
CSE	32.2 ± 12.9	33.1 ± 11.8	39.9 ± 10.9	40.7 ± 8.6	8.0 ± 14.4	7.6 ± 8.4	0.001	<0.001	0.84
Table 2	Pre			Post					
	Correlation Coefficient (R)		P	R		P			
HHL 6MWD vs. CSE	0.26		<0.0001	0.34108		0.0009			
LHL 6MWD vs. CSE	0.33		0.0001	0.378		0.01			

CONCLUSIONS: This work indicates a positive correlation between improvements in functional capacity and CSE over the course of CR for both LHL and HHL groups, highlighting the utility of CR in overcoming some of the risks of diminished functional capacity and CSE associated with LHL. The study also reflects the importance of HL as a criterion of risk and associated management modification.

Efficacy of a Newly Developed Phase II Cardiopulmonary Rehabilitation Program in the Rural Southeastern United States

Hayley V. MacDonald, Battogtokh Zagdsuren, Mark T. Richardson, Jonathan E. Wingo, FACSM, Avani Shah. *The University of Alabama, Tuscaloosa, AL.* (Sponsor: Jonathan E. Wingo, FACSM)
(No relevant relationships reported)

Healthy People 2020 has identified improving access to comprehensive, quality health care services, like cardiopulmonary rehabilitation (CR), as essential for reducing cardiovascular disease (CVD) burden in the United States (US). Yet, the utilization of CR programs in the US is low, especially among rural communities where patients experience additional challenges. Low levels of physical activity and higher prevalence of CVD risk factors in the southeastern US further exacerbate these issues. **PURPOSE:** To evaluate the efficacy of a newly developed phase II CR program in rural Alabama. **METHODS:** Medical records of 14 cardiac and pulmonary patients enrolled in CR at a small rural hospital between November 2016 and July 2017 were analyzed retrospectively. Patient demographics, cardiometabolic profile, and functional capacity (i.e., 6-minute walk test [6MWT]) were assessed at baseline and upon program completion. **RESULTS:** Nine of the 14 patients successfully completed CR (64%). On average, patients were (*M*±SD) overweight (body mass index: 29.3±10.4 kg/m[2]), middle-aged and older (range: 31-81 yr) adults (66.7% women; 37.5% Black) with dyslipidemia, who were taking ≥1 antihypertensive medication for their high blood pressure (BP) (systolic/diastolic BP: 135.0±20.9/76.0±7.5 mmHg). Baseline characteristics were similar among Black and White patients, with the exception of age: Black patients participating in CR tended to be younger than White patients (48±15 vs. 68±15 yr, p=0.07). Overall, patients attended the CR facility 1.8±0.2 d/wk and completed the 36-session program in 19.3±2.1 wk. Patients significantly improved their 6MWT distance post-CR compared to baseline (p=0.007), an estimated increase of 1.6±1.4 ml/kg/min (≈12.6%) in peak oxygen uptake. Participation in CR also produced small reductions in body weight (-2.1 kg, p=0.07). **CONCLUSIONS:** These preliminary results demonstrate that a newly developed phase II CR program in rural Alabama elicited favorable changes in body weight and functional capacity (i.e., 6MWT). Additional research is warranted to determine how CR programs can be tailored effectively to address challenges unique to rural communities while targeting the disproportionate burden of CVD in the southeastern US.

Sedentary Behavior Characteristics in Cardiovascular Patients versus Healthy Controls.

Thijs M. Eijsvogels, Esmée A. Bakker, Esther Meindersma, Maria T. Hopman, FACSM, Dick H. Thijssen. *Radboud university medical center, Nijmegen, Netherlands.* (Sponsor: Maria T. Hopman, FACSM)
(No relevant relationships reported)

BACKGROUND: Time spent sitting is strongly and independently associated with an increased risk for adverse health outcomes, such as incident cardiovascular disease (CVD), diabetes, cancer and all-cause mortality. Previous studies mainly assessed sedentary behavior characteristics in the general population, whereas relatively little is known about this type of behavior in individuals with CVD.
PURPOSE: To compare sedentary behavior characteristics between CVD patients and healthy controls.
METHODS: Sedentary behavior patterns of 19 CVD patients and 18 age- and gender-matched controls were measured for seven consecutive days using the activPAL micro monitor. We used sedentary time (hours/day) as primary outcome, and the number of sedentary breaks (n/day) and sedentary bout duration (min/bout) as secondary outcomes.
RESULTS: CVD patients were sedentary for 11.1±1.5 hours/day, which was significantly more compared to healthy controls who reported 9.1±1.3 hours/day of sedentary behavior (mean difference 2.0 hours/day, 95%CI: 1.0 - 2.9). CVD patients broke up their sedentary behavior 32±7 times per day with a mean duration of each sedentary period of 15.5±3.7 minutes. In contrast, healthy controls had 42±8 breaks of sedentary behavior (p=0.016), whilst the average sedentary period only lasted 10.6±2.7 minutes (p<0.001). The mean difference for the number of sedentary breaks was -9.6 (95%CI: -14.5 - -4.7), and for sedentary bout duration 4.9 minutes (95%CI: 2.7 - 7.0). **CONCLUSIONS**: CVD patients spent more time sedentary during wake hours compared with healthy controls. Specifically, CVD patients had sedentary bouts with a longer duration and less frequently broke up their sedentary behavior compared to healthy controls. These findings stress the importance of specific interventions that target sedentary behavior in CVD patients.

Seric Musclin is not Increased in Patients with Metabolic Syndrome and Insulin Resistance

Juan C. Calderón[1], Yeliana L. Sánchez[1], Leonardo A. Castro-Valencia[1], Juan C. Aristizábal[1], Mauricio Estrada[2], Raúl Narváez-Sánchez[1], Jaime A. Gallo-Villegas[1]. *[1]University of Antioquia, Medellín, Colombia. [2]Pablo Tobón Uribe Hospital, Medellín, Colombia.*
(No relevant relationships reported)

Skeletal muscle has now been recognized as an endocrine tissue, through the production and secretion of myokines. Musclin is a myokine mainly secreted by

fibers type II (FT-II) that induces insulin resistance (IR) in both cellular and murine models. We hypothesize that musclin could be involved in pathophysiology of metabolic syndrome (MS) in humans. **PURPOSE**: to evaluate the relationships among IR, seric musclin, area occupied by FT-II and muscle mass in adults with and without MS. **METHODS**: analytical study in adults with and without MS. Homeostatic model assessment (HOMA-IR) was used as indicator of IR, musclin was measured by ELISA, area of FT-II in right vastus lateralis muscle by proton magnetic resonance spectroscopy and both fat and lean mass of the body and the right thigh (absolute values in Kg, or indexes in Kg/m^2 and Kg/Kg body mass) by dual X-ray absorptiometry. Data presented as mean±standard deviation. **RESULTS:** 23 subjects with and 10 without MS, comparable in age (51.6±5.7 with MS vs 53.5±6.3 without MS; P>0.05) and gender were included. Subjects with MS had higher values of insulin (18.3±7.4 vs 6.7±2.5 μU/ml; P<0.05) and HOMA-IR (4.6±2.2 vs 1.6±0.6; P<0.05). There were no differences between groups regarding glycaemia (99.1±8.8 vs 93.2±12.7), musclin (609.9±203.4 pg ml^{-1} vs 657.9±240.5 pg ml^{-1}), area of FT-II (51.4±23.2% vs 49±26.7%) or absolute values or indexes of muscle mass. There were positive correlations between HOMA-IR and both body fat mass or thigh fat mass (r>0.46; P<0.05), between musclin and indexes of total lean mass (Kg m^{-2}, r=0.51; P<0.05) and thigh lean mass (Kg m^{-2}, r>0.54; P<0.05), also between area of FT-II and indexes of total lean mass (r>0.49; P<0.05). There was a negative trend between total lean mass and HOMA-IR (r=-0.34; P=0.07). We did not find correlation between HOMA-IR and musclin or area of FT-II. **CONCLUSIONS:** lean mass seems to determine seric musclin, however, this myokine was not associated to IR in our patients. These findings are in controversy with previous ones reported for cellular models. COLCIENCIAS 111562638757. CODI 2605. Interinstitucional 2016-1341. Colciencias doctoral scholarships 727-2015.

Ketone Bodies Induce Mitochondrial Biogenesis In Skeletal Muscle Cells

Rie ISHIZAWA[1], Shin TERADA[2], Mitsuru HIGUCHI, FACSM[1], Motoko TAGUCHI[1], Kazumi MASUDA[3]. [1]*Waseda University, Saitama, Japan.* [2]*The University of Tokyo, Tokyo, Japan.* [3]*Kanazawa University, Ishikawa, Japan.*
(No relevant relationships reported)

Previous studies have shown that a long-chain fatty acid-rich diet as well as endurance exercise induce increase in muscle mitochondria and enhance endurance capacity in rodents. We previously showed that a medium-chain fatty acid (MCFA)-rich diet increases mitochondrial protein levels in the skeletal muscles of non-obese rodents. However, its mechanism remains unclear. Most MCFAs are converted to ketone bodies, which are thereafter released into the blood. **PURPOSE:** The purpose of this study was to examine whether β-hydroxybutyrate (β-OHB), a ketone body, increases the levels of mitochondrial proteins in muscles (Exp. 1). We also evaluated the binding of β-OHB to peroxisome proliferator-activated receptors (PPARs), which regulate the expression of mitochondrial genes (Exp. 2). **METHODS:** Exp. 1: C2C12 mouse skeletal muscle cells were grown in Dulbecco's modified Eagle's medium (DMEM) with 10% fetal bovine serum and 1% penicillin/streptomycin (PS), and differentiated in DMEM with 2% donor bovine serum and 1% PS. After 5 days, the cells were treated with different concentrations (0.05, 0.1, 0.25, 0.5, or 1 mM) of β-OHB for 24 h. The levels of voltage-dependent anion channel (VDAC) and complex-IV (COX-IV) were then measured by western blotting. Exp. 2: PPARs-ligand-binding domain were incubated with buffer containing either agonists or β-OHB, and then with fluorescein-labeled coactivator peptide and terbium-labeled anti-GST antibodies. The fluorescence intensity was measured using time-resolved fluorescence resonance energy transfer. **RESULTS:** Exp. 1: Treatment of the cells with 0.25 mM, 0.5 mM, and 1 mM β-OHB increased VDAC levels compared with those in the control (3.5-, 2.6-, 3.7-fold, p < 0.05, respectively). Similarly, treatment with 0.25 mM and 0.5 mM β-OHB increased COX-IV expression compared with that in the control (2.0-, 2.5-fold, p < 0.05, respectively). Exp. 2: GW7674, an agonist of PPARα (EC50: 6.2±0.4 nM), and GW501516, an agonist of PPARδ (EC50: 10.3±3.6 nM), increased the fluorescence intensity ratio (520/495 nm). Treatment with β-OHB, however, did not increase the 520/495 nm ratio for either PPARα or PPARδ. **CONCLUSION:** The results indicate that β-OHB induces the expression of mitochondrial proteins in skeletal muscle cells of mice via a pathway different from the one associated with PPARs.

Cancer-Related Fatigue and Mitochondrial Function in Cancer Survivors

Aidan M. Flanagan, Elizabeth M. DePauw, Leslie J. Waltke, Linda B. Piacentine, Alexander V. Ng, FACSM. *Marquette University, Milwaukee, WI.*
(No relevant relationships reported)

Cancer-Related Fatigue (CRF) is a commonly reported symptom of cancer survivors during or after treatment and can contribute to decreased quality of life (QOL). The cause of CRF is largely unknown and is likely multifactorial. CRF has long

been hypothesized to result from decreased energy production due to impaired mitochondrial function. **PURPOSE**: To investigate if impaired mitochondrial function contributes to CRF. **METHODS**: Ten cancer survivors (CA, Prostate, Breast, Ovarian), reporting CRF to varying degrees and 5 control subjects with no history of cancer (C), participated in this pilot cross-sectional study. The following measurements were obtained from all subjects: CRF (FACIT-F), depression (CES-D), QOL (PROMIS Global Well-Being (GWB)). Physical function was indicated by handgrip strength (HG), 30 Seconds Sit-to-Stand (STS), timed 6 min walk test (6MWT), and Godin Leisure Time Questionnaire (Godin). Mitochondrial oxidative capacity of the wrist flexor muscles was indicated by the time constant (T$_c$) of muscle mVO$_2$ recovery measured with near-infrared spectroscopy (NIRS). The upper limb was chosen so to be relatively independent from ambulation or activity. Analyses were by unpaired T-tests. Pearson Correlations were obtained for variables that differed between groups. Sig. p ≤ 0.05. Data are mean (SD).**RESULTS**: No significant group differences (all ≥ 0.3) were noted in age (CA = 53.8 (10.3), C = 48.6 (10.5) yr.), height (CA = 168.7(7.2), C= 166.6(9.0) cm), weight (CA=81.7 (13.2), C=73.8(13.6) kg), or body fat (CA=28.7 (4.45), C=33.14(8.6) %, bioelectrical impedance). Significant differences or trends were noted between CA and C groups in FACIT-F (Ca = 36 (11), C = 49 (2), p =0.01), CES-D (Ca = 11 (9), C = 4 (4), p = 0.05), PROMIS-GWB (CA = 37 (7), C =46 (3), p =0.02), HG (Ca = 27 (9), C = 38 (7) kg, p = 0.04), and 30STS (Ca = 15 (4), C = 22 (4), p =0.01)), and Tc (Ca = 46 (9), C = 36 (9) s, p = 0.07). Significant correlations were noted between: FACIT-F and CESD (r = -0.84), PROMIS-GWB (r = 0.90), STS (r = 0.72), and Tc (r = -0.52). PROMIS-GWB was also correlated to HG (r = 0.57), STS (r = 0.74), and CES-D (r = -0.93). **CONCLUSIONS**: Mitochondrial oxidative capacity (i.e. Tc) may be lower in Ca reporting fatigue compared to C and contribute to CRF (i.e. FACIT-F). Further, Tc may mediate QOL through CRF.

Impaired Mitochondrial Function May Contribute to Disability and Symptoms of Multiple Sclerosis

Elizabeth M. DePauw, Aidan M. Flanagan, Alexander V. Ng, FACSM. *Marquette University, Milwaukee, WI.*
(No relevant relationships reported)

Multiple Sclerosis (MS) is a neurological disease of autoimmune origin. Cognitive, physical, and psychosocial symptoms arise which can interfere with activities of daily living and decrease quality of life (QOL) of persons with MS (PwMS). The cause of MS is unknown, but mitochondria have been implicated in the pathogenesis of the disease and may otherwise affect symptoms of MS including muscle endurance and symptomatic fatigue. Mitochondrial function in leg muscles has been studied in PwMS, but not in arm muscles which may indicate systemic effects independent of ambulation or activity.**PURPOSE**: The purpose of this study was to determine if altered mitochondrial function is associated with MS disability or symptoms. **METHODS**: Six PwMS and 5 healthy controls without MS (C) took part in this pilot cross-sectional study. All subjects were ambulatory. Measurements included QOL (PROMIS Global Well-Being), depression (CES-D), fatigue (FIS), Handgrip Maximal Voluntary Contraction (MVC), Symbol Digit Modalities Test (SDMT), Six Minute Walk Test (6MWT). Disability status was indicated by the MS Functional Composite Measure (MSFC) comprising: 25ft walk test, 9-Hole Peg Test, and PASAT. Mitochondrial oxidative capacity was indicated by the time constant (Tc) for the recovery of forearm muscle mVO2 using near infra-red spectroscopy (NIRS). T-tests and correlations were used with significance at p≤0.05. Data are mean(SD). **RESULTS**: MS and control (C) groups were similar in age, height, and weight (p ≥ .25 for all). Significant differences were noted between MS and C groups in QOL (MS=34.0(6.3), C=46.0(2.8)), CES-D (MS=15.3(8.2), C=3.8(4.0)), FIS (MS=60.3(37.8), C=4.2(5.0)), MSFC (MS=0.74(0.58), C=2.00(0.55)), and Tc (MS=54.4(9.8), C=36.0(8.8)s). For all participants, Tc was correlated with MSFC (r=-.751). In turn MSFC was also correlated with GWB (r.774), CES-D (r=-.673), FIS (r=-.698), 6MWT (r=.767), and SDMT (r=.643). Forearm Tc was not correlated to 6MWT (r=-.496, p=.145) suggesting some independence of this measure from ambulatory function. **CONCLUSIONS**: Mitochondrial oxidative function is related to disability status due to MS which in turn is associated with cognitive, physical, and psychosocial symptoms of MS. The results are consistent with a role for mitochondria in the pathogenesis and symptoms of MS.

Insulin Receptor-WNK1 Signaling Targeting Glut4 Trafficking Are Blunted In Diabetic Skeletal Muscle

In Deok Kong, Ji-Hee Kim, Hanul Kim, Kyu-Hee Hwang, Kyu-Sang Park, Seung-Kuy Cha. *Yonsei Univ. Wonju College of Medicine, Wonju, Korea, Republic of.*
(No relevant relationships reported)

PURPOSE: WNK1 kinase is a downstream effector of insulin receptor-phosphatidylinositol 3-kinase (PI3K) signaling and regulates ion homeostasis. Impaired insulin signaling in skeletal muscle disturbs trafficking of glucose transporter 4 (GLUT4) associated with the onset of type 2 diabetes (T2D). WNK1 is highly

expressed in skeletal muscle and is known to regulate trafficking of transporters including GLUT1. Here, we investigated if and how insulin receptor signaling cascade targeting WNK1 regulates cell surface abundance of GLUT4 in skeletal muscle and whether this regulation is altered in T2D.
METHODS: Insulin receptor-WNK1 signaling cascades targeting GLUT4 trafficking were examined using *in vivo* T2D *db/db* mice and *in vitro* C2C12 cell models.
RESULTS: Compared with control mice, T2D *db/db* mice exhibited significant insulin resistance and decreased WNK1 phosphorylation, TBC1D4 and GLUT4 expression. Insulin increased phosphorylation of the downstream kinase Akt as well as WNK1 in a PI3K-dependent mechanism. A biotinylation assay demonstrated that insulin stimulates GLUT4 surface expression by promoting its exocytosis suggesting that WNK1 is a novel regulator of insulin-stimulated GLUT4 trafficking in the skeletal muscle. **CONCLUSIONS**: These results provide a new perspective on WNK1 function beyond regulation of ion homeostasis and offer new insights for pathogenesis of hyperglycemia in T2D. ALDH2 Restores Exhaustive Exercise-induced Mitochondrial Dysfunction in Skeletal Muscle

Qiuping Zhang[1], Mengwei Sun[1], Jianheng Zheng[1], Jun Qiu[1], Xiahong Wu[1], Yangshuo Xu[1], Weili Shen[2]. *[1]Shanghai Research Institute of Sports Science, Shanghai, China. [2]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.*
(No relevant relationships reported)

Mitochondrial aldehyde dehydrogenase 2 (ALDH2) is highly expressed in heart and skeletal muscles, and is the major enzyme that metabolizes acetaldehyde and toxic aldehydes. The cardioprotective effects of ALDH2 during cardiac ischemia/reperfusion injury have been recognized. However, less is known about the function of ALDH2 in skeletal muscle.
PURPOSE: This study was designed to evaluate the effect of ALDH2 on exhaustive exercise-induced skeletal muscle injury.
METHODS: We created transgenic mice expressing ALDH2 in skeletal muscles. Male wild-type C57/BL6 (WT) and ALDH2 transgenic mice (ALDH2-Tg), 8-weeks old, were challenged with exhaustive exercise for 1 week to induce skeletal muscle injury. Animals were sacrificed 24 h post-exercise and muscle tissue was excised.
RESULTS: ALDH2-Tg mice displayed significantly increased treadmill exercise capacity compared to WT mice. Exhaustive exercise caused an increase in mRNA levels of the muscle atrophy markers, Atrogin-1 and MuRF1, and reduced mitochondrial biogenesis and fusion in WT skeletal muscles; these effects were attenuated in ALDH2-Tg mice. Exhaustive exercise also enhanced mitochondrial autophagy pathway activity, including increased conversion of LC3-I to LC3-II and greater expression of Beclin1 and Bnip3; the effects of which were mitigated by ALDH2 overexpression. In addition, ALDH2-Tg reversed the increase of an oxidative stress biomarker (4-hydroxynonenal) and decreased levels of mitochondrial antioxidant proteins, including manganese superoxide dismutase and NAD(P)H:quinone oxidoreductase 1, in skeletal muscle induced by exhaustive exercise.
CONCLUSIONS: ALDH2 may reverse skeletal muscle mitochondrial dysfunction due to exhaustive exercise by regulating mitochondria dynamic remodeling and enhancing the quality of mitochondria.

Heavy Load Exercise Causes Mitochondrial Dysfunction and Increases Mitophagy

Hua-yu SHANG[1], Sheng-chao Bai[2], Bo-ya Gu[2], Zhi Xia[3], Shun-chang Li[1], Rui-yuan Wang[2]. *[1]Chengdu Sport Institute, Chengdu, China. [2]Beijing Sport University, Beijing, China. [3]Jinggangshan University, Ji'an, China.* (Sponsor: Tong-jian You, FACSM)
(No relevant relationships reported)

Scientific Abstract
PURPOSE: To observe the effect of heavy load exercise on mitochondrial structure and function in skeletal muscle of rats and analyze the change of mitophagy protein of PINK1 and Parkin and related proteins, and to explore the role of PINK1/Parkin pathway in exercise-induced mitochondrial damage in skeletal muscle. **METHODS:** Male Sprague-Dawley rats were divided into quiet control group (C group, n=8) and exercise group (E group, n=40). Rats in the E group performed a running on a treadmill down a 16°incline at 16m/min for 90 min, and those were further divided into 0h,12h,24h,48h and 72h sub-groups (n=8), and at each time point the soleus muscle was collected under anesthesia. Mitochondrial ultrastructural changes in skeletal muscle were observed by a transmission electron microscope. The content of quatitative enzyme citrate synthase (CS) and the activities of mitochondrial respiratory chain Complex II and IV were measured by ELISA. Protein expression of skeletal muscle cytochrome c oxidease subunit I (COX I),PTEN-induced putative kinase 1 (PINK1) and mitochondrial Parkin,microtubule-associated protein 1 light

chain 3 (LC3) were determined by western blot. Mitochondrial co-localization with Parkin,ubiquitin (Ub),p62/Sequestosome 1 (p62) and LC3 was measured by the immunofluorescence double labeling technique. One-way ANOVA was used to evaluate statistical significance. **RESULTS:** After heavy load exercise, the mitochondrial structure appeared to be abnormal and formed a lot of mitophagosomes; the CS content and Complex II activity significantly decreased, whereas the Complex IV activity and COX I protein level remained unchanged; the expression of PINK1 (E12=2.552±0.141),Parkin (E24=2.535±0.100),Ub (E24=2.501±0.191) ,p62(E12=2.662±0.240) ,LC3 (E12=2.757±0.180) significantly increased (C=1.000, $P<0.05$ or $P<0.01$).
CONCLUSION: A heavy load exercise may activate the PINK1/Parkin pathway and promote the combination of Ub,p62,LC3 and mitochondria, and result in mitophagy and mitochondrial damage within skeletal muscle.

Hypermetabolic Effects of Dietary Ketones are Independent of Changes in Skeletal Muscle Mitochondrial Respiration

Sarah E. Deemer, Rachel A. H. Davis, Jonathan M. Bergeron, Jason T. Little, Jonathan L. Warren, Gordon Fisher, FACSM, Eric P. Plaisance. *University of Alabama Birmingham, Birmingham, AL.* (Sponsor: Gordon Fisher, FACSM)
(No relevant relationships reported)

Dietary ketone-mediated increases in energy expenditure (EE) have been attributed to increased adipose thermogenesis; however, little is known regarding the contribution of skeletal muscle to the hypermetabolic phenotype. **Purpose:** Determine if dietary ketone esters increase mitochondrial respiration in skeletal muscle. **Methods:** Thirty 5-wk old male C57BL/6J mice were placed on an *ad libitum* high fat diet (HFD) for 10 weeks. Mice were then randomized to one of three groups (n = 10 per group) for an additional 12 weeks: 1) Control (CON, remain on HFD); 2) Ketone Ester (KE, 22% kcal from KE); 3) Pair-fed (PF, pair-fed to KE group). Body composition was measured during the final week of the study by Quantitative Magnetic Resonance (QMR) and EE was examined by indirect calorimetry. Skeletal muscle mitochondrial respiration was measured by high-resolution respirometry in permeabilized muscle fiber bundles. **Results:** Body weight in the KE group was 27% lower and total adiposity 54% lower than the PF group (p < 0.05 for both) despite comparable energy intake. Differences in body weight and adiposity were attributed to higher resting (REE) and total (TEE) energy expenditure in the KE group (p<0.05). Markers of mitochondrial biogenesis and thermogenesis were increased in brown adipose and a browning phenotype was observed in inguinal white adipose. However, there were no differences in skeletal muscle mitochondrial respiratory capacity between groups. **Conclusions:** These results provide further support that dietary ketone esters increase brown and white adipose thermogenesis but do not appear to have effects on mitochondrial respiration in skeletal muscle.

Mitochondrial Respiratory Capacity and Coupling Control of Skeletal Muscle in Colon-26 Tumor-Induced Cachexia

Jessica L. Halle, Gabriel S. Pena, Hector G. Paez, Joseph P. Carzoli, Michael C. Zourdos, Michael Whitehurst, FACSM, Andy V. Khamoui. *Florida Atlantic University, Boca Raton, FL.* (Sponsor: Michael Whitehurst, FACSM)
(No relevant relationships reported)

Cancer cachexia is a life-threatening, paraneoplastic syndrome featuring unintended weight loss and skeletal muscle atrophy. Mitochondria, the major providers of cellular energy, couple oxygen consumption to ATP synthesis (i.e. oxidative phosphorylation, OXPHOS). Impaired mitochondrial bioenergetics (e.g. respiration) is associated with the pathophysiology of multiple diseases. The control of mitochondrial respiration in skeletal muscle during the induction and progression of cancer cachexia is not well understood. **PURPOSE:** To investigate mitochondrial respiratory capacity and coupling control of skeletal muscle in the colon-26 model of cancer cachexia.
METHODS: Balb/c males (10 wks) were assigned to control or colon-26 (C26). C26 mice were injected with 1×10^6 tumor cells, and tissue collected on days 7, 14, and 21 post-injection. In this model, mice develop palpable tumors at day 7, and cachexia by day 21. Controls were injected with PBS and tissue collected on day 0. Respiration was measured in permeabilized fibers from the medial gastrocnemius via high-resolution respirometry. A substrate-uncoupler-inhibitor titration protocol was used to evaluate Complex I OXPHOS (CI_p), Complex I+II OXPHOS ($CI+II_p$), and electron transfer system capacity (ETS). Efficiency of the OXPHOS system was determined from the ratio $CI+II_p/ETS$ (P/E). **RESULTS:** CI_p was significantly lower (p<0.05) at day 21 (4.8±1.6 pmol/s/mg) in comparison to day 0 (53.4±7.0), day 7 (57.4±6.5), and day 14 (60.0±2.9). $CI+II_p$ was significantly lower (p<0.05) at day 21 (22.3±2.3 pmol/s/mg)

in comparison to day 0 (65.5±7.8), day 7 (69.3±8.5), and day 14 (73.8±4.8). Maximal ETS was significantly lower (p<0.05) at day 21 (24.1 pmol/s/mg) in comparison to day 0 (83.7±13.8), day 7 (84.4±12.3), and day 14 (105.1±7.3). P/E was not significantly different across timepoints (p>0.05). **CONCLUSION:** Phosphorylating respiration with electron input from Complex I and I+II, and maximal electron transfer system capacity (i.e. non-coupled respiration) was significantly reduced at day 21 concomitant with cachexia, but not at earlier timepoints, suggesting that changes in oxidative metabolism occur as a consequence of cachexia rather than having a causative role. Loss of respiratory capacity may compromise muscle function and physical independence.

Localization Of Myoglobin In Mitochondria: Implication On Regulation Of Mitochondrial Respiration In Muscle

Kazumi Masuda[1], Tsubasa Shibaguchi[1], Tatsuya Yamada[2], Kazuya Okumura[1], Claudia Pérez López[1], Kokoro Yamashita[1], Thomas Jue[3]. *[1]Kanazawa University, Kanazawa, Japan. [2]Johns Hopkins University School of Medicine, Baltimore, MD. [3]University of California Davis, Davis, CA.*
(No relevant relationships reported)

PURPOSE: Mitochondria play a principal role for metabolism and have a primary role in regulating respiration and energy expenditure. Recently, we showed that the muscle-specific protein myoglobin (Mb) interacted with complex IV to augment mitochondrial respiratory capacity in skeletal muscles. However, the precise mechanism for the Mb-mediated upregulation remains under debate. The present study has focused on localizing Mb within the mitochondria.
METHODS: Muscle specimen from deep portion of m. Gastrocnemius in Wistar rat was homogenized. Crude mitochondria were isolated by differential centrifugations and washed with the mitochondrial isolation buffer. The isolated mitochondria were treated with proteinase K (PK), osmotic shock (OS), and SDS (or TriX) in order to digest proteins on the outer membrane and in the intramembrane. The final samples were subjected to SDS-PAGE and immunoblotting using antibodies to localize the proteins in the mitochondria.
RESULTS: Western blotting analysis revealed that the PK digests Tom20, which localized on the outer membrane of mitochondria. The Tom20 band intensity decreased with the amount of PK used. Other mitochondrial proteins such as cytochrome c (intermembrane space), COX-IV (inner membrane), and PDH (matrix), were not affected by PK treatment. PK treatment did not affect Mb. The results suggested that Mb did not localize on the outer membrane of mitochondria. The combined treatment of PK, OS and SDS (or TrX) allowed immunoblotting detection of the mitochondrial proteins in specific regions of the mitochondria. For example, cytochrome c disappeared with OS treatment. Timm22 disappeared with PK+OS treatment. However, Mb was detected with either PK or OS treatment. But it cannot be detected with a combined PK+OS treatment. The results suggest that Mb associated with the inner membrane (intramembrane side, not matrix side) of the mitochondria.
CONCLUSIONS: We conclude that Mb in muscle cells localizes in the cytosol and in the mitochondrial intermembrane space. Since exercise training increases Mb expressions of skeletal muscle, the increased Mb concentration may play a direct role in modulation skeletal muscle respiration and oxidative phosphorylation capacity.

Effects of PGC-1α Overexpression on Sirtuins, GCN5, and Mitochondrial Protein Acetylation in Aged Mouse Skeletal Muscle

Li Li Ji, FACSM, Dongwook Yeo. *University of Minnesota at Twin Cities, Minneapolis, MN.*
(No relevant relationships reported)

Mitochondrial dysfunction in skeletal muscle is well-documented in sarcopenia. Protein hyperacetylation in mitochondria is one of the emerging causes of the pathogenesis. The interplay between acetylases and deacetylases such as GCN5 and Sirtuins (SIRTs) plays an important role in maintaining mitochondrial quality, which is also controlled by PGC-1α. Thus, it is important to know how PGC-1α impacts on GCN5 and SIRT protein levels in aged skeletal muscle. **PURPOSE:** To investigate the effect of aging and PGC-1α overexpression (OE) on SIRTs and GCN5 protein expressions, global and mitochondrial protein acetylation in aged mouse muscle. **METHODS:** C57BL/6J mice at the age of 2 mo (young, Y; N=7) and 24 mo (old, O; N=7) were transfected *in vivo* with either PGC-1α DNA or GFP into the tibialis anterior (TA) muscle. For electroporation, mice were anesthetized, and a small incision was made through the skin covering the TA muscle. A 27-gauge needle was used to inject plasmid DNA solution into the proximal and distal ends of the muscle belly. Electric pulses were applied to proximal and distal myotendinous junctions. The incision was closed with surgical glue. **RESULTS:** Aging increased SIRT1 level by 1.9, and 2.4-fold (P<.01) in O and O/OE, respectively; PGC-1α OE enhanced this effect (P<.05). SIRT3 and 6 level were decreased by 70 and 80% with aging (P<.01), whereas this effect was attenuated with PGC-1α OE. GCN5 level was elevated by

~10-fold with aging (P<.01), and PGC-1α OE showed no effect. Total cytoplasmic and mitochondrial protein acetylation level was 1.5- and 1.2-fold higher in O vs. Y (P<.05), whereas no effect of PGC-1α OE was seen. **CONCLUSION:** GCN5 and global and mitochondrial protein acetylation levels were increased with aging in mouse skeletal muscle. PGC-1α OE exerted no effect on this aging phenomenon. However, PGC-1α OE upregulated SIRT1 and ameliorated age-associated reduction of SIRT3 and 6 protein levels.

Comparison Between The Slow Components Of HR Kinetics And Of V'O$_2$ Kinetics: Functional Significance

Lucrezia Zuccarelli[1], Letizia Rasica[2], Mauro Marzorati[3], Simone Porcelli[3], Bruno Grassi, FACSM[1]. *[1]Università degli Studi Udine, Udine, Italy. [2]University of Milan, Milan, Italy. [3]Institute of Bioimaging and Molecular Physiology, CNR, Milan, Italy.*
(No relevant relationships reported)

PURPOSE: Aerobic exercise prescription is often based on a linear relationship between pulmonary oxygen consumption (V'O$_2$) and heart rate (HR). The aim of the present study was to test the hypothesis that during constant work rate (CWR) exercises at different intensities the slow component of HR kinetics occurs at lower work rate and is more pronounced that the slow component of V'O$_2$ kinetics, thereby negating the linear relationship mentioned above. **METHODS:** Seventeen male (age 27±4 yr) subjects performed on a cycle ergometer an incremental exercise to voluntary exhaustion (to determine peak O$_2$ uptake [V'O$_2$ peak] and the gas exchange threshold [GET]) and several CWR exercises: 1) moderate CWR exercises (MOD), below GET 2) heavy CWR exercise (HEAVY), at 45% of the difference between GET and V'O$_2$ peak (Δ); 3) severe CWR exercise (SEVERE), at 95% of Δ 4) "HR controlled" exercise in which work rate was continuously adjusted to maintain a constant HR slightly higher than that determined at GET. Breath-by-breath V'O$_2$, heart rate and other variables were determined. **RESULTS:** In MOD, no slow component of V'O$_2$ kinetics was observed, whereas a slow component was observed for HR kinetics. During HEAVY, the amplitude of the HR slow component was more pronounced than that for the V'O$_2$ slow component. During the HR-controlled exercise the decrease in work rate needed in order to maintain a constant HR was associated with a decreased V'O$_2$. **CONCLUSION:** The HR slow component occurred at a lower work rate and was more pronounced than the V'O$_2$ slow component. The absence of a linear relationship between HR and V'O$_2$ during CWR at different exercise intensities has implications on exercise prescription and tolerance.

Oxidative Stress Impaired Irisin Synthesis and Mitochondrial Homeostasis in C2C12 Myoblast

Ziyi Zhang[1], Tiantian Wang[1], Hai Bo[1], Yong Zhang[1], Li Li Ji, FACSM[2]. *[1]Tianjin University of Sport, Tianjin, China. [2]University of Minnesota, Minnesota, MN.* (Sponsor: Li Li Ji, FACSM)
(No relevant relationships reported)

PURPOSE: In aging skeletal muscle, disrupted mitochondrial homeostasis and lower levels of Irisin were found to accompany with elevated oxidative stress. Recent research indicates that impaired mitochondrial homeostasis may lead to diminished Irisin biosynthesis during aging. In order to gain some insight into the role of Irisin in mitochondrial homeostasis, we investigated the effect of oxidative stress, induced by exogenous H$_2$O$_2$, on Irisin and its precursor FNDC5, as well as key markers of mitochondrial biogenesis and dynamics in C2C12 myoblasts. **METHODS:** Myoblasts were treated for 24 hours with prepared dilutions of H$_2$O$_2$ in culture medium resulting in a final concentration of 10, 20, 40, and 80 mM. Survival rate of cells was detected by MTT to determine the optimal concentration of H$_2$O$_2$. Flow cytometry was used to assess mitochondrial membrane potential and reactive oxygen species (ROS) generation. Confocal laser scanning microscopy was used to monitor the morphology of the mitochondrial reticulum. Protein content of Mfn1, Mfn2, OPA1, Drp1, FNDC5, PGC-1α, NF-κB and p38 MAPK were measured with Western blot. Content of Irisin in culture medium was determined by Elisa. **RESULTS:** Treatment of cells with 80μM H$_2$O$_2$ caused decrease in mitochondrial membrane potential (-65%, p<0.01), and Mfn1 (-41%, p<0.01), Mfn2 (-49%, p<0.05), OPA1 (-17%, p<0.05), Drp1 (-25%, p<0.05), FNDC5 (-36%, p<0.01), PGC-1α (-80%, p<0.01), and p38 MAPK (-22%, p<0.05). H$_2$O$_2$ exposure elevated MDA content (+107%, p<0.01), ROS generation (+71%, p<0.01), and NF-κB activation (+23%, p<0.01). H$_2$O$_2$ induced visible fragmentation of the mitochondrial reticulum. However, Irisin content showed no significant change. **CONCLUSION:** H$_2$O$_2$ -induced oxidative stress impaird Irisin biosynthesis, which may be caused by disruption of mitochondrial homeostasis in muscle cells. Unchanged Irisin level in the cell might result from a decreased export under oxidative stress. Supported by NSFC (No. 81370454, 31110103919).

Exercise Training Induced Anti-inflammatory IL-6 in Aged Skeletal Muscle: Role of Mitochondrial Homeostasis

Yong Zhang[1], Chao Song[1], Jingwen Zhang[1], Hai Bo[1], Li Li Ji, FACSM[2]. [1]Tianjin University of Sport, Tianjin, China. [2]University of Minnesota, Minnesota, MN. (Sponsor: Li Li Ji, FACSM)

(No relevant relationships reported)

Deleterious actions for IL-6 have been proposed, such as provoking aging-associated low-grade inflammation accompanied with pro-inflammatory cytokine TNF-α and IL-1β. However, anti-inflammatory effect of exercise may to some extent be associated with muscle-derived IL-6 through inducing anti-inflammatory cytokines such as IL-1a and IL-10. It is increasingly clear that mitochondria are directly involved in the activation of anti-inflammatory response. **PURPOSE:** To determine the relationship between mitochondrial homeostasis and biological effects of muscle-derived IL-6 in aging and exercise intervention. METHODS: Male C57BL/6J mice aged 3 months (young) and 16 months (aged) were randomly divided into four groups: young normal (YN), young exercise training (YT), aged normal (AN) and aged exercise training (AT). Trained animals were exercised on a treadmill for 12 weeks. ROS generation, ATP content, mitochondrial homeostasis protein, anti-inflammatory and pro-inflammatory cytokines were examined in gastrocnemius muscle. **RESULTS:** Aging elevated ROS generation (+175%, p<0.01) and protein content of IL-6 (+104%, p<0.01), TNF-α (+188%, p<0.01), IL-1β (+85%, p<0.01), and NFκB (+77%, p<0.01), when comparing AN vs. YN. Furthermore, AN mice showed decreased ATP content (-26%, p<0.01), protein levels of COX IV (-29%, p<0.05), Beclin1 (-27%, p<0.05), PINK1 (-23%, p<0.05), IL-1α (-26%, p<0.05) and PGC-1α (-43%, p<0.01). Compared with AN, AT increased ATP content (+30%, p<0.05), COX IV (+35%, p<0.05), Beclin1 (+100%, p<0.01), PINK1 (+116%, p<0.01), IL-1α (+90%, p<0.01) and PGC-1α (+41%, p<0.05) levels. Moreover, training decreased ROS generation (-55%, p<0.01), IL-6 (-42%, p<0.01), TNF-α (-49%, p<0.01), IL-1β (-28%, p<0.01), and NFκB (-28%, p<0.05) levels. **CONCLUSION:** Aging increased inflammatory cytokine expression and deteriorated mitochondrial function in mouse muscle. Exercise training promoted mitochondrial biogenesis and mitophagy, suppressed inflammatory cytokine production, and elevated anti-inflammatory cytokines, possibly due to upregulation of PGC-1α and inhibition of NFκB pathway.

Overexpression of PGC-1α Modulates Mitophagy in Aged Mice Skeletal Muscle

Dongwook Yeo, Li Li Ji, FACSM. *University of Minnesota at Twin Cities, Minneapolis, MN.*

(No relevant relationships reported)

Mitochondrial dysfunction may contribute to age-related muscle atrophy known as sarcopenia. PGC-1α has been shown to regulate selective mitochondrial autophagy (mitophagy) in skeletal muscles. However, its role in aged skeletal muscle is currently unclear. **PURPOSE:** To investigate the effect of aging and PGC-1α overexpression on autophagy and mitophagy protein markers, as well as mitochondrial ubiquitination (Ub) and content in skeletal muscle. **METHODS:** C57BL/6J mice at the age of 2 mo (young, Y; N=7) and 24 mo (old, O; N=7) were transfected in vivo with either PGC-1α DNA (OE) or GFP into the tibialis anterior (TA) muscle. For electroporation, mice were anesthetized and a small incision was made through the skin covering the TA muscle. A 27-gauge needle was used to inject plasmid DNA solution into the proximal and distal ends of the muscle belly. Electric pulses were applied to proximal and distal myotendinous junctions. The incision was closed with surgical glue. **RESULTS:** LC3II level increased 30% in O (P<.05) compared to Y, whereas PGC-1α OE had no effect on Y or O. P62 level was increased in O (70%, P<.05) vs. Y; however, PGC-1α OE abolished this effect (P<.05). RheB level was ~5.5-fold higher in both O and O/OE (P<.01), and PGC-1α OE reduced it by 22% (p<. 01). Beclin-1 level increased with aging (p<.01) but no effect of PGC-1α OE was seen. Aging decreased Bnip3 level (p<.01), whereas the effect was abolished with PGC-1α OE. PGC-1α OE increased Mfn2 level by 8.2 fold in Y/OE and 3-fold (p<.01) in O/OE, and Drp1 by 73% in O/OE (P<.05). Aging increased Fis-1 level by 20.1, and 14.4-fold (P<.01) in O and O/OE, respectively; however, PGC-1α OE attenuated this effect (p<.05). Mt PINK1 and Parkin level were increased by 3.6, 1.4-fold with aging (P<.01), whereas this elevation was diminished with PGC-1. Mt Ub was increased 1.5-fold in O vs. Y (P<.05), and suppressed by 20% (P<.05) in O/OE vs O. COX4 level was decreased 85% in O vs. Y (p<.01), but PGC-1α OE restore the level by 65% (P<.05). **CONCLUSION:** Aging disrupted mitophagy flux, upregulated fission, and reduced Mt contents, while PGC-1α OE ameliorated Mt homeostasis and dynamics.

Testosterone and Resistance Exercise Improved Body Composition and Basal Metabolic Rate after Spinal Cord Injury

Ashraf S. Gorgey, FACSM, Refka E. Khalil, Timothy Lavis, Teodoro Castillo, Robert A. Adler. *Hunter Holmes McGuire VA Medical Center, Richmond, VA.*

(No relevant relationships reported)

Spinal cord injury (SCI) results in a dramatic loss in lean mass and subsequent increase in fat mass (FM) with concomitant decrease in basal metabolic rate (BMR). These changes expose persons with SCI to lifelong chronic health comorbidities. **PURPOSE**: To investigate the effects of testosterone replacement therapy (TRT) with evoked resistance training (RT) using neuromuscular electrical stimulation (NMES) on body composition and BMR in men with motor complete SCI. **METHODS**: Twenty-two participants were randomly assigned to either TRT+RT (n=11) or TRT only (n=11) for 16 weeks. The TRT+RT group participated in a progressive ankle weight lifting program using NMES twice weekly while sitting in their wheelchairs. The TRT was provided via transdermal testosterone patches (4-6 mg/day) placed on their shoulders. Body composition (lean mass and %FM) using dual energy x-ray absorptiometry and BMR using indirect calorimetry were measured prior to-and post-training. **RESULTS**: In the TRT+RT group, ankle weights (*P*< 0.0001) increased over the 16-week period for the right (19.6±6.5 lbs.) and the left (20±6.1 lbs.) legs. Serum testosterone decreased by ~ 34-36% (TRT+RT: 413.5±147 to 265±183 ng/dl and TRT: 435±177 to 288±258 ng/dl; *P*< 0.05) following both interventions. Total body (33±11% to 32±11%; *P* =0.025) and leg (33±11% to 32±9%; *P*= 0.037) %FM decreased by 1% in the TRT+RT group with no changes in the TRT group. Leg lean mass increased by ~1.8 kg (14.5±3.2 to 16.3±2.7 kg; *P*= 0.037) in the TRT+RT group with a concomitant increase in BMR by 218 kcal/day (*P* =0.03), but no changes in the TRT group. **CONCLUSIONS**: TRT combined with RT may help to attenuate the decline in lean mass and BMR years after SCI. At this dose or vehicle of delivery, TRT only is ineffective in restoring lean mass or BMR in men with SCI.

Key Glycolytic Metabolites In Paralyzed Skeletal Muscle Are Altered 7 Days After Spinal Cord Injury In Mice.

Zachary A. Graham[1], Jacob A. Siedlik[2], Lauren Harlow[1], Hesham A. Tawfeek[1], William A. Bauman[1], Christopher P. Cardozo[1]. [1]James J. Peters VAMC, Bronx, NY. [2]Creighton, Omaha, NE.

(No relevant relationships reported)

Spinal cord injury (SCI) leads to rapid losses in muscle mass due to immobilization and loss of communication with the central nervous system. SCI is also associated with an oxidative-to-glycolytic fiber-type transition which likely results in muscle metabolic function. How paralysis affects the levels of major muscle metabolites in is not well-described. **Purpose:** The purpose of this study was to identify changes in metabolite levels in muscle paralyzed at 7 and 28 d following a complete SCI. **Methods:** Female C57BL6 mice aged 20 weeks underwent sham or complete SCI surgeries. The sham group (Sham) was sacrificed at 7 d and SCI animals were sacrificed at 7 d (7d SCI) or 28 d (28d SCI) post-surgery (n=5/group). Gastrocnemius muscles were removed at sacrifice and flash frozen. Primary metabolomics analysis was performed on the muscle samples using GC-TOF mass spectroscopy (West Coast Metabolomics, NIH). Statistical analyses of mass spectroscopy peaks was completed using Metaboanalyst 3.0 and R Software. Protein expression was determined using Western blotting. **Results:** A principle components analysis identified muscle metabolites at 7 d SCI as a distinct cluster when compared to Sham and 28 d SCI. Metabolomic profiling identified 88 known metabolites with 8 being statistically different: lactate, glucose, maltose, oxoproline, sorbitol, tryptophan, maltotriose and pyruvate. Because glucose, lactate and pyruvate are key metabolites of glycolysis, the expression of key glycolytic proteins were probed. GLUT4 levels were upregulated in 7 d SCI animals compared to Sham and 28 d SCI animals. There was a strong trend (p=0.07) for reduced pyruvate kinase expression in 7 d SCI animals compared to Sham and 28 d SCI animals while pyruvate dehydrogenase was greatly reduced in 28 d SCI compared to 7 d SCI. The level of lactate dehydrogenase approached statistical reductions (p=0.09) at 28 d. **Conclusions:** Paralysis following SCI leads to reductions in glucose, lactate and pyruvate at 7 d post-injury with levels recovering by 28 d. Reductions in levels of these are seen despite elevations in the expression of GLUT4 expression at 7 d, suggesting SCI leads to a disruption in glucose handling and glycolytic functioning in paralyzed muscle in the acute timeframe after injury. Funding was provided by a VA RR&D Service Center Award (B9212C) to W.A.B.

Type I Diabetes Suppresses Intracellular Calcium Ion Influx by Heat Stress in Rat Skeletal Muscle

Ryo Ikegami[1], Hiroaki Eshima[2], David C. Poole, FACSM[3], Yutaka Kano[1]. *[1]The University of Electro-Communications, Tokyo, Japan. [2]Juntendo University Graduate School of Medicine, Tokyo, Japan. [3]Kansas State University, Manhattan, KS.* (Sponsor: David C Poole, FACSM, FACSM)

(No relevant relationships reported)

Intracellular Ca^{2+} ($[Ca^{2+}]_i$) homeostasis following muscle contractions is profoundly impaired in diabetic skeletal muscle. Because heat stress activates transient receptor potential vanilloid 1 (TRPV1) and promotes Ca^{2+} influx from the extracellular space in skeletal muscle we questioned whether TRPV1 might play a role in this pathological response. **PURPOSE:** To test the hypothesis that impaired muscle Ca^{2+} homeostasis in type I diabetic rats is due to attenuated heat stress tolerance (mediated via TRPV1). **METHODS:** Male Wistar rats were randomly assigned to 1 of 4 groups: 1. diabetes 40 ℃ (DIA40℃), 2. diabetes 30℃ (DIA30℃), 3. control 40℃ (CONT40℃), 4. control 30℃ (CONT30℃). Heat stress of 40℃ was selected because it represents the activation threshold of TRPV1. Spinotrapezius muscles of Wistar rats were exteriorized *in vivo* and loaded with the fluorescent probe Fura-2 AM. $[Ca^{2+}]_i$ was estimated over 20 min using fluorescence microscopy (340/380 nm ratio) in quiescent muscle held at the required temperature by means of a calibrated heat source applied to the ventral muscle surface. Western blotting was performed to determine the protein expression levels of TRPV1 in spinotrapezius muscle. **RESULTS:** After 20 min heat stress, the CONT40℃ condition induced a 20.0 ± 7 % $[Ca^{2+}]_i$ ($P<0.05$) elevation that was markedly absent from the DIA40℃ or other conditions. Thus there was no significant differences found over the 20 min observation period between DIA40℃, DIA30℃ and CONT30℃ ($P>0.05$). The expression of TRPV1 was significantly decreased 40 ± 7 % in DIA compared with CONT ($P<0.05$). **CONCLUSION:** This study revealed that the diabetic condition actually suppresses the expression of TRPV1 and inhibits Ca^{2+} influx evoked by heat stress. These findings do not support the notion that impairments of Ca^{2+} homeostasis during exercise result from increased Ca^{2+} influx due to thermal stress *per se*.

Muscle Oxygenation Of The Quadriceps Femoris During Voluntary Or Femoral Nerve Stimulation Induced Fatiguing Contractions

Hiroshi Akima[1], Ryosuke Ando[2]. *[1]Nagoya University, Nagoya, Aichi, Japan. [2]Japan Institute of Sports Sciences, Kita, Tokyo, Japan.* (Sponsor: Katsumi Asano, FACSM)

(No relevant relationships reported)

Fatigue of the superficial muscles in quadriceps femoris (QF), notably focusing on vastus lateralis (VL), has been evaluated using near infrared spectroscopy (NIRS). Our previous study (Akima & Ando Clin Physiol Func Imaging, in press) showed that muscle oxygenation of deep vastus intermedius (VI) muscle in QF was significantly higher, i.e. less fatigue, than the other superficial muscles after a fatiguing voluntary contraction. It is unclear that this higher oxygenation in VI at muscle fatigue was whether specific response induced by voluntary contraction or the other physiological characteristics. **PURPOSE**: The purpose of this study was to compare oxygenation level of individual muscles of the QF at fatigue, which was induced by voluntary contraction or femoral nerve electrical stimulation elicited contraction. **METHODS**: Eight healthy men (age, 27 ± 8 years; height, 175 ± 7 cm; weight, 73 ± 12 kg) performed isometric knee extension with knee joint angle of 90° at 50% of maximum voluntary contraction (MVC) for 50 sec induced by voluntary or femoral nerve electrical stimulation (frequency, 20 Hz; pulse duration, 200 μs). The oxygenation level of the VI, VL, vastus medialis (VM) and rectus femoris (RF) were measured using NIRS during the two types of fatiguing contractions. Tissue saturation (StO_2) of each muscle was calculated at -10, 0, 10, 20, 30, 40, 50 sec of the contraction time. A two-way (times x muscle) analysis of variance with repeated measures was used to compare parameters. **RESULTS**: StO_2 of all four QF muscles were significantly decreased after voluntary contraction and nerve stimulation elicited contraction; however, StO_2 in VM during voluntary contraction at 40 and 50 sec was significantly lower than nerve stimulation elicited contraction. When comparison StO_2 among four individual QF muscles at the end of fatiguing contraction, VM was significantly lower than VI during voluntary contraction and RF was significantly lower than VI during nerve stimulation elicited contraction. **CONCLUSIONS**: Muscle oxygenation in VI could be less fatigued during nerve stimulation elicited contraction as well as voluntary contraction, suggesting slower muscle fatigue in VI was the intrinsic characteristics of physiological response.

mRNA Expressionin the Rat Spinal Cord Including Motoneurons Innervating Damaged Muscle

Hirofumi Miyata[1], Nami Matsuura[1], Hiroshi Nagahisa[1], Ryotaro Yamada[1], Takashi Yamada[2]. *[1]Yamaguchi Univ., Yamaguchi, Japan. [2]Sapporo Medical Univ., Sapporo, Japan.*

(No relevant relationships reported)

PURPOSE: There are several methods to examine the morphological properties of spinal motoneurons, but it is difficult to evaluate their functional properties. In this study, we developed a method to evaluate motoneuron plasticity using real-time RT-PCR for the entire spinal cord in rats.
METHODS: Male Wistar rats (9 weeks old) were anesthetized and subjected to 100 repeated eccentric contractions (ECC) of their left plantar flexion muscles. The ECC were induced by direct electrical stimuli (45 V, 50 Hz) to the surface of the gastrocnemius muscle and simultaneous dorsal flexion of the ankle joint (150 degree/s, 0-40 degree). The lumbar spinal cord and medial gastrocnemius muscles on both sides were removed at 2 and 4 days after the ECC, and real time RT-PCR analysis was then performed using the muscle and spinal cord. The right gastrocnemius muscle and right half of spinal cord were used as the non-damaged control. Glyceraldehyde-3-phosphate dehydrogenase and Beta actin in the muscle and spinal cord, respectively, were used as housekeeping genes.
RESULTS: The mRNA expression of IL-6 was 50-times higher in the left muscles compared with in the right muscles, indicating marked muscle damage due to the ECC. The mRNA expression of the motoneuron-related factors Choline acetyltransferase, Osteopontin and Estrogen-related receptor gamma was significantly higher in the damaged left half than in the right control of the spinal cord. Furthermore, the mRNA expression of neurotrophic factors and their receptors, Calcitonin gene-related peptide and Brain-derived neurotrophic factor, was higher in the left half of the spinal cord. However, the mRNA expression of Nerve growth factor was significantly lower in the left half of the spinal cord. The mRNA expression of oxidative metabolism related factors, PPAR gamma coactivator 1 and Vascular Endothelial Growth Factor, was not significantly different between the left and right spinal cord.
CONCLUSIONS: These results indicate that reconstruction of some neuro-muscular systems is facilitated in the muscle and motoneurons by muscle damage induced by ECC. We concluded that this standard method for the spinal cord may be a useful tool to clarify the role of each neurotrophic and myotrophic factor in the muscle regeneration process.

Effects Of Post-activation Potentiation On Neuromuscular Parameters

Sandro F. da Silva[1], Delvis M. Cardoso[2], Gaspar P. da Silva[1], Miller P. Guimarães[3], Cintia C. D. Rocha[3], Claudio H. Mosquera[4]. *[1]University of Lavras, Lavras, Brazil. [2]University of Pedro de Valdivia, Chillan, Chile. [3]Presbyterian College Gammon, Lavras, Brazil. [4]University of Los Lagos, Puerto Montt, Chile.*

(No relevant relationships reported)

PURPOSE: The aim of this study was to the effects of post-activation potentiation protocol (PAP) on neuromuscular parameters post-performance of an advanced resistance training method.
METHODS: Seventeen (n = 17) men who were experienced in resistance training (4.6 ± 1.4 years) completed PAP isometric protocol on the horizontal bench press, in the consisted in 3 sets of 3 seconds of maximum voluntary isometric contraction (MIVC). After interval 4 minutes was performed at the intervention with the resistance training where the Tri-set methodology of resistance training directed to upper limbs. Average power strength (POWs) and MVIC were assessed pre-potentiation and post-training. *Statistical:* for data analysis, the descriptive statistics was used with the determination of average and standard deviation. The Kolmogorov-Smirnov test with Lilliefors correction was performed to verify the data distribution. For the comparison analysis among the PAP mechanisms, the t test of paired samples was used. In all the analyses, the significance level was $p<0.05$.
RESULTS: in the POWs, there was a significant decrease ($p < 0.05$) among the pre ($712,96 \pm 124,70$ watts) and post assessments in both PAP stimuli (isometric: $559,13 \pm 118,98$ watts), in MVIC there was also a decrease without differences among PAP stimuli (control: 74.54 ± 19.48 kgf; isometric 62.72 ± 13.51 kgf).

CONCLUSIONS: We concluded that the PAP mechanism is ineffective after a tri-set method session, not showing plausible benefits that justify the daily routine in a gymnasium.

The Effect of Caffeine on Peak Torque, Muscle Fatigue and Prefrontal Cortex Blood Flow

Krishan Bhakta, Makenzie Stade, Joshua A. Cotter. *California State University, Long Beach, Long Beach, CA.*

(No relevant relationships reported)

Purpose: The purpose of this study was to assess the effect of caffeine consumption on prefrontal cortex (PFC) hemodynamics and muscular fatigue during maximal isokinetic exercise testing. **Methods:** Six active (exercise $\geq$3x/week, >1 hour per bout for >3 months) individuals (age 20.6$\pm$2.3yrs, body weight 72.1 $\pm$7.3kg, height 172.6 $\pm$ 14.5cm) participated in a double-blind placebo controlled study. Participants attended three separate exercise sessions on the Humac Norm Isokinetic Dynamometer. Each exercise session included three sets of 30 maximal knee extensions at 180° per second using their dominant leg. Exercise sessions were separated by one week and participants were instructed to refrain from consumption of caffeine 36 hours prior to testing. One hour prior to testing, participants were administered a placebo (NC), low caffeine (LC) (3mg/kg body weight) or high caffeine (HC) (6mg/ kg body weight) dose. Time-resolved near-infrared spectroscopy monitoring (TRS0-21, Hamamatsu) was utilized throughout testing to measure hemodynamics in the PFC. Peak torque and fatigue index were analyzed. **Results:** The fatigue index for HC (42.78%) and LC (42.82%) was lower when compared to the NC condition (47.39%; p<0.05). Peak torque per exercise session was found to increase during LC (124.17 N*m) compared to both NC (120.00 N*m) and HC (116.75 N*m). Additionally, LC showed a significant increase in total hemoglobin levels (141.21uM) compared to NC (101.05uM) and HC (97.618uM) in the PFC. **Conclusion:** The results of the study indicate that both high and low doses of caffeine were found to reduce fatigue across the bout of fatiguing exercise, but only LC resulted in increased peak torque and total hemoglobin to the PFC. Further examination of both PFC and local muscle hemodynamics should be explored to further understand the differential response between LC and HC.

Relationships between Motor Unit Behavior during Maximal Effort Contractions and Skeletal Muscle Phenotype

Ryan J. Colquhoun[1], Mitchel A. Magrini[1], Cody T. Haun[2], Tyler W.D. Muddle[1], Patrick M. Tomko[1], Michael J. Luera[1], Cameron S. Mackey[1], Christopher G. Vann[2], Jeffrey S. Martin[2], Kaelin C. Young[2], Jason M. DeFreitas[1], Michael D. Roberts[2], Nathaniel D.M. Jenkins[1]. *[1]Oklahoma State University, Stillwater, OK. [2]Auburn University, Auburn, AL.*

(No relevant relationships reported)

It has long been hypothesized that the physical properties of the muscle are related to motor unit behavior. Indeed, recent investigations have reported a relationship between skeletal muscle phenotype of the *vastus lateralis* and motor unit (MU) firing parameters during submaximal contractions. However, the nature of this relationship during maximal contractions in unknown and warrants further investigation. **PURPOSE:** The purpose of the current investigation, therefore, was to examine the relationships between motor unit firing behavior during a maximal voluntary contraction and Myosin Heavy Chain (MHC) isoform content of the *vastus lateralis* muscle in resistance-trained men. **METHODS:** Ten resistance-trained males (mean $\pm$ SD, age = 22 $\pm$ 2) completed a trapezoidal ramp contraction up to 100% of their maximal voluntary isometric strength (MVIC). During the contraction, surface electromyography was recorded from the VL using a multi-channel electrode array and decomposed to examine the firing characteristics of individual MUs. A skeletal muscle biopsy of the VL was also collected and the mean fiber area for type I and II muscle fibers was calculated for each individual subject. Regression analyses were performed to identify relationships between type II fiber area and the slopes or intercepts of the mean firing rate (FR_{MEAN}) vs. recruitment threshold (RT), max firing rate (FR_{MAX}) vs. RT, and RT vs. MU action potential amplitude ($MUAP_{PP}$) relationships. **RESULTS:** The mean type II fiber area was 65.8% ($\pm$ 13.5%). Each subject displayed a significant (p < 0.05) relationship for the FR_{MEAN} vs. RT (r = -0.95 to -0.82), FR_{MAX} vs. RT (r = -0.96 to -0.81), and RT vs. $MUAP_{PP}$ (r = 0.64 to 0.91) relationships. There were significant inverse relationships between type II fiber area and the y-intercept of the FR vs. RT relationship (p < 0.05). Additionally, strong relationships (r > 0.50) were found between type II fiber area and FR_{MEAN} vs. RT slope and RT vs. $MUAP_{PP}$ slope and intercept. **CONCLUSION:** These data further support the hypothesis that skeletal muscle phenotype is strongly related to MU behavior during isometric contractions. However, our data, in concert with previous investigations, may suggest that these relationships are influenced by the intensity of the contraction.

Music And Regular Physical Exercise:perception Of Practiitioners Regarding Duration And Performance.

Igor Roberto Dias[1], Elias de França[1], Jeferson O. Santana[1], Vinicius Hirota[2], Maria Luisa J. Miranda[1], Iris C. Sanches[1], Erico C. Caperuto[1]. *[1]Universidade São Judas Tadeu, São Paulo, Brazil. [2]Universidade Estácio de Sá, São Paulo, Brazil.*

(No relevant relationships reported)

Regular PE practice with music can improve subjective effort perception, motivation, extend the activity time and increase performance. Music is used by practitioners of different modalities and it is considered important by the practitioner, and this can influence the way music can be used in the training plan in order to improve performance, duration, engagement and quality of practice. The objective of this study was (1) to evaluate the use of music during different PE practices and (2) to evaluate how important music is to the practitioner. We used a questionnaire of musical taste and PE practice. The questionnaire assessed the relationship of the regular PE practitioner with music. We asked if the practitioner used music during the exercise and what was his preferred and current practice. The sample consisted of 50 participants, 28 men and 22 women, with a mean age of 36 years ($\pm$ 12.5). We used Google Forms to submit an electronic questionnaire, which was strictly forwarded to regular PE practitioners. Among the reported modalities we identified 28.6% resistance training, 18.4% running, 14.3% cycling and 10.2% walking. The level of physical activity of the participants was considered high, since most PE practices occurred either 2-3 times per week (46,9%) or 4 or more times per week (44,9%). The results show that 70% of the participants considered music necessary to perform the preferred PE, this result agrees with 71% of the participants that reported that listened music during their preferred PE. Also, 40% believed that music can change the PE session duration and 72.7% reported that music helps to improve performance during PE practice. Based on these results, we believe that music can stimulate greater engagement in PE practice, since most of the practitioners reported to listen to music during their PE practice. Also, according to the subjective perception reports of the participants, music became necessary for PE practice extension or it worked as a stimulant for PE performance improvement. These results suggest that music is an important factor for PE practice, especially in some modalities, and it should be included in the training program development (in a more elaborated way with the choice of musical style and rhythm) to improve the proposed training and not only as entertainment to be randomly chosen during PE.

Providing Estimates Of Fitness May Influence Subjects' Exercise

neeraj sathnur, james langland, kate picel, andrew olson. *university of minnesota, minneapolis, MN.*

(No relevant relationships reported)

PURPOSE: We investigated if providing measurements of cardiorespiratory and muscular fitness would influence subsequent self-reported physical activity. **METHODS**: The Exercise Vital Sign and current types of physical activity were obtained from 1315 individuals attending the 2014 and 2015 Minnesota State Fairs. The baseline mean Exercise Vital Sign was 213 min/week. Subjects were randomized in 1:1 fashion to control and intervention groups. The 656 intervention subjects were provided with personal measurements and age appropriate norms of cardiorespiratory fitness using a validated non-maximal step test to estimate VO2max and muscular strength using a hand grip dynamometer. All subjects were provided exercise recommendations based on current standards and follow up surveys conducted to determine subsequent physical activity. Follow up Exercise Vital Sign and physical activity type was obtained from 823 subjects (62.5%) over the following year. **RESULTS**: No significant changes in the Exercise Vital Sign were noted in the control group or intervention group at 3 months, 6 months or 1 year of follow-up. At 3 months resistance training activity was reported to increase in the intervention group from 29.1% to 42.8% while unchanged in the control group (26.3% to 31.4%) (p<0.05). The increase in resistance training was driven by a significant increase in those with grip strengths below normative values. Lifestyle physical activity was also reported increased in the intervention group at both 3 months (27.7% to 29.1%) and 6 months (25%) whereas it declined in the control group from 24.4% to 20.1% at 3 months and 18.7% at 6 months(p<0.05). Among the subjects who were less active at baseline (Exercise Vital Sign<150) we observed a significant increase in their Exercise Vital Sign from a baseline of 86 to 146 at 6 months (p<0.05). **CONCLUSIONS**: Recording the Exercise Vital Sign and providing exercise recommendations appears effective in increasing physical activity in less active

---

Abstracts were prepared by the authors and printed as submitted.

individuals. In an already very active population measuring grip strength and estimating VO2max using a step test may have short term positive effects on lifestyle activity and resistance training. Wider adoption of these measures could be effective in promoting physical activity and resistance training.

Associations Between The Physical Activity Vital Sign And Cardiometabolic Disease In High-risk Pediatric Patients

Vicki R. Nelson, Robert V. Masocol, Joseph A. Ewing, Michael Wiederman, Irfan Asif. *Greenville Health System, Greenville, SC.* (Sponsor: Kyle Cassas, MD, FACSM)

(No relevant relationships reported)

Purpose: To determine the utility of the physical activity vital sign (PAVS), and its association with the cardiometabolic disease biomarkers of body mass index (BMI) and blood pressure (BP).
Methods: All patients in a high-risk family medicine clinic (>99% Medicare/Medicaid/Uninsured, n = 2710) were assessed via the PAVS (minutes/week), a product of the reported days/week and minutes/day of physical activity. For pediatric patients (5-18 years, n = 255), individuals were categorized into 3 PAVS groups: inactive (PAVS = 0), under-active (1 - 299), and sufficiently active ($\geq$ 300). Pediatric patients were further classified into youth (5-11 years, n = 118) and adolescents (12-18 years, n = 137). Associations were tested between PAVS, BP and BMI utilizing ANOVA. Chi-square-tests were used to compare results to 2015-2016 National Health and Nutritional Examination Survey (NHANES) reported accelerometer data.
Results: Among pediatric patients, PAVS decreased with increasing age (p = 1×10^{-6}). The average level of physical activity reported for youth patients was 384.9 $\pm$ 218.1 with 72.9% reporting sufficient PA, 24.6% under-activity and 2.5% inactive. Adolescents reported a mean PAVS of 278.3 $\pm$ 199.6 with 51.8% reporting sufficient PA, 33.6% under-activity and 15.6% inactivity. Using the PAVS, only 24.3% of adults reported sufficient PA of $\geq$ 150 minutes per week (mean 97.9 $\pm$ 149.4). Similar to adults, pediatric males reported a higher PAVS than females (355.1 vs 298.6; p < 0.05). BMI (p < 3.4×10^{-7}) and systolic BP (p < 0.001) were inversely associated with PAVS in pediatric patients. Similar to adults, patients meeting PA guidelines demonstrated reductions in obesity (p < 0.05) and hypertension (p < 0.05).
In comparison to NHANES data, a greater number of children report meeting PA guidelines through the PAVS (73% vs. 42% for youth, p < 0.00001; 51.8% vs 8% for adolescents, p < 0.00001). PAVS values decline with age and by adulthood the inactivity burden leads to a smaller portion of patients meeting PA guidelines (24% vs 60% in NHANES).
Conclusion: The PAVS may under-estimate the burden of physical inactivity in pediatric patients. However, correlations with BP and BMI may suggest a role for the PAVS in identifying youth at risk for obesity and hypertension, which may allow earlier intervention.

Acute Effect of Three Different Exercise Training Modalities on Executive Function in Overweight Inactive Men: The BrainFit Study

Andrea del Pilar Quintero[1], María A. Domínguez-Sanchéz[2], Kely Bonilla-Vargas[1], Jorge E. Correa-Bautista[1], Gina Paola Velasco-Orjuela[1], Antonio García-Hermoso[3], Alejandra Tordecilla-Sanders[1], Robinson Ramírez-Vélez[1]. *[1]Universidad del Rosario, Bogotá D.C, Colombia. [2]Universidad de la Sabana, Chía, Colombia. [3]Universidad de Santiago de Chile, USACH, Bogotá D.C, Colombia.*

(No relevant relationships reported)

PURPOSE: There is currently a consensus about the positive effects of physical exercise on cognition. However, the exercise intensity-dependent effect on executive function remains unclear. Thus, the aim of this study was to compare the acute effects of high-intensity aerobic interval training (HIIT), resistance training (RT), or combined training (RT+ HIIT) on the cognitive inhibition and attention capacity in overweight inactive men adults (age 18-30 years old).
METHODS: Randomized, parallel-group clinical trial among 36 (23.6±3.5 years; 83.5±7.8 kg; 28.0±1.9 kg/m²), inactive men (i.e. <150 min of moderate-intensity exercise per week for greater than 6 months), with abdominal obesity (waist circumference $\geq$ 90 cm) or body mass index $\geq$ 25 and $\leq$ 30 kg/m² were randomly assigned to a HIIT (n=12), RT (n=7), RT+HIIT (n=7), and a control group (n=10) until the energy expenditure of 400-500 kcal. Cognitive inhibition and attention capacity were examined using Stroop Test and d2 Test of Attention respectively, before (pre) and 1-min post-exercise for each exercise training modalities.
RESULTS: For cognitive inhibition, significant differences were observed in HIIT and RT+HIIT protocols for congruent and neutral conditions, and in HIIT, RT and RT+HIIT for incongruent condition. The largest effect size was identified in RT+HIIT for congruent condition (*d*=1.70). Regarding attention capacity, there were significant

in RT+HIIT for concentration performance domain, and in RT and RT+HIIT with total performance. The largest effect size was found in RT+HIIT for concentration performance domain (*d*=1.23).
CONCLUSIONS: Acute RT+HIIT session reported larger effect sizes than RT and HIIT alone for congruent condition. Combined exercise seems to favor acute benefit on executive function and could be particularly recommended in inactive overweight men. Overall, combined RT+HIIT seems to favor acute benefit on executive function in inactive overweight men. **TRIAL REGISTRATION:** ClinicalTrials.gov NCT02915913 (Date: September 22, 2016).

An Evaluation of an Unstructured and Structured Approach to Increasing Recess Physical Activity

Whitney M. Holeva-Eklund[1], Timothy K. Behrens, FACSM[1], Carmen Luna[2], Dick Carpenter[3], Elizabeth Tucker[3], Julaine Field[3], Cheryl Kelly[2]. *[1]Northern Arizona University, Flagstaff, AZ. [2]Kaiser Permanente Colorado, Denver, CO. [3]University of Colorado Colorado Springs, Colorado Springs, CO.*

(No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate the effectiveness of structured and unstructured programs implemented to increase physical activity (PA) for students during the recess period of the school day. **METHODS**: Two suburban school districts in Colorado (USA) implemented different techniques to increase recess PA during the 2015-16 school year. The structured program implemented in one school district included planned activities and games for students, led by a recess paraprofessional. The unstructured program implemented in the second school district provided equipment to students during recess by instructing teachers to roll out equipment carts at the beginning of the recess period. Students were able to use equipment, although it was not required. The amount of available equipment was recorded by the school district implementing the unstructured program. PA was observed using the System for Observing Play and Leisure Activity in Youth (SOPLAY). Evaluators recorded baseline and follow-up observations for sedentary activity, moderate activity (MPA), and vigorous activity (VPA). Observations from individual schools were aggregated so data analyses could be performed at the district level, and the distribution pattern for each variable was examined and noted to be either normally distributed or not normally distributed. Descriptive statistics were calculated for each variable of interest at the district level, and parametric and nonparametric tests were used to determine if the differences were statistically significant after adjusting for compounded error with a Bonferroni correction ($p < 0.004$). **RESULTS**: For the unstructured program (i.e., increased equipment): MPA increased and VPA significantly ($p < 0.004$) increased, while sedentary behavior decreased. For the structured program: MPA and VPA did not increase, whereas sedentary behaviors were higher following the program, though changes were not significant. **CONCLUSIONS**: This study indicates that the degree of effectiveness may vary between structured and unstructured recess PA programs. However, additional variables outside of the scope of this study such as teachers' interaction with students or the fidelity of the program may influence student PA during recess, and should be evaluated in future research.

887   Board #148   May 30 3:30 PM - 5:00 PM

Associations Between Self-Efficacy and Acculturation on Leisure-Time Physical Activity in Hispanic Men Enrolled in a Weight Loss Intervention

Julio C. Loya[1], Luis A. Valdez[2], Melanie Bell[2], Brooke Rabe[2], Steven P. Hooker, FACSM[3], David O. Garcia[2]. *[1]University of Missouri - Columbia, Columbia, MO. [2]University of Arizona, Tucson, AZ. [3]Arizona State University, Phoenix, AZ.* (Sponsor: Steven Hooker, FACSM)

(No relevant relationships reported)

Background: Hispanic men have the highest prevalence of obesity-related chronic diseases when compared to men in other racial/ethnic groups. Benefits of regular leisure-time physical activity (LTPA) to improve health outcomes are demonstrable. There is limited information on how acculturation status and self-efficacy for exercise influence LTPA for Hispanic men. **Purpose:** To examine associations between acculturation, changes in self-efficacy for exercise behaviors, and changes in LTPA in response to a gender-and culturally-sensitive weight loss intervention (GCSLWI). **Methods:** Thirty-five Hispanic men (mean age: 41.5 (SD 11.2) yrs.; mean BMI: 34.8 (5.5) kg/m²) enrolled in a 12-week GCSWLI. Participants attended weekly in-person individual sessions guided by a trained bilingual Hispanic male lifestyle coach, were prescribed a daily reduced calorie goal, and 225 minutes of moderate-intensity physical activity per week. A free gym membership was provided to facilitate engagement in LTPA. The Acculturation Rating Scale for Mexican Americans (ARSMA-II) measured acculturation related to language, ethnic identity, and ethnic interaction at baseline. Self-efficacy for exercise and LTPA, assessed by the Global Physical Assessment Questionnaire (GPAQ), were measured at baseline and week 12. **Results:** On the ARSMA-II, 22 (63%) scored Very Mexican or Mexican Oriented, 9 (26%) scored

Slightly Anglo, and 4 (11%) scored Strongly Anglo. None scored Very Assimilated. At baseline, self-efficacy for exercise was 3.82 (SD 0.86) on a 5-point scale with 1 low and 5 high self-efficacy. Over 12-weeks, mean self-efficacy changed slightly by -0.18, (95% CI (-0.46,0.09)), mean LTPA increased by 200.1 (4.01, 396.3) minutes/week, with moderate and vigorous LTPA increasing by 90.1 (-23.2, 203.7) and 109.9 (16.1, 203.6) minutes/week, respectively. Change in vigorous LTPA was weakly positively correlated with change in self-efficacy score (Spearman's rho=0.30, p=0.08). We found no significant associations between ARSMA-II scores and LTPA. **Conclusions:** Significant improvements in LTPA were observed for Hispanic men participating in a GCSWLI. Acculturation and self-efficacy were not associated with this change. Studies examining additional factors that influence LTPA in this health disparate group are needed.

Low-Frequency High-Intensity Interval Training (HIIT) Improves Cardiorespiratory Fitness and Body Composition in Overweight Adults

Parco Siu, FACSM[1], Edwin Chin[1], Stephen Wong, FACSM[2], Daniel Fong[1], Derwin Chan[1], Heidi Ngai[1], Paul Lee[1], Patrick Yung[2]. [1]The University of Hong Kong, Hong Kong, Hong Kong. [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong.
(No relevant relationships reported)

PURPOSE: This study examined the effects of 8 weeks of low-frequency high-intensity interval training (HIIT) on cardiorespiratory fitness and body composition. **METHODS:** Twenty-three overweight/obese young men (mean age 22.7 ± 2.8 years, BMI 25.5 ± 1.8, percent body fat $22.3 \pm 2.2\%$) were randomly assigned to HIIT and no-intervention control (CON) groups. Participants assigned to HIIT group performed 12 bouts of 1-min 30-meter shuttle runs at 90% of heart rate reserve (HRR), interspersed by 1-min of active recovery at 70% of HRR once weekly. Participants in control group were instructed to maintain their daily lifestyle habit for 8 weeks. VO_{2max} was measured by beep test and body composition was assessed by bio-impedance segmental body composition analyzer before and after the study period. **RESULTS:** VO_{2max} was significantly increased after 8 weeks of HIIT intervention (HIIT +17.5% vs. CON -0.3%). Total body fat mass, percent body fat and waist circumference were significantly reduced after 8 weeks of HIIT intervention (fat mass: HIIT -7.9% vs. CON +4.7%, percent body fat: HIIT -7.6% vs. CON +2.9%, waist circumference: HIIT -4.5% vs. CON +0.8%). **CONCLUSION:** Our results demonstrate that low-frequency HIIT (i.e., performed once weekly) improves cardiorespiratory fitness and body composition in overweight/obese men.

The Influence of Nutritional Intervention Program onthe Dietary Habits of High School Students

Daniel S. Moran, FACSM[1], Ran Kanon[2], Yoram Epstein, FACSM[3]. [1]Ariel University, Ariel, Israel. [2]Washington College, Yavne, Israel. [3]Sheba Medical Center, Tel Hashomer, Israel.
(No relevant relationships reported)

The increase in obesity and sedentary lifestyle has caused many educational bodies to develop intervention programs in an attempt to implement healthier life style. **PURPOSE:** To assess the efficiency of an educational program embedded in a high-school curriculum on dietary habits of the students. **METHODS:** Fifty eight 10th grade students (15-16 yrs) participated in this study. 29 students were chosen randomly to attend four lectures on healthy nutrition habits. The lectures were given once a month for 4-month period by their physical education teacher, who had an appropriate background in nutrition. The other 29 students served as a control group and did not attend the lectures. All students were asked to fill-out a questionnaire before the intervention and three month after the last lecture. **RESULTS**: After the intervention program, the study group was found to adopt healthier dietary habits, expressed by higher consumption of grains (p<0.019), and vegetables (p<0.0039) in comparison to the control group. Interestingly, no differences were found between the two groups in the level of the students' knowledge on nutrition habits at the end of the intervention program. **CONCLUSIONS**: A nutrition intervention program for high school students as part of their curriculum has an effect on their nutritional habits and can lead to a positive change in their eating habits. Including lessons on nutrition and wellness in school should be encouraged, in order to increase students' awareness and implementation of healthy life style behaviors.

Effect of A Neuromotor Intervention on Balance and Strength

Anna M. Carman, Rachel M. Whorton, Joshua D. Guggenheimer. *Saint Catherine University, Saint Paul, MN.* (Sponsor: Mark Blegen, FACSM)
(No relevant relationships reported)

Falls are the most common mechanism of injury and a leading cause of accidental death in the elderly. Therefore, functional independence for the elderly is clearly contingent upon fall prevention. **PURPOSE** : The purpose of this study was to determine the effectiveness of a neuromotor-based exercise intervention on balance, balance confidence, and strength in older adults. **METHODS** : Nine individuals (eight female) with a mean age of 78.3 ± 9.3 years were assessed before and after a 16-session exercise intervention implemented over eight weeks. Balance was assessed using the Berg Balance Scale (BBS); lower-body strength and endurance was assessed using a 30-second sit-to-stand test (30 SSTS); balance confidence was assessed using the Activities Specific Balance Confidence Scale (ABC); finally, a handgrip dynamometer was used to assess grip strength. Participants were instructed in an exercise session two times per week consisting of the following exercises: squats, chair dips, lunges, band rows, hip flexion and extension, bicep curls, plantarflexion and dorsiflexion with band resistance, and a balance progression series. Two sets of 10 repetitions were completed for each exercise. **RESULTS** : There was a significant difference in balance, as indicated by an improvement in BBS from 44.5 ± 14.5 to 47.6 ± 14.6, ($p < 0.05$) after the intervention. Although not statistically significant, there was an 18 percent increase in 30 SSTS performance, from 11.0 ± 4.7 to 13.1 ± 3.9 repetitions. Similarly, ABC scores improved practically but not significantly, from $73.6\% \pm 14.8$ to $79.2\% \pm 15.7$. Pre- and post-test scores for grip strength performances were not statistically different. **CONCLUSION** : The findings of this study indicate that a 16-session neuromotor-based exercise intervention has a positive influence on balance in older adults. Moreover, there was a clinically significant improvement in 30 SSTS and ABC measures. It is strongly recommended that the elderly be encouraged to participate in similar neuromotor-based training, as this type of intervention may reduce falls and enhance independent living.

Health And Wellness Coaching Improves Body Composition and Quality Of Life With No Diet Prescription

Paula Helena Dayan[1], Luciana Oquendo Pereira-Lancha[2], Antônio Herbert Lancha Junior[1]. [1]Physical Education and Sport School, University of São Paulo, São Paulo, Brazil. [2]Instituto de Bem Estar e Saúde, São Paulo, Brazil.
(No relevant relationships reported)

Global obesity rates have reached epidemic proportions. However, it is estimated that 95% of the dieters find difficulty in maintaining weight loss and return to gain it for up to 2 years. The desire for long lasting behavioral and weight changes motivated health professionals to seek for new approaches to stop the obesity growing rates. Health and wellness coaching (HWC) comes up as a behavioral change approach, based on a client-centered process, without a diet prescription, and seems to be more likely to promote long lasting changes. The subject of this study had previously tried different diets, all of which failed to achieve lasting weight loss.
PURPOSE:the aim of this case report is to present and evaluate HWC in promoting sustainable lifestyle changes especially in body composition, eating pattern and self-assessment of quality of life.
METHODS: body composition, quality of life (WHOQOL-bref) and nutritional intake were assessed at baseline (P1), after 12 weeks of HWC (P2) and 14 weeks after the end of the intervention (P3). 12 HWC sessions were completed, which were held weekly (1 hour each), and 36 physical activity sessions, which were held 3 times a week (1 hour each). No diet was prescribed during the whole process.
RESULTS: In P3, HWC and physical activity sessions were associated with reductions in body weight (-5.1 kg), fat mass (-5.2 kg), BMI [from 29.6 (P1) to 27.8 kg/m^2 (P3)], and waist circumference (-7.1cm). From P1 to P3, we also observed maintenance of the fat free mass (54,1 kg), a decrease in total energy intake (-300 kcal/day) and fat intake (-44%). Great improvement in all aspects of self-rated quality of life was also shown. This outcomes emphasize the effectiveness of HWC in promoting behavioral changes with high impact in health parameters and quality of life.
CONCLUSIONS: HWC was effective once the new eating pattern and weight loss achieved during the process were maintained in the medium term after the end of the sessions.

Epidemiology Of Self-reported Physical Activity In Eight Latin American Countries: Findings From Elans Study

Gerson Luis de Moraes Ferrari[1], Irina Kovalskys[2], Mauro Fisberg[3], Georgina Gómez[4], Attilio Rigotti[5], Lilia Yadira Cortés[6], Martha Cecilia Yépez[7], Rossina G. Pareja[8], Marianella Herrera-Cuenca[9], Ioná Z. Zimberg[3], Viviana Guajardo[2], Michael Pratt[10], Carlos Pires[11], Dirceu Solé[3]. *[1]CELAFISCS - UNIFESP, Itu, Brazil. [2]International Life Science Institute, Buenos Aires, Argentina. [3]UNIFESP, São Paulo, Brazil. [4]Universidad de Costa Rica, San José, Costa Rica. [5]Departamento de Nutrición, Diabetes y Metabolismo, Santiago, Chile. [6]Pontificia Universidad Javeriana, Bogotá, Colombia. [7]Universidad San Francisco de Quito, Quito, Ecuador. [8]Instituto de Investigación Nutricional, Lima, Peru. [9]Universidad Central de Venezuela, Venezuela, Venezuela, Bolivarian Republic of. [10]Hubert Department of Global Health, Atlanta, GA. [11]13-Centre for Mathematics of the University of Trás-os-Montes e Alto Douro, Vila Real, Portugal.*
(No relevant relationships reported)

BACKGROUND: The prevalence of physical inactivity in Latin America was one of the highest reported worldwide. The purpose of this study was a comparative international study of population PA prevalence across eight countries from Latin American. **METHODS:** Data from the Latin American Study of Nutrition and Health (ELANS) were included in the analysis. The sample included 9,218 adolescents and adults aged 15-65 years. PA was assessed using the International Physical Activity Questionnaire. PA was compared among countries, gender, age group, socioeconomic, educational level and different PA domains. In addition to using the MET-minutes/week rank, we also used the rating in active or insufficiently active based in minutes/week. Individuals were categorized as active (mean $\geq$150 min/week) or insufficiently active (mean $\leq$150 min/week). **RESULTS:** The prevalence of physically active individuals was 52.5%. Men were more active than women in all countries. Only 13.4% of the population had high PA level and 27.4% showed moderate PA level. More than half (59.3%) of subjects exhibited low levels of PA. The prevalence of physically active individuals slightly, increased from low to high socioeconomic level. Regarding the educational level, the prevalence of physically active individuals was similar among those who have a lower educational levels, high school studies, and university degrees (52.4, 52.0, and 52.3%). The largest fraction of transportation time was explained by walking time (87%). Vigorous-intensity PA was the one that contributes the most for the total leisure time (52%). Recreation/sport time contributes with 25% to total leisure time. The total of minutes of PA is explained in 55% by leisure time and in 45% by transportation time. Most of the countries more than 80% of total MET-minutes/week were explained by walking (44%) and vigorous-intensity PA (39%). The only exceptions were Ecuador and Chile, the two countries with the highest levels of PA. **CONCLUSIONS:** The high percentage of Latin American subjects insufficiently active people and with low levels of PA should be of concern. Measures are needed to promote the practice of PA. If assessment methods are used consistently over time within this world region, trend data will inform countries about the success of their efforts to promote PA.

Efficacy Of A Workplace Wellness Program On The Staff Of A Hemodialysis Clinic

Alana P. Y. Harris, Nicole P. Evans, Brett T. Burrows, Luis M. Perez, Kenneth R. Wilund. *University of Illinois at Urbana-Champaign, Urbana, IL.* (Sponsor: Jeffrey Woods, FACSM)
(No relevant relationships reported)

Current evidence indicates that health and wellness programs in the workplace provide numerous benefits with respect to altering indices of health. **PURPOSE**: The purpose of this pilot study was to assess the feasibility of a workplace wellness program (WOW) as a means of improving participation in habitual physical activity and improving dietary choices amongst the staff at a hemodialysis clinic and to assess the indirect impact of a workplace wellness program (WOW) on the hemodialysis patients. **METHODS**: 16-staff members (age: 45±8 y; BMI: 32±9 kg/m^2) from a hemodialysis clinic (nurses, technicians, and administrative staff) participated in a 12-week workplace wellness program (WOW) consisting of weekly counseling sessions, the provision of educational resources, physical activity incentive challenges, and healthy dietary choices challenges. Body weight (kg), height (cm), blood pressure, BMI (kg/m^2), waist circumference (cm), and hip circumference (cm) were collected 1-week prior to the intervention, at 6-weeks, and within 1-week following the conclusion of the intervention. **RESULTS**: On average participants lost 2.7±3 kg. (P<0.0002). There was a systolic blood pressure change of -16.86±19.81 mm Hg. BMI changed by an average -1±1.7 (P<0.0002). Waist Circumference changed by -2.6±3 cm (P<0.0016)

and Hip Circumference changed by -3.29±4 cm (P<0.0001). **CONCLUSION:** Our data demonstrated that the staff of a hemodialysis clinic improved BMI values in response to WOW. The pilot study suggests that a workplace wellness program has the potential to improve health indices of the staff of a hemodialysis clinic and may positively impact the health behaviors in the hemodialysis patients under their care.

Changes in Physical Activity Using Motivational Interviewing in Law Enforcement Officers

Rachele M. Kappler, Ronald Otterstetter, FACSM. *The University of Akron, Akron, OH.*
(No relevant relationships reported)

PURPOSE: The purpose of this study was to investigate the effects on physical activity with the utilization of motivational interviewing (MI) on sedentary law enforcement officers (LEOs). In addition, this study considered the reasons why LEOs choose to be participate in physical activity or to stay sedentary. The incidence of cardiovascular disease and early mortality are prevalent in LEO, additional behavior change technique research may have a positive impact in their long term health and wellness. **METHODS**: The LEOs in this study represent veteran officers from the Midwest region of the United States, over the age of 35 years, who were not getting greater than 150 minutes a week of exercise. of the five officers involved in the study received four MI sessions in 6 weeks. Data collection procedures for this included transcripts from MI sessions, pre/post results from the Self-Efficacy for Exercise (SEE) scale (Bandura, 2006), the Stages of Exercise Behavior Change scale (SEBC) (Marcus, 1992), and 6 weeks of accelerometer data. A descriptive case study of five law enforcement officers was presented with examples drawn from data, followed by a cross-case comparison of the five officers. **RESULTS**: Overall, the number of steps for the participants increased a total of 20.6% from the pre-MI (420,044 steps/week) to the post-MI (506,780 steps/week. The SEE score increased by 18%. Positive movement in the SEBC was seen from pre-MI to post-MI in three out of five of the case study participants. The findings from this study also indicated four major themes regarding why officers make the physical activity choices that they make: (1) their life depends on it, (2) competition is key, (3) I'm too tired, who has energy to exercise, and (4) they choose to fail. **CONCLUSIONS**: Based on this study, sedentary LEOs can increase physical activity, increase SEE and help individuals to move closer to making behavior changes. Motivational interviewing can used an effective behavior change technique in LEOs. It can also be noted that officers have distinct barriers that keep them from participating in physical activity. Allied health care professionals and worksite wellness could benefit from information gained from this study.

Health Professionals Trained As Diabetes Educators Are Influential In Their DM2 Patients´ Lifestyle

Sergio Márquez-Gamiño, Alejandro Castro-Rosales, Karla S. Vera-Delgado, Cipriana Caudillo-Cisneros, Fernando Sotelo-Barroso, Montserrat G. Vera-Delgado, Carolina Cabrera-de la Cruz. *Universidad de Guanajuato, León, Mexico.*
(No relevant relationships reported)

Diabetes mellitus (DM) is a pandemic disease. In 2015, 422 million people around the world were living with DM, 80% in developing countries. 642 million are expected to have DM by 2040; North America and the Caribbean will contribute with 60.5 million. Since long time ago it has been claimed that DM's treatment for control, as well for secondary and tertiary prevention should be based on education. **PURPOSE**: to compare life style in type 2 DM (DM2) patients being attended by health professionals trained or not as diabetes educators (HP-DE and HP-nonDE, respectively). **METHODS**: 160 DM2 patients, receiving health service in public health centers in Central Mexico, signed an informed consent, and answered a validated questionnaire to assess lifestyle in persons living with DM2 (IMEVID). The survey contains 25 items, distributed in seven domains, i.e. Nutrition, Physical Activity, Information on Diabetes, Adherence to Treatment, Alcohol Consumption, Emotion Management and Tobacco Consumption. Descriptive and inferential analysis was done using SPSSv21. **RESULTS**: 160 DM2 patients (70.6% women and 29.4% men) of 57.7±9.2 years (□±s.d.; n=152) were assigned to two groups: 1) 84 (55.0%) participants being attended by HP-DE; 2) 72 (45.0%) patients being served by HP-nonDE. The IMEVID total scores and the separated dimensions' scores were analyzed with Kolmogorov-Smirnov Tests. Total scores mean, HP-DE = 78.6±10.0/HP-nonDE = 61.3±12.7 were compared using a *Student's t* test for independent samples, resulting statistically different (*p<0.001)*. Six out of the seven dimensions were as well different (U-Mann Whitney): Nutrition, Physical Activity, Diabetes Information, Adherence to Treatment (p=0.001 for the previous four), Alcohol Consumption (p=0.02) and Emotion Management (p=0.04). **CONCLUSION**: training health professionals as diabetes educators have a positive impact on the lifestyle of their DM2 patients.

Enhancing Goal Achievement: Do Implementation Intentions Influence Goal Achievement in a Worksite Pedometer Program?

Anna I. Rinaldi-Miles[1], Bhibha M. Das[2], Rumit Singh Kakar[3]. [1]Illinois State University, Normal, IL. [2]East Carolina University, Greenville, NC. [3]Ithaca College, Ithaca, NY. (Sponsor: David Q. Thomas, FACSM)
(No relevant relationships reported)

For behavioral change, having strong goal intentions does not guarantee goal achievement. Implementation intentions (II) are specific plans of action concerning when, how, and where an intended behavior will be enacted. This self-regulatory skill combined with self-monitoring from daily pedometer use may influence goal achievement. **PURPOSE:** To examine physical activity (PA) goal achievement between participants that used both II and a pedometer and those that just used a pedometer. **METHODS:** Sedentary employees (<150 minutes of moderate to vigorous PA/week) (N = 54) at a mid-sized public university were recruited to participate in an 8-week intervention. A 2-arm randomized trial was used to compare the effectiveness of: 1) only pedometers (PED) (n = 26) and 2) pedometers and II (PED + II) (n = 28) on goal achievement. All participants were asked to track steps daily. Participants in the PED + II group were asked to write three II for each perceived barrier to meeting their step goals in Weeks 1 and 4. Daily step goals for Weeks 1-3 were based on baseline data, increasing daily goals each week 10% (Time 1). At Week 4, participants were able to individually revise or keep their daily step goals for the remainder of the study to promote autonomy (Time 2: Weeks 4-8). Goal achievement was evaluated as whether the participant met their daily step goal each day that week (YES) or not (NO). **RESULTS:** For Time 1, at least one day/week goal achievement was higher in the PED group (97.4%; 25 ± 1) compared to the PED+II group (83.3%; 23.3 ± 3), as well as for Time 2 the PED was higher (84.6%; 22 ±2.8) than the PED+II group (70.0%; 20 ± 5.9). For ≥3 day/week goal achievement, the PED group again had higher goal achievement Time 1 (75.6%; 20 ± 2) and for Time 2 (57.1%; 16 ± 4) compared to the PED+II group (42.3%; 11 ± 5.3) and (35.5%; 10 ± 5.4); respectively. **CONCLUSIONS:** The PED group had higher goal achievement at both time points compared to the participants in the PED+II. Implementation Intentions have been promoted as a behavioral strategy to bridge the gap between intention and behavior, with specific emphasis on improving goal achievement (Gollwitzer & Sheeran, 2006). These results question the utility of II to enhance goal achievement. Further research is needed to examine if this contradictory finding is unique to worksite pedometer-based II.

Do Bike Fix-It Stations Influence Active Transportation Awareness and Behaviors in a School Setting?

Timothy K. Behrens, FACSM[1], Whitney M. Holeva-Eklund[1], Carmen Luna[2], Dick Carpenter[3], Elizabeth Tucker[3], Julaine Field[3], Cheryl Kelly[2]. [1]Northern Arizona University, Flagstaff, AZ. [2]Kaiser Permanente Colorado, Denver, CO. [3]University of Colorado Colorado Springs, Colorado Springs, CO.
(No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate the influence of the installation of bike fix-it stations on active transportation (AT) awareness and behaviors among middle school students. Self-reported barriers to active transportation (AT) were also recorded. **METHODS**: Three suburban middle schools in Colorado (USA) installed bike fix-it stations on school property that were available for students to use to perform minor repairs to their bikes. A questionnaire was developed by the school district that inquired about AT behaviors (e.g., day·wk[-1] biking to school) and awareness and use of the fix-it station. The questionnaire was administered before installation of fix-it stations (pre-survey) at the various schools between October 2015 and October 2016. Approximately one semester after installation of the fix-it station at each school, post-surveys were collected. Survey results from individual schools were aggregated at the district-level. Descriptive statistics were calculated for variables of interest and nonparametric tests were used to determine if the differences existed, pre- to post. **RESULTS**: The vast majority (80%) of respondents had not used their school's fix-it station at the time of the post-survey. There was no significant difference in the number of days respondents biked to school each week, pre-to post-survey. Both those who were aware of the station and those who said they did not need training on its use were more likely to ride their bikes to school, though these relationships were not statistically significant. The most commonly selected barriers to active transportation were time (43%), distance (42%), weather (36%), and having things to carry (38%). Between genders, boys were more likely commute via AT than girls (p < 0.05). **CONCLUSIONS**: The installation of bike fix-it stations alone does not appear to increase AT, although the students in this survey were often not aware of or trained to use the station which may have affected these results. Other barriers should be addressed to make AT a more feasible choice for students.

Comparing Home- And Group-based Physical Activity Interventions For People Living With HIV

Jason R. Jaggers[1], Gregory A. Hand, FACSM[2]. [1]University of Louisville, Louisville, KY. [2]West Virginia University, Morgantown, WV.
(No relevant relationships reported)

The transition of HIV infection from a terminal illness to a chronic disease requires a focus on lifestyle interventions to address health challenges in this vulnerable population. Social, mental and physical barriers to recruitment/retention of participants can create challenges to acquiring accurate measurements during studies. **PURPOSE**: The purpose of this investigation is to compare the methodologies and results of two approaches to community-based health interventions for people living with HIV (PLWH). **METHODS**: Data from an ongoing support group-based (SGB) intervention designed to improve health-related quality of life (HRQOL) through classes that teach and reinforce healthy lifestyle habits, like increasing physical activity (PA), for disease and symptom management was compared to that of a previously published home-based (HB) intervention by the investigators. The same accelerometer brand and psychometric questionnaires were used in each study. The SGB approach included the addition of Fitbits to help set goals and track progress. The approaches of each investigation were compared using the average changes from baseline in an independent t-test. **RESULTS**: The SGB study participants significantly increased daily steps from 4,326 ± 389.83 to 8,400 ± 487.58 (p=0.01), as well as mental health (p=0.03) and physical function (p=0.04) as measured by the SF-36. A decreasing trend in weight and perceived stress was also observed. The HB approach resulted in no significant change in daily step counts (p= 0.49). In comparison the HB intervention was more successful in retention rates and gathering reliable follow-up data with 57 participants. Although only 5 participants (out of 15) were retained at follow-up, the SGB study, however, did have more success increasing daily PA by 94% compared to a -5% change in the HB. **CONCLUSIONS**: Our results indicate that compared to an individualized HB program a SGB approach could be more effective in changing healthy behavior, like increased PA and stress reduction, to improve HRQOL in vulnerable populations. With minimal funding and no incentives offered, the SGB study encountered survival bias so it would be prudent for future investigations to find creative ways to keep participants involved in the program to determine their feasibility and effectiveness more reliably.

College Students' Situational Motivation and Physiological Outcomes during Single and Double Player Exergaming Conditions

Daniel McDonough[1], Zachary Pope[1], Jung Eun Lee[2], Nan Zeng[1], Zan Gao, FACSM[1]. [1]University of Minnesota - Twin Cities, Minneapolis, MN. [2]University of Minnesota - Duluth, Duluth, MN.
(No relevant relationships reported)

PURPOSE: College students' psychological and physiological outcomes during single and double player exergaming conditions remain largely unexplored. The purpose of this study was to examine differences in college students' situational motivation, physiological responses and PA levels during single player and double player exergaming conditions.
METHODS: Twenty Chinese elite athletes (18 females; X_{age} = 27.3 ± 4.3 years; $X_{wt.}$ = 63.5 ± 9.9 kg) completed two separate exergaming conditions: 1) Xbox 360 Reflex Ridge-single player; and 2) Xbox 360 Reflex Ridge-double player. Participants' situational motivation (intrinsic motivation [IM], identified regulation [IR], extrinsic motivation [ER], amotivation [AM]) was examined following each exergaming condition using an established questionnaire. Blood Pressure (BP) response to each exergaming condition was measured using an Omron HEM-705CP digital BP cuff, with light PA (LPA), moderate-to-vigorous PA (MVPA), and energy expenditure (EE) assessed using ActiGraph GT3X+ accelerometers.
RESULTS: One-way ANOVAs suggested that no significant differences were observed for any outcome between the two exergaming conditions, F (1, 38) = 0.002-1.9, p = 0.2-1.0; n^2 = 0.0-0.05. However, it is noteworthy that participants demonstrated higher levels of IM and IR (5.5; 4.7, respectively) compared to ER and AM (3.4; 2.2, respectively) during both exergaming conditions. Further, participants engaged in slightly greater MVPA during the single player condition (8.8 minutes) compared to the double player condition (7.8 minutes)—resulting in greater EE being observed during the single player condition (63.7 kcalories) compared to the double-player condition (52.8 kcalories).
DISCUSSION: Findings suggest both single player and double player exergaming conditions may promote motivational states which are more predictive of long-term PA participation (i.e., IM and IR) and that a single player exergaming condition might be more physically demanding than a double player condition. The non-significance between conditions may due to small sample size, and thus future research with larger samples is warranted.

Comparison of Caloric Expenditure in a Smart Watch and Portable Metabolic Cart

Andrew Rioveros, Evan Glasheen, Antoinette Domingo, Taylor Penaflor, Brian Panaligan, Jochen Kressler. *San Diego State University, San Diego, CA.*
(No relevant relationships reported)

Purpose: To validate a Smart Watch (SW) for wheelchair users by comparing caloric energy expenditure (EE) against expired gas analysis. Valid activity tracking will be helpful for clinicians, patients and consumers and may help increase physical activity levels among wheelchair users.
Methods: Five wheelchair users (age=50.0(5.6)) and three able-bodied (age=25.3(3.2)) participants completed a series of exercises including wheelchair treadmill propulsion at 30, 45, and 60 strokes per minute (spm) and arm cycle ergometry at 45, 60, and 80rpm. They were equipped with a SW on their dominant hand, heart rate monitor, and a portable metabolic tracking cart. The bundled workout app was used for each task. Caloric expenditure data was extracted from both devices and compared by Bland-Altman analysis. **Results:** For treadmill tasks, the SW reported the average EE at 30, 45, and 60spm frequencies were 7(2.0), 8(2.3) and 9(2.0) kcals, respectively. At the same frequencies, the metabolic cart expenditures read 10(3.9), 12(5.3), and 15(6.7). Bland-Altman analysis showed relatively poor agreement between the cart and watch at 30spm (mean difference 3 with limits of agreement (LoA) -4–9). Mean absolute percent error (MAPE) was 21.56%. Agreement worsened at higher stroke frequencies, 45spm (4(-4–12)) and 60spm (6(-4–10)). MAPE was 29.11% and 35.88%, respectively. For arm ergometry, the average EE reported by the watch at 45, 60, and 80rpm were 7(1.0), 9(1.5), and 11(1.4). Metabolic cart expenditures were 6(3.0), 7(2.4), and 8(2.8) at the same frequencies. Bland-Altman analysis showed good agreement at 45rpm (-0.4(-6–5)) with a MAPE of 32.69%. Agreement worsened at higher frequencies, 60rpm (-3(-6–1)) and 80rpm (-2(-7–2)). MAPE was 58.57% and 48.54%, respectively. **Conclusion:** While performing a treadmill task, the SW underestimated caloric expenditure, but overestimated for arm ergometry. The activity tracker records EE with good validity only at lower frequency tasks.

Weight Loss Involving Exercise Increases Older Women's Perceived Ability To Accomplish Their Physical Roles

R.E. Salyer[1], G.M. Frederick[1], R.A. Reed[1], A.C. Berg[1], C.R. Straight[2], M.A. Johnson[1], P.J. O'Connor, FACSM[1], E.M. Evans, FACSM[1]. *[1]University of Georgia, Athens, GA. [2]University of Massachusetts, Amherst, MA.* (Sponsor: Ellen Evans, FACSM)
(No relevant relationships reported)

PURPOSE: Older women are known to be at higher risk for both obesity and physical disability compared to their male counterparts. Reductions in perceived physical function (P-PFx) contribute to a decreased health-related quality of life (HRQoL). Weight loss can improve HRQoL in the domain of P-PFx, but the weight loss method that elicits the greatest improvements in both P-PFx and physical role limitations (PRL), such as difficulties or limitations in habitual daily physical activities, is less well characterized in older women. Thus, this study aimed to evaluate the relative efficacy of a weight loss program, with or without exercise, on changes in P-PFx and PRL in inactive overweight and obese older women.
METHODS: Women (n=53; 64-77 & 69.3±3.6 yo; 31.0±4.8 kg/m²) were randomized to either diet only (D; n=19) or diet+exercise (D+EX; n=34) treatment groups for 6 months. The diet component involved reductions of ~500 kcal/day and was designed to elicit ~10% weight loss. The EX program was comprised of 3 x 75-minute sessions/week with cardiorespiratory, resistance, flexibility, and balance modes. Outcomes of interest were related to physical domains and were assessed using SF-36 subscales that measure P-PFx and PRL.
RESULTS: Mean weight loss was similar in D and D+EX groups (9.9% vs. 9.1%, p>0.05). Within groups, both D and D+EX improved in P-PFx and PRL (all p<0.05). ANCOVA, controlling for baseline measures, revealed no group difference for change in P-PFx (p>0.05), but a group effect for PRL was evident with D+EX having a 16.5% greater change compared to D (p<0.01). Comparing groups, Cohen's d effect sizes were 0.18 and 0.86 for change in P-PFx and PRL, respectively. In the total sample, change in weight was not associated with change in P-PFx and PRL (r=-0.09 and 0.04, respectively, both p>0.05).

CONCLUSIONS: P-PFx is improved in older overweight and obese women after a weight loss intervention irrespective of whether it included exercise. Perceived ability to accomplish physical roles improved to a greater extent with exercise inclusion in the weight loss intervention in this older adult cohort.

A Comparison of Changes in Strength And Dynamic Balance Following 8 Weeks of Eccentric Training in Older Adults

Samantha Johnson[1], Corey Gray[2], Bunny Donnelly[3], Dana Fuller[1], Jennifer Caputo[1]. *[1]Middle Tennessee State University, Murfreesboro, TN. [2]University of Kansas Medical Center, Kansas City, KS. [3]Donnelly Physical Therapy, Murfreesboro, TN.*
(No relevant relationships reported)

PURPOSE: To compare changes in leg strength and dynamic balance following training on an eccentric step trainer. **METHODS:** Participants ($N = 14$; 63.5 ± 2 years) completed 2 training sessions per week across 8 weeks, with session duration ≤ 10 minutes. Pre- and post-assessments included a 30-second repeated chair stand (RCS), the timed-up-and-go (TUG), and maximal eccentric strength (MES). Pre-test values for the sample were compared to population averages for the RCS and the TUG, to characterize the sample. Percent change was calculated using: [(Pre-test - Post-test)/Pre-test] x 100 and paired sample t-tests were conducted to compare changes on RCS, TUG, and MES. **RESULTS:** All participants met or exceeded the population average on the TUG and, overall, the sample began at a higher level on the TUG relative to this average ($p = .031$). In contrast, the sample for RCS began training below the population average ($p = .041$) and only 4 of 14 initiated training at or exceeding the population average. There was a significantly smaller percent improvement for TUG than MES ($p < .001$) and RCS ($p = .001$). There was no significant difference in percent improvement between RCS and MES. **CONCLUSIONS:** The positive changes in RCS and MES indicate similar improvements in eccentric and functional strength following the 8 week eccentric training program. The smaller percent change on the TUG may be attributable to the higher baseline performance. Further investigation using other assessments of general function and dynamic balance should be considered for samples with above average TUG performance.

Changes in cortical gray matter following a 12-mohth physical activity intervention in older adults
Chelsea Stillman*[1], Jamie Cohen*[1], Arthur F. Kramer[2], Edward McAuley[3], Kirk Erickson[1]
[1]University of Pittsburgh; [2]Northeastern University; [3]University of Illinois
*dual first authors
PURPOSE: Aging is characterized by reductions in gray matter volume. Cardiorespiratory fitness is associated with higher cortical and subcortical gray matter volume in older adults, and several interventions have indicated that some brain areas might increase in volume after the intervention. However, volumetric changes in *cortical* regions have been under-examined in the context of controlled interventions. In the present study, we examined whether a 12-month randomized, controlled aerobic exercise intervention in older adults would change cortical gray matter volume.
METHODS: 116 participants were assigned to either an aerobic **walking** or **control** (stretching and toning) group. All participants completed MRI sessions before and after the intervention, which included high resolution structural scans. Our initial analyses focused on participants who maintained at least 75% adherence (N = 79 total; mean age = 66.94; 31 males). Thus, our primary analyses include 43 participants from the walking and 36 from the control groups. Gray matter volume was assessed via voxel-based morphometry (VBM) in FSL. Longitudinal VBM analyses were conducted on the images to test for differences between groups.
RESULTS: Following the intervention, gray matter volume increased in the bilateral frontal poles and middle/inferior temporal gyrus, as well as in the left anterior parahippocampus and posterior cingulate in the walking group compared to the control group. Unexpectedly, several regions increased in volume in the control group relative to the walking group, including the cerebellum and precentral gyrus.
CONCLUSIONS: Aerobic exercise is associated with plasticity in cortical gray matter in older adults. Among the most modified regions were those especially vulnerable to aging, including the prefrontal and medial temporal lobes. The reduction in volume in several motor and balance-related regions in the walking versus the control group may suggest that the effects of aerobic exercise on brain plasticity are regionally specific.

904　　Board #165　　　　　May 30 3:30 PM - 5:00 PM
Impact Of BAILAMOS© Dance Program On Self-reported Physical Activity In Older Latinos

Guilherme M. Balbim[1], Isabela G. Marques[1], Jaqueline Guzman[1], Susan Aguiñaga[2], Priscilla M. Vasquez[1], David X. Marquez, FACSM[1]. [1]*University of Illinois at Chicago, Chicago, IL.* [2]*University of Illinois at Urbana-Champaign, Champaign, IL.*
(No relevant relationships reported)

By 2050, 20% of the older population in the US will be comprised of Latinos. However, Latino health is often poorer than that of non-Latinos whites, with a higher prevalence of chronic diseases and Alzheimer's disease. In addition, Latinos engage in low leisure-time physical activity (LTPA) levels. **PURPOSE:** Test the impact of the BAILAMOS© dance program on lifestyle PA at 4 months and BAILAMOS© maintenance activities on lifestyle PA at 8 months. **METHODS:** Older Latino adults (N= 333; M_{age} = 64.89±7.08) were randomized into the dance (n=167) or health education (HE) (n=166) groups. Inclusion criteria were: (1) aged ≥55 years old; (2) self-identification as Latino/Hispanic; (3) Spanish speaker; (4) participation in ≤2 days/week of aerobic exercise; (5) at risk for disability; (6) Mini-Mental State Examination >14; (7) Danced <2 times/month over past year. The dance group participated in 4 months of Latin dancing, two times per week, plus a 4-month maintenance program. The HE group participated in health education classes once per week for 4 months. The Community Healthy Activities Model Program for Seniors (CHAMPS) Physical Activity Questionnaire was administered. A random-intercept mixed model with data imputation was performed, adjusting for baseline covariates of age, sex, education, income, and health status. **RESULTS:** Total PA significantly increased at 4-months in both dance (M=899.3 ± 538.6) and HE groups (M=870.4 ± 555.8) compared to baseline (Dance, M=718.2 ± 529.4; HE, M=702.3± 437.9; Estimate=137.08, SE=57.52, p=0.017). It was also observed that total LTPA increased in the dance (M=578 ± 433.2) and HE group (M=464.2 ± 394.6) at 4 months compared to baseline (Dance, M=385.3 ± 416.9; HE, M=364.8 ± 332.7; Estimate=89.9, SE=43.81, p=0.04); and from baseline to 8 months (Dance, M=536.1 ± 470.6; HE, M=436.3 ± 336.5; Estimate=104.09, SE=47.36, p=0.028). The mean change in LTPA between dance and HE at 4-months was statistically significant (M=114.24, SE=48.84, p=0.019). However, there was no group*time interaction (p > 0.05). **CONCLUSION:** The results demonstrated that both study groups increased their self-reported total and leisure-time PA after 4 and 8 months, suggesting a positive impact of both dance and the HE program on PA levels in older Latinos. Supported by NIH Grant 1R01NR013151-01.

Effects Of Lower-leg Training With CLX Bands On Balance, Strength, And Mobility In Older Women

Michael E. Rogers, FACSM, Nicole Rogers. *Wichita State University, Wichita, KS.*
(No relevant relationships reported)

Weakness in the lower-leg, particularly the tibialis anterior, can negatively impact balance and mobility, and thus exacerbate the risk for falls. Although a variety of interventions have been shown to improve strength and balance, such programs often require extensive time and trained professionals. Furthermore, targeting the muscles of the lower-leg is difficult using traditional resistance exercises. The advent of CLX elastic bands with their continuous-loop design has made it easier to perform such exercises. However, the efficacy of such training is unknown. **PURPOSE**: The purpose of this study was to determine if performing two lower-leg exercises using CLX bands for short periods of time (10 min) each day in a home-based setting improves strength, balance, and mobility in older women. **METHODS**: Eleven women (age=78.8±4.8yr) participated in exercise training and 10 women (age=77.7±4.5yr) served as controls. All participants were sedentary retirement community residents. Training consisted of chair-based dorsiflexion and plantar flexion exercises using CLX bands performed in the residents' apartments for 3 sets of 10 repetitions on 5 d/wk for 8 wk. Performance was assessed before and after the intervention. Isometric dorsiflexion and plantar flexion strength was assessed using a hand-held dynamometer. The Limits of Stability (LoS) test, performed on a force platform, was used to assess dynamic balance. Mobility was assessed by the Timed Up-and-Go (TUG) test. **RESULTS**: Compared to controls, CLX band training improved (p<0.05) both dorsiflexion and plantar flexion by approximately 20%. LoS improved in the forward and backward (but not other) directions by 7% and 9%, respectively. TUG performance did not change in either group. **CONCLUSIONS**: Lower-leg training with CLX bands appears to improve dorsiflexion and plantar flexion strength as well as LoS in the forward and backward directions, but not mobility, in older women. These improvements may reduce the risk of falls.

Combined Aerobic And Resistance Training In The Elderly: Effects Of Exercise Order On Arterial Stiffness

Yoko Shiotsu, Masahiko Yanagita. *Doshisha University, Kyotanabe, Japan.*
(No relevant relationships reported)

PURPOSE: Prescribing aerobic and resistance training in conjunction is proposed as an optimum strategy to target cardiovascular as well as musculoskeletal functions in the elderly. However, few studies have examined the effects of intra-session exercise order on arterial stiffness in the elderly. This study investigated the effects of aerobic exercise before and after resistance training on arterial stiffness, body composition, and muscle strength in older men. **METHODS:** Forty-five older men (70.5±3.5 years) were randomly assigned to one of three groups that performed aerobic exercise first (AR: 16), performed resistance training first (RA: 16), and did not perform any training (CON: 13). The AR and RT groups performed aerobic exercise consisted of cycling at 60% heart rate reserve (HRR) and resistance training consisted of 5 types of exercises (leg curl, leg press, chest press, seated row, shoulder press) at 70-80% one repetition maximum (1RM) twice a week for 10-week. Body composition was evaluated by height, weight, body fat percentage, lean body mass and waist circumference. Muscle strength was measured by 1RM and arterial stiffness was evaluated by carotid-femoral pulse wave velocity (cfPWV). Pre- and post-intervention group comparisons were analyzed using a two-way ANOVA with repeated measures. **RESULTS:** A significant group difference was observed in cfPWV (F=3.464, P=0.042). cfPWV significantly reduced in the RA group (9.3±2.1 m/s to 8.2±1.9 m/s,P<0.05), while did not change in the AR group (8.4±2.1 m/s to 8.7±1.5 m/s, P=0.413). Significant group differences were observed in all exercise types (leg press: F=9.814, P=0.001; leg curl: F=26.667, P=0.001; chest press: F=17.223, P=0.001; seated row: F=15.648, P=0.001; shoulder press: F=13.244, P=0.001), and waist circumference (F=10.516, P=0.001). However, there were no significant differences between AR and RA. **CONCLUSION:** Based on our results, aerobic exercise after resistance training reduced arterial stiffness and a difference of intra-session exercise order was observed.

The Relationships Of Physical Exercise To Executive Function And Mental Health In Elderly Individuals

Yukie Kikukawa[1], Toru Ishihara[2], Nobuyasu Tomabechi[1], Yukiko Tomita[1], Masao Mizuno[1]. [1]*Hokkaido University, Sapporo, Japan.* [2]*Hokkaido University and Tamagawa University Brain Science Institution, Sapporo and Machida, Japan.*
(No relevant relationships reported)

PURPOSE: In exchange for a life of greater convenience, the pandemic of physical inactivity has become a worldwide public health concern. This study aimed at evaluating the relationships of the intensity and types of daily physical activity and weight status to cognitive function and mental health among elderly individuals. These examinations may provide a useful evidence of how intense and what types of exercise improve cognitive function and mental health. **METHODS**: The total number of 307 healthy individuals (110 males, 197 females; 42 to 84 years old) was studied. The amount, frequency, intensity, and type of daily exercise were assessed by the questionnaire. The performance of inhibitory control as an index for executive function was evaluated by the Stroop Test. The status of mental health was evaluated by the General Health Questionnaire 28.
RESULTS: As the results, moderate intensity exercise habits were positively related to performance on Stroop Test after controlling for age, sex, and BMI (β = .10, p = .01). The interaction effect between sex and BMI on Stroop Test performance was observed after controlling for age, sex, and exercise habits (β = .10, p = .01). The over-weight was associated with poorer Stroop Test performance in females (β = .12, p = .02) but not in males (β = -.09, p = .16). No significant relationships of exercise type and performance on Stroop Test was detected. No significant relationships of age, sex, weight-status, and exercise habits to mental health status was observed, whereas resistance training was positively associated with mental health status (β = .12, p = .03).
CONCLUSIONS: This study suggests that daily physical activities with moderate intensities, but not with vigorous intensities, are associated with better executive function in elderly individuals. Furthermore, the relationships of weight-status and executive function may be moderated by sex. Resistance training appears to be useful exercise for enhancing mental health status in elderly individuals. Current results provide the evidence to help forming efficient strategies to personalize their active approaches.

Effects Of 24 Months Resistance And Endurance Training On Muscle Quality, Quantity And Physical Functions In Elderly With Long-term Care

Akito Yoshiko[1], Takashi Kaji[2], Hiroki Sugiyama[2], Teruhiko Koike[1], Yoshiharu Oshida[1], Hiroshi Akima[1]. *[1]Nagoya University, Nagoya, Japan. [2]Kajinoki Medical Clinic, Gifu, Japan.* (Sponsor: Katsumi Asano, FACSM)
(No relevant relationships reported)

Muscle quality has been determined the fat tissue content within a skeletal muscle (i.e. intramuscular fat content). Muscle quality become worse with aging and disuse as a result of increasing of intramuscular fat and/or decreasing of muscle tissue. Intramuscular fat content is known as a negative contributor to force production and physical functions. We have reported the unique change of muscle quality by the 12 months resistance and endurance training in elderly; however, it is not well understood how the muscle quality, quantity and physical functions change by further 12 months (totally 24 months) trainings. **PURPOSE**: The purpose of this study was to assesse the effects of 24 months training on muscle quality, quantity and physical functions in elderly who need long term-care. **METHODS**: Ten elderly men and women (6 women and 4 men, age, 77 ± 6 years; height, 154 ± 7 cm; weight, 54 ± 9 kg) participated in this study, and they needed long-term care while they could do almost all activities of daily living. They performed physical training consisting of resistive exercises, stretching, and aerobic exercises as a part of rehabilitation program once or twice a week for 24 months. B-mode transverse ultrasonographic images were taken from rectus femoris (RF) and biceps femoris (BF). Echo intensity (EI) as an index of muscle quality and muscle thickness as an index of muscle quantity was calculated from these muscles. We measured their physical performance tests, i.e. isometric knee extension peak torque (PT), one-leg stand, chair stand, handgrip strength, 5-m normal/maximal walk, and timed up and go, before and after the training. **RESULTS**: EI in RF and BF did not change through the intervention, but BF thickness was significantly increased after the training. PT, 5-m normal/maximal walk, and timed up and go were improved after the 24 months training. Percent change of PT was the only independent variable to explain the percent change of EI in RF (regression coefficient = 1.24, R = 0.91, adjusted R^2 = 0.82, $P < 0.001$), implying that improvement of PT could be induced increasing EI in RF. **CONCLUSIONS**: Twenty-four months concurrent training induced muscle hypertrophy with the improvement of physical functions. Furthermore, in this type of long-term training, the increase of EI RF could be a key to improve PT.

909 Board #170 May 30 3:30 PM - 5:00 PM

Physical Function, Cardiorespiratory Fitness, and Body Composition in Older Individuals

Patrick Saracino[1], Justin Mason[1], Arun Maharaj[2], Salvador Jaime[3], Michael Ormsbee, FACSM[1], Arturo Figueroa, FACSM[2]. *[1]Florida State University, Tallahassee, FL. [2]Texas Tech University, Lubbock, TX. [3]University of Wisconsin, La Crosse, WI.*
(No relevant relationships reported)

Advanced age is often accompanied by deterioration of body composition and physical function. These alterations can lead to reduced performance of activities of daily living and autonomy. It has been purported that regular aerobic exercise may enhance physical function in older adults.
PURPOSE: To determine the effects of habitual physical activity on physical function (5m gait time, 5m gait speed, and total gait time), cardiorespiratory fitness (VO_{2max}), and body composition (body fat percentage, total lean mass, and bone mineral density) outcomes in older adults.
METHODS: 27 active and 35 inactive older adults (70 ± 5yrs, 73.4 ± 15.0 kgs, 170 ± 8.0 cm, 30.7 ± 7.5% body fat) were recruited for this study. The perceptually-regulated treadmill exercise test was used to estimate VO_{2max}. Body composition was determined by a whole body DXA scan. Gait variables were assessed via the 400m walking test. The Yale Physical Activity Survey (YPAS) was used to determine self-reported activity.
RESULTS: Active individuals had better 5m gait time (2.78 ± 0.24 vs 3.02 ± 0.48 seconds, p <0.05), gait speed (1.81 ± 0.15 vs 1.68 ± 0.24 m/s, p <0.05), total gait time (273.3 ± 21.6 vs 297.4 ± 43.0 seconds, p <0.05), VO_{2max} (41.3 ± 9.1 vs 26.0 ± 4.1 ml/kg/min, p <0.01), and reduced body fat (25.8 ± 6.6 vs 34.1 ± 6.24 %, p < 0.01) compared to sedentary individuals. Age was positively correlated with 5m gait time (r= 0.39 P <0.01) and negatively correlated with gait speed (r= -0.40, p <0.01), but was not a determining variable for any other physical function or body composition outcome. Exercise time (7.9 ± 5.8 hrs/week) was positively correlated with gait speed (r= 0.27, p <0.05) and negatively correlated with 5m gait time (r= -0.30, p <0.05), total gait time (r= -0.30, p <0.05), and body fat percentage (r= -0.33, p <0.01). VO_{2max} was negatively correlated with gait total time (r= -0.258, p <0.05) and body fat percentage (r= -0.580, p <0.01).

CONCLUSION: While aging is considered a main determinant for decrements in physical function, these data suggest that habitual exercise, low body fat percentage, and increased cardiorespiratory fitness are better determinants of improved physical performance in active older men and women.

910 Board #171 May 30 3:30 PM - 5:00 PM

Impacts of Multidimensional Exercise Program for Older Adults on Mild Cognitive Impairment

Hsiu-Hua Wang[1], M. J. Lin[2], C. Y. Huang[3]. *[1]National Chung Cheng University, Chia-Yi, Taiwan. [2]National Chiayi University, Chia-Yi, Taiwan. [3]Nahua University, Chia-Yi, Taiwan.*
(No relevant relationships reported)

Substantial evidence suggest that the prevention and improvement were a crucial factor of the early stage of dementia. Although the exercise programs were found to improve positive effects of cognitive function, there is a lack of research on the impacts of their use in multidimensional exercise program design on functional fitness on mild cognitive impairment for older adults. **PURPOSE:** To examine the impacts of multidimensional functional fitness program design on mild cognitive impairment for older adults. **METHODS:** A pre -post one group experimental design for this study. The pool of available participants in this study were 25 volunteer with mild cognitive impairment elder (on age 65 or above) enrolled in a multi-exercise prescription program. For random reasons were not available for 10 subjects. The final analysis were performed on a sample of 15 volunteer participants.(age: 78.76±7.06,height: 150.9±9.2,weight: 56.4±7.24. The material as measurement on cognitive function for participants was a Mini Mental State Examination, MMSE. The study was implemented during ten- weeks period. Each week was performed 90 min. on a multi-exercise prescription program. A multidimensional functional physical and mental fitness platform designed were performed on the program. Data analysis were applied to each of the dependent variables. A t-test was use for pre -post one group experimental design. After participants completed 10 weeks of training program, a post-test was delivered. Calculations were made using the Statistical Package for the Social Sciences(SPSS). All tests of significance adopted an alpha level of .05. **RESULTS:** The participants demonstrated positive increased cognitive function on three dimensions: total score of MMSE (17.07±3.127 vs 21.93±3.845), reaching a significant difference (p=.001, p < .05). The average score increased from 17.07 before the intervention to 21.93 after the intervention. The results also revealed that two variables among MMSE score were significantly different for cognitive function performance including short-term memory (p=.000, p < .05) and understanding (p=.002, p < .05). **CONCLUSIONS:** The multidimensional functional fitness program intervention on mild cognitive impairment may result in older adults processing cognitive function more effective.

911 Board #172 May 30 3:30 PM - 5:00 PM

Association Between Light Intensity Physical Activity And Sedentary Behavior Among Active Older Women

Luis Adriano Lima, Diana Carolina Gonzalez, João Pedro Silva Junior, Timóteo Leandro Araujo, Sandra Mahecha Matsudo, Victor Keihan Rodrigues Matsudo. *CELAFISCS, São Caetano do Sul, Brazil.*
(No relevant relationships reported)

Objective: to examine the association between light intensity physical activity (LIPA) and sedentary behavior (SB) among active older women. **Methods:**Physical activity intensity was based on the accelerometer scale sedentary, light, moderate, total moderate vigorous physical activity (MVPA), vigorous and very vigorous. Sample consisted of 75 women, with mean age 69.2 ±8.6 years old, BMI 20.2 ±14.4 kg/m². They were involved in a exercise program of 2 times sessions per week, 50 min duration each in a Municipal Elderly Center. All off them taken part in the Longitudinal **Project on Aging and Physical Fitness** from São Caetano do Sul. An accelerometer (*Actigraph GT3X+)* was used in the waist by the participants 24 hours per day, during 10 days in a row. Seven days data, including one weekenday, were considered for calculation, and accelerometer data from 6 am to 9 pm were taken for analysis. **Statistical Analysis:** The regression linear model was used with 95% Confidence interval for β to predict LIPA using SPSS 20.0, and a level of p<.05 was taken as significant. **Results:** 43% of participants reached the international recommendation for physical activity and health (at least 150 min per week). They spent 9.2 ±1.7 hour per day on sedentary behavior, 5.6 ±1.4 hours per day sitting time and 5.4 ±1.5 hours per day light-intensity physical activity. The prediction between light intensity physical activity (minutes per week) and sedentary behavior (minutes per week) time (β=-.986; 95% -.95 to -.88), and sitting time (β=.278;95% .001 to .009) and other intensities of physical activity are in the table below. **Conclusion:** Objectively measured of light-intensity physical activity time was significantly associated with sitting time,sedentary behavior time, modarate activity time, MVPA time and vigorous time among active older women.

Light Intensity Physical Activity (LIPA) Time (*N= 75*)	Adjusted R Square	95% Confidence Interval	p
Sitting Time	.065	(.001 - .009)	.001
Sedentary Behavior Time	.973	(-.947 - -.876)	.000
Moderate Physical Activity Time	.111	(.702 - 3.024)	.002
Moderate/Vigorous Physical activity Time	.112	(.702 - 2.999)	.002
Vigorous Physical Activity Time	.071	(24.368 - 191.241)	.012

Effects Of A 12-week Self-managed Exercise Program On Fatigability In Older Adults

Mutasim D. Alharbi, Baian A. Baattaiah, Lisa MK Chin, Clinton J. Wutzke, Jeffrey E. Herrick. *George Mason University, fairfax, VA.* (Sponsor: Randall Keyser, FACSM)
(No relevant relationships reported)

Aging is associated with greater fatigability and reduced participation in physical activity. Exercise training in older adults has been associated with a number of health benefits; however, less is known about the effects of self-managed exercise on perceived and performance fatigability. **PURPOSE:** Compare the effects of a 12-week self-managed exercise program on perceived (PercF) and performance (PerfF) fatigability in a group of unimpaired older adults. **METHODS**: 28 older adults participated in a self-managed exercise program (15 men and 13 women; age 71.3 ± 4.2 years). The program consisted of educational lectures on aerobic (AT), resistance (RT), and balance (BT) training methods as described by the National Institute of Aging. 17 adults completed the 12-week program in three exercise groups: AT only (n=8), AT/RT (n=5), and AT/RT/BT (n=4). Fatigability was assessed following a standardized 10-minute walk test at a self-selected speed at baseline (PRE) and at the conclusion of the 12-week exercise program (POST). PercF was calculated at the completion of walking by dividing participant-perceived changes in fatigue by the total distance walked in meters. PerfF was calculated as the change in walking velocity (at 2.5 and 10 minutes), divided by the total distance walked. Within-group data were analyzed with a paired *t*-test and between-group effects using one-way ANOVA. **RESULTS**: Within the AT and AT/RT groups, significantly lower PerfF was observed at POST ($p = .011$ and $p = .035$, respectively) with no differences found in the AT/RT/BT group ($p = .437$). PercF was unchanged in all groups (AT, $p = .50$, AT/RT, $p = .65$, AT/RT/BT, $p = .70$). No difference was observed between groups for PercF ($F(2,14) = 0.443$, $p = .651$) or PerfF ($F(2,14) =. 528$, $p = .601$). Further, Cohen's effect size for changes in PerfF was moderate for AT ($d = .48$), AT/RT ($d = .38$), and AT/RT/BT ($d = 38$). **CONCLUSIONS**: Participation in a 12-week self-managed exercise program reduced performance fatigability in unimpaired older adults. However, our results did not reveal specific exercise recommendations for older adults to improve both performance and perceived fatigability. Future studies are needed to investigate the influence of exercise training on measures of fatigability to optimize exercise interventions.

Physical Activity And Technology: Older Latinos' Perceptions

Isabela G. Marques, Jackelyn Cantoral, David X. Marquez, FACSM. *University of Illinois at Chicago, Chicago, IL.*
(No relevant relationships reported)

The Latino community in the U.S. experiences a high prevalence of chronic diseases that can be prevented or improved by physical activity (PA), yet Latinos engage less frequently in leisure-time PA (LTPA) than non-Latino whites. Technology can impact PA levels both negatively and positively. **PURPOSE:** To examine older Latinos' motivators and barriers for LTPA engagement and their perceptions on how technology can influence LTPA participation. **METHODS:** Six focus groups were conducted with 27 middle-aged and older Latinos, 55+ years old, who speak Spanish, and own a cell phone. Participants were recruited from a primarily Latino neighborhood in Chicago. Participants were asked about their overall perceptions and experiences with PA and technology. Participants' perceptions of the impact of technology on PA and sedentary behavior (SB) were specifically asked if these themes did not emerge from the discussion. Discussions were recorded, transcribed verbatim in Spanish, and translated to English. Directed content analysis was conducted. **RESULTS:** Participants reported improvements in health as the main motivator for PA engagement. Participants reported walking and dancing as the most common types of PA they participated in. Common barriers to engaging in LTPA were distance to facilities, and the need of companionship and extrinsic motivators. Participants mentioned that technology can both decrease and increase their PA levels. It was stated that the convenience of driving everywhere, using remote controls and paying bills online leads to more SB. On the contrary, participants mentioned that PA levels can be increased using technology with the example of the use of wearables. Perceptions about wearables varied from a great interest in using wearables as a motivating tool to the idea that

---

wearables are unnecessary. **CONCLUSION:** Older Latinos reported being aware of the health benefits of participating in LTPA, and the majority of those who engage in PA participate in culturally-appropriate types of PA. Participants were aware of the negative changes in lifestyle PA with the advances of technologies on a daily bases; however, most of them were interested in using wearables as motivators for PA. Using wearables in PA interventions targeting older Latinos might be feasible.

Changes in Global Health Status in Older Adults Following a Self-Managed Exercise Program

Saad A. Alhammad, Michele Nofal, Clinton J. Wutzke, Lisa M.K. Chin, Jeffrey E. Herrick. *George Mason University, Fairfax, VA.* (Sponsor: Randall E. Keyser, FACSM)
(No relevant relationships reported)

Regular exercise has been shown to improve the health status of older adults, however less is known regarding the effects of a short-term, self-managed exercise program **PURPOSE**:To examine the effect of self-directed exercise on global health status in unimpaired older adults. **METHODS**: Older adults attended a series of educational seminars based on the National Institute of Aging guidelines for aerobic (AT), resistance (RT) and balance training (BT). Following exercise clearance by their physician, participants chose a combination of AT, RT and BT to perform over 12 weeks. 17 adults completed the self-managed exercise program and were grouped according to their reported activity: AT only (G1) n=8, 73±2 years; AT&RT (G2) n=5, 68±3 years; AT,RT,BT (G3) n=4, 70±1 years. Before and after the 12-week program, participants completed the PROMIS-43 Adult Profile Instrument to assess global health status, and the International Physical Activity Questionnaire for evaluation of weekly physical activity (expressed as energy expenditure, EE). A one-way ANOVA evaluated within group differences, while Cohen's effect sizes were calculated for combined groups in each domain. A regression analysis assessed the relationship between changes in each domain and EE at each timepoint. **RESULTS**: Depression was improved within G2 (P=0.038), however no difference was observed across other PROMIS-43 domains (P≥0.30) among the 3 groups. A trend toward significance was found for anxiety and sleep disturbance for G2. Collectively, all 3 groups showed large effect sizes for lower depression (d=1), and medium effect sizes for lower anxiety (d=.54) following the 12-week program. Small effect sizes were found for fatigue, social role, physical function and pain interference (d≥.4). EE predicted anxiety scores (β=.2, R^2=.3, P=.01), while G2 showed an association between depression and EE (β=.43, R^2 =.8, P=.026). **CONCLUSIONS**:Improvements in mental health were observed in older adults participating in a self-managed exercise program consisting of AT and RT. However, regardless of the training mode, anxiety and depression were reduced for participants that reported higher EE. This suggests a greater role for physical activity participation over type of exercise in older adults for improving mental health with a self-managed exercise program.

Reducing Sedentary Behavior and Improving Physical Function in Older Adults

Brianna Leitzelar[1], Kevin M. Crombie[1], Angelique G. Brellenthin[1], Laura D. Ellingson, FACSM[2], Kelli F. Koltyn, FACSM[1]. [1]*University of Wisconsin-Madison, Madison, WI.* [2]*Iowa State University, Ames, IA.* (Sponsor: Kelli F. Koltyn, FACSM)
(No relevant relationships reported)

Older adults spend 60-70% of their waking hours sedentary, increasing their risk for negative health outcomes. Thus, interventions that reduce sedentary behavior (SB) are needed. **PURPOSE:** Three pilot studies were conducted. The first two studies tested a small group intervention to reduce SB and improve physical function in older adults. The third study used a focus group to assess how to engage African American (AA) older adults in similar trials. **METHODS:** The interventions were based on self-regulation theory and consisted of 4 wkly sessions involving group discussions, goal setting, action plans, self-monitoring, and problem solving. SB and physical function were measured via self-report (SB questionnaire & SF-36) and objective measures (accelerometry & the Short Physical Performance Battery). Study 1 participants (N = 12; mean age=69 ± 5 yrs) completed assessments pre- and post-intervention; study 2 participants (N = 9; mean age=68 ± 2 yrs) completed assessments pre- to post-intervention and at a 4 wk follow up. Due to the pilot nature of this research, data were analyzed with effect sizes (Cohen's *d*). A 90-min focus group was then conducted with 10 AA women (mean age=71 ± 6 yrs). The session was recorded, transcribed, and summarized. **RESULTS:** *Study 1:* There were moderate to large reductions in SB (self-report *d* = 0.95; accelerometers *d* = 0.53) and a moderate improvement in physical function (self-report *d* = 0.41) post-intervention. *Study 2:* Post-intervention, there were small to moderate improvements in SB (self-report *d* = 0.49; accelerometers *d* = 0.15) and gait speed (*d* = 0.22) with further improvements at follow up (SB self-report *d* = 0.85; accelerometers *d* = 0.57; gait speed *d* = 1.16). Results from the focus group revealed positive attitudes towards the intervention, potential barriers for participation

---

Abstracts were prepared by the authors and printed as submitted.

WEDNESDAY, MAY 30, 2018

(e.g., scheduling, location), and specific marketing strategies (e.g., pictures of AA adults on brochures, partner with a community sponsor). **CONCLUSION:** A group-based intervention targeting sedentary time showed promise for changing SB and improving function in older adults. With attention to scheduling, location and marketing, this intervention may be translatable to AA communities.
Supported by the Greater Wisconsin Agency on Aging Resources & the UW Virginia Horne Henry Fund.

Physical Activity Policy for Older Adults in China:A Textual Analysis

Bing Zhan[1], Weimo Zhu, FACSM[2]. [1]*University of Physical Education and Sports, Beijing, China.* [2]*University of Illinois Ubana Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
(No relevant relationships reported)

PURPOSE: As a country under increasing financial pressure and with the largest aging population, China has launched a series of policies to promote the health of older adults through physical activities (PA). The purpose of this study was to analyze those policies. **METHOD:** An effort was made first to collect all related policies enacted between 1960 and 2017. The taxonomy of innovation policy proposed by Rothwell and Zegveld (1981) was then used to build the analysis framework for this study. Accordingly, 3 policy groups and 5 influencing factors classifications were derived to textually analyze policies collected. **RESULT:** A total of 44 related policies were identified. It was found that the Chinese government took an active role in environmental related polices (58%), followed by demand (14%) and supply (28%) related policies as figure 1. Specifically, the government focused more on launching strategies, developing infrastructure, and setting objectives for implementation. While the government still plays a key role in facilitating PA promotion for older adults, it also started to increase efforts to promote organizational participation. However, PA policies to support older adults' individual needs and PA in more scientific way in different settings, such as communities, workplace, and senior centers, were overlooked as figure 2. **CONCLUSION:** Presently, the policy for promoting PA among older adults by the Chinese government has been focused on environmental aspects. Future policy should recognize the diversity of older adults by taking into consideration of their health conditions so as to promote PA at a variety of ability levels. Finally, more scientific evidence-based health promotion programs should be developed and promoted through multi-sector and collaborative partnerships along with all related governmental offices.

Efficacy Of Bingocize®: A Game-centered Mobile Application To Improve Physical And Cognitive Performance In Older Adults

K. Jason Crandall, Matthew Shake, Rilee P. Mathews, Kathryn Dispennette. *Western Kentucky University, Bowling Green, KY.* (Sponsor: Scott Lyons, FACSM)

Reported Relationships: K. Crandall: *Intellectual Property; Western Kentucky University.*

PURPOSE: Adherence to health-promoting programs is a significant barrier to improving the health and well-being of older adults. The present study examined whether Bingocize®, a game-centered mobile app that combines exercise, health education, and bingo, could improve community-dwelling older adults' physical and cognitive performance. METHODS: Participants (N=85) used the app for approximately one hour, twice per week, for 10 weeks. Each using a tablet, they played the game in small social groups, and were randomly assigned to either an Experimental (Bingo + Health Education + Exercise; n=47) or Control (Bingo + Health Education; n = 38) group. Pre and Post-intervention assessments of (a) functional performance, (b) fluid cognition, and (c) knowledge of two health topics (osteoarthritis and fall risks) were administered. RESULTS: Two (Experimental/Control) x Two (Pre/Post) interactions were found for Arm Curls (F (1,81)=4.78, p=.03, ES=.06) and Chair Stands (F (1,81)=4.44, p=.04, ES=.05) and one domain of cognition (updating, a component of executive functioning) (F (1,79)=5.75, p=.02, ES=.07), such that the Experimental group improved more relative to the Control group. Both groups improved their knowledge of the two health topics (F (1,83)=275.56, p<.001, ES=.77). Alpha was set at .05. CONCLUSION: Our findings suggest the fun and interactive nature of Bingocize® may serve as an effective way to potentially improve multiple aspects of quality of life for community-dwelling older adults.

The Effects of Pedometers on Body Weight and Metabolic Factors in Patients with Prediabetes

James J. Pinola, Patricia Davidson, Melissa Whidden, Melissa Reed. *West Chester University, West Chester, PA.*
(No relevant relationships reported)

Sedentary behavior, increased total body weight, elevated blood glucose levels and hyperlipidemia increase the risk of prediabetes. Individuals diagnosed with prediabetes (fasting blood glucose (FBG) between 100-125mg/dL) are recommended to perform a minimum of 150 minutes of physical activity (PA) per week and decrease total body weight by 7% to reduce the likelihood of developing type 2 diabetes. However, there is little known about the role of pedometers with regards to a Diabetes Prevention Program (DPP) **PURPOSE:** To determine if pedometer use could aid in the reduction of total body weight, cholesterol, and blood glucose levels as a part of the Centers for Disease Control National DPP. **METHODS:** Body weight, FBG and lipids (total cholesterol, high-density lipoproteins (HDL) and low-density lipoproteins (LDL)) were measured prior to the start of the DPP and 16 weeks following the intervention. All participants were either diagnosed as prediabetic or at risk for prediabetes based on the CDC screening tool. The pedometer group (PG) (n=9) received pedometers and the control group (CG) (n=8) did not. All participants received the same educational sessions that explained dietary changes and strategies to increase PA. The PG was asked to wear a pedometer on their belt for all waking hours of the day, seven days a week, for sixteen weeks. At each weekly DPP meeting, step counts from pedometers were recorded and pedometers were reset and returned to the participants. A 2x2 ANOVA was performed to examine differences. **RESULTS:** The PG experienced significant (p<0.05) weight loss from pre to post-test (186.2lbs $\pm$ 9.7 to 180.7 $\pm$ 8.9) while the control group did not (191.3lbs $\pm$ 16.8l to 190.1 $\pm$ 17.0). Interestingly, HDL significantly decreased from pre to post-test (p>0.05) in the PD group (58.1mg/dL $\pm$ 4.0 to 54.1mg/dL $\pm$ 3.6) while the CG remained unchanged (50.9mg/dL $\pm$ 5.1 to 50.5mg/dL $\pm$ 4.8). There were no differences between any other variables. **CONCLUSION:** It appears that the addition of pedometers into the DPP can contribute positively to weight loss. It is possible participants experienced a sense of greater accountability due to the added tracking tool. Further research and a larger participation population is needed to elucidate the mechanisms that contribute to the changes in body weight and lipid profile.

MVPA And DXA-derived Adiposity In Adolescents With And Without Down Syndrome

E. Andrew Pitchford[1], Chelsea Adkins[2], Joseph E. Hornyak[3], Rebecca E. Hasson, FACSM[3]. [1]*Iowa State University, Ames, IA.* [2]*Michigan State University, East Lansing, MI.* [3]*University of Michigan, Ann Arbor, MI.*
(No relevant relationships reported)

PURPOSE: Obesity is a highly prevalent secondary health condition among adolescents with Down syndrome (DS). It is thought that low levels of physical activity may promote excess adiposity in this population. However, reported associations between body mass index (BMI) and moderate-to-vigorous physical activity (MVPA) have been small and non-significant. The purpose of this study was to compare group differences in adiposity derived from dual-energy x-ray absorptiometry (DXA) and accelerometer-measured physical activity between adolescents with and without DS and then examine associations within each group.
METHODS: Thirty-nine adolescents (22 with DS and 17 typically developing (TD) controls), aged 12-18 years participated in the study. Groups had similar distributions of age, sex, and Tanner pubertal stage. Body composition was assessed by DXA, BMI, and BMI percentile. MVPA was measured with Actigraph GT3X+ accelerometers over 7 days. Group differences were analyzed with multivariate analysis of covariance (MANCOVA) while controlling for age, sex, Tanner pubertal stage, and accelerometer wear-time. Pearson product-moment correlation coefficients and linear regression were used to examine the associations between MVPA and adiposity among adolescents with DS and TD.
RESULTS: Adolescents with DS had significantly higher BMI, BMI percentile, and DXA-derived percent body fat (BF%), as well as lower minutes of MVPA compared to TD controls (p < .05). Associations between MVPA and BF% in adolescents with DS were moderate (r = -.39, p = .07), but substantially stronger than BMI (r = -.19, p = .40). However, linear regression analyses identified Tanner stage (β = -.77, p <

WEDNESDAY, MAY 30, 2018

.001) and MVPA (β = -.34, p = .047) as statistically significant predictors of BF%. No relevant associations between body composition and MVPA were observed in adolescents with typical development (p > .05).
CONCLUSION: Our findings suggest that MVPA is associated with adiposity among adolescents with DS when properly measured with DXA. This study also provides further evidence of significantly higher levels of adiposity and significantly lower levels of physical activity among adolescents with DS compared to their TD peers, clearly reflecting a source of health disparity and need for targeted intervention.

Cancer Cachexia: Metabolic Changes In Carbohydrate Metabolism Of The Liver

Sarah Ramey[1], Megan E. Rosa-Caldwell[1], Jacob L. Brown[1], Richard A. Perry[1], Wesley A. Haynie[1], Aaron R. Caldwell[1], Tyrone A. Washington[1], Michael P. Wiggs[2], Nicholas P. Greene[1]. *[1]University of Arkansas, Fayetteville, AR. [2]University of Texas at Tyler, Tyler, TX.* (Sponsor: Dr. Stephen Crouse, FACSM)
(No relevant relationships reported)

One negative side effect of cancer that dramatically affects cancer prognosis is the development of cancer cachexia. Cancer cachexia is defined as cancer-associated muscle wasting. This is thought to be at least partially mediated by increased energy expenditure and is responsible for the death of 20-40% of all cancer patients. Although the liver is known to be the predominant regulator of whole body metabolism, there is little known about its relationship to the development of cancer cachexia. **PURPOSE:** The purpose of this exploratory study was to investigate alterations in liver metabolism by examining measures of glycogen storage throughout the progression of Lewis Lung Carcinoma (LLC) induced cancer cachexia. **METHODS:** C57BL/6J mice were injected with 1X10⁶ LLC Cells in the left posterior leg, and the control group with phosphate buffered saline (PBS). The experimental groups included PBS, 1wk, 2wk, 3wk, and 4wk of cancer progression with 10-16 in each group. Sections of liver (n=~8/group) were cut and periodic acid-Schiff (PAS) stain for glycogen was completed. Images were analyzed for total area of stain as well as intensity of stain using NIS-Elements imaging software. A Welch's one-way analysis of variance was used to determine differences between groups, a Tukey post hoc was used to determine differences between means. Significance was denoted at p<0.05. **RESULTS:** 4wk animals had ~30% larger livers compared to all other groups with no other differences detected (~1000mg compared to ~1300mg, p<0.05). However, there were no statistical differences detected between groups on either PAS area stained (~50% across groups, p>0.05) or intensity of stain (Arbitrary Intensity Unit ~30 across groups, p>0.05). Furthermore, neither glycogen area nor intensity correlated with liver size (r = 0.12 and r = 0.16 respectively). **CONCLUSION:** Differences in liver sizes are not attributable to glycogen storage. Though there were no differences in glycogen content, the increase in liver size suggests disruption of other processes in the liver. For future projects, we will further investigate mechanisms for liver hypertrophy in order to determine the relationship between the liver and cancer cachexia progression.
This study was supported by The Arkansas Bioscience Institute and National Institutes of Health R15AR069913.

Time-Dependent Alterations in Liver and Adipose Mitochondrial Respiration During Colon-26 Cancer Cachexia

Gabriel S. Pena, Jessica L. Halle, Joseph P. Carzoli, Hector G. Paez, Michael C. Zourdos, Michael Whitehurst, FACSM, Andy V. Khamoui. *Florida Atlantic University, Boca Raton, FL.* (Sponsor: Michael Whitehurst, FACSM)
(No relevant relationships reported)

Nearly half of all cancer patients undergo cachexia, a life-threatening condition characterized by weight loss and skeletal muscle atrophy. Recent frameworks describe cachexia a systemic condition in which several non-muscle organs are reprogrammed or remodeled. Mitochondria are organelles with a major role in cellular energy metabolism, and impairment of mitochondrial function is linked with a number of diseases. Adipose and liver are energy-regulating tissues implicated in cachexia. The control of mitochondrial respiration in these tissues during the induction and progression of cancer cachexia is not well-defined. **PURPOSE:** To investigate oxidative phosphorylation (OXPHOS) and electron transfer system (ETS) capacity in white adipose and liver during colon-26 tumor-induced cachexia. **METHODS:** Balb/c males (10 wks) were assigned to control or colon-26 (C26). C26 mice were injected with 10⁶ tumor cells and euthanized for tissue at 7, 14, and 21 days post-injection. By day 21, C26 mice exhibit significant muscle atrophy. Controls were injected with PBS and euthanized for day 0 tissue. Epididymal white adipose tissue (eWAT) was immediately analyzed by high-resolution respirometry. The liver was permeabilized via mechanical separation prior to respiration. Saturating levels of substrates were used to evaluate Complex I OXPHOS (CI_p), Complex I+II OXPHOS ($CI+II_p$), and ETS.

RESULTS: In comparison to day 0 liver (78±15 pmol/s/mg), CI_p was lower at day 14 (26±6, p=0.08) and day 21 (8±4, p<0.05). CI_p was also lower in day 21 liver vs. day 7 (p<0.05) and day 14 (p=0.06). In comparison to day 0 liver (157±26 pmol/s/mg), $CI+II_p$ was lower at day 14 (49±5 pmol/s/mg, p=0.05) and day 21 (34±11, p<0.05). $CI+II_p$ was also lower (p<0.05) in day 14 and day 21 livers when compared to day 7 (112±9). In comparison to day 0 liver (221±38 pmol/s/mg), maximal ETS was lower at day 14 (70±13, p=0.06) and day 21 (40±14, p<0.05). ETS was also lower (p<0.05) in day 14 and day 21 livers when compared to day 7 (176±14). Respiration of eWAT was not different across time points (p>0.05). **CONCLUSION:** Coupled respiration with electron supply from Complex I and I+II, and non-coupled respiration (i.e. ETS) decreased during the progression of cachexia, suggesting that changes in liver oxidative capacity are associated with the development of this comorbidity.

Dietary Fat Intake Predicts Aortic Stiffness Independent of Physical Activity

Jessica J. Gadberry[1], Nicholas A. Carlini[2], Summer L. Burke[1], Marilyn S. Campbell[1], Bradley S. Fleenor[2]. *[1]University of Kentucky, Lexington, KY. [2]Ball State University, Muncie, IN.*
(No relevant relationships reported)

PURPOSE: To determine if increased dietary fat consumption predicts aortic stiffness independent of physical activity.
METHODS: Men and women 18-60 years of age were recruited for this cross-sectional study. Body mass, height, body fat percentage (bioelectrical impedance analysis), aortic stiffness (carotid-femoral Pulse Wave Velocity; cfPWV), habitual dietary intake (NIH's validated Dietary History Questionnaire-II; DHQ-II), and physical activity (International Physical Activity Questionnaire; IPAQ) were assessed for all subjects. Univariate linear regression analyses were implemented to determine dietary correlations with cfPWV, and partial correlations were employed to adjust for traditional risk factors using SAS 9.4.
RESULTS: The study population consisted of predominately young men and women (23.5 ± 7.9 years, 70.0% female) with a normal body mass index (BMI = 23.6 ± 4.3 kg/m²) and mean cfPWV of 5.8 ± 0.9 meters/second. Weekly physical activity was estimated at 5,547.6 ± 5,478.2 MET-minutes per week. Habitual daily caloric intake was 1,921.0 ± 798.9 calories, consisting of 46.0 ± 0.1% carbohydrate, 36.8 ± 0.1% fat, and 16.3 ± 0.0% protein. Greater consumption of total discretionary solid fat was associated with increased cfPWV ($R^2 = 0.155$, P = 0.031). However, total calories from dietary fat (R2 = 0.093, P = 0.101), total grams of fat ($R^2 = 0.047$, P = 0.248), and total discretionary oil fat ($R^2 = 0.008$, P = 0.650) were not associated with cfPWV. The correlation between discretionary solid fat and cfPWV remained after adjustment for age, body fat percentage, BMI, and physical activity ($R^2 = 0.160$, P = 0.043). Among food choices contributing to the increased discretionary calories from solid fat, cheese intake was positively correlated with cfPWV ($R^2 = 0.134$, P = 0.047). Additionally, specific fatty acids that predicted cfPWV included trans fatty acid, trans-hexadecenoic acid ($R^2 = 0.179$, P = 0.020), and monounsaturated fatty acids, hexadecenoic acid ($R^2 = 0.148$, P = 0.036) and myristoleic acid ($R^2 = 0.206$, P = 0.012).
CONCLUSIONS: Increased dietary discretionary fat consumption within the habitual diet predicts aortic stiffness independent of physical activity. Cheese consumption and specific fatty acids may be novel contributors to increased aortic stiffness independent of regular physical activity.

High Intensity Circuit Training Versus Moderate Strength Training On Body Composition In Obese Adults

Neil McMillan[1], Gary Miller[1], Sandy Combs, Jr[1], Tiffany Gibson[1], Jamy Ard[2]. *[1]Wake Forest University, Winston-Salem, NC. [2]Wake Forest Baptist Health, Winston-Salem, NC.* (Sponsor: Michael J. Berry, FACSM)
(No relevant relationships reported)

Weight loss has been shown to adversely affect body composition due to the loss of fat free mass that accompanies fat mass loss during negative energy balance. Exercise has been recommended as a therapy to ameliorate fat free mass loss during weight loss interventions. **PURPOSE:** The primary purpose of this study was to compare the effectiveness of high-intensity circuit training (HICT) versus moderate strength straining (ST) on body composition in obese adults. **METHODS:** Obese adults (10 women and 1 man) completing a medically supervised weight loss program were randomized into one of two 12-week exercise training groups: HICT (n=5) or ST (n=6). Baseline (BL) testing included height, weight, and DEXA scans to assess total and regional body composition. Each group underwent a supervised exercise training program of upper and lower body exercises (30 minute sessions; 3 times per week for 12 weeks); follow-up (FU) testing was performed after 12 weeks. The HICT consisted of 8-12 exercises of 2-3 sets, with rest periods of approximately 30 seconds. Exercise intensity corresponded to 80-95% of their VO_2peak. The ST group completed progressive resistance training which included 2-3 sets of 10-12 repetitions

---

Abstracts were prepared by the authors and printed as submitted.

of each exercise. **RESULTS:** When examining changes in body mass index (BMI), total fat mass (FFM), total fat free mass (FFM), trunk fat mass (TFM) , and estimated visceral fat mass (VFM), mixed model ANOVA revealed no significant group x time interaction (p>0.05) nor a main group effect (p>0.05) for the variables. However, there was significant time (BL vs FU) main effect for BMI (38.7 ± 1.5 vs. 33.1 ± 1.7, respectively, p<0.001); FM (48.4 ± 4.0 vs 38.7 ± 3.8 kg, respectively, p<0.001); TFM (26.1 ± 2.1 vs. 19.6 ± 1.8 kg, respectively, p=.001); and VFM (1.5 ± .19 vs. 1.0 ± .13 kg, respectively, p=.001). **CONCLUSION:** Both the 12-week HICT and ST program in conjunction with the medical weight loss program produced successful weight loss and FM changes. Furthermore, FFM was retained in both groups, suggesting both programs are viable options to improve or maintain body composition through substantial weight loss.

Continuous Exercise Training Reduces Arterial Stiffness In An Exercise Dose Dependent Manner in Adults With Prediabetes

Mahnoor Khurshid, Natalie Z.M. Eichner, Julian M. Gaitan, Nicole M. Gilbertson, Eugene J. Barrett, Arthur Weltman, FACSM, Steve K. Malin, FACSM. *University of Virginia, Charlottesville, VA.*

(No relevant relationships reported)

PURPOSE: Although prior work highlights an exercise dose-response relationship for glucose regulation, no study has assessed if exercise energy expenditure is related to reductions in arterial stiffness in an intensity based manner. We tested the hypothesis that increased exercise dose would correlate with reduced arterial stiffness in obese adults with prediabetes. **METHODS**: In this randomized trial, 26 adults (Age: 61.4±2.5 y, BMI: 32.1±1.0 kg/m^2) were screened for prediabetes using American Diabetes Association criteria (75g OGTT and/or HbA$_{1c}$). Aerobic fitness (VO$_2$peak) was measured on a cycle ergometer by indirect calorimetry. Subjects performed either supervised continuous exercise (CONT; n=13) at 70% of HR$_{peak}$ or underwent interval training (INT; n=13) for 3 min at 50% HR$_{peak}$ and 3 min at 90% HR$_{peak}$ for 60min/d over 2-weeks. Arterial stiffness (augmentation index; AI) and glucose tolerance were determined during a 75g OGTT and analyzed by total area under the curve (tAUC) before and after training. Exercise dose was assessed using VO$_2$-heart rate derived linear regression equations. **RESULTS**: Mean energy expenditure during CONT and INT training was 312.5±12.0 and 399.9±19.6 kcal/session, respectively (P=0.001). Exercise training had no effect on body weight, but it did significantly improve VO$_2$peak (P=0.001), independent of intensity. Both CONT and INT intervention also reduced glucose tAUC$_{180min}$ (P=0.01) and AI tAUC$_{180min}$ (P=0.03). However, this reduced arterial stiffness tended to correlate with increased exercise energy expenditure from CONT (r=-0.53, P=0.06) but not INT (r=-0.005, P=0.98) training. Improved VO$_2$peak was also related to reduced AI tAUC$_{180min}$ (r=-0.63, P=0.02) only after CONT exercise. **CONCLUSIONS**: Short-term exercise training reduces arterial stiffness independent of intensity. However, only CONT training improves arterial stiffness in an energy dose-dependent manner. These findings suggest that intensity of exercise may exert different mechanisms for enhancing vascular function in adults with prediabetes to lower diabetes and cardiovascular risk.

Influence Of Sex On The Relationship Between Two Estimates Of Visceral Adipose Tissue

Gregory L. Nuckols, Kara C. Anderson, Austin M. Peterjohn, Katie R. Hirsch, Malia N.M. Blue, Alexis A. Pihoker, Eric T. Trexler, Abbie E. Smith-Ryan, FACSM. *UNC Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)

(No relevant relationships reported)

Magnetic resonance imaging (MRI) is the gold standard for estimating visceral adipose tissue (VAT) area. However, MRI machines are not available to all laboratories, and other methods of estimating VAT, including dual-energy X-ray absorptiometry (DXA) and B-mode ultrasound (US), are often more readily available, cost effective, and feasible. DXA and US have been reported to be valid methods of VAT determination, but their relationship has yet to be evaluated. PURPOSE: To determine the relationship between estimates of VAT derived from DXA and US in college-aged females and males with a normal body mass index (BMI). METHODS: Sixty-three female (Mean ± SD; Age= 19.6 ± 1.4 yrs; Height= 1.64 ± 0.07m; Weight= 58.7 ± 6.3kg; BMI= 21.7 ± 1.6) and 29 male (Age= 19.3 ± 1.6 yrs; Height= 1.79 ± 0.09m; Weight= 71.6 ± 9.9kg; BMI= 22.3 ± 2.0) subjects were enrolled in this study. Exclusion criteria included age <18 or >25 years old and BMI <18.5kg/m^2 or >24.9kg/m^2. The participants reported to the laboratory 8 hours fasted, and were required to have abstained from alcohol consumption and vigorous physical activity for at least 24 hours prior to testing. DXA scans were completed, and estimates of VAT mass (kg) were reported using the core scan feature of a total body scan (Lunar iDXA). US scans of the abdomen were completed 2 cm above the umbilicus, and VAT depth (cm) was estimated by measuring the distance between the posterior surfaces of the linea alba and the descending aorta.

RESULTS: There was no significant correlation between VAT estimates derived from DXA and US (R=0.07, p>0.05) in females. However, there was a significant correlation in males (R=0.77, p<0.001). Furthermore, there was a significant relationship when combining males and females (R=0.45, p<0.001). CONCLUSIONS: There was no relationship between the two estimates of VAT quantity in females in this population, but there was a significant relationship in males and in the combined sample. This highlights the importance of considering sex as an important moderating variable when selecting an instrument to assess body composition.

The Effect Of Single Stair-Climbing/Descending Bouts Of Varying Lengths On Postprandial Glycemic Responses

Eric Bartholomae, Jeff Moore, Kathryn Ward, Zach Johnson, Jochen Kressler. *San Diego State University, San Diego, CA.*

(No relevant relationships reported)

Impaired glucose tolerance is strongly associated with cardiometabolic disease risk. Single bouts of exercise can improve insulin sensitivity and attenuate the rise in postprandial glucose. **PURPOSE**: To investigate the effects of moderate intensity stair climbing of various durations on postprandial glycemic responses in healthy men and women. **METHODS**: Eight males (27.1±5.9y) and seven females (25.7±5.4y) completed a 75g oral glucose tolerance test (OGTT). On three subsequent visits, participants completed an OGTT combined with either 1min, 3min, or 10min of stair-climbing, all ending 28 min after completion of glucose consumption in randomized order. Blood measurements were taken at baseline and thirty minutes post-glucose consumption and analyzed for glucose and insulin as well as insulin resistance and sensitivity. **RESULTS:** All stair-climbing trials reduced peak (30 min) postprandial glucose levels compared to control, however the 10 min bout yielded a significant difference (30.5±5.9mg/dL, p<.001), whereas neither the 1 min bout (8.6±5.6mg/dL, p=.147) nor the 3 min bout (6.3±4.9mg/dL, p=.221) were significant. Insulin concentration was also significantly reduced following the 10 min trial (5.18±1.68μIU/mL, p<.010), however there were no significant differences for the 1 min trial (0.62±0.94μiu/mL, p=.524) or the 3 min trial (1.41±0.83μIu/mL, p=.113) compared to control. There was a significant decrease in HOMA-IR following the 10 min bout (3.96±0.79, p<.001) compared to control. No significant differences in HOMA-IR were seen for the 1 min (0.82±0.64, p=.222) or 3 min (0.89±0.46, p=.077) trials. Insulin sensitivity index values increased significantly following the 10 min trial (2.24±0.71, p<.007), while no significant differences were seen for 1 min (0.35±0.62, p=.584) or 3 min (0.02±0.79, p=.980) trials compared to control. **CONCLUSIONS**: Ten minutes of moderate intensity stair-climbing/descending exercise is effective at improving postprandial glycemic responses in healthy adults while shorter bouts of 1 and 3 min were not.

Self-Regulation in Early Childhood Predicts Adolescent Metabolic Syndrome Profile Membership

Laurie Wideman, FACSM[1], Jessica Dollar[1], Lenka Shriver[1], Susan D. Calkins[1], Susan P. Keane[1], Lilly Shanahan[2]. [1]*UNC-Greensboro, Greensboro, NC.* [2]*University of Zurich, Zurich, Switzerland.*

(No relevant relationships reported)

The prevalence of full-blown clinical metabolic syndrome (MetS) in adolescence ranges between 5-9%. Many adolescents fail to meet the rigid criterion thresholds for MetS but may still have an increased risk for chronic disease. Thus, a continuous MetS score has been used to circumvent these issues. Recent research suggests, however, that other factors, such as self-regulation, may influence chronic disease through a variety of processes and may be critical for identifying cardiometabolic risk in younger populations. **PURPOSE**: To determine if self-regulation in early childhood predicts MetS profile membership in adolescence. **METHODS**: As part of a large longitudinal study, adolescents visited a lab (N=117, 59% female) and completed anthropometric measures, resting blood pressure and a fasted blood draw at age 16. All biomarkers were assessed using colorimetric assay techniques using commercially available items or a multiplex system. All dimensions of self-regulation were assessed at age 5 using age-appropriate, laboratory-based tasks and parent-report measures. Latent profile analysis (LPA) and one-way analysis of variance (ANOVA) were employed to address the study aims. **RESULTS**: The best-fitting LPA model identified 3 groups (BIC=6597.12, Entropy=.92, Adj. p LMR-LRT=81.65, p=ns); a low risk group (LRG; n=48) had low leptin (L), glucose (G), and non-HDL, but high HDL, a moderate risk or dyslipidemic group (DLG; n=58) had high G and non-HDL, but low HDL, L, waist circumference (WC), mean arterial pressure (MAP), and C-reactive protein (CRP), and a high-risk group (HRG; n=11) had high L, G, WC, MAP, CRP, and moderate non-HDL. Adolescents in the HRG showed lower emotion regulation (F = 5.19, p < .01), attentional focusing (F = 6.39, p < .01), and inhibitory control (F = 2.66, p < .05), at age 5 compared to adolescents in LRG. Physiological self-regulation (assessed by vagal withdrawal or RSA) at age 5 was higher (greater self-regulation) in LRG

compared to the DLG ($F = 3.23$, $p < .05$). **CONCLUSIONS**: These data suggest that self-regulation in early childhood is a significant *modifiable* construct influencing risk for cardiometabolic disease in adolescence and should be investigated as a potential target for future behavioral interventions. Changes In Liver And Skeletal Muscle Sensitivity In Response To Acute And Chronic Calorie Restriction On A Low Carbohydrate Diet

Erik Kirk, FACSM[1], Dominic Reeds[2], Samual Klein[3]. *[1]Southern Illinois University Edwardsville, Edwardsville, IL. [2]Washington University in St. Louis School of Medicine, St. Louis, MO. [3]Washington University in St. Louis School of Medicine, Saint Louis, MO.*

(No relevant relationships reported)

PURPOSE: We determined the effects of acute and chronic calorie restriction with a low-carbohydrate diet on hepatic and skeletal muscle insulin sensitivity. **METHODS**: Twelve obese subjects (body-mass index, 36.1 ± 1.0kg/m^2) followed a low-carbohydrate (<60g/d) energy-deficit diet (1,200kcals/day). Magnetic resonance spectroscopy, muscle biopsies, and a euglycemic-hyperinsulinemic clamp were used to determine insulin action, cellular insulin signaling and intrahepatic triglyceride content before, after 48 h, and after ~12 wks (7% weight loss) of diet therapy. **RESULTS**: Intrahepatic triglyceride content significantly decreased at both 48-h ($28.6\pm3.8\%$) and 7% weight loss ($-38.0 \pm 4.5\%$; $p<0.05$) compared to baseline. Basal glucose production rate significantly decreased at 48 h ($21.8\pm3.2\%$, $p<0.001$) and after 7% weight loss ($20.8\pm3.4\%$, $p<0.001$). Insulin-mediated glucose uptake did not significantly increase at 48 h ($4.4\pm12.7\%$, $p>0.05$) but did significantly increase at 7% weight loss ($35.2 \pm 8.4\%$, $p<0.05$). Insulin-stimulated phosphorylation of Jun N-terminal kinase decreased by ($-15.4 \pm 18.1\%$, $p>0.05$) and -41.3 ± 19.5, $p<0.05$) and phosphorylation of Akt increased by $19.2 \pm 26.9\%$ ($p>0.05$) and $36.1 \pm 12.4\%$,($p<0.05$), after 48-h and 7% weight loss respectively. **CONCLUSIONS**: A low carbohydrate calorie diet acutely reduced intrahepatic triglyceride content and improved hepatic insulin sensitivity whereas moderate weight loss is necessary to improve insulin sensitivity in the skeletal muscle.

Exercise Training Attenuates Non-Alcoholic Fatty Liver Disease in rats with Diabetes via Endoplasmic Reticulum Stress

Junhan Li[1], Derun Gao[1], Junzhi Sun[1], Kai Zou[2], Quansheng Su[1]. *[1]Chengdu Sport University, chengdu, China. [2]University of Massachusetts, Boston, MA.* (Sponsor: Tongjian You, FACSM)

(No relevant relationships reported)

Non-alcoholic fatty liver disease (NAFLD) is highly prevalent in type 2 diabetes (T2D). Recent evidence supports that endoplasmic reticulum (ER) stress plays a critical role in the development of NAFLD. Although exercise training has been commonly prescribed for the treatment of NAFLD, the effects of different types of exercise on ER stress in NAFLD under type 2 diabetic condition are largely unknown. **PURPOSE**: The purpose of this study was to determine the effects of aerobic and resistance exercises on hepatic ER stress response and NAFLD in rats with T2D. **METHODS**: Male Sprague-Dawley rats were randomly assigned to four groups (n=10/group): Control (CON), T2D, T2D with aerobic exercise (T2D+AE; treadmill walking at 30 m/min, 0° incline, 60 mins/day, 5 day/week, for 8 weeks) and T2D with resistance exercise (T2D+RE; climbing a 80° incline vertical ladder with weights progressively increased from 50% to 100% of maximal carrying capacity on the tail, 3 times/day, 5 days/ week, for 8 weeks). Liver tissue samples were collected for histopathological analysis of the density of lipid droplets, and immunoblot analysis of expression levels of ER stress proteins, including glucose-regulated protein (GRP78), C/EBP homologous protein (CHOP), caspase 12, and c-Jun N-terminal kinase (JNK). One-way ANOVAs and Tukey's -test were used for data analysis. **RESULTS:** The density of lipid droplets in the liver was significantly higher in the T2D group than in the CON group ($p<0.01$), but was significantly lower in the T2D+AE and T2D+RE groups when compared to the T2D group (both $p<0.01$). In addition, the T2D group had significantly higher levels of protein expression of GRP78, CHOP, caspase 12 and JNK when compared to the CON group (all $p<0.01$). Both exercise groups had significantly lower levels of protein expression of GRP 78, CHOP, Caspase 12 and JNK when compared to the T2D group ($p<0.05$ to $p<0.01$). **CONCLUSION**: Our findings suggest that both aerobic and resistance exercises are protective against NAFLD in rats with T2D by potentially regulating proteins involved in ER stress response.

Effect of Exercise and/or Spirulina maxima On Body Composition In Overweight/Obese Humans

Marco A. Hernández-Lepe[1], Abraham Wall-Medrano[1], José A. López-Díaz[1], Marco A. Juárez-Oropeza[2], Rosa P. Hernández-Torres[3], Arnulfo Ramos-Jiménez[1]. *[1]Universidad Autónoma de Ciudad Juárez, Ciudad Juárez, Mexico. [2]Universidad Nacional Autónoma de México, Ciudad de México, Mexico. [3]Universidad Autónoma de Chihuahua, Chihuahua, Mexico.*

(No relevant relationships reported)

Overweight and obesity are the main risk factors for cardiovascular diseases, which are the leading causes of death worldwide. As a consequence of this, it is indispensable to apply a nutritional intervention involving both a healthy diet adjustment and to promote an active lifestyle, since they are effective in preventing and reducing weight gain and excessive accumulation of body fat.
PURPOSE: To determine the independent and synergistic effect of a systematic physical exercise program and/or *Spirulina maxima* supplementation on body composition in overweight and obese subjects.
METHODS: Through a randomized, double-blind, placebo-controlled, counterbalanced crossover study design, overweight and obese adults (N= 52, 25.12 ± 4.88 y, 1.71 ± 0.11 m, 88.14 ± 16.99 kg) were evaluated during a 12 wk of 4.5 g a day of supplementation (6 wk *Spirulina maxima* and 6 wk placebo) and/or a systematic physical exercise program (three days a week 20 to 30 min of aerobic exercise with intensities between 50% and 80% of maximum heart rate (HR max) and two days 20 to 30 min between 80% and 90% of HR max using high-intensity interval training (HIIT) intervention); the participants were divided in four groups: exercise and *Spirulina maxima* supplementation (ES), exercise and placebo supplementation (E*), Spirulina maxima* supplementation without exercise (S), and the control one, placebo without exercise (C). Body weight, body mass index (BMI) and body fat percentage (BFP) were assessed. Differences between treatments comparisons in all response variables were made using and ANOVA test. The present study was approved by bioethics committee of Universidad Autónoma de Ciudad Juárez.
RESULTS: The differences between individuals usually are of wide range, for that reason the results are shown like differences between final and initial evaluations. All the treatments showed statistical differences compared with the control in body weight (kg) (ES= -2.36 ± 0.84, E= -0.89 ± 0.68, S= -0.91 ± 0.73, C= 0.04 ± 1.28), BMI (kg.m^{-2}) (ES= -0.72 ± 0.41, E= -0.26 ± 0.29, S= -0.31 ± 0.48, C= 0.01 ± 0.44), and BFP (%) (ES= -1.15 ± 0.20, E= -0.49 ± 0.21 S= -1.46 ± 0.45, C= -0.04 ± 0.13).
CONCLUSION: *Spirulina maxima* intake joint a HIIT have an individual and a synergistic effect on body composition (decrease of body weight, BMI and BFP) in overweight and obese adults.

Restricted Carbohydrate Diet and Exercise Increase BDNF, Cognitive Function, and Metabolic Profiles

Amy M. Gyorkos[1], Mark Baker[1], Alex Eason[1], Deborah Lown[1], Lauren Miutz[2]. *[1]Grand Valley State University, Allendale, MI. [2]University of Calgary, Calgary, AB, Canada.* (Sponsor: Timothy J. Michael, FACSM)

(No relevant relationships reported)

Metabolic syndrome (MetS) has been recognized as one of the most important clinical challenges and global health issues of today. Growing evidence suggests that mechanisms of energy metabolism may play a key role in mediating aspects of cognitive function. Brain-derived neurotrophic factor (BDNF) is one such factor well known for its critical role in neuronal plasticity, including memory and learning, and more recently metabolic processes, including body weight control, food intake and energy homeostasis. **PURPOSE**: The purpose of this study was to investigate the effect of diet and exercise on cognitive and metabolic function in individuals characterized with MetS. **METHODS**: Eleven subjects with MetS followed a crossover design with two 4-wk interventions, including a restricted carbohydrate paleolithic-based diet (RCPD) with high intensity interval training (RCPD-Ex) and a RCPD with sedentary activity (RCPD-Sed), separated by a 4-wk washout period. A two-way analysis of variance with repeated measures was performed with post-hoc analysis using simple effects analysis with a Bonferroni adjustment. The level of statistical significance was established a priori as $P < 0.05$. Values are reported as means ± SD. **RESULTS**: Compared to baseline, RCPD-Sed and RCPD-Ex improves cognitive function, including improving serum BDNF by 20% and 38% (15.4 ± 5.2 verse 18.5 ± 4.6 and 21.2 ± 6.4 ng/mL), psychomotor speed and cognitive flexibility (-14%, -14%), and self-perceived cognitive symptoms and functioning (+8%, +16%), respectively. Compared to baseline, RCPD-Sed and RCPD-Ex also improves metabolic markers, reducing waist adiposity (15%, 18%), weight loss (-3%, -5%), body fat % (BF%; -7%, -12%), fasting plasma glucose (GLU; -20%, -27%), triglycerides (TG; -47%, -52%), mean arterial pressure (MAP; -28%, -34%), and increases HDL-C (+22%, +36%), respectively. RCPD-Sed and RCPD-Ex reduces fasting insulin by -34% and -39% (12.8 ± 9.1, 11.3 ± 9.4 µUI/ml), HOMA-IR by -37% and -41% (1.7

WEDNESDAY, MAY 30, 2018

± 1.4, 1.4 ± 1.7), and increases adiponectin by +33.7% and +38% (6.18 ± 2.8, 6.89 ± 3.9 ng/ml), respectively, when compared to baseline. **CONCLUSION**: RCPD-Sed and RCPD-Ex were able to improve cognitive and metabolic factors, while RCPD-Ex outperformed RCPD-Sed in all measured factors. These effects may be dependent on BDNF as a metabotrophin mediator.

Normalized Grip Strength Thresholds for the Detection of Metabolic Syndrome in Colombian Collegiate Students

Katherine González-Ruíz[1], Antonio García-Hermoso[2], Alejandra Tordecilla-Sanders[3], Jorge E. Correa-Bautista[3], Aura Cristina Quino-Ávila[4], Carolina Sandoval-Cuellar[4], Mónica Liliana Ojeda-Pardo[4], Andrea del Pilar Quintero[3], Robinson Ramírez-Vélez[3]. [1]Universidad Manuela Beltrán, Bogotá D.C, Colombia. [2]Universidad de Santiago de Chile, USACH, Santiago de Chile, Chile. [3]Universidad del Rosario, Bogotá D.C, Colombia. [4]Universidad de Boyacá, Tunjá, Colombia.
(No relevant relationships reported)

PURPOSE: Evidence shows an association between grip strength and health; however, grip strength cut-offs for the detection of metabolic syndrome (MetS) risk in Latin-American populations are scarce. The purpose of this study was to determine cut-offs of normalized grip strength (NGS) in a large collegiate student population from Colombia (2014-2017). **METHODS**: A total of 1,795 volunteers (61.4% female, mean age = 20.68 (2.9) years old), ranging between the ages of 18 and 30 years participated in the study. Strength was estimated using a hand-held dynamometer and normalized to body mass (handgrip strength [kg]/body mass [kg]). Anthropometrics, serum lipids indices, blood pressure, and fasting plasma glucose were measured. Body composition was measured by bioelectrical impedance analysis (BIA). MetS was defined as including ≥3 of the metabolic abnormalities according to the International Diabetes Federation definition. A metabolic risk score was computed from the following components: waist circumference, triglycerides, high-density lipoprotein cholesterol, glucose, and systolic and diastolic blood pressure. Receiver operating curve (ROC) analysis showed a significant discriminatory accuracy of NGS in identifying the thresholds and risk categories. **RESULTS**: Lower strength was associated with increased prevalence of MetS. In males, weak, intermediate, and strong NGS values at these points were <0.47, ≥0.47 to 0.62, and >0.62, respectively. In females, these cut-off points were <0.33, ≥0.33 to 0.44, and >0.444, respectively. **CONCLUSIONS**: In summary, our sex-specific cut-off points of NGS could be incorporated into a clinical setting for identifying college students at cardiometabolic disease risk.

Effect Of 12-weeks Of Moderate Versus High-intensity Interval Exercise Training On Postprandial Lipemia, Vascular Function And Arterial Stiffness After High-fat Meal Ingestion In Inactive Adults

Jorge E. Correa-Bautista, Alejandra Tordecilla-Sanders, Viviana Aya-Aldana, Luis Andres Téllez-T, Jhonatan Peña-Ibagon, Robinson Ramírez-Vélez. Universidad del Rosario, Bogotá D.C, Colombia.
(No relevant relationships reported)

PURPOSE: The aim of this study was to determine the effect of 12-weeks of moderate continuous training (MCT) and high-intensity training (HIT) on postprandial lipemia, vascular function and arterial stiffness after high-fat meal (HFM) ingestion in inactive adults. **METHODS**: A randomized clinical trial was conducted in 20 healthy, inactive aged adults (31.6 ±7.1 years). Participants completed two exercise protocols, namely, HIT and MCT, for 12 weeks. To induce a state of postprandial lipemia (PPL), all subjects received an HFM containing 1049 kcal, 31 g of protein, 79 g of fat (31 g of saturated fat), 666 mg of cholesterol and 69 g of carbohydrates. Endothelial function was measured using flow-mediated vasodilation (FMD), normalized brachial artery FMD (nFMD), aortic pulse wave velocity (PWV) and augmentation index (AIx). Plasma total cholesterol, High-density lipoprotein cholesterol (HDL-c), triglycerides and glucose were also measured. The effects of the HFM were measured in a fasted state and 60, 120, 180, and 240 minutes postprandially. **RESULTS**: The area under the curve from 0 to 240 minutes [AUC$_{(0-240)}$] for glucose was lower after HIT than after MCT (10%, P=0.008). FMD and nFMD AUC$_{(0-240)}$ were increased in HIT compared with MCT (46.9%, P=0.021 and 67.3%, P=0.009, respectively). Regarding between-group differences, the results showed for glucose, and nFMD. In addition, the average delta of nFMD value was significantly higher in HIT than MCT (P = 0.03) **CONCLUSIONS**: Supervised exercise-training mitigate endothelial dysfunction and glucose response induced by PPL. Exercise intensity plays an important role in these protective effects, suggesting that HIT might be more effective than MCT in reducing postprandial glucose levels and attenuating vascular impairments.

The Acute Effect of Moderate Intensity Stair-Climbing on Postprandial Blood Glucose

Jeff Moore, Eric Bartholomae, Kathryn Ward, Zach Johnson, Jochen Kressler. San Diego State University, San Diego, CA.
(No relevant relationships reported)

PURPOSE: To investigate the effects of moderate intensity stair-climbing of various durations on postprandial glucose response in healthy men and women. The postprandial glucose response is strongly associated with cardiometabolic disease risk. **METHODS**: Twenty males (26.8±6.0y) and fourteen females (24.8±4.5y) completed a 75g oral glucose tolerance test (OGTT). On three subsequent visits, participants completed an OGTT combined with either 1min, 3min, or 10min of stair-climbing, all ending 28 min after subjects finished the drink. Fingerstick blood glucose measurements were taken at baseline and every fifteen minutes thereafter for one hour. **RESULTS**: All stair-climbing trials reduced peak (30 min) postprandial blood glucose levels compared to the control (12±31 to 35±30mg/dL, p≤.001-.038). At the 45min time point, there were significant reductions compared to the control for the 3 and 10min trials (11±29 and 23±30mg/dL, p=.037 and p≤.001), but not between 1min and control (2±33mg/dL, p=.701). No significant differences exist in BG between any trials at baseline, 15, or 60min time point (Δ=-0.3- 5.1mg/dL, p=.391-.882). There were significant differences in AUC compared to the control for the 3min and 10min trials (436±1126and 896±1108mg/dL*min, p=.036 and p≤.001) but not for the 1min (272±1112mg/dL*min, p=.177). For iAUC, there were significant differences compared to the control for the 3 min and 10 min trials (424±1124 and 901±903mg/dL*min, p=.038 and ≤.001) but not for the 1 min (107±918mg/dL*min, p=.509). **CONCLUSIONS**: Moderate intensity stair-climbing bouts as short as one minute in duration are effective at attenuating peak postprandial blood glucose with longer bouts producing more substantial benefits.

Increase In Beta-hydroxybutyrate After High-fat Meal In Metabolically Healthy Overweight/obese Adults

Ryan Davies, Stephanie Wilson, Sarah Bronsky, Seth Walk, Carl Yeoman, Mary P. Miles, FACSM. Montana State University, Bozeman, MT.
(No relevant relationships reported)

Ketone synthesis is of interest for several clinical purposes including obesity, weight loss and diabetes. Beta-hydroxybutyrate (BHB) is the predominant ketone found in the blood and an indicator of ketone synthesis, which is elevated when carbohydrate availability is low. However, little is known about ketone synthesis in metabolically healthy overweight/obese (MHO) adults with mixed diets.
PURPOSE: To investigate BHB concentrations and responses to a high-fat meal in MHO adults.
METHODS: Adults (n=23), 23-54 y of age with BMI 27-35 kg·m^{-2} were assessed for body composition, self-reported physical activity level, and VO$_2$max. After Fasting blood collection, a high-fat meal (50g fat, 54g carbohydrate, and 12g protein) was consumed and blood was collected hourly for 4 hours for measurement of glucose, insulin, triglycerides, and BHB.
RESULTS:

Metabolic Responses to High-Fat Meal					
Time (h)	0	1	2	3	4
BHB (mmol/L)	.23 (.01)	.23 (.01)	.22 (.01)*	.25 (.01)	.31 (.02)*
GLU (mg/dl)	96.9 (1.5)	108.4 (3.6)*	95.6 (2.7)	93.0 (1.6)*	91.9 (1.5)*
TG (mg/dl)	139.4 (16.8)	158.1(17.2)*	193.7 (19.8)*	216.1 (24.0)*	225.0 (32.2)*
INS (µU/ml)	8.1 (1.3)	35.3 (4.7)*	18.1 (2.9)*	10.4 (1.5)	8.2 (1.4)
Values = mean (SEM); *p <0.05 compared to time 0					

Glucose and insulin both increased 1 hour after a high-fat meal. At 2 hours post meal, insulin was still elevated and BHB decreased. At 3 and 4 hours post-meal, glucose decreased below fasting levels and BHB elevated above fasting levels. These data indicate that there was an inverse relationship between BHB with blood glucose and insulin levels, and that a potential rebound increase in BHB occurred when blood glucose dropped below fasting levels and insulin returned to baseline. Blood TG increased at each measurement over the course of 4 hours.
CONCLUSION: These findings support a pattern in the sequence of metabolic responses to a high-fat meal of increased then decreased blood glucose and insulin levels followed by increased BHB. An unexpected increase in blood BHB 4 hours after a single high-fat meal containing a significant amount of carbohydrate warrants additional research.

Postprandial Serum Concentrations of Trimethylamine N-oxide in Metabolically Healthy Adults with Low and High Inflammation

Stephanie Wilson, Jesse Peach, Brian Bothner, Adam Maes, Carl Yeoman, Seth Walk, Sarah Bronsky, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*

(No relevant relationships reported)

Trimethylamine (TMA) is a bioactive amine made by gut microbes that is converted to trimethylamine-N-oxide (TMAO) in the liver. The conversion of TMA to TMAO is downregulated by insulin. TMAO is pro-inflammatory and has been linked with the development of atherosclerosis. It is hypothesized that TMAO may be an underlying factor differentiating metabolically healthy overweight or obese (MHO) individuals with low (LO) versus high (HI) systemic inflammation. **PURPOSE**: To compare serum TMAO concentrations and metabolic responses to a high fat meal challenge between LO and HI MHO individuals. **METHODS**: Adults (n=25), 28-54 years old with BMI 27-35 kg·m^{-2} were measured for interleukin (IL)-1β, IL-6, IL-17, IL-23, tumor necrosis factor-α (TNF-α), and granulocyte-macrophage colony-stimulating factor (GM-CSF) measured after an overnight fast. A subsample of individuals was grouped to LO (n=5; above median in ≤ 1 of 6 cytokines) and HI (n=4; above the median in ≥ 5 of 6 cytokines). Blood samples were collected immediately before ingestion of a high-fat meal (50g FAT, 54g CHO, 12g PRO) and hourly for 4 hours postprandial for measurement of TMAO, glucose (GLU), insulin (INS), and triglycerides (TG). TMAO concentrations were determined through ultra-high performance liquid chromatography-tandem mass spectrometry. **RESULTS**: Fasting TMAO concentrations were similar in HI compared to LO (11.0 ± 5.5 vs 5.9 ± 2.8 μmol·l^{-1}). After correction for fasting insulin concentrations and removal of one outlier participant, TMAO decreased from fasting (9.6 ± 2.2 μmol·l^{-1}) to 1 h (p=0.061; 6.2 ± 1.1 μmol·l^{-1}) and 3 h (p=0.04; 3.7 ± 0.9 μmol·l^{-1}). Postprandial increases (p<0.05) were measured for glucose at 1 h, insulin and 1-2 h, and TG at 1-4 h. **CONCLUSION**: Our preliminary analysis indicates that TMAO concentrations were not higher in MHO individuals with higher inflammation. However, TMAO decreased in the postprandial period after insulin was elevated. Thus, TMAO concentrations fluctuate postprandially and its influence on inflammation warrants further investigation, particularly to determine if TMAO synthesis increases with insulin resistance.

Obese Hispanic Females Improved Plasma Glucose and Lipid Profiles Following Aerobic Exercise Training

Yonghyeon Jo[1], Kaylee Clyma[1], Katie Martin[1], Kyung-sin Park[2], Yunsuk Koh[1]. *[1]Baylor University, Waco, TX. [2]Texas A&M International University, Laredo, TX.*

(No relevant relationships reported)

Obesity is strongly associated with elevated morbidity and mortality, especially, within the population of Hispanic women. Although exercise can improve obesity, the role of different intensities of exercise in plasma glucose and lipid profiles has not been explored in the obese Hispanic population. **PURPOSE:** To examine the effects of 12-week aerobic exercise training at low- and high- intensity on plasma glucose and lipid profiles in obese Hispanic females. **METHODS:** Thirty sedentary, obese females (age = 26.07±4.4 years, height = 161.4±4.1cm, body weight = 89.8±8.1kg, and % body fat = 40.9±4.9%) were randomly assigned to three groups: control (n=10, no exercise), low-intensity (LI, n=10, 50% VO$_2$max), and high-intensity exercise (HI, n=10, 70% VO$_2$max). Participants in low- and high-intensity exercise groups performed a supervised treadmill exercise training for 12 weeks according to the following progressive exercise protocol: weeks 1 - 4 (3 days per week to expend 13.5 METs·hr/w), weeks 5 - 8 (4 days per week to expend 18.0 METs·hr/w), and weeks 9 - 12 (5 days per week to expend 22.5 METs·hr/w). Overnight fasting blood samples were collected at pre- and post-exercise training (POST). Changes in plasma glucose and lipid parameters, including total cholesterol (TC), lipoprotein (a) [Lp(a)], low-density lipoprotein cholesterol (LDL-C), and high-density lipoprotein cholesterol (HDL-C) were analyzed using a 2 x 3 analysis of variance with repeated measures along with a Tukey post-hoc test (*p* < 0.05). **RESULTS:** Both LI and HI groups decreased body weight up to 2.1 and 3.4kg, respectively. TC at POST in the LI group (116.53±5.32 mg/dL) was significantly lower (*p*=0.012) than in the control (139.12 mg/dL). The LI group also had significantly lower LDL-C at POST (50.25±5.24 mg/dL) than the control (67.17±5.24 mg/dL, *p*=0.006) and the HI group (62.83±5.24 mg/dL, *p*=0.036), respectively. Plasma glucose at POST in both LI (75.32±2.71 mg/dL, *p*= .024) and control groups (80.1±2.71 mg/dL, *p*=0.001) was lower than in the

HI group (90.77±2.78 mg/dL). **CONCLUSION:** Although the 12-week aerobic exercise training at either low- or high-intensity can improve body weight and body composition, it seems that low-intensity exercise training can provide more favorable effects on plasma glucose and lipid profiles in obese Hispanic women.

939   Board #200   May 30 2:00 PM - 3:30 PM

Downregulation Of Angptl6 Expression By Exercise In Mice And Human

Byung Il Yeh[1], Min-Jeong Kim[2], Jae-Seung Chang[1], Jun Namkung[1], Kyu-Sang Park[1], In Deok Kong[1]. *[1]Yonsei University Wonju College of Medicine, Wonju, Korea, Republic of. [2]Sungkyunkwan University School of Medicine, Suwon, Korea, Republic of.*

(No relevant relationships reported)

Angiopoietin-like protein 6 (ANGPTL6) has been introduced as an anti-obesity and insulin-sensitizing hepatokine in mice models. But in human studies, paradoxical upregulations of ANGPTL6 were reported in type 2 DM and metabolic syndrome. Although these phenomena have been understood as compensatory ones, regulatory mechanisms still remain unclear. **PURPOSE**: The objective of this study is to investigate the changes of ANGPTL6 levels by exercise in mice and human. **METHODS**: 1) Animal study: Male C57BL/6 mice were grouped into standard chow diet-fed, high fat diet-fed, and high fat diet-fed with swimming exercise. After 12 weeks of intervention, serum and liver tissues were harvested for analysis. 2) Human study: 20 healthy female subjects (47.75±2.09 years) performed one hour of supervised aerobic exercise four to five times per week for 12 weeks. Pre and post-training measurements were made. **RESULTS**: 1) Animal study: Swimming exercise significantly inhibited weight gain (final body weight 36.61±0.61 vs. 29.46±0.56g, p<0.001) and visceral fat accumulation on high fat diet in mice. Increased serum leptin levels on high fat diet were diminished on exercise intervention (41.5±6.3 vs. 28.1±4.5ng/mL, p<0.001). Hepatic *Angptl6* expressional profile showed same trend of leptin (relative expression 1.00±0.06 vs. 0.72±0.04, p<0.01). 2) Human study: After training program, there was a significant increase in maximal exercise capacity (VO$_2$max 31.25±1.18 vs. 35.51±1.17ml/min/kg, p<0.001) with decreased body mass index (24.80±0.66 vs. 24.05±0.64kg/m^2, p<0.001). Serum leptin (7.49±1.24 vs. 5.22±0.69ng/ml, p=0.022) and ANGPTL6 (414.02±24.93 vs. 348.25±18.45ng/ml, p=0.015) concentrations were significantly decreased by exercise intervention. **CONCLUSIONS**: Our study shows that habitual exercise significantly decreases ANGPTL6 expression in mice and human. As alterations of leptin were accompanied with ANGPTL6 changes, regulation of ANGPTL6 might be related to leptin signaling.

Coagulation Activation Pathway May Be Altered in Individuals Comorbid with HIV and Type 2 Diabetes

Anthony S. Wolfe, Julie A. Zuniga, Michelle L. Harrison. *The University of Texas at Austin, Austin, TX.* (Sponsor: Edward F Coyle, FACSM)

(No relevant relationships reported)

The expected lifespan of persons living with human immunodeficiency virus (PLWH) has increased significantly due to improved treatment options. However, an unintended consequence has been an increased prevalence of chronic diseases such as type 2 diabetes mellitus (T2D). It is therefore important to explore underlying biological mechanisms for this increased risk of T2D among PLWH as it is not yet well understood. Investigation of specific biomarkers may help define the pathogenesis of T2D in PLWH and yield positive outcomes including the detection of at risk individuals as targets of early interventional strategies along with identification of new diagnostic criteria. **PURPOSE:** The aim of this research was to identify specific biomarkers which differentiate PLWH and those comorbid with HIV and T2D (PLWH+T2D). **METHODS:** 16 PLWH (47.9±2.7 y/o; 10 male) and 16 clinically diagnosed PLWH+T2D (53.6±1.4 y/o; 10 male) were recruited for the study. Blood was drawn via venipuncture for assessment of HbA1c and biomarkers associated with inflammation (IL-1β, IL-6, hsCRP, insulin, adiponectin, leptin, and TNF-α, along with soluble receptor counterparts sIL-1RI, sIL-1RII, sIL-6RI, sTNF-RI, and sTNF-RII), vascular function (ADAMTS13, slCAM-1, sVCAM-1, SAA, and, SAP), and coagulation activation (fibrinogen, D-dimer, and, vWF). **RESULTS:** As expected, HbA1c was lower in PLWH (5.8±0.1 vs 7.0±0.4%, p<0.05). As further confirmation of T2D diagnosis, all individuals in the PLWH+T2D group were taking prescribed oral diabetes medication. Predictably, hsCRP levels were elevated; however, not significantly different between groups (7.8±1.4 vs 11.0±2.8 mg/L, p>0.05). Differences were found between PLWH and PLWH+T2D in indicators of coagulation activation, specifically vWF (2.39±0.42 vs 3.88±0.55 mg/dL, p<0.05) and fibrinogen (1425±103.1 vs 1914±184.2 ng/mL, p<0.05). No significant differences between PLWH and PLWH+T2D were seen in any biomarkers associated with vascular function or inflammation. **CONCLUSIONS:** We believe this is the first time biomarkers of vascular function and coagulation activation have been assessed in this comorbid

WEDNESDAY, MAY 30, 2018

population. The significant increase in vWF and fibrinogen in PLWH+T2D suggests that pathways involving coagulation may be the first altered in the transition to this comorbid state.

Antibiotics Reduce While Forced-Exercise Increases Inflammation in the Small Intestine

Paul J. Wisniewski II[1], Laurie B. Joseph PhD[2], Stanley A. Lightfoot MD[3], Robert A. Dowden MS[1], John Guers PhD[4], Stephen F. Vatner MD[4], Sara C. Campbell PhD, FACSM[1]. [1]Rutgers University, New Brunswick, NJ. [2]Ernest Mario School of Pharmacy, Piscataway, NJ. [3]Oklahoma City VA Health Care System, Oklahoma City, OK. [4]Rutgers New Jersey Medical School, Cardiovascular Research Center, Newark, NJ. (Sponsor: Sara C. Campbell, PhD, FACSM)

(No relevant relationships reported)

Risk of metabolic and intestinal inflammatory disorder development increases significantly with age. In contrast, exercise has shown to reduce disease risk and promote longevity. Interestingly, adenylyl cyclase 5 knock out (AC5KO) mice demonstrate an enhanced exercise capacity and improved longevity. **PURPOSE:** We aimed to examine the inflammatory status along the gastrointestinal tract of AC5KO mice compared to Wild type (WT) mice. **METHODS:** 21 C57BL WT and AC5KO male mice were randomly assigned to one of 2 groups: (1) sedentary and (2) exercise for 12 weeks. Mice had *ad libitum* access to food and water. Exercised mice were trained for 4 weeks at 60-70% max speed for 1 hr each session, 5 d/wk. WT sedentary and exercised groups were given antibiotics via oral gavage during the last 7 days of the exercise protocol. At the end of 4 weeks, mice were sacrificed and intestinal tissues were fixed for histological analysis and immunohistochemistry for cyclooxygenase-2 (COX-2), a marker of inflammation. Group means of staining score were analyzed using a one-way ANOVA and LSD post hoc tests. A difference of mean with a p value of ≤ 0.05 was considered statistically significant. **RESULTS:** In the duodenum, COX-2 expression was isolated in the lamina propria and staining occurred predominately within macrophages. COX-2 expression in the duodenum was less in sedentary animals given antibiotics ($p \leq 0.015$). In the ileum, COX-2 expression was localized to both the crypts and lamina propria. Expression in ileal crypts was less in sedentary animals given antibiotics compared to WT exercised animals ($p = 0.02$) while expression in the ileal lamina propria was increased in WT exercised animals ($0.001 \leq p \leq 0.009$). **CONCLUSIONS:** Antibiotics reduce small intestinal inflammation. COX-2 expression localizes differently in the mucosa along the small intestine. Forced-exercise increases inflammation to a greater degree in the lamina propria of the distal small intestine.

Effects of Early Life Undernutrition on Maximum Treadmill Running Capacity in Mice

Logan A. Pendergrast, Joe R. Visker, Ashley N. Triplett, Eric C. Leszczynski. *Michigan State University, East Lansing, MI.*

(No relevant relationships reported)

Undernourishment in early life has been shown to impair cardiovascular function, which could potentially influence maximum exercise capacity in adulthood. **PURPOSE:** To determine the effects of early life undernutrition on maximal exercise capacity in adulthood. **METHODS:** Using a cross fostering model, pups were undernourished either during gestation (GUN) or lactation (PUN; PN1-21) by feeding the dam a low-protein diet (8% protein) to decrease milk production. Control pups were born and suckled to dams fed an isocaloric diet with 20% protein content. At postnatal day 21 (PN21), all mice were weaned and switched to a control diet. To assess exercise capacity, mice began a 5-day treadmill acclimation protocol at PN61. At PN67, mice underwent a maximum work test, which began at 10 meters/minute with a 10% grade. Speed was increased every two minutes until exhaustion. The amount of work completed by each mouse was calculated as: Maximum Work(J)= 9.8 x Maximum Speed (m/min) x grade(radians) x Time (min) x Weight (kg). A two-way ANOVA was used to determine differences in maximal work and cardiac parameters between groups with the effects of gender and diet. **RESULTS:** GUN (0.3312±0.037 J) mice performed higher than PUN (0.2527±0.050 J) and CON (0.2674±0.030 J) mice on a maximum work test (p<0.05). There was no gender effect. **CONCLUSION:** Undernourishment during lactation leads to lower work capacity, indicating that developmental programing during the first 21 days of life impairs work capacity during adulthood.

Metabolic and Microbial Responses to Exercise in C57 Wild-type and Adenylyl Cyclase 5 KO Mice

Robert A. Dowden[1], Paul. J. Wisnieski[1], John Guers[2], Macro Oydanich[2], Stephen F. Vatner[2], Lora McGuinness[1], Lee Kerkhof[1], Sara Campbell, FACSM[1]. [1]Rutgers, The State University of New Jersey, New Brunswick, NJ. [2]Rutgers, New Jersey Medical School, Cardiovascular Research Center, Newark, NJ. (Sponsor: Dr. Sara Campbell, FACSM)

(No relevant relationships reported)

Healthy aging has been observed in our adenylyl cyclase type 5 knock out (AC5KO) model. Aging is also associated with alterations in composition and diversity of the gut microbiota. The extent to which the microbiota contributes to the healthy aging phenotype is unknown. **PURPOSE**: To examine the role of the microbiota in diabetes and exercise tolerance in AC5KO mice compared to wild type (WT). **METHODS**: 17 (n=6/group) 6-week old C57BL/6J male WT and AC5KO mice were randomly assigned to one of the following four groups: (1) wild type-exercise (WT-EX), (2) wild type-sedentary (WT-CON), (3) AC5-exercise (AC5-EX) and (4) AC5-sedentary (AC5-CON). Mice underwent a treadmill test to determine maximal oxygen uptake (VO$_2$max) and max exercise performance (i.e. running distance). Mice were exercised via forced treadmill running at 60-70% VO$_2$max for 60-minutes 5 days/week, for 5 weeks. Following exercise training, mice were given oral antibiotics for five days to eliminate gut microbiota. Measurements were taken: 1- prior to exercise, 2- post training/pre-antibiotic and 3- post antibiotic. Fecal samples underwent phenol-chloroform extraction and ribosomal operons were amplified with 10 ng of genomic DNA using the universal 16S rRNA-27Forward primer, 23S rRNA-2241Reverse primer and a High Fidelity/Proofreading Taq polymerase. The MinION was used for library preparation and we used Poretools and Geneious sequence analysis software for sequencing. Finally, fasted glucose tolerance (i.p; 2 ul/kg [BW]) and insulin tolerance (i.p;1 ul/kg [BW]) were measured. **RESULTS**: AC5KO mice have a unique microbiota with *Helicobacter typhlonius & Bacteroides sartorii spp.* being dominant in AC5KO and not in WT mice. Furthermore, AC5-EX mice showed altered glucose tolerance (33325 vs. 23025 AUC, p<0.05) and reduced exercise performance (517m vs. 258m, p<0.05) following antibiotic treatment. Post antibiotic AC5-EX mice showed insulin sensitivity following antibiotic treatment. **CONCLUSION**: AC5KO mice have a unique microbiota compared to WT mice and their insulin/glucose control phenotype may be dependent on the microbiota.

Anti-apoptosis Effects Of Diosgenin In D-galactose-induced Aging Brains

Shin-Da Lee[1], Yi-Yuan Lin[1], Shiu-Min Cheng[2], Chih-Yang Huang[1]. [1]China Medical University, Taichung, Taiwan. [2]Asia University, Taichung, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of this study was to evaluate the effects of diosgenin on the D-galactose-induced cerebral cortical widely dispersed apoptosis.
METHODS: Male Wistar rats at 12-week-old were divided into four groups: Control (1 mg/kg/day of saline, i.p.), DD0 (150 mg/kg/day of D-galactose, i.p.), DD10 and DD50 (D-galactose+10 or 50 mg/kg/day of diosgenin orally). After eight weeks, histopathological analysis, positive TUNEL and Western blotting assays were performed on the excised cerebral cortex from all four groups.
RESULTS: TUNEL-positive apoptotic cells, the components of Fas pathway (Fas, FADD, active caspase-8 and active caspase-3) and mitochondria pathway (t-Bid, Bax, cytochrome *c*, active caspase-9 and active caspase-3) were increased in the DD0 group compared with the Control group whereas they were decreased in the DD50 group (p<0.05). The components of survival pathway (p-Bad, Bcl-2, Bcl-xL, IGF-1, p-PI3K and p-AKT) were increased in the DD50 group compared to the Control group, whereas the levels of Bcl-xL, p-PI3K and p-AKT were also compensatorily increased in the DD0 group compared to the Control group (p<0.05).
CONCLUSIONS:Taken together, diosgenin suppressed neuronal Fas-dependent and mitochondria-dependent apoptotic pathways and enhanced the Bcl-2 family associated pro-survival and IGF-1-PI3K-AKT survival pathways, which might provide neuroprotective effects of diosgenin for prevention of D-galactose-induced aging brain.

The Characterization of Normal Weight Obesity in College Students

Kara C. Anderson, Katie R. Hirsch, Malia N.M. Blue, Austin M. Peterjohn, Gregory L. Nuckols, Eric T. Trexler, Alexis A. Pihoker, Abbie E. Smith-Ryan, FACSM. *University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Abbie Smith-Ryan, FACSM)

(No relevant relationships reported)

While normal weight obesity (NWO) has become an important health topic, to date no data exist describing physiological characteristics among this group. **PURPOSE:** The primary aim was to characterize NWO in college-age males and females through body composition and cardiometabolic measures. The secondary aim was to observe the relationship between waist to hip ratio (WHR) and body mass index (BMI) with body fat percentage (BF%). **METHODS:** Ninety-two college students (Mean ± SD; Age: 19.5 ± 1.4 yrs.; Height: 171.9 ± 9.4 cm; Weight: 67.9 ± 8.2 kg, BF%: 26.0 ± 6.2 %; males n=29; females n=63) participated in this study. NWO was defined being above NHANES body fat 25th percentile based on age and sex. Body composition variables including BF%, lean mass (LM), and visceral adipose tissue (VAT) were assessed by dual energy x-ray absorptiometry. The same technician measured waist and hip circumferences. Mean arterial pressure (MAP) and metabolic biomarkers [total cholesterol (TC), high density lipoproteins (HDL), non-high density lipoproteins (NHDL), and glucose (GLU)] were evaluated for cardiometabolic health. Blood pressure was measured in a seated position with an automated cuff; biomarkers were assessed by a fasted blood draw. **RESULTS:** Forty percent of the sample (n=37) was identified as NWO, with 31% of the females (n=19) being NWO, whereas 62% of males (n=18) were. NWO individuals had significantly higher BF% (28.4 ± 6.7% vs. 24.4 ± 5.2%, p<0.001), VAT (0.20 ± 0.15 kg vs. 0.07 ± 0.10 kg, p=0.002), and larger WHR (0.76 ± 0.40 cm 0.72 ± 0.41 cm, p=0.003) compared to normal weight lean (NWL). Although not significant, NWO had higher LM (46.2 ± 8.5 kg; NWL: 41.7± 10.3 kg, p>0.05) and MAP (NWO: 84.4 ± 6.8 mmHg; NWL: 82.5 ± 7.0 mmHg, p>0.05) compared to NWL. NWO also had higher levels of GLU, and lower levels of TC, HDL, and NHDL; however, biomarkers were not significantly different between groups (p>0.05). While WHR was significantly correlated with BF% (R= -0.293, p=0.005), BMI was not (p>0.05). **CONCLUSION:** The occurrence of NWO among otherwise healthy college students is high. Identification of these individuals may be an effective approach to obesity prevention and treatment. Determining effective methods to measure both body fat and abdominal obesity in this population is essential, as BMI may mask obesity in a young adult population.

946   Board #207   May 30 2:00 PM - 3:30 PM

Effects of Acute Exercise and Green Tea Supplementation on Glucose Homeostasis in Overweight/Obese Postmenopausal Women

Shannon L. Jordan[1], Sarah E. Deemer[2], Vic BenEzra[3], David Nichols, FACSM[3]. *[1]Lamar University, Beaumont, TX. [2]The University of Alabama at Birmingham, Birmingham, AL. [3]Texas Woman's University, Denton, TX.* (Sponsor: David Nichols, FACSM)

(No relevant relationships reported)

Menopause is associated with decreased estrogen levels, increased adiposity, negative changes in adiponectin and TNF-α, and increased insulin resistance. Decreased adiponectin and increased TNF-α are associated with impaired glucose uptake. Exercise enhances glucose uptake several hours post-exercise. Polyphenols in green tea extract (GTE) increase insulin sensitivity and adiponectin while decreasing TNF-α. Orzechowski (2003) proposed using antioxidants as a "preconditioning" method to prevent development of Type 2 Diabetes (T2D). **PURPOSE:** To investigate independent and combined effects of acute exercise or GTE on glucose homeostasis and adipokines in overweight to obese postmenopausal sedentary women. **METHODS:** Eight women (52 ± 7 yrs, BMI 32.04 ± 4.95 kg/m²) were randomly assigned to complete four trials (Control [C], green tea [GT], exercise [EX], green tea + exercise [GTEX]). For each trial the participant consumed 400 mg of placebo (rice flour, C and EX) or green tea extract (GT and GTEX) with lunch and dinner the day prior and the morning of (1 hr prior) an oral glucose tolerance test (OGTT). Exercise trials (EX and GTEX) consisted of walking exercise at 65% heart rate reserve (400 Kcal) and were completed 12-14 hours prior to the OGTT. **RESULTS**: Fasting glucose (C 5.7 ±.8, GT 6.1 ± 1.7, EX 5.6 ± .8, GTEX 5.4 ± .8 mmol) and insulin (C 11.93 ± 4.75, GT 11.66 ± 6.17, EX 11.31 ± 4.12, GTEX 12.23 ±6.05μU/ml) were not different between trials as well as no differences in area under the curve for both glucose and insulin. There were also no differences between trials for TNF-α (C 5.45 ± 3.68, GT 4.73 ± 1.38, EX 3.55 ± 1.46, GTEX 3.87 ± 1.81 pg/ml) or total adiponectin (C 7443 ± 2941, GT 4497 ± 3070, EX 10060 ± 7393, GTEX 5335 ± 3193 ng/ml). **Discussion:** An acute bout of exercise or green tea supplementation may not be sufficient to see a favorable impact in glucose homeostasis or adipokines within this population. Elevated TNF-α (> 1.36 pg/ml) and low adiponectin levels observed in all trials may reflect an inflammatory state that could be associated with menopause. Inflammation is known to alter glucose metabolism. Postmenopausal woman present a unique challenge with prevention of T2D, as increased adiposity and decreased estrogen levels negatively effects adipokines, which negatively impacts glucose homeostasis.

Family History of Diabetes Does Not Affect Exercise-Induced Improvements in Insulin Sensitivity and Metabolic Flexibility

Manuel Amador[1], Cesar Meza[1], Mario Garcia[1], Christopher Figueroa[1], George King, FACSM[1], Andrew McAinch[2], Sudip Bajpeyi[1]. *[1]Universtiy of Texas at El Paso, El Paso, TX. [2]Victoria University, St. Albans Campus, Melbourne, Australia.* (Sponsor: George King, FACSM)

(No relevant relationships reported)

A Family History of Diabetes Does Not Affect Exercise Induced Improvement in Insulin Sensitivity and Metabolic Flexibility
Manuel Amador, Cesar Meza, Mario A Garcia, Christopher Figueroa, George King, Andrew McAinch, Sudip Bajpeyi
A family history of diabetes (FH+) is considered a risk factor to develop insulin resistance and type 2 diabetes. However, it is not known whether exercise induced improvement in insulin sensitivity (IS) and metabolic flexibility (MF) are impacted by a FH+, compared to those without (FH-).
PURPOSE: To determine if a FH+ limits exercise induced improvements in IS, MF, body composition, and strength following an 8-week combined aerobic and resistance training intervention.
METHODS: 19 sedentary, normoglycemic, Mexican-American males underwent 8 weeks of combined exercise training 3 times/week (35-min aerobic & 45-min resistance training/session). A controlled diet was provided 5 days before pre/post intervention tests. IS was assessed by hyperinsulinemic euglycemic clamp. MF was assessed by change in respiratory quotient (ΔRQ) at the insulin stimulated state of the clamp compared to the fasted state. Body composition was measured using DXA. Upper/lower body strength were measured by 1 repetition maximum bench press and leg strength dynamometer.
RESULTS: IS is significantly improved in both groups (FH- 2.95±31 to 3.84±0.31ml/ kg estimated mean body size (EMBS), p=0.03; FH+ 3.6±0.5 to 4.8±0.5ml/kg EMBS; p=0.002). MF significantly improved in both groups (FH- 0.72±0.009 to 0.78±0.008, p=0.001; FH+ 0.70±0.01 to 0.80±0.02, p=0.0001). Fat free mass significantly improved in both groups (FH- 56.6±2.1 to 58.5±2.1kg, p=0.01; FH+ 51.8±1.95 to 53.4±1.79kg, p=0.01). Upper body strength (FH- 172.78±20.95 to 200.56±20.74lb, p=0.0001; FH+ 136.5±14.06 to 168.33±15.29lb, p=0.0001) and lower body strength (FH- 368.89±31.02 to 431.11±22.58lb, p=0.007; FH+ 341.0±22.03 to 412.78±16.22lb, p=0.0001) significantly increased in both groups. Degrees of improvement in IS was not different between groups (FH- 28.3±13.6% vs. FH+ 41.66±11.9%; p>0.05).
CONCLUSION: FH+ is not a limiting factor for exercise induced improvements in IS, MF, body composition, and strength in normoglycemic Mexican Americans.

Physical Activity and Glycemic Control in Low Versus High Inflammation Phenotypes in Metabolically Healthy Adults

Morgan Chamberlin, Jamie Ritter, Adam Maes, Stephanie Wilson, Sarah Bronsky, Seth Walk, Carl Yeoman, Mary P Miles, FACSM. *Montana State University, Bozeman, MT.*

(No relevant relationships reported)

Metabolically healthy overweight or obese (MHO) individuals may be studied to better understand the relationship of low-level inflammation to physical activity (PA) and fitness, metabolic syndrome, glycemic control, and postprandial responses. It was hypothesized that individuals with lower inflammation would have greater volume of PA, cardiorespiratory fitness (VO₂max), and metabolic health.
PURPOSE: To compare PA, VO₂max, glycosylated hemoglobin (HbA1c), metabolic syndrome criteria, and metabolic responses to a high-fat meal between low (LO) and high (HI) inflammation phenotypes within a group of MHO adults.
METHODS: Adults (n=25), 23-54 y of age with BMI from 27-35 kg·m⁻² were assessed for body composition, self-reported PA, VO₂max, and fasting/resting concentrations of interleukin (IL)-1β, IL-6, IL17-, IL-23, tumor necrosis factor-α (TNF-α), and granulocyte-macrophage colony stimulating factor (GM-CSF). LO (n=11) were below the group median for ≥ 4 of the cytokines; HI (n=12) above for ≥ 4. Two participants were between phenotypes. After fasting blood collection, a high fat meal (50 g fat, 54 g carbohydrate, and 12 g protein) was consumed and 4 hourly, postprandial blood samples were collected for measurement of glucose, insulin, and triglycerides (TG).
RESULTS: Mean cytokine concentrations were 1.8 to 4.3-fold higher (p<0.05) in HI compared to LO for IL-1β, IL-6, IL17-, IL-23, TNF-α, but not (p=0.12) GM-CSF. The frequency of aerobic activity was higher (p<0.05; mean ± SEM; 5.2 ± 0.5 vs 3.1 ± 0.4

d·wk⁻¹) while VO₂max was similar (p=0.21; 42.9 ± 2.7 vs 38.3 ± 2.2 ml·kg·min⁻¹) for LO vs HI. Contrary to our hypothesis, LO were higher (p<0.05) in HbA1c (5.38 ± 0.08 vs 5.10 ± 0.07%) and 1-h postprandial glucose (116.6 ± 5.7 vs 102.1 ± 3.5 mg·dl⁻¹). TG and insulin responses, BMI, body fat (%), visceral adipose (l), and metabolic syndrome criterion scoring for waist circumference, blood pressure, and fasting TG, glucose and HDL were similar between groups.
CONCLUSION: The current data support the beneficial influence of physical activity on inflammation; however, the unexpected finding of healthier glycemic control in individuals with higher inflammation warrants additional research.

Reduced Insulin Sensitivity in Young, Normoglycemic Subjects, Alters Tissue Oxygenation During Post Occlusive Reactive Hyperemia

Esther E. Wu[1], Thomas J. Barstow, FACSM[2], Dana K. Townsend[1]. [1]Wheaton College, Wheaton, IL. [2]Kansas State University, Manhattan, KS. (Sponsor: Thomas J. Barstow, FACSM)

(No relevant relationships reported)

INTRODUCTION: Near-infrared spectroscopy (NIRS) measures of the tissue oxygen saturation ([StO₂]) reperfusion rate during post occlusive reactive hyperemia (PORH) has recently been correlated with flow mediated dilation (%FMD) of the popliteal artery (McLay et.al. 2016). Cardiovascular disease is associated with impairments in %FMD. Reduced insulin sensitivity may negatively affect the vascular system for many years prior to a pre-diabetic/diabetic diagnosis. **PURPOSE:** To determine if static and dynamic, [StO₂] parameters during PORH are correlated with metabolic markers in healthy, young, normoglycemic subjects. **METHODS:** Glucose (G) and insulin (I), both in fasting (F) conditions and during an oral glucose tolerance test (OGTT), were measured in twenty-three, young (18-26y), healthy subjects (12M/11F). Each subject underwent upper limb, PORH with oxy- ([O₂Hb]) and deoxy- [hemoglobin + myoglobin], ([HHb]) measured in the skeletal muscle of the antebrachium by NIRS. [StO₂] was calculated [O₂Hb]/ Total hemoglobin ([O₂Hb] + [HHb]) at rest, during the cuff, and during PORH. Parameters describing the amplitude and time course of the response were measured. Hepatic insulin sensitivity (ISI_HOMA), whole body insulin sensitivity (Matsuda Index), area under the curve for I and GLU, FI and FG and 2-HR GLU were measured. **RESULTS:** FI (range 2.43 - 12.51 µIU/ml) was significantly negatively correlated (r=0.43, P=0.02) with the amount of change of [StO₂] during reperfusion (Δ [StO₂]) (range 13.94 - 38.66%) and significantly positively correlated (r=0.52, P=0.005) with the minimum [StO₂], a measure of extraction, during the cuff (Min [StO₂]) (range 35.97 - 61.87%). ISI_HOMA (range 0.37-2.07) was significantly positively correlated (r=0.57, P=0.002) with Δ [StO₂] and significantly negatively correlated (r=0.56, P=0.006) with Min [StO₂]. There was no significant correlation between any metabolic parameter and [StO₂] upslope (initial slope of [StO₂] following cuff release). **CONCLUSIONS:** Δ [StO₂], a measure of the amount of reperfusion, and Min [StO₂], a measure of extraction during the cuff, were correlated with FI and ISI_HOMA, two of the longest used markers of metabolic function. NIRS-derived [StO₂] may be a useful tool for assessing levels of reduced insulin sensitivity in normoglycemic, young adults.

Lower Glucose Tolerance in Normoglycemic, Healthy Hispanics with a Family History of Type 2 Diabetes

Cesar Meza[1], Manuel Amador[1], Mario Garcia[1], Christopher Figueroa[1], Andrew McAinch[2], Sudip Bajpeyi[1]. [1]University of Texas at El Paso, El Paso, TX. [2]Victoria University, St Albans, Australia.

(No relevant relationships reported)

Obesity and type 2 diabetes are associated with impaired glucose homeostasis and blood lipid profiles. Further, a family history of diabetes (FH) increases the risk for development of insulin resistance. However, it is unclear whether differences in glucose tolerance, blood glucose and lipid profiles exist between individuals with/ without a FH.
PURPOSE: To investigate whether a FH impairs glucose tolerance and blood lipid profile in healthy, sedentary Hispanic males.
METHODS: 22 sedentary, normoglycemic, Mexican American males (mean±SEM: age:23±0.56 yrs; BMI: 26.9±0.98 kg/m²) with/without FH participated in the study. Glucose tolerance was assessed by calculating glucose area under the curve (AUC) following an oral glucose tolerance test. Participants were fed a 5-day standardized diet (55/15/30% Carbohydrate/Protein/Fat) before testing. Serum was collected for analysis of blood glucose and lipid panels by a diagnostic center (Lab Corp, Burlington, NC).
RESULTS: AUC was significantly greater in individuals with a FH compared to controls without FH (FH- vs FH+: 311.91±7.30 vs 355.35±11.91 AU; p=0.008). Fasting glucose (75.9±2.07 vs 79.1±2.85 mg/dL; p=0.40) and HOMA-IR (2.64±0.48

vs 1.81±0.19 AU; p=0.26) were not different between groups. There was no difference in fasting insulin between groups. Lastly, no differences in total cholesterol (p=0.18), triglycerides (p=0.28) or LDL cholesterol (p=0.24) were detected regardless of FH.
CONCLUSION: Fasting glucose, insulin, insulin resistance measure by HOMA-IR, and lipid profiles were not different between individuals with and without a FH. However, glucose AUC may be an early indicator of risk for developing insulin resistance in young adults with a family history of type 2 diabetes, despite an otherwise normal clinical health status.

Restricted Carbohydrate Diet and Exercise Improves Metabolic and Inflammatory Profiles in Metabolic Syndrome

Lauren Miutz[1], Alex Eason[2], Mark Baker[2], Deborah Lown[2], Amy M. Gyorkos[2]. [1]University of Calgary, Calgary, AB, Canada. [2]Grand Valley State University, Allendale, MI. (Sponsor: Timothy J. Michael, FACSM)

(No relevant relationships reported)

One approach to slow the pandemic of obesity and chronic disease is to look to our evolutionary past for clues of the changing behaviors contributing to the emergence of 'diseases of civilization'. Diet and exercise that resemble our ancestral behaviors independently reduce risk factors for the development of chronic disease. To date, little research has examined the effects of combining a Paleolithic diet with high intensity exercise. **PURPOSE**: The purpose of this study was to investigate the effects of diet and exercise patterns that more closely resemble those of our evolutionary past on inflammatory and metabolic profiles in individuals characterized as having Metabolic Syndrome (MetS). **METHODS**: Eleven subjects with MetS followed a crossover design with two 4-wk interventions, including a restricted carbohydrate Paleolithic-based diet (RCPD; ≤50gCHO) with high intensity interval training (RCPD-Ex) and a RCPD diet with sedentary activity (RCPD-Sed), separated by a 4-wk washout period. A two-way analysis of variance with repeated measures was performed with post-hoc analysis using simple effects analysis with a Bonferroni adjustment. The level of statistical significance was established a priori as $P < 0.05$. Values are reported as means ± SD. **RESULTS**: Compared to baseline, RCPD-Sed and RCPD-Ex improves VO²_max by 22% and 29% (28 ± 5.5, 31 ± 6.1 mL·kg-1·min-1), respectively and improves metabolic markers including waist adiposity (-15%, -18%), weight loss (-3%, -5%), body fat % (BF%; -7%, -12%), fasting plasma glucose (GLU; -20%, -27%), triglycerides (TG; -47%, -52%), HDL-C (+22%, +36%), mean arterial pressure (MAP; -28%, -34%), fasting insulin (-34%, -39%), HOMA-IR (-37%, -41%), adiponectin (+33.7%, +38%), and leptin (+33.7%, +38%), levels, respectively when compared to baseline. RCPD-Sed and RCPD-Ex also improves inflammatory markers reducing hsCRP by -32% and-36% (2.8 ± 1.4, 2.5 ± 1.4 pg/mL), TNF-alpha by -35% and -41% (2.3 ± 0.6, 1.9 ± 0.4 pg/ml), and IL-6 by -29% and -40% (2.7 ± 0.8, 2.1 ± 0.6 pg/ml), respectively, when compared to baseline. **CONCLUSION**: Adopting behaviors from our evolutionary past, including diet and exercise, shows favorable metabolic and inflammatory profiles in those that characterize with MetS.

Metabolic Inflexibility Among Obese Pregnant Women May Lead to Unfavorable Downstream Metabolic Outcomes

Rachel A. Tinius[1], Maire Blankenship[1], Bailey Pitts[1], Alyssa Olenick[1], Donald L. Hoover[2], Kevin J. Pearson[3], W. Todd Cade[4], Jill M. Maples[1]. [1]Western Kentucky University, Bowling Green, KY. [2]Western Michigan University, Kalamazoo, MI. [3]University of Kentucky, Lexington, KY. [4]Washington University School of Medicine, St. Louis, MO.

(No relevant relationships reported)

PURPOSE: The inability to upregulate fat oxidation in response to a high-fat meal during pregnancy (i.e. metabolic inflexibility) may result in a positive lipid balance and excessive gestational weight gain (GWG); both of which may lead to long-term obesity. Metabolic inflexibility may also lead to lipid accumulation and subsequent impaired insulin signaling; playing a role in exaggerated insulin resistance during pregnancy. With obesity, excessive GWG, and insulin resistance being some of the most common and concerning obstetric issues, understanding mechanisms that contribute to these conditions is vital. The purpose of this study was to determine the role of obesity on metabolic inflexibility during pregnancy, and how metabolic inflexibility may contribute to subsequent maternal and neonatal outcomes.
METHODS: After an overnight fast, baseline lipid oxidation (via indirect calorimetry) and insulin resistance (HOMA-IR) were assessed in pregnant women (32-39 weeks gestation). A high-fat shake was consumed (62% fat) and the same metabolic parameters were assessed 4 hours post-shake consumption. Metabolic inflexibility was calculated as fold change in lipid oxidation from baseline to 4-hours post high-fat shake. **RESULTS**: Participants included 56 pregnant women: 31 lean (pre-pregnancy BMI= 22.3±1.6 kg/m², age= 30.1± 4.6 y), 11 overweight (pre-pregnancy BMI=

26.9±1.2 kg/m², age: 29.9 ±1.0 y), and 14 obese women (pre-pregnancy BMI= 35.9± 5.3 kg/m², age= 29.0 ± 3.6 y). Fasted lipid oxidation values were higher among obese women (0.09±0.03g/min) compared to lean women (0.07±0.04g/min) (p=0.05), and were positively correlated to GWG among all participants (r=0.38, p<0.01). Obese pregnant women were less able to upregulate fat metabolism in response to the high-fat meal (i.e. metabolically inflexible) compared to lean women (fold change in lipid oxidation- lean: 59.6 ± 50.6% vs. obese: 36.5 ± 49.9%, p=0.06). There was a trending relationship between metabolic inflexibility and insulin resistance (r=0.33, p=0.07). Data collection and analysis are ongoing. **CONCLUSIONS**: Obese pregnant women failed to upregulate lipid metabolism to the same extent as lean pregnant women in response to a high-fat meal. This "metabolic inflexibility" may contribute to unfavorable maternal and neonatal outcomes.

Exercise And Diet In Circadian Control Of Postprandial Glycemia

Katarina T. Borer[1], Naveen Sharma[2], Andrew Stefan[1].
[1]University of Michigan, Ann Arbor, MI. [2]Central Michigan University, Mount Pleasant, MI.
(No relevant relationships reported)

PURPOSE: On the recommended 45 to 65% high-carbohydrate, low-fat diets, evening meals, but not morning meals, produce glucose intolerance (GLU-INT). We have recently tested the hypothesis that the high carbohydrate (CHO) content of the diet contributed to evening postprandial GLU-INT and found a 30% reduction in evening postprandial insulin and in HOMA-IR measure of insulin resistance after one day of low (30%), relative to 60% CHO diet (Lin & Borer, PLoS ONE 2016). Two hours of exercise before the two daily meals did not alter this dietary effect but increased GLU-INT after both diets. The purpose of the present study was to test the hypothesis that (1) one day of low-CHO diet will reduce postprandial insulin and glucose at both extremes of the circadian period, and (2) that exercise after the meals will lower or eliminate evening GLU-INT.
METHODS: Subjects were 8 postmenopausal women who for 24 h ate a 25%-CHO diet with the final meal at 7 am or 7 pm . Meal was followed by 10-minute blood collection over 4.5 hours for measurement of glucose and insulin. Two trials were sedentary and in two others 1 h of moderate-intensity exercise started 40 minutes after the test meals. Glucose oxidase was used to measure glucose and radioimmunoassay for insulin.
RESULTS: Circadian time had no effect on postprandial insulin in either sedentary or exercise trials. However, postprandial GLU-INT was observed after evening compared to morning meals. Post-meal exercise attenuated by about 50%, but did not abolish, evening GLU-INT.
CONCLUSIONS: Evening postprandial GLU-INT persists even on 25%-CHO diet. Higher postprandial insulin resistance after evening relative to morning meal reflects higher plasma glucose but unchanged insulin response in the evening compared to morning. One h of exercise after the meals attenuated, but did not eliminate, evening postprandial GLU-INT. Therefore, a combination of low-CHO diet and post-meal, but not pre-meal, exercise reduces evening GLU-INT.

The Postprandial Glycemic Response to Acute Bout of Exercise in Healthy Adults

Rui Li, Hannah Doolittle. *Northeastern University, Boston, MA.*
(No relevant relationships reported)

Short bouts of exercise can better fit into a busy schedule and have been shown health benefits for glycemic control. However, postprandial glycemic response to a short bout of exercise during mid-day remains to be explored. **Purpose**: This study was to examine glucose responses to short bouts of exercise following different meals at lunch time among healthy adults. **Methods:** Ten healthy young adults (28.2±7.7 yrs) participated in the study with a 2×2 factorial design. Each participant completed four different trials on nonconsecutive days with a different meal and exercise combination. The meal offered was either a standard burger, approximately 740 calories or a prepacked Mediterranean Sandwich, approximately 560 calories. Thirty minutes after the meal, the participants performed either a 10-min treadmill walking at 3 mph with no incline or a 10-min stair stepping on a 7-inch step at a cadence of 92 steps per minute. The combination of meal and exercise was randomized for each trial. Blood glucose was monitored at baseline, 5 minutes post meal, 30 minutes post meal, 5 minutes during exercise, immediately post exercise and 15 minutes post exercise. Blood pressure, heart rate, RER, and VO_2 were also monitored at the corresponding time points. **Results:** Statistical analysis was performed to determine the effect of diet and exercise on glycemic response. Blood glucose level (mg/dL) was measured as 95.13 ± 20.46 at baseline with a significant increase at 30 min post meal (112.73 ± 20.54, P = 0.00). Blood glucose was significantly reduced at 5 min during exercise (105.43 ± 20.06, P=0.024), immediately post exercise (94.51 ± 23.6, P = 0.00) and 15 min post exercise (102.97 ± 17.34, P = 0.005) compared with 30-min post-prandial blood glucose. Multivariate analysis shows a significant main effect for exercise (P =

0.037). No significant effect was found for diet (P = 0.305) or interaction of diet by exercise (P = 0.386). Post hoc analysis further revealed that the only exercise effect was found at 5 min post meal, which was disregarded due to no true exercise effect. **Conclusion:** The finding suggests that a 10-min short bout of exercise significantly lowered post-prandial blood glucose among healthy individuals during midday. The types of the meal consumed and exercise performed made no difference on glycemic responses.

Low-Calorie Diet Plus Interval Exercise Training Improves Metabolic Flexibility and Insulin Sensitivity in Obese Women

Nicole M. Gilbertson, Natalie Z.M. Eichner, Emily M. Heiston, Monique Francois, Julian M. Gaítan, James H. Mehaffey, Taryn E. Hassinger, Peter T. Hallowell, Arthur Weltman, FACSM, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven Malin, FACSM)
(No relevant relationships reported)

PURPOSE: Metabolic flexibility has been implicated in the regulation of insulin sensitivity and glucose homeostasis. Although low-calorie diets (LCD) and interval exercise (INT) have been independently shown to improve metabolic flexibility and insulin sensitivity, the combined effect of these therapies is unknown in obese adults. We tested the hypothesis that LCD+INT would enhance fuel selection to a greater extent than a LCD alone, and this change would correlate with insulin sensitivity. **METHODS**: Twenty-four women (Age: 48.2±2.4y, BMI: 37.8±1.3kg/m²) were randomized to a LCD (n=12; mixed meals of ~1200kcal/d) or LCD+INT (n=12; 60min/d of supervised INT at 90% and 50% HR_{peak} for 3 min each, respectively). LCD+INT subjects received an additional 350kcal post-exercise to equate energy availability between groups. Fitness (VO_2peak), percent body fat (BodPod), and insulin sensitivity (Matsuda Index; 180min 75g OGTT) were assessed pre- and post-intervention. Respiratory exchange ratio (RER; indirect calorimetry) was measured at 0, 60, 120, and 180 min of the OGTT to determine metabolic flexibility, which was defined as the slope of fasting to post-prandial (PP; average of 60-180 min) RER. **RESULTS**: LCD and LCD+INT had similar reductions in caloric intake (*P*<0.001), percent body fat (*P*<0.001), fasting plasma glucose (*P*=0.04), fasting RER (*P*<0.001) and improvement in insulin sensitivity (*P*=0.02). However, LCD+INT improved VO_2peak (*P*=0.04), insulin iAUC$_{180min}$ (*P*=0.08), and metabolic flexibility (*P*=0.007) as well as maintained PP RER (*P*<0.001) compared with LCD. Maintenance of PP RER (r=-0.50, *P*=0.01) and reductions in percent body fat (r=-0.45, *P*=0.02) were significantly associated with improved insulin sensitivity. Further, increased metabolic flexibility was directly associated with improved VO_2peak (r=0.48, *P*=0.01). **CONCLUSIONS**: Adding INT to a LCD accentuates metabolic flexibility in relation to insulin sensitivity in obese women. These findings highlight that INT-induced adaptations may be additive for glucose regulation during a weight-loss intervention.

The Effects Of Age And Sex On Obesity And Insulin Action In C57bl/6j Mice

Allison Dalton, Lucas Calzini, Andrei Tuluca, Stephen Ives, Thomas H. Reynolds, IV. *Skidmore College, Saratoga Springs, NY.* (Sponsor: Donald Dengel, FACSM)
(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine the effects of age and sex on body composition, energy expenditure, physical activity, and glucose tolerance in C57BL/6J mice. **METHODS:** Young (YG, 20-25 weeks old) and aged (AG, 72-76 weeks old) mice were housed in metabolic cages to measure energy expenditure (EE) and physical activity (PA), underwent body composition analysis by magnetic resonance imaging, and were subjected to an intraperitoneal glucose tolerance test (GTT) to assess insulin action. **RESULTS:** Body composition analysis revealed that AG male mice had a significantly greater body mass (42.2±1.9 vs 30.0±0.4 g, P<0.0001), fat mass (18.7±2.0 vs 3.3±0.4 g, P<0.0001), and percent body fat (43.0±3.0 vs 11 vs 11.0±1.5%, P <0.0001) than YG male mice. In AG female male mice, body mass was significantly higher (32.8±1.6 vs 26.3±0.9 g, P<0.02), but fat mass (13.3±2.0 vs 9.5±1.3 g, P<0.24) and percent body fat (37.8±4.8 vs 35.5±3.8%, P=0.67) were similar when compared to YG female mice. Interestingly, lean body mass was higher in AG female mice (16.9±0.6 vs 14.7±0.6, P<0.008) but lower in AG male mice (18.4±0.4 vs 22.6±0.5, P<0.0001) when compared to their young counterparts. AG male mice had significantly higher body mass (42.2±1.9 vs 32.8±1.6 g, P=0.001) and fat mass (18.7±2.0 vs 13.3±2.0 g, P=0.04) compared to AG females, however, percent body fat (43.0±3.0 vs 37.8±4.8%, P=0.28) was similar between AG male and female mice. Surprisingly, EE was higher in both AG male (24.0±0.8 vs 19.0±0.4 kcal/hr, P=0.004) and female mice (26.4±2.0 vs 20.7±0.4 kcal/hr, P=0.001) compared to respective YG mice; however, EE does not appear to explain the sex-dependent differences in body composition. Physical activity tended to be higher in AG female mice compared to AG male mice, but this effect was not significant (P=0.12).

Abstracts were prepared by the authors and printed as submitted.

Regarding the effect of aging on insulin action, the area under the GTT curve was significantly higher in AG males (95,102±6,818 vs 64,005±2031, P=0.002) but not AG female mice (50,168±2345 vs 47,369±4,089, P=0.55). **SUMMARY:** Our findings indicate that C57BL/6J female mice, unlike male mice, are protected from age-related obesity and insulin resistance. The mechanism responsible for this protection is yet to be identified.

Bovine Colostrum Has No Effect on Mucosal Immunity Before or After Exercise in a Hot and Humid Environment

Trevor Gillum, Zachary McKenna, Quint Berkemeier, Ashley Naylor, Austin Kleint, Felipe Gorini. *California Baptist University, Riverside, CA.*

(No relevant relationships reported)

Intro: It is known that strenuous or prolonged exercise can lead to exercise-induced immune impairments in mucosal immunity. Further, exercise in the heat reduces salivary lysozyme (Lys). Bovine Colostrum (BC) can enhance mucosal immunity associated with strenuous exercise. However, the effects of BC remain unclear during exercise in hot and humid conditions. **Purpose:** The purpose of this study was to quantify the effects of BC supplementation on salivary lactoferrin (Lac) and Lys following exercise in a hot and humid environment. **Methods**: 10 males (20±2 years, VO_{2max} 55.8±3.7 mL kg^{-1} min^{-1}, 11.8±2.7% body fat) ran for 46±7.7 min at 95% of V_T in 40° C and 50% RH following a 14-day double-blinded supplementation with either BC or isocaloric placebo (Pla). There was a 3 week washout period before the groups were switched and the procedures repeated. Core temperature, skin temperature, heart rate, and rating of perceived exertion were recorded every 5 min during exercise. Unstimulated salvia was collected pre, post, 1 h, and 4 h post exercise. Lac and Lys concentrations were quantified via ELISA. **Results**: Exercise resulted in an immediate increase in concentration and secretion rate for Lac and Lys (p<0.05), but BC had no effect. Mean body temperature was similar between groups (beginning: 36.11 ± 0.30°C, ending: 39.52 ± 0.28°C (BC); beginning: 35.96 ± 0.43°C, ending: 39.42 ± 0.38°C (Pla)). Saliva flow rate was not different between groups (pre: 0.54 ± 0.3, post: 0.44 ± 0.3, +1: 0.67 ± 0.3, +4: 1.0 ± 0.4 mL/min (BC); pre: 0.58 ± 0.2, post: 0.37 ± 0.1, +1: 0.63 ± 0.2, +4: 0.83 ± 0.4 mL/min (Pla)). **Conclusion**: Contrary to previous work, exercise in the heat did not reduce mucosal immunity. Further, despite similar supplementation protocols that showed enhanced mucosal immunity, BC provided no benefit, either at baseline or in response to exercise. Thus, 45 min of running near V_T, in a hot and humid environment, did not impair mucosal immune parameters.

Phd2/hif-1α Axis Regulates Intestinal Barrier Function After Strenuous Swimming

Die Wu[1], Beibei Luo[1], Dao Xiang[2], Peijie Chen[1]. *[1]Shanghai University of Sport, Shanghai, China. [2]Naval Medical Research Institute, Shanghai, China.*

(No relevant relationships reported)

PURPOSE: Exercise decreases tissue blood flow in the gastrointestinal (GI) system. The hypoxia inducible factor-1α (HIF-1α) and its regulator, prolyl hydroxylases 2 (PHD2), are pivotal in the transcriptional responses to the oxygen flux. Strenuous exercise induces immunosuppression and may lead to intestinal barrier dysfunction. Therefore, we hypothesized that PHD2/HIF-1α axis is involved in the intestinal barrier function after strenuous swimming. **METHODS:** Four mouse models were used in this study (male, 8-week, n=6/group). (1) ROSA26 ODD-Luc/+ mice were applied to monitor HIF-1α expression in the intestine. (2) C57BL/6 mice were randomized into 4 groups (n=8/group): control (C), strenuous swimming (S), intraperitoneal injected PHDs inhibitor DMOG (D); injected HIF-1α inhibitor PX-478 before swimming (PS). Intestinal segments were stained with HE and AB-PAS. Intestinal permeability was quantified with FITC-dextran. Bacterial translocation was determined by quantification of colony forming units (CFUs) in cultured mesenteric lymph nodes, livers, kidneys and spleens. (3) Villin-Cre mediated, intestine-specific deletions of HIF-1α (Vil-Hif1a$^{-/-}$) or (4) PHD2 (Vil-PHD2$^{-/-}$) mouse models were developed to verify the function of PHD2/HIF-1α axis in regulating the intestinal antimicrobial responses related genes expression. **RESULTS:** (1) One session of strenuous swimming markedly increased *in vivo* HIF-1α in the intestine (C: Radiance$_{max}$ = 0.31, S: Radiance$_{max}$ = 2.17, 10^{7}p/sec/cm^2/sr, P<0.01). (2) One session of strenuous swimming increased bacteria translocation (C: 0.61±0.15, S: 6.25±2.49, 10^5CFU/g, P<0.01) and intestinal permeability (C: 1, S: 1.87±0.21, folds, P<0.01). (3) The antimicrobial responses related genes expression was significantly decreased in Vil-Hif1a$^{-/-}$ (P<0.01, compared to the controls), including Il12a, Irak3, Irf5, Lbp, Lyz2, Nlrp1a, Ticam2, Tlr4, Tlr9 and Tnfa. **CONCLUSION:** Strenuous swimming induces intestinal barrier dysfunction. PHD2/HIF-1α axis plays an important role in the regulation of intestinal barrier dysfunction related genes expression after strenuous swimming in mice.

Effects Of Diet Before Endurance Exercise On Hepcidin Response In Young Females

Nanako Hayashi, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.* (Sponsor: Robert R Kraemer, FACSM)

(No relevant relationships reported)

PURPOSE: The purpose of the present study was to examine the effects of diet before prolonged exercise on hepcidin response in young female subjects. **METHODS**: Ten young, untrained-female subjects [age 20.6 ± 0.8 years; height 157.5 ± 1.0 cm; weight 54.4 ± 1.5 kg; peak oxygen uptake (VO2max) 35.9 ± 1.1 ml/kg/min] participated in the present study. Subjects completed a 60-min bout of cycling at 65% of VO2max after with consuming (FED) or not consuming (CON) a meal before the exercise. The two experimental sessions were conducted with a crossover design, and these sessions were separated by about a month (each trial was performed during the follicular phase). Blood samples were collected before exercise, immediately after exercise and 3-h after exercise. **RESULTS** : Blood glucose levels were significantly elevated immediately after exercise in the FED (from 91 ± 2 mg/dL to 114 ± 5 mg/dL, P < 0.05). Serum iron level was significantly elevated after exercise in both FED (from 82 ± 14 µg/dL to 99 ± 16 µg/dL, P < 0.05) and CON (from 70 ± 14 µg/dL to 83 ± 15 µg/dL, P < 0.05). However, plasma interleukin-6 and hepcidin levels were not altered significantly during 3-h of post-exercise period in either condition (interaction, main effects for trials and time, P > 0.05). **CONCLUSIONS** : Diet before endurance exercise did not affect exercise-induced hepcidin elevation in young females.

Aerobic Training Status Enhances the Pentraxin 3-Mediated Innate Immune Response Following Maximal Exercise

Aaron L. Slusher, Tiffany M. Zúñiga, Edmund O. Acevedo, FACSM. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: Edmund O. Acevedo, FACSM)

(No relevant relationships reported)

PURPOSE: Pentraxin 3 (PTX3) is a vital regulator of innate immune function. Although plasma PTX3 concentrations are enhanced by aerobic exercise, the capacity of aerobic exercise to alter PTX3 functioning at the cellular level in aerobically trained (Tr) and untrained (UTr) subjects remains unknown.

METHODS: Fifteen Tr and 15 UTr participated in an acute bout of maximal exercise to examine *ex vivo* PTX3 production from whole blood (WB) and isolated peripheral blood mononuclear cells (PBMCs) exposed to LPS or palmitate. The capacity of PTX3 to regulate the *ex vivo* production of inflammatory cytokines was also examined in isolated PBMCs.

RESULTS: Elevated plasma PTX3 concentrations prior to exercise were positively associated with the percent change (pre to post exercise) in plasma PTX3 concentrations following acute exercise (r = 0.428, *p* = 0.018), independent of training status and cardiorespiratory fitness (VO_{2max}). In response to acute exercise, while *ex vivo* PTX3 production from LPS stimulated WB was unaltered following acute exercise in all subjects, the production of PTX3 from LPS stimulated PBMCs tended to be lower in Tr compared to UTr subjects (*p* = 0.098). Likewise, PTX3 production from palmitate stimulated PBMCs was reduced in Tr compared to UTr subjects (*p* = 0.017). In addition, plasma PTX3 concentrations in Tr, but not UTr, subjects were positively associated with the LPS- and palmitate-mediated production of PTX3 from PBMCs at rest and in response to acute exercise (*p* ≤ 0.050). Next, isolated PBMCs were stimulated with PTX3. As a result, PTX3-mediated production of the anti-inflammatory cytokines IL-10 and TGF-B1 decreased following acute exercise in both Tr and UTr subjects (*p* = 0.004, *p* ≤ 0.001, respectively). To the contrary, although PTX3-mediated IL-6 production was unaltered following acute exercise, the percent change in IL-6 production was positively associated with elevated plasma PTX3 concentrations at rest and in response to acute exercise in Tr subjects only (*p* ≤ 0.050). **CONCLUSIONS**: Aerobic exercise training may enhance the utility of plasma PTX3 concentrations to serve as a biomarker of the PTX3-mediated innate immune response to acute exercise.

The Effect Of Exercise On CD4+ T-cell Activation And Their Susceptibility To HIV-1

Alexander K. Holbrook, Michael A. Belshan, Eric C. Bredahl, Jacob A. Siedlik. *Creighton University, Omaha, NE.* (Sponsor: Joan Eckerson, FACSM)
(No relevant relationships reported)

HIV-1 can efficiently infect and replicate in activated CD4+ cells, including T cells and macrophages. Quiescent CD4+ T cells are susceptible to virus binding and entry, but infect poorly due to a lack of transcriptional and metabolic factors. We previously showed that circulating T cell populations undergo significant functional changes after short episodes of intense exercise. We hypothesize these changes can prime T cells for HIV-1 infection, and possibly facilitate the development of latent infection. **PURPOSE**: To identify if exercise-induced changes in CD4+ T cell physiology alter susceptibility to HIV-1 infection. **METHODS:** Subjects participated in both a control (no exercise) and exercise session. Venous blood samples were obtained at baseline (Pre) and immediately after each session (Post) in sodium heparin vacutainers. Blood samples were immediately processed and CD4+ T cells isolated with a human CD4+ T cell enrichment kit. A subset of cells was activated by stimulation with anti-CD3 and -CD28 antibodies. Unstimulated cells were immediately inoculated with NLX HIV-1 at a multiplicity of infection (MOI) of ~0.1 for 4 h, washed, and cultured in XF T Cell media supplemented with 50 U/mL IL-2. After 3 d of stimulation, the activated cells were similarly infected and cultured. Cultures were incubated for 17 d and supernatants collected, clarified by centrifugation, and stored at -20°C every 3-4 d for measurement of virus replication. At 14 d post infection, the resting cells were activated for 3 days with human CD3/CD28/CD2 T cell activator beads to test for latent infection (activated cell group was not restimulated). Virus replication was quantified by HIV reverse transcription assay. **RESULTS:** Preliminary data from the initial subjects suggests there is not a statistically significant change in viral replication levels between baseline and post exercise cells. In one subject however, a 1702% increase was observed in viral replication after reactivation of control resting cells compared to a 55% increase in reactivated exercise cells. **CONCLUSIONS:** While evidence suggests acute exercise alters the phenotypic state of T cells, it may not alter overall T cells susceptibility to infection with HIV-1.

High-fat Diet Attenuated Plasma sCD130 and sCD163 In Trained Men

Yunsuk Koh[1], Eric K. O'Neal[2]. *[1]Baylor University, Waco, TX. [2]University of North Alabama, Florence, AL.*
(No relevant relationships reported)

High-fat (HF) diets have been shown to favorably influence weight management and exercise performance. Inflammation is closely related to cardiovascular and other metabolic diseases. Yet, the responses of inflammatory markers to HF diets have not been extensively studied. **PURPOSE:** To examine the effects of a short-term high-fat (HF) diet and an acute bout of exercise on inflammatory markers in trained men. **METHODS:** Aerobically trained men (N = 8, VO_2max = 48.5±4.5 mL/kg/min, age

= 39.5±9.9 years) that had been on a typical high-carbohydrate (HC) diet (60-70% of carbohydrate) maintained their HC diet during the first phase of the study and switched to the HF diet (~70% of total calories from fat with carbohydrate < 50 g) for 3 weeks during the second phase. At the end of each phase, the participants performed a treadmill exercise for 50 minutes at varying race paces followed by an outdoor 5-km time trial. Overnight fasting serum samples were collected at pre- and 24-hours post-exercise at the end of each phase to analyze the inflammatory markers, including sCD30, sCD163, chitinase-3-like protein 1, glycoprotein 130, TNF-α, sTNF-R1, IL-1, IL-6, and CRP by a multiplex flow immunoassay. Data were analyzed using a factorial analysis of variance with the Sidak's multiple comparisons when necessary (p < 0.05). **RESULTS:** The inflammatory markers were not altered following an acute bout of exercise. However, the 3-week HF diet significantly lowered the following markers: sCD30 (421.61±27.71 to 290.25±23.80 pg/mL, p=0.09), sCD163 (87570.01±8081.49 to 61708.73±6754.50 pg/mL, p=0.020), chitinase-3-like protein 1 (8127.80±775.56 to 5481.72±606.47 pg/mL, p=0.020), and gp130 (41472.71±1761.09 to 33603.12±2048.81 pg/mL, p=0.029), whereas other inflammatory markers were not different between the HC and HF diets. **CONCLUSION:** High-fat diets have been typically thought to negatively influence cardiometabolic health. However, a short-term high-fat diet demonstrated its positive role in inflammation in trained middle-aged men. It is highly recommended that the future studies focus on examining the effects of a long-term high-fat diet on inflammatory markers in a variety of subject populations.

Adding Short-Term Interval Exercise to a Low-Calorie Diet Favorably Influences Appetite in Obese Adults

Emily M. Heiston, Nicole M. Gilbertson, Natalie Z.M. Eichner, Julian M. Gaitan, Monique E. Francois, James H. Mehaffey, Taryn E. Hassinger, Peter T. Hallowell, Arthur Weltman, FACSM, Steven K. Malin, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Steven Malin, FACSM)
(No relevant relationships reported)

Purpose: Appetite is influenced by gut-derived hormones and behavioral factors. Caloric restriction is suggested to reduce satiation and increase hunger, thereby contributing to challenges in long-term weight loss. Although intense exercise is suggested to attenuate appetite, no data exist testing the effects of interval exercise (INT) during a low-calorie diet (LCD) on appetite regulation. We hypothesized that LCD+INT would favorably influence satiety when compared with LCD in obese adults. **Methods:** Seventeen obese adults (50.5 ± 3.0 yrs; 35.9 ± 1.4 kg/m²) were randomized to either LCD (n=8; mixed meals of ~1200 kcal/d) or LCD+INT (n=9; 60 min/d of supervised interval exercise at 90% HR_{peak} for 3 min and 50% HR_{peak} for 3 min). An additional 350kcal (shake) was provided to LCD+INT individuals post-exercise to equate energy availability between groups. Total PYY, acyl ghrelin (AG) and des-acyl ghrelin (dAG) were measured at 0, 30 and 60 min of a 75g OGTT before and after the intervention. Visual analog scales were also administered at 0 and 120 min of the OGTT to assess subjective appetite. Food logs were recorded prior to and during the intervention to evaluate caloric intake. **Results:** Both interventions decreased food intake (*P*=0.001) and body fat (*P*<0.01). LCD+INT decreased fasting PYY (*P*<0.01) and increased post-prandial PYY stimulation (27.0 ± 7.0 vs. 37.0 ± 11.0%) when compared with LCD (20.1 ± 11.6 vs. 15.8 ± 3.4%, *P*=0.11). LCD+INT increased fasting AG (*P*=0.07) and increased suppression (6.8 ± 5.1%) compared to LCD (-8.3 ± 5.9%, *P*=0.08). Both interventions increased circulating dAG following the OGTT (*P* = 0.06). Interestingly, LCD+INT attenuated the rise in fasting hunger seen with LCD (*P*=0.05). **Conclusion:** Interval exercise favorably influences PYY, AG and perceived hunger during a LCD in obese adults. Further research is warranted to determine how adding interval exercise to long-term caloric restriction may mitigate obesity and related cardiometabolic disease.

Effects Of Obesity And Exercise On Bone Marrow And Leukemia Cells Following Radiation

Matthew Ngu[1], Russell Emmons[2], Diego Hernández-Saavedra[2], Hong Chen[2], Michael De Lisio[1]. *[1]University of Ottawa, Ottawa, ON, Canada. [2]University of Illinois at Urbana-Champaign, Urbana, IL.*
(No relevant relationships reported)

Radiation-induced leukemia is a serious late effect of radiation therapy partially due to long-term alterations in the bone marrow (BM) environment. Obesity and sedentary lifestyles, two host factors that remodel the bone marrow, are common amongst cancer survivors and linked to increase leukemia risk. Whether alterations to the bone marrow environment induced by obesity and physical activity alter leukemia risk following ionizing radiation (IR) exposure remains unknown. **PURPOSE:** Determine how exercise training and obesity modulate the BM environment and leukemia blast viability following sub-lethal IR exposure. **METHODS:** 4 week old CBA mice were fed a control (CON; n=20) or 45% high fat diet (HF; n=20). At 9 weeks old, CON and HF mice were divided into sedentary (SED, n=10) or exercise groups (EX,

n=10). At 13 weeks, mice were administered a uniform radiation dose of 3 Gy and continued their specific diet and exercise regimen for 4 weeks. BM stromal cells were quantified by flow cytometry and marrow adipose tissue (MAT) was determined by μCT. Conditioned media (CM) from isolated BM stromal cells was analyzed by cytokine array and applied to the KG-1 leukemia cell line to assess cell viability by MTT assay. **RESULTS:** The number of mesenchymal stromal cells in CON+EX increased compared to CON+SED (p<0.05). EX increased the quantity of osteoblasts and endothelial progenitor cells compared to SED mice (both p<0.05). EX reduced MAT compared to SED, even in the presence of HF diet following sub-lethal IR (p<0.05). Inflammatory cytokines were also increased in the CM of HF-SED compared to CON-SED, and this effect was reduced with EX. CM from HF mice increased KG-1 viability, but not CM from EX (p<0.05). **CONCLUSION:** Overall, exercise increased BM stromal cell content and reduced BM inflammation while obesity increased BM adiposity and leukemia cell viability. These data suggest that exercise may be a therapeutic intervention to reduce secondary leukemias following radiation therapy, particularly in obese cancer survivors.

Exercise-induced Th17 Lymphocyte Response And Their Relationship To CVD Risk Factors In Obese, Post-menopausal Women

Maria A. Cardenas[1], Michael M. Levitt[1], Bryan Richie[1], Shaohan Lu[1], Elise E. Erickson[1], Carmen Cook[1], Jay Haynes[2], Andreas Kreutzer[1], Joel B. Mitchell, FACSM[1], Melody D. Phillips, FACSM[1]. *[1]Texas Christian University, Fort Worth, TX. [2]John Peter Smith Hospital, Fort Worth, TX.* (Sponsor: Melody Phillips, FACSM)

(No relevant relationships reported)

Obesity-induced inflammation promotes type 2 diabetes and cardiovascular disease (CVD). A causative link between adaptive immunity and pathogenesis of obesity-associated diseases has been established.
PURPOSE: To examine the effects of exercise on circulating T-helper (Th) 17 lymphocytes in overweight/obese post-menopausal women.
METHODS: Twenty-seven overweight/obese women (BMI 32.7 ± 5.1 kg×m^{-2}, 55-75 yr) were randomly assigned to the exercise (EX, n=14) or education (ED, n=13) groups. EX performed a 25-min walk (75-80% HRR) and 2 sets of 8 resistance exercises (70-80% 1RM) with blood samples obtained at: pre-exercise, post-exercise, one-hour and two-hour post-exercise. Blood samples were obtained at the same time points in resting ED. Whole blood was stained using the extracellular markers CD4, CD196, CD194, CD26, and CD161 to identify Th17 lymphocytes via flow cytometry. **RESULTS**: Acute exercise increased lymphocyte number (p = 0.0001), but decreased percent of CD4$^+$ cells (p = 0.019) at PO. We observed a diurnal response (main effect) where CD26 expression was significantly lower by 2H compared to PRE (PR: 10631 ± 208; 2H: 9961 ± 271 MFI). There was a main effect (p=0.024) of group for CD26 expression (EX: 10745 ± 251; ED 9880 ± 260 MFI). The difference may have been driven by the apparent exercise-induced plateau of CD26 expression at 2H, which minimized the diurnal reduction observed in ED (p > 0.05). There was a tendency (p = 0.09) for a group x time interaction in Th17 cell number at 1HR (EX = 25.3 ± 4.8; ED =37.2 ± 5.2 x 10^3 cells x ml^{-1}). BMI was significantly correlated with Th17% (r = 0.5, p = 0.008). HbA1c was positively correlated with Th17 number and percentage (r = 0.598, p = 0.003; r = 0.614, p = 0.001, respectively), as well as CCR4$^+$ Th17 cells (r = 0.421, p = 0.036). Multiple regression analysis revealed that BMI and HbA1c were significant predictors (50%, r^2 = 0.497) of Th17 cell %.
CONCLUSION: Exercise reduced CD26 expression, the receptor responsible for Th17 cell migration, but did not significantly alter Th17 concentration (p = 0.09). CD26 upregulation may indicate that Th17 cells, via chemokine release, promote the stress-dependent migratory response of T-helper cells (CD4$^+$). Obese individuals may experience a preferential differentiation of Th17 cells, based on their association with adiposity (BMI) and HbA1c.

Acute Exercise-Induced Response of Platelet-Monocyte Complexes in Obese Postmenopausal Women

Michael M. Levitt[1], Maria A. Cardenas[1], Bryan Richie[1], Carmen A. Cook[1], Kara Steck[1], Shaohan Lu[1], Jay Haynes[2], Andreas Kreutzer[1], Joel B. Mitchell, FACSM[1], Melody D. Phillips, FACSM[1]. *[1]Texas Christian University, Fort Worth, TX. [2]John Peter Smith Health Network, Fort Worth, TX.* (Sponsor: Melody D. Phillips, FACSM)

(No relevant relationships reported)

Inactivity-related diseases such as cardiovascular disease (CVD) are linked to chronic low-grade, systemic inflammation. Platelet-monocyte complexes (PMCs) are markers of *in vivo* platelet activation and atherosclerosis, and may be early indicators of subclinical inflammation.
PURPOSE: To examine the effects of a single exercise bout on PMCs in those at risk for CVD.
METHODS: Twenty-five overweight-obese (BMI 32.7 ± 5.2 kg·m^{-2}, 55-75 yr) women were randomly assigned to either the exercise (EX, n=13) or non-exercise control (CON, n=12) group. EX performed 2 sets of 8 resistance exercises and a 25-min treadmill walk at 70-80% HRR. Blood was obtained pre-exercise (PR), post- (PO), 1-hour and 2 hours post-exercise (1HR and 2HR). Blood was obtained at the same time points in CON. PMCs were identified via flow cytometry and analyzed in each monocyte phenotype. Monocyte phenotypes were defined as: Mon1 (CD14$^+$CD16$^-$CCR2$^+$), Mon2 (CD14$^+$CD16$^+$CCR2$^+$), and Mon3 (CD14$^+$CD16$^+$CCR2$^-$). All events positive for both CD14 and CD42a (marker for platelets) were considered PMCs. **RESULTS**: A main effect for time revealed an increase in total PMC number at PO (p=0.036). This increase appears to have been driven by EX (EX = 61.5%; CON = 33.8% increase). Mon1 and Mon2 PMC responses were similar. A significant time x group interaction for Mon3 PMCs (p=0.002) indicated an increase from PR to PO (PR = 5218±1170 cells·ml^{-1}, PO = 8195±1152 cells·ml^{-1}), and a decrease from PO to 1HR and 2HR (1HR = 3767±820 cells·ml^{-1} 2HR = 3818±814 cells·ml^{-1}). PMC number remained constant for CON at all timepoints. Estimated VO2max was negatively correlated with CD42a MFI (a marker of platelet density per monocyte) (r = -0.583, p = 0.003). Systolic blood pressure (SBP) positively correlated with percent PMC (% CD42a positive monocytes; r = 0.458, p = 0.042).
CONCLUSIONS: Aerobic fitness appears to reduce platelet activation indicated by the negative relationship between VO2max and CD42a MFI. Chronic elevations in resting SBP are linked to PMC percentage, possibly due to sheer stress-induced platelet activation. It is possible that PMC elevation at PO is at least partially driven by exercise-induced increases in BP. These results support previous literature, indicating that PMCs are a marker CVD risk and may elucidate one mechanism by which physical fitness reduces risk for CVD.

B-70   Free Communication/Poster - **Concussion I**

967   Board #228   May 30 3:30 PM - 5:00 PM

Effects Of A Musculoskeletal Injury On Rebaseline Concussion Assessment Performance

Kelsey Bryk[1], Ryan DeWolf[2], Jessie Oldham[1], Melissa DiFabio[1], Katherine Breedlove[3], Thomas Kaminski[1], Thomas Buckley[1]. *[1]University of Delaware, Newark, DE. [2]Massachusetts General Hospital, Boston, MA. [3]University of Wisconsin - Eau Claire, Eau Claire, WI.*

(No relevant relationships reported)

A multifaceted baseline concussion assessment is a crucial component of properly assessing and managing concussions with post-injury values compared to baseline performance. While concussion adversely affects performance on these tests, musculoskeletal injury (MSI) also adversely affects test performance acutely post-injury; however, the prolonged effect of a MSI on concussion test performance is unknown. If MSI has a prolonged adverse effect on concussions testing, this could reduce the efficacy of the concussion test battery in the event of a suspected concussion.
PURPOSE: To determine the effects of lower-body MSI on pre-season baseline concussion tests.
METHODS: Division I collegiate student-athletes completed annual baseline concussion assessments in successive years. Athletes who sustained a lower-body MSI prior to their rebaseline tests (n=33) were compared to uninjured matched controls (n=33) based on sex, height, weight and sport. Baseline assessment included the Standard Assessment of Concussion (SAC), Balance Error Scoring System (BESS),

King-Device (KD) Test, Clinical Reaction Time (CRT), a computerized neurocognitive assessment (CNT), and tandem gait (TG). A 2 (group) x 2 (time) repeated measures ANOVA was performed for each dependent variable.

RESULTS: There were no statistically significant interactions for any of the dependent variables. There were significant main effects of time with improved performance during the second year for SAC (Baseline 1: 26.5 ± 1.9 and Baseline 2: 27.3 ± 1.8, p = .001), KD Test (Baseline 1: 38.4 ± 6.4 sec and Baseline 2: 37.1 ± 6.3 sec, p = .025), and CRT (Baseline 1: 204.3 ± 24.3 msec and Baseline 2: 195.4 ± 24.6 msec, p = .013), but no differences in BESS, CNT, and TG. There were no significant group effects for all tests.

CONCLUSION: Sustaining a MSI did not adversely affect performance on the concussion baseline tests. This suggests that a student-athlete's initial concussion baseline assessment performance is valid to compare with post-injury performance, even if a lower body MSI was sustained after the initial assessment. As expected, improvements on certain tests were observed with repeat administration. These results suggest that a rebaseline concussion assessment for collegiate student-athletes is unnecessary.

Fighting In The Nhl 5 Year Review: Fists Of Fury But Few Concussions, Believe It!

Neustadtl Aidaan[1], Dave milzman[1], zach tannebaum[1], Andrew Lincoln[2], JEREMY ALTMAN[1]. *[1]georgetown u school of medicine, Washington, DC. [2]MEDSTAR SPORTS MED AND GEORGETOWN MED SCHOOL, Washington, DC.*

(No relevant relationships reported)

In recent years, there has been a unified call to end fighting in the NHL to reduce concussive injury. However, no published data to prove fighting leads to more concussions has been produced, only anecdotal cases. Purpose:To analyze a consecutive NHL Fights from 2010-11 to 2014-15 seasons, recording all resulting injuries and number of games that the player missed. Methods: Public domain 'Hockeyfight' web sites were used to identify and view all fights and injuries were confirmed through two independent sources, the NHL and/or the team or independent press sources. The study received IRB waiver for use of public data. Stat Analysis was performed using available software. Results: The NHL had 992 fights in 1,950 games over 2 seasons with a fight/game rate of: 50.9% (range 38.-65% annually in NHL over past decade). 30 injuries resulted to the 1,984 combatants (n=992 fights) for an injury rate of 1.5/100 per fighters. Specifically looking at concussions, 6 mTBI resulted (20% of injuries) for a rate: 0.2/100 mTBI/fight rate which is ten-fold less than the reported concussion rates in standard NHL play (3.0 mTBI per 100 player games). The 10 players with most fights in NHL annually, for the past 5 seasons, tallied 1,012 fights from 50 players (fights/season range 17-33) with: all injury rate of 3/100 fights and mTBI rate of .15/100 fights. Discussion: Although fighting may appear a direct causative factor to concussions the data does not prove it. The difference of punching on ice compared to land appears to actually offer some protection over significant forces being generated and may explain the greater 'safety' of fighting in the NHL without injury. Currently, we are compiling similar data from the 2015-16 and 2016-2017 to compare changes in injury rates following NHL rule changes intended to better protect players. We expect to have this data completed and ready for presentation at the time of ACSM18. <!--EndFragment-->

Determining the Appropriate Timing of Administration of Computerized Neurocognitive Testing Following Maximal Exertion- Preliminary Analysis

Samantha A. Mohler, Cory L. Butts, Zachary J. Sebghati, Katie L. Stephenson-Brown, Brendon P. McDermott, FACSM, Matthew S. Ganio, FACSM, R.J. Elbin. *University of Arkansas, Fayetteville, AR.* (Sponsor: Matthew Ganio, FACSM)

(No relevant relationships reported)

Computerized neurocognitive testing (CNT) is part of a multi-faceted approach to sport-related concussion assessment. Accurate baseline (pre-injury) CNT scores aid post-concussion management which allows the athlete to serve as their own control. Prior research suggests maximal exertion negatively affects CNT scores immediately following exercise. However, the appropriate wait time for administering CNT following maximal exertion is unknown. **PURPOSE:** To compare differences in neurocognitive performance and symptoms following maximal exertion with varied recovery intervals in healthy college-aged students. **METHODS:** A prospective, randomized cross-over, repeated measures design was used for this study. Twenty-six participants (22 ± 2y) completed four experimental visits. Three visits consisted of a maximal effort graded exercise treadmill test (VO$_2$ max), with a prescribed post-exertion rest period, and CNT administration. Prescribed post-exertion recovery intervals were defined as: <2 min (immediate), 10-min, or 20-min. The fourth visit served as a control (baseline); participants performed a CNT without a preceding VO$_2$ max test. All four experimental visits occurred at least one week apart and

were randomly counterbalanced. A series of one-way repeated measures analysis of variance (ANOVAs) were performed on CNT composite outcome and symptom scores. Statistical significance was set at a Bonferroni-corrected $p \leq .01$. **RESULTS:** There was a significant within-subjects effect for prescribed post-exertion recovery intervals on total symptom scores (Wilks $\lambda = .62$, $F[3, 23] = 4.64$, $p = .01$, $\eta^2 = .38$). Total symptom scores were significantly higher at the immediate ($p < .001$), 10-min ($p = .02$), and 20-min ($p = .05$) post-exertion recovery intervals compared to baseline. There were no significant differences for processing speed ($p = .05$), visual memory ($p = .07$), verbal memory ($p = .06$), or reaction time ($p = .40$). **CONCLUSION:** Baseline symptom scores were negatively influenced by maximal exertion, and continued to be elevated 20 minutes post-exertion. However, cognitive performance was unaffected. Sports medicine professionals should wait at least 20 minutes following maximal exertion to obtain a more accurate representation of symptoms.

Does Greater Susceptibility to Neck Injury Put Females at Higher Risk of Prolonged Sport-Related Concussion Recovery?

Sumit Kanwar[1], Manisha R. Chand[1], Evan Peck[2]. *[1]Cleveland Clinic Florida, Weston, FL. [2]Cleveland Clinic Florida, West Palm Beach, FL.*

(No relevant relationships reported)

PURPOSE: An increase in female participation in contact sports has resulted in an increase in female athletes presenting with sport-related concussion (SRC). It has been theorized that females have longer SRC recovery time related to lower neck strength compared to males, which may also relate to concomitant neck injury. We proposed that female athletes with SRC have a higher incidence of acute cervical strain, resulting in a longer duration of SRC symptoms. Additionally, we investigated if athletes with acute cervical injury were more likely referred to a neuropsychologist in the post-SRC period compared to those without neck injury.

METHODS: This retrospective study assessed male and female youth, high school, and collegiate athletes (n=431; ages=12-21 years old) for post-SRC symptoms. We analyzed whether females who suffer a SRC are more prone to having an accompanying neck injury in comparison to males. Additionally, we assessed whether athletes who suffer an SRC with a neck injury display longer post-SRC recovery times, leading to increased referrals to a neuropsychologist; Statistical analyses were conducted using chi-square tests.

RESULTS: Of the 431 SRC cases, 92 reported concomitant acute neck strain. When comparing recovery time between male and female athletes, a significant difference was seen with females requiring more time to recover (p<0.001). However, when comparing recovery time in males and females with SRC and acute cervical strain, no significant differences were found (p=0.416). Additionally, when comparing the initial symptom burden using the post-concussion symptom scale in athletes with acute neck injury, females have a non-significant increased number of symptoms compared to males (p=0.157). Athletes with an SRC and neck injury are more likely to need a neuropsychology referral compared to those without a neck injury (p=0.027).

CONCLUSIONS: Evidence has been established that females have an extended recovery time following SRC when compared to males. A sex-based difference in regards to neck injury altering the recovery time were not found in our study. However, a concomitant neck injury with SRC increases the likelihood of neuropsychology referral. Further research is warranted to determine etiologic factors contributing to more prolonged SRC recovery in females versus males.

The Interrelationship and Diagnostic Utility of Memory and Reaction Time in Concussed Students

Margaret E. Bristow[1], Cali A. VanValkenburg[1], Gianna D. Maragliano[1], Vincent C. Nittoli[2], Adam W. Shunk[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.*

(No relevant relationships reported)

More than 40 million American youth participate in interscholastic, community-based, and collegiate sports. A risk of participation is traumatic brain injury (TBI). In up to 40% of TBI cases, athletes experience persistent functional and cognitive deficits. It is important to understand the variables that lead to these deficits to improve diagnosis and prognostic management. **PURPOSE:** To evaluate memory and reaction time as markers of TBI severity among patients experiencing prolonged recovery. **METHODS:** We retrospectively analyzed student-athletes admitted to a Midwestern outpatient clinic for neuropsychological evaluation; 78 patients had relatively comprehensive profiles and were included in the analysis. We conducted a health history, a 22-item post-concussion symptom inventory, and the ImPACT computerized test, which evaluated memory and reaction time. Pearson's and point-biserial correlation coefficients tested the direction and strength of association between memory, reaction time, and markers of injury severity. Logistic, negative binomial, and linear regressions tested memory and reaction time as predictors of whether symptoms

were reported, the number of reported symptoms, and the severity of symptoms. **RESULTS:** Patients were 16.0 ± 2.6 years of age, 56.3% were male, and they had experienced 1.2 ± 1.5 previous concussions. Reaction time was 0.64 ± 0.13 seconds; visual motor speed score was 44.7 ± 34.6; visual memory score was 92.0 ± 69.3; verbal memory score was 98.0 ± 80.9; cognitive efficiency score was 0.34 ± 0.12. Reaction time was a significant predictor ($p<0.05$) of balance problems, dizziness, mental fogginess, and sensitivity to light and noise; it was a trending predictor ($p=0.061$) of the summed severity of symptoms. Verbal memory was a significant predictor ($p<0.05$) of balance problems, sleeping problems, and fatigue. Visual memory, visual motor speed, and cognitive efficiency index were poor predictors of injury severity. **CONCLUSIONS:** Reaction time and memory are common components of testing batteries for concussed athletes. In our sample, reaction time and verbal memory emerged as useful predictors of severity among patients suffering long-term symptoms of TBI. It may be of value for coaches and athletic trainers to establish baseline values at the onset of a competitive season.

972   Board #233   May 30 3:30 PM - 5:00 PM

No Increased Lower Extremity Injury Risk Following Concussion in Youth Tackle Football Players

Robert C. Lynall[1], Erin B. Wasserman[2], Timothy C. Mauntel[3], Zachary Y. Kerr[4], Eric E. Hall, FACSM[5], Thomas A. Buckley[6]. [1]University of Georgia, Athens, GA. [2]Datalys Center for Sports Injury Research and Prevention, Indianapolis, IN. [3]Walter Reed National Military Medical Center, Bethesda, MD. [4]University of North Carolina at Chapel Hill, Chapel Hill, NC. [5]Elon University, Elon, NC. [6]University of Delaware, Newark, DE.

A growing body of literature suggests athletes are at increased risk for acute musculoskeletal injury following return to play after concussion. The association between concussion and musculoskeletal injury has yet to be explored in youth athletes. **PURPOSE:** Compare the proportions of acute lower extremity injuries between youth football players following concussion and upper extremity injury. **METHODS:** Injury surveillance was conducted on 19 youth tackle football leagues (336 teams; 5,177 unique athletes; 6,799 athlete-seasons) from 2012-2015. Athletic trainers entered injury information into an electronic medical record, from which data were de-identified and aggregated for analysis. Musculoskeletal injuries to the lower (at and distal to the hip joint) and upper (at and distal to the shoulder joint) extremities and concussions were identified. The proportion of subsequent acute lower extremity injuries was compared between athletes suffering one of two initial injuries: 1) Concussion, or 2) Time-loss (sport participation loss > 24 hours) upper extremity injury. Only musculoskeletal injuries in the same season as the index injury were analyzed. **RESULTS:** Of the 209 unique athletes who suffered a concussion, 14 had a subsequent same-season acute lower extremity injury (6.7%; 95% CI: 3.2%, 10.2%). Of the 141 unique athletes sustaining a time-loss upper extremity, 10 sustained a subsequent same-season acute lower extremity injury (7.1%; 95% CI: 2.7%, 11.5%). There was no difference in the proportion of youth athletes who sustained an acute lower extremity injury after concussion or time-loss upper extremity injury ($p=0.89$; mean diff.=0.4%; 95% CI: -4.9%, 6.5%). **CONCLUSIONS:** This is the first study to examine musculoskeletal injury risk in youth football athletes following concussion. Although evidence suggests that high school, college, and professional athletes are at increased risk for musculoskeletal injury following concussion, no increased risk was observed in this sample of youth football players. Our findings may be limited by the short time span of the youth football season, providing limited opportunity for re-injury. Despite these null findings, further research is needed to clarify the relationship between concussion and subsequent musculoskeletal injury in youth football athletes.

973   Board #234   May 30 3:30 PM - 5:00 PM

Head Impact Exposure of Youth Football Players During Their 7th and 8th Grade Seasons

Jason C. Dorman[1], Verle D. Valentine, FACSM[1], Paul A. Thompson[2], Thayne A. Munce, FACSM[1]. [1]Sanford Sports Science Institute, Sioux Falls, SD. [2]Sanford Research, Sioux Falls, SD. (Sponsor: Thayne A. Munce, FACSM)

(No relevant relationships reported)

Nearly 70% of US football players are younger than high school age, yet little is known about the potentially damaging effects of repetitive head impacts in this population. Cross-sectional studies indicate that head impact exposure increases with older levels of play, though little is known about changes in the same group of players from year to year. **PURPOSE:** To evaluate changes in head impact exposure among youth football players between their 7th and 8th grade seasons. **METHODS:** During a five-year span (2012-2016), head impact exposure of thirty middle school football players (12.6 ± 0.4 yr) was assessed during their 7th and 8th grade seasons while

participating in a community tackle football program. Subjects played on the same team during their 7th and 8th grade seasons. Head impact frequency, severity (linear acceleration [LA]; rotational acceleration [RA]) and location during each practice and game were measured using the Head Impact Telemetry (HIT) system, consisting of a helmet-mounted accelerometry array. **RESULTS:** Mean head impacts per player were significantly higher in practices (7.4 vs. 5.8 impacts / player; $P = 0.035$) but not significantly different in games (10.1 vs. 12.4 impacts / player; $P = 0.134$) comparing the 7th to 8th grade seasons, respectively. Furthermore, from the 7th to 8th grade season, mean LA (25.30 g vs. 25.95 g; $P = 0.345$), median LA (20.77 g vs. 21.39 g; $P = 0.225$), mean RA (1741 rad $\cdot$ sec^{-2} vs. 1744 rad $\cdot$ sec^{-2}; $P = 0.950$) and median RA (1481 rad $\cdot$ sec^{-2} vs. 1503 rad $\cdot$ sec^{-2}; $P = 0.538$) did not differ significantly. Finally, no differences in distribution of head impacts by location (Front: 46% vs. 48%; $P = 0.461$; Top: 10% vs. 11%; $P = 0.607$; Back: 26% vs. 23%; $P = 0.159$; Right: 9% vs. 10%; $P = 0.382$; Left: 8% vs. 8%; $P = 0.717$) were found between the 7th and 8th grade seasons, respectively. **CONCLUSIONS:** Individual head impact exposure was similar during two consecutive seasons of youth football, despite increased age and playing experience during the second season. Thus, extrinsic factors such as game rules, practice structure and coaching style may have a greater influence on head impact exposure from year to year in youth football, making those aspects of play key targets for strategies aimed at reducing repetitive head impacts in this population.

Concussion Baseline Performance on Rapid Number and Picture Naming Tests

Melissa S. DiFabio, Jessie R. Oldham, Thomas W. Kaminski, FACSM, Thomas A. Buckley. *University of Delaware, Newark, DE.*

(No relevant relationships reported)

Concussion may inflict widespread disturbance throughout the brain, including visual network impairments. The King-Devick (KD) test is a rapid number naming test of oculomotor functioning, however, it is limited to evaluating networks involved with saccadic eye movements and vergence. Recently, the Mobile Universal Lexicon Evaluating system (MULES), which requires object identification and color perception, was developed to encompass additional networks which may be a beneficial addition to concussion assessment. However, no published data describes MULES scores in an athlete-specific cohort. **Purpose:** To compare the relationship between KD and MULES scores in an athletic population. **Methods:** Twenty-nine ice hockey players (17.1 ± 3.3 years old, 27M/2F) completed both tests at baseline. The MULES consists of two cards, totaling 54 color pictures of foods, animals and objects; KD consists of 3 cards totaling 120 numbers in random order. Both tests were administered twice and the fastest time without errors was recorded as the "best" time. Descriptive statistics were used to describe test scores and a Pearson correlation examined the relationship between the tests. **Results:** Mean scores of "best" KD and MULES trials were 47.8 ± 9.4 seconds (Range: 31.77-68.0) and 37.7 ± 6.7 (Range: 27.73-50.47), respectively. Every MULES trial 2 improved from trial 1 with a mean improvement of 6.8 ± 3.7 seconds; KD mean change between trials was 2.4 ± 7.3 seconds, where 8/29 subjects performed slower on the second trial. Pearson correlation revealed a significant ($p=0.003$) moderate relationship between KD and MULES best times ($r=0.543$). **Conclusion:** These data are the first to report on MULES test scores in an athletic-specific cohort. While the significant correlation denotes a relationship exists between the two tests, the moderate strength suggests that the two may be providing somewhat different information. This may be due to the MULES utilizing additional neurological resources as it requires additional object and color recognition. These findings support the use of MULES in a clinical concussion testing battery, as it is also easy to administer and takes a short time to complete. Future studies should focus on MULES scores through concussion recovery.

Concussion recovery trajectories among United States Service Academy Members

Kathryn L. O'Connor[1], C. Dain Allred[2], Kenneth L. Cameron[3], Darren E. Campbell[2], Christopher J. D'Lauro[2], Megan N. Houston[3], Jonathan Jackson[2], Brian R. Johnson[2], Tim Kelly[3], Gerald McGinty[2], Patrick G. O'Donnell[4], Karen Y. Peck[3], Steven J. Svoboda[3], Paul Pasquina[5], Thomas McAllister[6], Michael McCrea[7], Steven P. Broglio, FACSM[1]. [1]*University of Michigan, Ann Arbor, MI.* [2]*United States Air Force Academy, Colorado Springs, CO.* [3]*United States Military Academy, West Point, NY.* [4]*United States Coast Guard Academy, New London, CT.* [5]*Uniformed Services University of the Health Sciences, Bethesda, MD.* [6]*Indiana University, Indianapolis, IN.* [7]*Medical College of Wisconsin, Milwaukee, WI.* (Sponsor: Steven P Broglio, FACSM)

(No relevant relationships reported)

Purpose: Describe concussion/mild traumatic brain injury (mTBI) recovery durations by sex and injury-related activities in US Service Academy cadets.
Methods: Injury data (2014-2017) from three US Military Service Academies were examined to describe concussion/mTBI characteristics (n=800 injuries, 301 female). Of the documented injuries, there were 738 injured individuals, of which, 679 had one injury, 56 individuals had two injuries and three individuals had three injuries. The recovery trajectories for all injuries were examined across sex and injury activity. Three durations were examined: days until asymptomatic, duration of return to activity (RTA) protocol, and days of total time lost. Duration was examined using Kaplan-Meier and log-rank tests. Due to the right skewed distribution, medians and interquartile range (IQR) are reported.
Results: Across all cadets, the median days until asymptomatic was 9 (IQR: 5-16). The median duration of RTA protocol was 5 days (IQR: 5-7). The total time lost due to concussion/mTBI was 20.68 days (IQR: 12.78-33.12). There was a significant effect of sex for days until asymptomatic and total time lost (p's < 0.01). Across all recovery metrics, females were more likely to have more days until asymptomatic (11 vs. 8.0 median days) and total time lost (24.6 vs 18.8 days). A significant effect of injury activity was observed for days until asymptomatic and total time lost (p's < 0.05). Injuries occurring during free-time activities had the greatest median number of days until asymptomatic (13 days IQR: 10-15) while injuries occurring during varsity athletics or academy specific training had the fewest median days until asymptomatic (both 6 days). Injuries occurring during varsity athletics had the shortest median total time loss of 12.9 days (IQR: 11.95-15.73). All other injury mechanisms were associated with median time loss of more than 20 days.
Conclusions: These analyses show significant effects of sex and injury activity on recovery duration. Differences may also reflect varying approaches to injury management by the medical provider. Further investigation is needed to determine an individualized approach to clinical care.

Discordance of Autonomic Discharge to the Cardiovascular System following Concussion

Michael F. La Fountaine[1], Anthony J. Testa[1], Joseph P. Weir, FACSM[2]. [1]*Seton Hall University, South Orange, NJ.* [2]*University of Kansas, Lawrence, KS.* (Sponsor: Joseph Weir, FACSM)

(No relevant relationships reported)

Previous evidence indicates that a transient cardiovascular autonomic dysfunction emerges after concussion. The baroreflex buffers perturbations to systolic blood pressure (SBP) through changes in efferent autonomic discharge to the sino-atrial node inducing a reciprocal change in heart rate (HR) and to the vascular smooth muscle to modulate peripheral resistance. Mayer waves (MW) represent the baroreflex adjustments to the target tissue and appear in the low frequency (LF) band of the HR and SBP power spectrum at a frequency of 0.1Hz. **PURPOSE**: To evaluate changes in MW amplitudes in recently concussed athletes and non-injured controls during the first week following injury. **METHODS**: A prospective, parallel-group, and repeated-measures study was performed in 19 athletes with concussion (age: 20±2 years; height: 1.76±0.14 meters; weight: 75.3±15.1 kilograms) and 19 non-injured athletes (age: 20±1 years; height: 1.71±0.11 meters; weight: 70.2±14.4 kilograms). Cardiovascular autonomic function (i.e., digital electrocardiogram and continuous beat-to-beat BP) was assessed at rest within 48 hours (48H) of concussion and 1 week (Wk1) later. Fast-Fourier transform was performed and power calculated from HR and SBP components for LF spectra and MW activity. The variables (e.g., LF-BP, LF-HR, MWBP, MWHR) were $\log_{10}$ transformed and a difference score was computed between the MWBP and MWHR (CMW) for each subject. **RESULTS**: Data are presented as group mean (95% CI) and there were no group differences for demographics, HR, SBP, LF-BP, LF-HR or MWHR at 48H or Wk1. At 48H, the concussion group had a significantly lower MWBP [p<0.05; 1.38 (1.11, 1.68) vs. 1.92(1.64, 2.21) mmHg2/Hz] and CMW [p<0.01; -3.06 (-3.35, -2.77) vs. -2.49 (-2.78, -2.20)] compared to the control group.

These group differences were gone by Wk1. **CONCLUSIONS**: These findings demonstrate that efferent autonomic discharge to the peripheral vasculature was reduced as evidenced by the MW, but not the LF-BP, LF-HR. The CMW demonstrated a dramatically greater discordance in autonomic discharge after concussion such that the majority of the concussion group distribution fell below the lower limit of the 95% CI of controls. Thus, the central autonomic mechanism(s) regulating MW discharge were discordant after concussion with apparent resolution by 1 week.

Effects of 3D Multiple Object Tracking on Head Impacts and Cognition in Ice Hockey

Lee Spahr, Erin Marchesseault, Daniel Nguyen, Jasmine Honey, Caroline Beals, John M. Rosene. *University of New England, Biddeford, ME.*

(No relevant relationships reported)

Ice hockey is a high intensity contact sport with elevated risk of injuries including concussion. Three dimensional multiple object tracking (3D MOT) has been proposed as an intervention to reduce the incidence of concussion, and potentially improve cognitive function. **PURPOSE:** The purpose of this study was to examine the effect of using 3D MOT on the frequency and force of head impacts and cognitive function (CTMT and Stroop) in men's ice hockey. **METHODS:** Eight male collegiate ice hockey players (NCAA Division III) (mean age = 22.87 ± 1.46 yrs; mean ht = 177.48 ± 16.82 cm; mean wt = 90.31 ±1.46 kg), had head impacts and cognitive function assessed throughout the regular season without 3D MOT versus with 3D MOT. Paired samples t-tests were performed to test for differences between first half (without 3D MOT) and second half (with 3D MOT) for all measures. **RESULTS:** Utilizing 3D MOT did not reduce the number of head impacts. With 3D MOT there was an increase in rotational force versus without 3D MOT (rotational acceleration (p = 0.010) 3.49 ± 2.31 vs. 3.88 ± 2.29 krads sec[-2] respectively); (rotational velocity (p = 0.001) (16.21 ± 8.71 vs. 14.35 ± 8.38 krads sec[-1] respectively); as well as force applied to the right side (p = 0.001) (13.10 ± 7.34 vs 16.67 ± 9.73 krads sec[-1]), and base of the head (p = 0.019) (13.26 ± 8.40 vs 17.25 ± 9.43 krads sec[-1]). CTMT improved with 3D MOT (p = 0.004) (49.57 ± 35.97 vs 65.15 ± 36.36%), while Stroop had no significant differences. **CONCLUSION:** The use of 3D MOT during the second half of the competitive ice hockey season did not reduce the number of head impacts. The increase in rotational forces when using the 3D MOT may be attributed to the different time in the season that 3D MOT was utilized, where more aggressive play leading to higher forces was possible. CTMT improvement was not surprising as the CTMT measures all qualities the 3D MOT intervention improves, while the Stroop only measures working memory and opposition to distraction.

Baseline Visual Measures in High School Football Players With and Without Previous Concussion

Christina B. Vander Vegt, Johna K. Register-Mihalik, Vashoula T. Kostogiannes, Kody R. Campbell, Kevin M. Guskiewicz, FACSM, Jason P. Mihalik. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.* (Sponsor: Kevin Guskiewicz, FACSM)

(No relevant relationships reported)

Visual impairments are common following sport-related concussion and may negatively affect athlete performance and safety if unresolved. **PURPOSE:** To examine differences in baseline visual assessment measures in high school football players with and without previous concussion. A secondary purpose was to examine the correlations between these asessments. **METHODS:** High school varsity football players (n=64, n=24 with concussion history) from a single high school (mean age=15.6±1.3 years) were enrolled in the study. Participants completed the following assessments prior to the start of the competitive football season: 1) three near-point of convergence (NPC) trials, 2) vision and sensory performance testing via the Senaptec Sensory Station, and 3) a demographic questionnaire. The independent variable was previous concussion history (with vs. without). Primary outcomes were average NPC across three trials (measured in centimeters) and the Senaptec Sensory Station scores for: visual clarity, contrast sensitivity, depth perception, near-far quickness, perception span, multiple object tracking, and hand-reaction time. Independent samples t-tests were used to examine differences in visual assessments between those with and without previous concussion. Pearson correlations examined relationships between all Senaptec Sensory Station and mean NPC measures. Alpha level was set to $P < 0.05$ *a priori*. **RESULTS:** Over half (62.5%) of those who reported a concussion history indicated that their most recent concussion was within the last year. There was no significant effect of concussion history on any of the visual assessment measures. There was a significant, but clinically insignificant correlation between mean NPC and binocular visual clarity (r=0.26; P=0.03). No other significant correlations among the visual assessment measures were identified ($P < 0.05$). **CONCLUSION:** High school football athletes, regardless of concussion history, exhibit similar baseline clinical and

---

performance visual measures. Our data suggest that NPC and binocular visual clarity, while statistically correlated are clinically independent of one another and both worthy of evaluation in assessing concussion.

The Affect of ADD on Baseline King-Devick and Clinical Reaction Time Performance In The Pediatric Population

Paul J. Gubanich, FACSM[1], Blake Simpson[1], Eric W. Slattery[2], Kelsey Logan[1]. *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH. [2]Miami University, Oxford, OH.*
(No relevant relationships reported)

PURPOSE: It is estimated that 1.5-3.5 million concussions occur annually in the US related to sports participation. Recent studies of the King-Devick (KD) and Clinical Reaction Time Test (CRT) have shown promise in the diagnosis and management of concussive injuries in older teens and young adults. The purpose of this study is to evaluate if a history of ADD may affect the baseline performance and hence interpretation of these novel tests in the pediatric and adolescent population.
METHODS: Non-concussed, 6-18 year-olds were recruited from sports medicine clinics during evaluation of other conditions or during participation in their schools' baseline concussion surveillance program. Participants whom were felt to be limited in their ability to perform these tests due to comorbid conditions or injuries were excluded from the study. History of ADD or related medication use was assessed through review of the patient's intake questionnaire or through examination of their past medical history and medication list as previously documented in the EMR on the day of assessment. Subjects completed the KD and CRT tests as previously described in the literature.
RESULTS: 563 participants (333 M, 230 F) were included in the study. Participants (44) were categorized as having a diagnosis of ADD (20 M, 24 F). The average age in the normative group was 12.55($\pm$2.71) versus 14.25($\pm$2.38) years in the ADD group. Baseline KD performance was 50.17($\pm$12.42)s in the normative group versus 48.54($\pm$11.89)s in the ADD group (p=0.43). CRT-RH was measured at 232.32($\pm$23.27) ms versus CRT-RH=223.89($\pm$22.71)ms (p=0.02) and CRT-LH=231.81($\pm$23.38)ms versus CRT-LH=224.75($\pm$22.75)ms (p=0.07) in the normative and ADD groups, respectively. Stratification by age group (6-13 vs. 14-18) did not reveal a difference in performance between groups on either test.
CONCLUSIONS: Baseline performance on the KD and CRT tests did not differ in this population of subjects with or without a history of ADD. Although limited by sample size, this study provides evidence that children with ADD perform similar to their peers on these baseline measures. Clinicians may therefore interpret these scores without adjustment. Additional factors which influence test performance need to be evaluated.

Treating Pediatric Acute Sport-Related Traumatic Brain Injuries with Hyperbaric Oxygen Therapy: A Case Series

Patricia R. Combs[1], Robert C. Lynall[2], Stephen W. Marshall[1], Janna C. Fonseca[3], James R. Stevens[4], Jason P. Mihalik[1]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC. [2]University of Georgia, Athens, GA. [3]Duke University, Durham, NC. [4]Carolina Family Practice & Sports Medicine, Raleigh, NC.* (Sponsor: Kevin Guskiewicz, FACSM)
(No relevant relationships reported)

Athletes often experience symptoms and neurologic deficits following sport-related concussion. Higher initial symptom burden is associated with longer recovery times. The current standard of care for concussed athletes includes cognitive rest and non-specific subthreshold physical activity until self-reported symptom resolve and objective concussion measures demonstrate clinical recovery. There is a paucity of treatment options beyond this wait-and-see approach. Hyperbaric oxygen (HBO_2) therapy has benefited severe and moderate traumatic brain injury patients. It is unknown how HBO_2 therapy affects acute post-injury symptom burden and recovery time following concussion. **Purpose:** To explore the effect of HBO_2 therapy on reducing initial symptom burden in acutely concussed high school student-athletes compared to two different placebo treatments. **Methods:** Eight high school student-athletes suffering from sport-related concussion were randomly assigned into one of three blinded clinical intervention groups: 1) HBO_2 therapy (n=3); 2) hyperbaric therapy with compressed medical-grade air (HBA) (n=2); or 3) normobaric 100% O_2 therapy (n=3). All groups completed five one-hour treatments within the first 10 days following their injury. Main outcome measures included change from initial post-concussion symptom burden and days until the physician (blinded to study group) permitted the student-athlete to return to activity. **Results:** The HBO_2 treatment group experienced a considerably larger mean symptom reduction (Δ symptom score = -54.5) than the HBA (Δ symptom score = -27.8) or O_2 placebo treatment groups (Δ symptom score = -22) over the 5 treatment sessions. Despite the considerably higher symptom

burden of those randomly assigned to the HBO_2 therapy arm, all treatment and placebo groups returned to activity in a similar timeframe (HBO_2 = 13.7$\pm$5.1 days; HBA=13.0$\pm$5.7 days; O_2 =19.0$\pm$16.5 days). **Conclusion:** HBO_2 therapy may be an effective option to acutely treat post-concussion symptoms, particularly in young athletes presenting with high symptom burdens. Future research is needed to determine appropriate and standardized treatment protocols for HBO_2 therapy in this population following concussion.

Emerging Practice of Speech-Language Pathologists in Sport Related Concussion Care: A Systematic Review

Jennafer D. Best[1], Bentley A. Krause[1], Thomas M. Best, FACSM[2]. *[1]Ohio University, Athens, OH. [2]University of Miami, Coral Gables, FL.* (Sponsor: Thomas Best, FACSM)
(No relevant relationships reported)

Speech-Language Pathologists (SLP) prevent, assess, and treat cognitive-communication and swallowing disorders. Due to their experience in caring for people with cognitive-linguistic disorders following traumatic brain injury, SLPs have the potential to play an important role in the management of sport-related concussion (SRC) using strategies that promote increased focus, attention, memory and mental agility.**PURPOSE**: The goal of this systematic review was to summarize the emerging practice roles of SLPs in SRC concussion management.**METHODS**: The following databases were accessed: MEDLINE, CINAHL, PsycInfo, Cochrane Library, and SPORTDiscus. Key words included in the searches were: concussion, mild traumatic brain injury, speech-language pathologist, speech-language pathology, speech therapy and cognitive communication. All articles included were published in peer-reviewed journals prior to October 2017. Studies on traumatic brain injury or papers that investigated concussion and military personnel were excluded. **RESULTS**: A total of 360 articles were identified for formal review. Forty-two articles met our inclusion criteria. The earliest published article was in 2002, but 41 articles (97.6%) were published 2009 or later. Only three studies (7.14%) were level III evidence and one (2.38%) level IV case series was identified. Thirty-seven papers (88.1%) were either literature reviews or perspectives on the role of SLPs in concussion management. Our search revealed no high-quality, randomized controlled trials or systematic reviews related to the role of SLPs in concussion management.**CONCLUSIONS:** A common theme of the studies we reviewed suggest a recent interest in highlighting the value of SLPs in a comprehensive team approach to concussion care. Concussion management continues to evolve, including the identification of clinical subtypes and rehabilitation trajectories. SLPs may assist in neurocognitive testing administration and the assessment of verbal memory, language processing, attention deficits and behavioral aspects of communication. Finally, SLPs may contribute to the planning and implementation of academic accommodations and returning to learning strategies.

Maintenance of Health-Related Fitness Gains Following Underwater Treadmill Training in Adults with Type 2 Diabetes

Ryan T. Conners[1], John M. Coons[2], Dana K. Fuller[2], Youngdeok Kim[3], Don W. Morgan, FACSM[2]. *[1]University of Alabama in Huntsville, Huntsville, AL. [2]Middle Tennessee State University, Murfreesboro, TN. [3]Texas Tech University, Lubbock, TX.* (Sponsor: Dr. Don W. Morgan, FACSM)
(No relevant relationships reported)

PURPOSE: To document short- and long-term effects of a 12-week aquatic exercise walking program on components of health-related fitness in middle-aged adults with type 2 diabetes.
METHODS:Thirteen adults with type 2 diabetes (age = 59.5 $\pm$ 4.5 yrs; 7 females, 6 males) completed 12 weeks of underwater treadmill training (UTT) (3d·wk^{-1}), followed by a 12-week follow-up period that involved no UTT. Exercise intensity and duration, which were initially set to 40-50% of heart rate reserve (HRR) and 30 minutes (three 10-min bouts) were systematically and progressively increased to 50-70% HRR and 60 minutes (three 20-min bouts) by week 12. During the follow-up period, study participants maintained their current diet and were given permission to perform any type or amount of physical activity except a formalized exercise program.

Primary outcome variables included cardiovascular function [resting heart rate (RHR) and 6-min walk for distance (6MWFD)]; body composition [body mass (BM), body fat percentage (BF%), waist circumference (WC)]; and leg strength [hamstring and quadriceps isokinetic peak torque at $30°·sec^{-1}$ and $60°·sec^{-1}$)]. Baseline, post-UTT, and post-follow-up scores were analyzed using 1-way repeated measures analysis of variance.

RESULTS: Compared to baseline scores, significant ($p < .05$) improvements in cardiovascular function (decreased RHR, increased 6MWD), body composition (decreased BM, BF%, and WC), and leg strength (greater peak hamstrings torque at $60°·sec^{-1}$, and peak quadriceps torque at $30°·sec^{-1}$), were observed after UTT. Three months following completion of UTT, positive changes in nearly all HRF variables (6MWD, BM, BF%, WC, peak hamstrings torque at $60°·sec^{-1}$, peak quadriceps torque at $30°·sec^{-1}$) were maintained ($p < .05$) relative to baseline values.

CONCLUSIONS: Our findings indicate that improvements in HRF resulting from 12 weeks of UTT persist three months after cessation of UTT in middle-aged adults with type 2 diabetes.

A Bout of High-Intensity Interval Training Increases Seric Musclin in Adults with Metabolic Syndrome

Jaime A. Gallo-Villegas[1], Leonardo A. Castro-Valencia[1], Miguel Alzate[2], Luis Valbuena[3], Yeliana L. Sánchez[1], Juan C. Aristizábal[1], Raúl Narváez-Sánchez[1], Juan C. Calderón[1]. [1]University of Antioquia, Medellín, Colombia. [2]Politécnico Jaime Isaza Cadavid, Medellín, Colombia. [3]Indeportes Antioquia, Medellín, Colombia.
(No relevant relationships reported)

Musclin is a myokine which induces insulin resistance (IR) in vitro, also proposed to favor aerobic capacity in murine models, which seems contradictory. Because of that, and since exercise contributes to improve IR in metabolic syndrome (MS) probably by regulating myokines, it is necessary to understand exercise´s role in regulating musclin in humans. **PURPOSE**: to study the effect of a bout of high-intensity interval training (HIIT) on seric musclin in adults with MS and IR. **METHODS**: 11 men and 4 women with MS and IR were evaluated in an experimental, pilot study. Musclin was measured by ELISA, and both glycemia and insulin by standard methods, at: 1) fasting conditions, 2) 60 minutes after a breakfast of 408 Kcal (55.1 g carbohydrates, 17.4 g fat, 9.2 g proteins), and 3) immediately after a session of HIIT (100 min after breakfast). Homeostatic model assessment (HOMA-IR) was used as indicator of IR. The HIIT session lasted 19 minutes and consisted of 5 cycles, each of them with one minute of high intensity (85% of VO2max) and two minutes of moderate intensity (50% of VO2max). Three minutes of warming up and cooling down at 3 MET intensity was always done. Data are presented as median (interquartile range). Comparisons were done with Friedman test. **RESULTS**: patients had an age of 52 years (45-59), a body mass index (BMI) of $26.8 kg·m^{-2}$ (24.9-30.1), oxygen consumption (VO2max) of $34.6 ml·kg^{-1}·min^{-1}$ (30.2-38.2) and HOMA-IR of 3.3 (2.6-4.3). Musclin values post-HIIT ($709.6 pg·ml^{-1}$ (585.2-833.9)) showed a trend to be higher than fasting (599.1 $pg·ml^{-1}$ (506.2-724.5), P=0.088) and refeeding (593.0 $pg·ml^{-1}$ (466.4-918.2), P=0.061) conditions. Fasting musclin correlated with diastolic blood pressure during the HIIT bout (r=0.62, P<0.05). Insulin of 13.9 $μU mL^{-1}$ (10.4-16.6), 59.4 $μU mL^{-1}$ (23.1-159.8) and 30.8 $μU mL^{-1}$ (22.4-41.5) and glycemia of 102.4 $mg dl^{-1}$ (89.9-108), 111 $mg dl^{-1}$ (84.4-127.4) and 97.1 $mg dl^{-1}$ (87.3-110.3), were measured at conditions 1 to 3, respectively. **CONCLUSIONS**: a bout of HIIT trend to increase circulating musclin in humans with MS and IR, which does not support the idea of a myokine that induces IR. Future experiments will test if the increase in musclin could be explained by an increase in insulin. Colciencias 111562638757. CODI 2605. Interinstitucional 2016-1341. Time-efficient Sprint Interval Exercise Improves 24-h Glycaemic Control In Men With Type 2 Diabetes

Richard S. Metcalfe[1], Conor McClean[2], Sinead Fitzpatrick[3], Gary McDermott[2], Noel Brick[2], Ben Fitzpatrick[2], Gareth Davison[2]. [1]Swansea University, Swansea, United Kingdom. [2]Ulster University, Belfast, United Kingdom. [3]Altnagelvin Area Hospital, Derry-Londonderry, United Kingdom.
(No relevant relationships reported)

PURPOSE: Reduced-exertion high-intensity interval training (REHIT) is a genuinely time-efficient exercise intervention that has been shown to improve aerobic capacity and blood pressure in men with type 2 diabetes. However, the acute effects of REHIT on 24 h glycaemic control in type 2 diabetes have not been determined. **METHODS**: Eleven men with type 2 diabetes (mean ± SD: age, 52±6 years; BMI, 29.7±3.1 kg/ m^2; HbA1c, 7.0±0.8 %) participated in a randomised four-trial crossover study, with continual interstitial glucose measurements captured during a 24 h period including either: (1) no exercise (CON); (2) 30 min of continuous exercise (CE); (3) 10 x 1 min at ~90 HR$_{max}$ (HIIT; time commitment, ~25 min); and (4) 2 x 20 s 'all-out' sprints

(REHIT; time commitment, 10 min). Nutritional intake and timings of consumption were standardised within participants. The 24 h monitoring period started prior to breakfast and the exercise was performed 30 min after breakfast. Comparisons for 24 glycaemic variables were made using one-way repeated measures ANOVA and Holm-Sidak corrected t-tests for pre-planned contrasts (exercise conditions *versus* control). Cohens d was used as a measure of effect size with the following thresholds: small ($d = 0.2$), medium ($d = 0.5$) and large ($d = 0.8$) effect. **RESULTS**:Compared with CON (8.1±1.1 mmol/l), both REHIT (7.5±0.9 mmol/l, $p<0.05$, $d=0.55$) and CE (7.7±1.1 mmol/l, $p=0.06$, $d=0.35$) lowered mean 24 h glucose, and this was largely driven by a markedly lower glycaemic response (AUC) to dinner in both instances (-11%, $p<0.05$ and $d>0.8$ for both). The prevalence of hyperglycaemia was reduced with all three exercise bouts compared with CON (REHIT: -112 min; CE: -115 min; HIIT -125 min, all $p<0.05$, all $d>0.5$), whilst measures of glycaemic variability were not significantly altered. **CONCLUSIONS**: These data suggest that REHIT may offer a genuinely time-efficient alternative exercise option for improving 24 h glycaemic control in men with type 2 diabetes.

The Acute Effects of Exercise Intensity on Blood Glucose Levels in Type 1 Diabetics

Charles Fountaine, Christine Laughlin, Shane Blechinger. *University of Minnesota Duluth, Duluth, MN.* (Sponsor: John R. Keener, FACSM)
(No relevant relationships reported)

For individuals with Type 1 diabetes mellitus (T1DM), regular physical activity is a fundamental strategy in the management of glycemic control. Previous studies have shown that continuous, moderate-intensity exercise in individuals with T1DM decreases blood glucose concentrations, often resulting in hypoglycemia, whereas vigorous-intensity exercise can increase blood glucose, impacting the risk of hyperglycemia. Sprint interval training (SIT), characterized by brief, all-out bursts of supramaximal exercise, has been shown to improve indices of cardiometabolic health, despite a minimal time commitment. However, the effects of low volume SIT on individuals with T1DM is largely unknown. **PURPOSE**: to contrast the acute effects of exercise intensity on blood glucose levels in Type 1 diabetics. **METHODS**: Four recreationally active college-age students with T1DM, completed a treadmill test to determine maximal aerobic speed (MAS), and performed each of the following 20-min treadmill-based protocols: 1) Moderate-intensity continuous training (MICT): 5-min warm-up (WU), 10 minutes at 70% MAS, 5-min cool-down (CD); 2) high-intensity interval training (HIIT): 5-min WU, 1-min at 90% MAS, 1-min at 30% MAS repeated 5 times, 5-min CD; 3) SIT: 5-min WU, 30-sec at 120% MAS, 2-min, 50-sec at 30% MAS repeated 3 times, 5-min CD. Blood glucose was monitored via glucometer every 5-min during exercise and for 45-min after. **RESULTS**: A statistically significant decline in blood glucose was observed in both the MICT and HIIT conditions (p <0.001, respectively) but not in the SIT condition (p = 0.696). From baseline to the 45-min mark, blood glucose decreased by 27% in both the MICT (180 ± 27 to 132 ± 39) and HIIT (183 ± 29 to 132 ± 15) protocols, but only 11% in the SIT (193 ± 41 to 165 ± 70) protocol. **CONCLUSIONS**: The results of this study provide initial proof-of-concept that a low volume SIT protocol can maintain target blood glucose levels while exercising in individuals with T1DM.

Exercise Reduces HbA1c in Type 2 Diabetics, but Improved Strength Associates with Poorer Outcomes

Cynthia Villalobos[1], Paul D. Vosti[2], J. Mark VanNess[1], Courtney D. Jensen[1]. [1]University of the Pacific, Stockton, CA. [2]St. Joseph's Hospital, Stockton, CA.
(No relevant relationships reported)

More than 25 million Americans have type 2 diabetes. Exercise is an effective method to prevent, delay, or manage the disease; however, fewer than 40% of patients report engagement in physical activity and more than 20% of this group overestimate their engagement. Structured exercise is warranted. Both aerobic and resistance training may be more effective than either mode in isolation, but studies reporting this are limited by their combined groups having greater volumes of exercise. **PURPOSE:** To evaluate different volumes of combined aerobic and resistance exercise on HbA1c levels in adults with diabetes. **METHODS:** 67 patients were randomly assigned to one of two groups: Group 1 performed supervised aerobic and resistance exercise twice per week. Group 2 performed the same exercise as Group 1 but also walked for 60 min on two additional days. At baseline, health history, seven tests of physical functioning, and measured cardiometabolic parameters, including HbA1c was performed. Following 10 weeks of exercise, follow-up data were collected. Independent-samples t tests compared baseline data and rates of improvement between the two groups. Multiple linear regression tested predictors of improvement in HbA1c. **RESULTS:** Group differences at baseline were minimal. Patients in Group 2 were 4.7 years older (p=0.063), body mass index was 3.3 points lower (p=0.058), and they walked an additional 72.7 meters in the 6-minute walk (p=0.009). There were no differences in

body fat percent (p=0.507), HbA1c (p=0.512), other cardiometabolic parameters, or the other six assessments of physical functioning. The patients who completed the exercise intervention improved in 13 of 15 assessments (p<0.05), including HbA1c (p=0.045). There were no differences in improvement between exercise groups. Regression analysis found elevated baseline body fat percent (p=0.001) and improvements in strength, assessed by arm curls (p=0.009) and grip strength (p=0.042) to correspond to poorer outcomes in HbA1c; the overall model was significant (R^2=0.733; p<0.001). **CONCLUSIONS:** Ten weeks of combined aerobic and resistance exercise improved cardiometabolic profiles of diabetic patients, including HbA1c. Additional volume of aerobic exercise did not enhance outcomes and improvements in strength associated with poorer outcomes.

The Effects Of Simulated Hypoxia Bouts On Resting Blood Glucose Levels And Hemodynamics Of A Type 1 Diabetic: A Case Study

Devin J. Rettke, Scott Drum, FACSM. *Northern Michigan University, Marquette, MI.* (Sponsor: Scott Drum, FACSM)
(No relevant relationships reported)

Individuals diagnosed with diabetes may choose adventure travel vacations at higher altitudes, thereby perturbing formerly controlled sea level (SL) blood sugar (BG) levels. **Purpose:** We sought to describe change in resting BG concentration, heart rate (HR), and mean arterial pressure (MAP) during repeat acute exposure to simulated altitude bouts in a type 1 diabetic (T1D) vs a non-diabetic (ND). We hypothesized T1D would encounter less stable readings on all variables. **Methods:** Two male participants (n=2), a T1D and ND, 22 and 23 years old, respectively, completed this case study. Participants, simultaneously, visited a lab on six different days [i.e., three days in a row one week (M, T, W) and the same three days the following week (M, T, W)]. They ingested the same meals the night before and day of (1.5-hrs before chamber use). At each visit, BG (Contour Next Link; Parsippany, NJ), HR (Polar, Lake Success, NY), and MAP (Briggs Healthcare, Waukegan, IL) were assessed at rest at SL and during 2-hr/bouts at 10-min intervals using a hypoxic chamber (Hypoxico Inc., New York, NY) set randomly to varying altitudes: SL; 915 m; 1,829 m; 2,743m; 3,658m; and 4,572m. **Results:** For each variable, magnitude of change (Δ) was averaged over the 6 lab visits and compared at SL and across altitude levels. SL ΔBG (mg/dL), ΔHR (bpm), and ΔMAP (mmHg) for T1D and ND, respectively, were: 19, 16, 18; and 34, 18, 12. T1D maintained a more stable BG at SL over 6 days. When averaging the five altitude levels over 6 days, ΔBG (mg/dL), ΔHR (bpm), and ΔMAP (mmHg) for T1D and ND, respectively, were: 58, 9, 10; and 47, 9, 10. Notably, T1D had a less stable BG during hypoxic exposure. **Conclusion:** Simulated hypoxia perturbed BG to a greater extent in T1D. This could have practical application for when a T1D travels to higher, natural elevations, at which point they should more closely monitor their BG levels with normal food and fluid intake.

Effects of Aerobic Exercise on Plasma Metabolites in Prediabetes Subjects

Bowen Li[1], Mian Jia[1], Ningning Zhang[1], Chaojun Li[1], Yan Wang[1], Xianbo Zhang[2], Juan Wang[1], Zhengzhen Wang, FACSM[1]. *[1]Beijing Sport University, Beijing, China. [2]Beijing Hospital, Beijing, China.* (Sponsor: Zhengzhen Wang, FACSM)
(No relevant relationships reported)

Objective: Regular exercise can improve the insulin sensitivity in Prediabetes(PDM). However, the mechanisms remain unclear. This study aimed to examine the effect of aerobic exercise on PDM subjects·plasma metabolites. **METHODS:** 24 PDM subjects were selected [mean age of (54.41±10.34) yr, body mass index of (25.70±3.80)kg/cm², 8 males]. Each 10 age and sex-matched normal subjects and new-onset T2DM subjects were enrolled. PDM subjects received exercise (n=13) or health education (n=12) for 12 weeks. Exercise training: 3 times/week, 50 min per session at 40%-60% of of VO_2 reserve. The body composition (dual-energy x-ray absorptiometry) and cardiorespiratory fitness (VO_2peak) were detected before and after exercise. Plasma metabolites were analyzed by using liquid chromatography/mass spectrometry (LC/MS). **RESULTS:** After training, the body fat percentage, 2-hour OGTT plasma glucose, and low density lipoprotein cholesterol of PDM patients were significantly reduced (by 4.6%, 16.22% and 9.27%, on average). The metabolic characteristics were significantly different before and after exercise, there were 31 endogenous metabolites (VIP > 1 and P < 0.05), of which 25 were increased and 6 were decreased. Main metabolites that changes with training included phosphatidylcholine, lysophosphatidylcholines, sphingomyelin, betaine, linoleic acid,oleic acid and docosahexaenoic acid. **CONCLUSION:** Aerobic exercise intervention has a marked effect on the plasma metabolites in PDM patients, which can improves the glucose and lipid metabolism by regulating the metabolic pathway of linoleic acid and phospholipid. These findings may lead to a better understanding of the mechanism

of aerobic exercise in preventing T2DM. Supported by Key Projects of State General Sports Administration of China (2014B007),Specialized Research Fund for the Doctoral Program of Higher Education of China (20131112110002).

A Curious Relationship Between Obesity, Diabetes, and Dementia

Megan L. Darling[1], J. Mark VanNess[1], Jonathan M. Saxe[2], Michelle M. Amaral[1], Lewis E. Jacobson[2], Courtney D. Jensen[1]. *[1]University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.*
(No relevant relationships reported)

Among American adults (age ≥ 18), 36.5% have obesity, 9.3% have diabetes, and more than 4 million have dementia. These pathologies do not develop and progress independently. Compared to adults with a body mass index (BMI) less than 23, overweight adults (BMI>25) have a 10-fold increase in the odds of developing diabetes. In turn, body weight and diabetes appear to exert independent effects on the risk of dementia. More work is necessary to elucidate these relationships. **PURPOSE:** To assess the effects of obesity and diabetes on incidence of dementia. **METHODS:** We analyzed a hospital population that included 2,306 consecutively admitted patients. We conducted a health history, diagnosed cerebral, metabolic, and cardiovascular diseases, and measured anthropometric and cardiometabolic parameters. Chi-square tests analyzed rates of dementia among patients with and without obesity and diabetes. Logistic regression tested the effects of obesity and diabetes on odds of a dementia diagnosis, holding constant potential confounders. **RESULTS:** Across the total sample, 16.3% of patients were obese, 14.3% had diabetes, and 4.6% had dementia. Among obese patients, 26.0% had diabetes; 12.0% of non-obese subjects had diabetes (p<0.001). Among obese patients, 1.6% had dementia; 5.1% of non-obese patients had dementia (p=0.003). Among patients with diabetes, 8.8% had dementia; 3.8% of patients without diabetes had dementia (p<0.001). Logistic regression, holding age and history of stroke constant, found trends for obesity to reduce odds of dementia by 56% (p=0.079) and diabetes to increase odds by 63% (p=0.060). Sex (p=0.418), depression (p=0.608), mean arterial pressure (p=0.837), smoking status (p=0.920), and histories of heart attack (p=0.250), congestive heart failure (p=0.627), and peripheral vascular disease (p=0.943) were not significant. Among patients age ≥ 65 (n=724), 13.8% were obese, 27.2% had diabetes, and 14.0% had a diagnosis of dementia. The same logistic regression preserved its trends for obesity (OR=0.376; p=0.054) and diabetes (OR=1.600; p=0.079). **CONCLUSIONS:** Obesity appears to carry a protective role, lowering risk of dementia, while diabetes elevates risk. Given the absence of a relationship with vascular disease, this is more likely a consequence of glucose, insulin, and amyloid metabolism.

The Dose Effect of Whey Protein on Insulin Responses in Pre-Diabetic and Type 2 Diabetics

Todd J. Castleberry, Christopher Irvine, Michael Oldham, Matthew Brisebois, Sarah E. Deemer, Ryan Gordon, Aubrien Henderson, Vic Ben-Ezra. *Texas Woman's University, Denton, TX.* (Sponsor: David Nichols, FACSM)
(No relevant relationships reported)

BACKGROUND: People with pre-diabetes and type 2 diabetes have shown an increase in insulin secretion after ingesting 55 g of whey protein coupled with a glycemic challenge. However, the effect of lower amounts of whey protein on insulin responses remains unclear. Our hypothesis was that both 20 g and 30 g of whey consumption prior to an oral glucose tolerance test (OGTT) would produce an increase in insulin secretion, with 30 g producing the greatest increase compared to a control.

PURPOSE: The purpose of this study was to examine the effect of two different doses of whey protein ingested 30 min prior to a 50 g OGTT on glucose, insulin, C-peptide, and glucagon responses.
METHODS: Diabetic or pre-diabetic participants (n=9, mean ± SD; age: 64.3 $\pm$ 8.1 yrs; BMI: 29.4 $\pm$ 6.0 kg/m²; body fat percentage: 42.5 $\pm$ 7.8 %; fasting plasma glucose: 6.9 $\pm$ 1.2 mmol/l; HbA1c: 6.4 $\pm$ 0.6 %) completed three trials. The randomly assigned trials consisted of: 250 ml of water (CON), 250 ml of water + 20 g whey (20g), and 250 ml of water + 30 g whey (30g), followed by an OGTT. Blood was collected at -30, 0, 15, 30, 60, 90, 120, and 150 min for the measurement of glucose, insulin, C-peptide, and glucagon. The whey protein mixture was administered immediately following the -30 min blood draw, and the 50 g OGTT began immediately following the 0 min blood draw. Glucose was analyzed using a YSI 2900D glucose analyzer and insulin, C-peptide, and glucagon were measured via multiplex fluorescent detection (MagPix). A one-way repeated measures ANOVA (p<.05) with a Bonferroni post hoc was used for statistical analysis for each dependent variable.
RESULTS: Integrated area under the curve (AUC) for glucose presented no difference between the 3 trials. Insulin AUC was significantly increased from CON to 20g (p=0.004, 36.3%), CON to 30g (p=0.002, 61.7%), and 20g to 30g (p=0.030, 18.6%). C-peptide and glucagon AUC significantly increased from CON to 20g (p=0.018, 20.6%; p=0.046, 33.1%) and CON to 30g (p=0.001, 30.1%; p=0.017, 33.7%).
CONCLUSION: Whey protein elicited a dose response on plasma insulin, increasing concentrations from CON to 20g, and 20g to 30g, however plasma glucose was unaffected. 20g and 30g displayed similar responses for glucagon. Neither 20 g nor 30 g of whey protein may be adequate to provide glycemic improvement in the disease management of type 2 or pre-diabetes.

A Bout Of Intense Exercise Cannot Substitute Antihypertensive Medication But When Combined, Enhances Medicine Actions.

MIGUEL RAMIREZ-JIMENEZ, FELIX MORALES-PALOMO, JUAN FERNANDO ORTEGA, RICARDO MORA-RODRIGUEZ. *UNIVERSIDAD DE CASTILLA-LA MANCHA, TOLEDO, Spain.*
(No relevant relationships reported)

Purpose: We studied the blood pressure lowering effects of a bout of exercise and/or antihypertensive medicine with the goal of studying if exercise could substitute or enhance pharmacologic hypertension treatment. **Methods:** Twenty-three hypertensive metabolic syndrome patients chronically medicated with angiotensin receptor blockade antihypertensive medicine underwent 24-hr monitoring in four separated days in a randomized order; *a)* after taking their habitual dose of antihypertensive medicine (AHM trial), *b)* substituting their medicine by placebo medicine (PLAC trial), *c)* placebo medicine with a morning bout of intense aerobic exercise (PLAC+EXER trial) and *d)* combining the exercise and antihypertensive medicine (AHM+EXER trial). **Results:** In trials with AHM subjects had lower plasma aldosterone/renin activity ratio evidencing treatment compliance. Before exercise, the trials with AHM displayed lower systolic (130±16 vs 133±15 mmHg; P=0.018) and mean blood pressures (94±11 vs 96±10 mmHg; P=0.036) than trials with placebo medication. Acutely (i.e., 30 min after treatments) combining AHM+EXER lowered systolic blood pressure below the effects of PLAC+EXER (-8.1±1.6 vs -4.9±1.5 mmHg; P=0.015). Twenty-one hours monitoring revealed no differences among trials in body motion. However, PLAC+EXER and AHM lowered systolic blood pressures below PLAC during the first 10 hours, time at which PLAC+EXER effects faded out (i.e., at 19 PM). Adding exercise to medication (i.e., AHM+EXER) resulted in larger reductions in SBP that lasted most of the night (Figure 1). **Conclusion:** One bout of intense aerobic exercise in the morning cannot substitute the long-lasting effects of antihypertensive medicine in lowering blood pressure, but their combination is superior to their separated effects.

(No relevant relationships reported)

THE IMPACT OF PERIPHERAL HEMODYNAMICS ON DERIVED CENTRAL PRESSURE WAVEFORMS. Gabriel Zieff[1], Simon Fryer[2], Keeron Stone[2], James Faulkner[3] Lee Stoner[1].[1]UNC Chapel Hill, NC. [2]University of Gloucestershire. [3]University of Winchester. **Introduction:** Central hemodynamic parameters, such as aortic systolic pressure (cSBP), augmentation index (AIx), and pressure wave forms (Pb) may offer clinicians superior prognostic information to peripheral systolic pressure (SBP). It is unknown whether changes in peripheral hemodynamics affect central hemodynamic measurements. **Purpose:** To investigate whether changes in peripheral hemodynamics, induced using upper limb tilting, affect central hemodynamic parameters. **Methods:** A single visit, repeated measures design, 20 healthy young adults (BMI: 24±2.8; 55% F). Brachial pressure waveforms were simultaneously measured in a supine position using an oscillometric device on an experimental (SphygmoCor XCEL) and control (Oscar, SunTech) arm. The experimental arm was positioned 30⁰ above, 30⁰ below, and at heart level, in a randomized order. The control arm remained at heart level. **Results**: For the experimental arm, there was a large effect change in SBP (eta=0.82, p<0.001) and cSBP (eta=0.81, p<0.001) when the arm was above (cSBP Δ4.9, SBP Δ4.6) and below (cSBP Δ-12.5, SBP Δ-9.8). AIx increased (p=0.023) when the arm was below but not above. No change occurred in Pb. In the control arm, no change occurred in SBP or cSBP, but AIx decreased when the experimental arm was above (p=0.04). **Conclusions:** Changes in peripheral hemodynamics result in large changes in cSBP and AIx, but not in Pb. Findings provide a rationale for standardizing the upper limb position during BP measurement, and may have important clinical implications regarding pharmacological prescription.

Body Composition and Blood Pressure Comparisons of Older Runners and Younger Non-Running African American Women

Doris J. Morris. *Georgia State University, Atlanta, GA.* (Sponsor: L. Jerome Brandon, FACSM)
(No relevant relationships reported)

African American women(AAW) are among the more sedentary and obese segments of the American population. A major question is if body composition and blood pressure responses of active older AAW (OAAW) are different than younger sedentary AAW (YAAW)? **Purpose**: This study was designed to determine if body fat percentage (fat%), bone density and blood pressure (BP) would be different between OAAW and YAAW. **Methods**: A cross-sectional research design with 61 women (18 older runners -age 59.6 5.7 yrs. and 43 younger runners -age 40.6 8.2 yrs.) was evaluated for DXA body composition and blood pressure. The older runners had been runners for a minimum of 12 months and ran a minimum of 10 miles per week. **Results:** The women differed (p<0.05) on fat% (OAAW 38.4 ± 6.0 and YAAW 33.2 ± 9.5%), bone mineral density (BMD) (OAAW 1.133 and YAAW 1.217 g/cm²) and the groups were near different (p=0.054) for systolic BP (OAAW 119 ± 10.8 and YAAW 113.4±10.9). **Discussion:** The anticipated difference between the groups due to age was not

---

WEDNESDAY, MAY 30, 2018

observed for many of the body composition and diastolic BP variables. The differences observed for BMD and fat% may have been related to the number of years the OAAW had been running. These data suggest that greater physical activity participation by AAW can aid in managing many aspects of body composition. Since BP and fat% are cardio-metabolic risks for cardiovascular disease, an active lifestyle may aid in increasing the quality and perhaps the quantity of their lives.

Effect of Intra-Venous Antioxidant Infusion on the Development of Neuromuscular Fatigue During Whole Body Exercise in Hypertensive Middle-Age Individuals

Taylor S. Thurston[1], Joshua C. Weavil[1], Thomas J. Hureau[2], Jayson R. Gifford[3], Russell S. Richardson[1], Markus Amann[1]. [1]University of Utah, Salt Lake City, UT. [2]University of Strasbourg, Strasbourg, France. [3]Brigham Young University, Provo, UT.
(No relevant relationships reported)

PURPOSE: To investigate the effect of intravenous antioxidant supplementation on the development of neuromuscular fatigue during whole body exercise in middle-age hypertensive patients. **METHODS:** Clinically diagnosed hypertensive males performed fatiguing, constant-load cycling exercise to exhaustion (80% W_{peak}, 150 ± 27 W) following both a 2 g intra-venous infusion of L-ascorbic acid (AOX; dissolved in 20 mL saline) and saline (PLA; 20 mL) randomized and separated by at least 5 days. The trial characterized by shorter exhaustion time was later repeated (i.e., iso-time) under the opposite supplemental condition. Peripheral fatigue was quantified as the pre- to post-exercise change in quadriceps twitch torque (ΔQ_{tw}; supramaximal electrical femoral nerve stimulation), maximal rate of force development ($\Delta mRFD$), and peak relaxation rate (ΔPRR). Central fatigue was quantified as the exercise-induced change in voluntary activation (ΔVA). Femoral arterial blood flow (Doppler ultrasound; Q_L) was quantified during cycling at 25, 50, and 75 W. Cardiopulmonary responses were recorded continuously. Exercise-induced fatigue was quantified during time-matched trials. **RESULTS:** AOX had no effect on blood pressure at rest (MAP: 107 ± 2 mmHg) or during the final minute of exercise (MAP: 137 ± 3 mmHg; P < 0.05). Q_L was similar between conditions at baseline and during exercise (~0.2, ~1.5, ~2.1, ~2.7 L/min, respectively). Furthermore, heart rate (~153 BPM), minute ventilation (~117 L/min), O_2 consumption (~2.2 L/min), and CO_2 production (~2.5 L/min) during the final minute of exercise were similar between trials. While ΔVA (~-6%) and $\Delta mRFD$ (~-45%) were not altered by AOX, ΔQtw and ΔPRR were attenuated in AOX compared to PLA (-40 ± 9% vs -58 ± 9%; -19 ± 12 vs -44 ± 9%, respectively; P < 0.05). Finally, AOX had no effect on cycling time to exhaustion (PLA: 488 ± 22 s vs AOX: 487 ± 65 s). **CONCLUSION:** AOX attenuates the development of fatigue while not altering the cardiopulmonary response and locomotor muscle blood flow during cycling exercise in hypertensive males. This ergogenic effect is likely determined by intracellular mechanisms and independent of muscle O_2 transport. Importantly, the observed AOX-induced reduction in the development of peripheral fatigue does not appear to improve endurance capacity in hypertensive patients.

Effects of High Intensity Interval Exercise Training on Blood Pressure in Patients with Hypertension

Jung Jun Park[1], Eun-Ah Jo Jo[1], Kyoung-Im Cho[2], Do-sun Im[3]. [1]Pusan National University, Busan, Korea, Republic of. [2]Kosin University, Busan, Korea, Republic of. [3]Korea University, Seoul, Korea, Republic of.
(No relevant relationships reported)

PURPOSE: To compare the effects of HIIT and CAE on changes in blood pressure reduction and endothelial function in hypertensive patients.
METHODS: Seventeen hypertensive patients, aged 52.1±7.6, participated in this study, tapered off their medications, if necessary, and were randomized to either HIIT (n=9) or CAE (n=8) group. HIIT was composed of 5 sets of 3 min exercise at 80% HRR, and each interval was separated by 3 min recovery at 40% HRR. CAE was composed of 35 min exercise at 60% HRR. Both groups were designed to use same energy expenditure, and performed exercise 5 days per week for 4 weeks. Endothelial function was determined by assessing endothelial progenitor cells (EPCs) using flow cytometry and flow mediated dilation (FMD) using ultrasonography. Arterial stiffness was measured by pulse wave velocity (PWV). Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were measured at rest and during exercise at 60% HRR by using automatic blood pressure monitor.
RESULTS: At rest, SBP was significantly decreased in HIIT ($p<0.01$) and CAE ($p<0.05$), and DBP was significantly decreased in HIIT ($p<0.001$), but not in CAE. During exercise, SBP was significantly decreased in CAE ($p<0.05$), but not in HIIT, and DBP was significantly decreased in HIIT ($p<0.01$), but not in CAE. FMD and EPCs were significantly improved in HIIT ($p<0.01$ and $p<0.05$, respectively), but not in CAE. There were significantly different changes in DBP during exercise and EPCs between groups ($p<0.05$). However, PWV was not changed in both groups.

CONCLUSIONS: The results of this study suggest that HIIT and CAE equally have beneficial effects on blood pressure reduction at rest and during exercise. However, HIIT may improve endothelial function greater than CAE. Therefore, HIIT could be a better exercise program than CAE for hypertensive patients.

24 Hour Ambulatory Blood Pressure Dipping And Variability Characteristics Following Maximal Treadmill Exercise In Community Dwelling Healthy Older Adults.

Thomas R. Petrella, Narlon C. B. S. Silva, Ashleigh De Cruz, Alan Salmoni, Robert J. Petrella, FACSM. Western University, London, ON, Canada. (Sponsor: Robert Petrella, FACSM)
(No relevant relationships reported)

Abnormal blood pressure (BP) response to maximal exercise may lead to compromised cardiovascular health. **PURPOSE**: To examine the 24-hour ambulatory blood pressure response in older adults following a maximal exercise treadmill test. **METHODS**: Ambulatory BP was recorded every 30 minutes (daytime) and 60 minutes (nighttime) on the day preceding and then 24 hours following a symptom limited maximal exercise treadmill test. Participants were a convenience sample of healthy older adults free of cardiovascular and musculoskeletal limitations who were participants in a community-based exercise program in London, Ontario, Canada. Symptom limited exercise was performed in the AM in a fasted state, during which VO2max was estimated. The study outcomes included mean systolic and diastolic BP (daytime, nighttime and 24-hour), as well as mean change in BP from daytime to nighttime (BP dipping), and BP variability (average real variability [ARV]). Mixed between-within ANOVA was used in the statistical analysis, exploring main effects for time (pretest vs posttest), grouping factors (presence of hypertension [normotensive vs hypertensive], gender [men vs women], and fitness level [low, average and high VO2max]), and interaction effects for time × grouping factors.
RESULTS: 11 men and 9 women, mean age 71.5 (SD=5.4) years were included in the analysis. Mean VO2max was 34.8 (SD=7); 10 subjects had documented hypertension. No difference in the mean pre-exercise systolic ABP was 129.2 (120.3-138.1) vs 124.8 (116.7-132.9) and post-exercise systolic ABP was 126.3 (118.8-133.9) vs 122.8 (116-129.6) in normotensive and hypertensive subjects respectively (p=0.7). Nighttime diastolic BP dipping differed according to VO2max groups, whereby it increased in participants with low VO2max, while it decreased in those with average VO2max and high VO2max (p=0.037). As well, post-exercise systolic BP variability was decreased in men but increased in women (p=0.07). **CONCLUSIONS**: Healthy older normotensive and hypertensive subjects had similar post 24-hour systolic BP dipping. However, nighttime diastolic blood pressure as significantly different according to fitness level and systolic BP variability was reduced in men suggesting low fitness and male gender may alter BP response to maximal exercise in older adults.

Post-isometric Exercise Hypotension After Moderate intensity Handgrip Exercise In Hypertensive Elderly

MILTON R. MORAES[1], VIVIAN E. MORAES[1], JOYCE B. VICENTE[1], GEIZIANE R. MELO[1], RAFAEL R. OLHER[1], IORRANY C. SOUSA[1], LUIZ H. PERUCHI[2], RODRIGO V. NEVES[1], THIAGO S. ROSA[1], APARECIDO P. FERREIRA[1], LUIZ R. SOUZA[1]. [1]CATHOLIC UNIVERSITY OF BRASILIA, BRASILIA, Brazil. [2]University of Mogi das Cruzes, Mogi das Cruzes, Brazil.
(No relevant relationships reported)

Hypertension is common in people aged 65 or more. The isometric handgrip (IHG) is a model of effective exercise in reducing blood pressure (BP). However, the mechanisms involved in post-isometric exercise hypotension (PIEH) remain unclear. Nitric oxide (NO) is a potent vasodilator and may be involved in PIEH.**PURPOSE**:To determine the response hypotensive and mechanism involving in older with arterial hypertension. **METHODS**:Ten sedentary hypertensive elderly (73.2±2.2 years), underwent two experimental sessions using a portable isometric handgrip dynamometer Jamar; (i) sham session with 3 percent of maximal voluntary isometric contraction (MVIC); and (ii) experimental isometric session with 30 percent of MVIC, total of 8 sets of 1 min contraction and 1 min rest pause. The BP and heart rate (HR) were evaluated at rest and post-exercise (1, 5, 10, 15, 30, 45 and 60 min). Saliva samples were collected at rest, 0, 30 and 60 min post-exercise. **RESULTS**: Systolic BP (SBP) presented a reduction from the 10th min post-exercise to 30 percent MVIC (p < 0.05). At 60 min post-exercise the SBP was lower 30 percent vs. 3 percent MVIC (p = 0.006). There were no differences for diastolic BP, mean arterial pressure, HR and NO metabolites. The results demonstrated that IHG exercise at 30 percent MVIC was tolerated by elderly individuals and induced an PIEH for up to 60 min, but there was no association with NO- salivar metabolite. **CONCLUSIONS**: Yet, this portable equipment of cost-effective, easy performance and short duration can be an excellent adjuvant strategy in the control and prevention of arterial hypertension in elderly.

Effects Of Isometric Handgrip Versus Aerobic Exercise On Blood Pressure In Elderly Hypertensive Patients

Sae Young Jae, Eun Sun Yoon, Hyun Jeong Kim. *University of Seoul, Seoul, Korea, Republic of.*

(No relevant relationships reported)

PURPOSE: The aim of this study was to compare the antihypertensive effects of isometric handgrip exercise (IHE) versus aerobic exercise (AE) on office, central and 24-h ambulatory blood pressures in elderly hypertensive patients. **METHODS**: We conducted a randomized controlled trial with a three-arm design. Thirty-seven elderly hypertensive patients (mean age 69±6 years) were randomized to IHG training (n=14), AE training (n=11), or non-exercise control group (n=12) for 12 weeks. Bilateral IHG training was performed at 30% of maximal voluntary contraction using a digital handgrip device. AE training was performed brisk walking for 30-min at moderate intensity with 3 times per week. Resting office, central, and 24-h ambulatory blood pressures were obtained at baseline and after intervention. **RESULTS**: No group differences were found at baseline for any variable. Following 12 weeks, resting office blood pressures decreased in both IHG and AE groups (IHG: SBP 135.4±14.1 to 125.8±9.9mmHg (p=0.004), DBP 84.8±8.5 to 79.6±5.8mmHg (p=0.005); AE: SBP 130.3±13.3 to 123.1±8.1mmHg (p=0.022), DBP 80.5±7.0 to 76.8±5.0mmHg (p=0.037)), without any improvement in the control group. Furthermore, central SBP (122.0±13.5 to 117.0±9.8mmHg (p=0.05)) and mean 24h ambulatory DBP (80.3±8.8 to 75.6±7.2mmHg (p=0.021)) decreased only in the IHG group, but not in the AE or control groups. **CONCLUSIONS**: These findings suggest that both IHG and AE trainings reduce resting office blood pressure, but only IHG training is effective in improving central and ambulatory blood pressures. Thus, IHG training may be an alternative antihypertensive therapy for the elderly hypertensive patients.

Effects of Whole-body Vibration On Strength, Body Composition, and Function in Skilled Nursing Home Residents

Brandon F. Grubbs[1], Arturo Figueroa, FACSM[2], Jeong-Su Kim, FACSM[3], Karla Schmitt[3], Lynn B. Panton, FACSM[3]. *[1]Middle Tennessee State University, Murfreesboro, TN. [2]Texas Tech University, Lubbock, TX. [3]Florida State University, Tallahassee, FL.* (Sponsor: Lynn B. Panton, FACSM)

(No relevant relationships reported)

PURPOSE: To compare the effects of 12 wks of whole-body vibration training (WBVT: n=10) to standard care, which served as the control (CON: n=10), on strength, body composition, and functional performance in 20 (16 female) pre-frail and frail skilled nursing home residents (82±5 yrs).
METHODS: Participants were screened for frailty syndrome using the FRAIL scale. Isometric knee extension strength (KE) was measured using a mechanical push-pull dynamometer. Bioelectrical impedance analysis was used to measure lean mass (LM) and fat mass (FM). The short physical performance battery (SPPB) was used to assess function. Participants were assigned to 12 wks of WBVT (2x/wk) or CON. WBVT consisted of 3 sets of 10 reps of 4 lower body exercises (partial squat, narrow squat, wide squat, calf raises) during vertical vibration (25-40 Hz). Data were analyzed using two-way ANOVA (group x time) and post-hoc paired t-tests. Significance was set at p≤0.05.
RESULTS: There were no changes in LM or FM. There were significant group-by-time interactions for KE and SPPB. Post-hoc paired t-tests found WBVT improved KE (WBVT: 22.3±4.0 to 29.0±4.5 kg; CON: 23.8±6.3 to 23.6±9.6 kg) and improvement in SPPB performance approached significance (WBVT: 4.5±2.3 to 5.2±2.1 units, p=0.09; CON: 4.1±1.9 to 3.7±2.3 units).
CONCLUSIONS: WBVT was well tolerated and occurred without adverse health complications. WBVT can be used to counteract losses in leg strength. Interventions of greater frequency and duration may help improve functional performance in pre-frail and frail older adults. WBVT was well tolerated and occurred without adverse health complications. WBVT can be used to counteract losses in leg strength. Interventions of greater frequency and duration may help improve functional performance in pre-frail and frail older adults. This study was supported by grants from the College of Human Sciences and FSU.

The Association of Muscular Strength and Treadmill-Based Walking Economy in Older Men and Women.

Paul M. Gallo, FACSM[1], Nicole M. Hafner[1], Peter Ronai, FACSM[2]. *[1]Norwalk Community College, Norwalk, CT. [2]Sacred Heart University, Fairfield, CT.*

(No relevant relationships reported)

Ageing is linearly associated with increased body fat percentage (BF%) and decreased muscular strength, which may lead to lower force production and decreased physical function (PF) in older adults (age 60+ yrs.). The magnitude at which age-related decrements affect energy expenditure associated with walking economy (WE) is not well understood. A better understanding of the relationship between BF%, lower body muscular strength (LBMS), and PF, and the degree to which these variables are related to WE is important for the clinical exercise approach with older adults. **PURPOSE:** To determine the association of BF%, LBMS, and PF on WE in older adults when walking at three separate treadmill speeds. **METHODS:** Twenty-three older adults (12 men, 11 women; age 70 ± 6 yrs.) were recruited to participate. Session 1 included screening, protocol familiarization, and body composition assessment measure (BodPod®). During sessions 2 and 3, participants performed either a treadmill walking (TMW) protocol (three separate 6-minute TMW bouts at set speeds of 0.45, 0.89, and 1.34 m·sec^{-1}) or a LBMS measure (1RM Leg Press) and PF test battery (SPPB). Session, walking speed, and strength/functional testing order was counter-balanced and WE was calculated as an index (kcal·min^{-1}·W^{-1}). Steady state oxygen uptake was used to calculate energy expenditure for all TMW bouts. A linear mixed effects model was used to determine associations between BF%, LBMS, and PF on WE at the three TMW bouts. An *a priori* alpha of $p \leq 0.05$ was set for statistical significance. **RESULTS:** Twenty-one older adults (11 men, 10 women; age 70 ± 6 yrs.) completed the study. There were no significant correlations for BF% ($r^1 = 0.19$, $p^1 = 0.41$), LBMS ($r^1 = -0.07$, $p^1 = 0.78$), and PF ($r^1 = 0.14$, $p^1 = 0.55$) on WE at the 0.45 m·sec^{-1} speed. Correlations were also not significant on WE at the 0.89 m·sec^{-1} speed [BF% ($r^2 = -0.22$, $p^2 = 0.34$), LBMS ($r^2 = 0.01$, $p^2 = 0.96$), and PF ($r^2 = 0.18$, $p^2 = 0.44$)] and the 1.34 m·sec^{-1} speed [BF% ($r^3 = 0.09$, $p^3 = 0.71$), LBMS ($r^3 = 0.14$, $p^3 = 0.54$), and PF ($r^3 = -0.26$, $p^3 = 0.25$)]. **CONCLUSION:** BF%, LBMS, and PF may not be associated with age-related decrements in WE with older adults during treadmill walking. Future research is needed to better determine the interactions of these variables on WE in older adults.

Passive Mobilization-induced Vascular Function: Adaptations In Bedridden Oldest-old.

Massimo Venturelli[1], Anna Pedrinolla[1], Silvia Pogliaghi, FACSM[1], Alessandro Colosio[1], Ettore Muti[2], Emiliano Ce[3], Stefano Longo[3], Fabio Esposito[3], Federico Schena[1]. *[1]University of Verona, Verona, Italy. [2]Mons Mazzali Foundation, Mantua, Italy. [3]University of Milan, Milan, Italy.*

(No relevant relationships reported)

PURPOSE: With aging, vascular function (VF) declines. Indeed, a conspicuous number of oldest-old individuals are in chronically bedridden, and literature indicates that chronic immobility exacerbates VF decline. Although studies have suggested that passive mobilization of the limbs (PM) may improve local VF, the effect of PM on nitric oxide (NO)-mediated VF has not been studied yet. Therefore the aims of this study were determine whether PM is effective to counteract VF worsening in bedridden oldest-old. We hypothesized that bedridden patients who underwent a month of PM would have gained significant improvement in NO-mediated VF. **METHODS**: Twenty bedridden individuals (86±7 yrs) were randomly assigned to PM or control (CT) group, treated with standard therapies only. PM groups underwent a program of 30 min of passive knee (flexo-extension) mobilization (4-week, twice a day/5 days a week) in addition to their standard therapies. Pre and post treatment, NO-mediated VF was measured by means of single passive limb movement (sPLM) test.
RESULTS: All PM patients completed all sessions. Concerning sPLM test, PM group improved significantly sPLM$_{peak}$ (+33%), ΔPLM (+55%), as well as Area Under the Curve (AUC, +200%). CT group did not exhibit any change in VF.
CONCLUSIONS: Results suggest that the reduction in VF exhibited in chronically bedridden oldest-old individuals can be reversed by a PM program. PM seems to be an effective strategy to counteract the deleterious effects of bedridden.

Comparing Post-Exertional Symptoms Following Serial Exercise Tests

Lariel J. Mateo[1], Lily Chu[2], Staci Stevens[3], Jared Stevens[3], Christopher R. Snell[3], Todd Davenport[1], Mark VanNess[1]. [1]University of the Pacific, Stockton, CA. [2]Independent Contractor, Burlingame, CA. [3]Workwell Foundation, Ripon, CA.
(No relevant relationships reported)

Post-exertional malaise (PEM) is an exacerbation of symptoms that leads to a reduction in functional ability. Recognizing the triggers, onset, symptoms and duration of PEM is important for the diagnosis of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). PEM following serial exercise tests has not been examined. **PURPOSE**: To compare descriptions of symptoms by ME/CFS and control subjects after two maximal exercise tests, each separated by 24 hours. **METHODS**: Open-ended questionnaires were provided to 11 control subjects and 49 ME/CFS patients who underwent two maximal exercise tests, 24 hours apart. Each subject evaluated how they felt immediately after the first exercise test, before and immediately after the second exercise test, and in the week following the tests. Responses were analyzed and categorized by two reviewers, blinded to subject diagnosis. Repeated measures ANOVA was used to examine differences between groups. **RESULTS**: Over the two days of testing, ME/CFS subjects reported an average of 15.4±7.7 symptoms compared to 5.5±1.8 in the control group. Following the tests, ME/CFS subjects reported an average of 5.0±2.8 symptoms compared to 0.1±0.3 in the control group. Among the ME/CFS subjects, fatigue, cognitive dysfunction, and sleep problems were reported with the greatest frequency. Out of the eighteen symptom categories, ME/CFS subjects reported seventeen at a higher frequency than control subjects. The largest differences were observed in cognitive dysfunction, headache, light-headedness, muscle/joint pain and weakness. Other symptoms included decreased function, pain, flu-like and gastrointestinal symptoms. Forty-nine percent of ME/CFS subjects recovered within an average of 4.5 days while fifty-one percent had not recovered by day seven. In contrast, all but one control subject recovered within 1 day. **CONCLUSION**: A standardized exertional stimulus produces prolonged and more diverse symptoms in ME/CFS subjects compared with those seen in control subjects. Understanding PEM more comprehensively may provide clues to the underlying pathophysiology of ME/CFS and lead to improved diagnosis and treatment.

1003   Board #264   May 30 2:00 PM - 3:30 PM
Exercise Ventilatory Limitation To Exercise In Dyspneic Iraq And Afghanistan Veterans

Jacquelyn C. Klein-Adams, Anays M. Sotolongo, Duncan Ndirangu, Nancy Eager, Michael J. Falvo. VA NJ Health Care System, East Orange, NJ.
(No relevant relationships reported)

Veterans of Iraq and Afghanistan frequently report dyspnea on exertion following deployment despite the presence of normal pulmonary function testing. Determining underlying causes of exertional dyspnea is difficult due to the variety of potential contributing factors, but a ventilatory limitation to exercise is one factor that may contribute to the perception of dyspnea. **PURPOSE:** The goal of the present study was to determine the frequency of ventilatory limitation to exercise and compare pulmonary function between those individual with (VL+) and without (VL-) ventilatory limitation. **METHODS:** 83 deployed Iraq and Afghanistan Veterans (43.5±9.8 years; 72 men and 11 women) were referred to our dyspnea clinic and completed pulmonary function and cardiopulmonary exercise testing (CPX). VL+ during CPX was defined as a peak exercise ventilation (VE) that was ≥ 80% of the maximal voluntary ventilation (VE/MVV > 0.80). All Veterans completed pulmonary function testing (PFT) including body plethysmography, spirometry, diffusing capacity and forced oscillometry testing (FOT). Veterans with abnormal baseline PFTs and current smokers were excluded from analysis. **RESULTS:** 30.1% of our sample (25 of 83) demonstrated VL+ during exercise. Groups were similar in age (VL+ vs. VL-; 43.9±9.9 vs. 43.2±9.7 years) and body mass index (31.7±5.6 vs. 30.3±3.7 kg/m^2). In comparison to VL-, Veterans with VL+ had a reduced total lung capacity (TLC % pred; 90.5±9.3 vs. 97.4±13.8, p = 0.027); however, all other pulmonary function indices were similar between groups. CPX patterns differed between groups such that Veterans with a VL+ demonstrated greater peak exercise capacity (Peak VO2 % pred: 90.6±18.0 vs. 73.4±13.7%, p < 0.001) and ventilatory anaerobic threshold (% of peak VO2: 57.2±11.5 vs. 48.9±12.1%, p = 0.015). **CONCLUSIONS:** Approximately 30% of our clinical sample referred for evaluation of dyspnea demonstrated a ventilatory limitation to exercise (VL+). However, pulmonary function was similar between groups, and CPX performance was superior in those with VL+. Given the persistence of respiratory symptoms across both groups, these data may suggest that VE/MVV is an insensitive method to evaluate exertional dyspnea in this population.

The Validity of an Energy Cost Prediction Equation for Unloaded Cycling

Jacqueline H. Gallagher, Victoria S. Danner, April M. Daly, Dianne M. Babbitt. Cedar Crest College, Allentown, PA.
(Sponsor: Michael D. Brown, FACSM)
(No relevant relationships reported)

American College of Sports Medicine (ACSM) metabolic equations estimate energy cost from known workloads. These equations may be used in healthy and clinical populations for exercise testing and prescription to determine the metabolic cost and required intensity associated with a desired level of energy expenditure. A constant of 3.5 mL/kg/min is used in the cycle ergometry equation to represent resting VO2 and a constant of 3.5 mL/kg/min represents the energy cost of 'unloaded' cycling; however this does not account for the energy cost variability in RPMs. **Purpose:** The purpose of this study was to evaluate the validity of ACSM's energy cost prediction equation for unloaded cycling at various RPMs in college females. **Methods:** Subjects included 10 females (20-26 y/o) who performed three exercise trials. Prior to the exercise trials, seat height on a Monark cycle ergometer was standardized with a 5-10 degree knee bend in the pedal-down position with the sole of the foot parallel to the floor. The subjects pedaled at 50, 70, and 90 RPM with no belt resistance on the flywheel for 7 minutes each with 10 minutes of rest between trials. Heart Rate (HR) and VO2 were recorded for each minute. Data from the 6th and 7th minutes were averaged and used for statistical analysis. A one-way within subjects ANOVA was conducted to compare the effect of RPM on HR and VO2. Bonferroni correction was applied for post hoc comparisons. **Results:** Mean HR was 98 ± 12 bpm at 50 RPM, 102 ± 13 bpm at 70 RPM, and 115 ± 13 bpm at 90 RPM. Mean VO2 was 6.68 ± 0.78 mL/kg/min at 50 RPM, 8.03 ± 0.88 mL/kg/min at 70 RPM, and 11.23 ± 1.45 mL/kg/min at 90 RPM. There was a statistically significant difference in HR between 50 and 70 RPM (p = 0.030) and between 70 and 90 RPM (p < 0.001). Statistically significant differences were found in VO2 between all of the RPM trials (p < 0.001). When comparing the VO2 data from each RPM trial to a constant of 7 mL/kg/min, statistical significance was found at 70 RPM (p = 0.030) and 90 RPM (p < 0.001) with no significance at 50 RPM (p = 1.000). **Conclusion:** The effect of RPM on energy cost revealed VO2 at 70 and 90 RPM to be significantly greater than the constant of 7 mL/kg/min used in ACSM's metabolic cycling equation. This may have negative health implications when prescribing a constant level of exercise intensity, particularly for low-level exercise in a clinical population.

Metabolic Cost of Walking in Low Functioning Older Adults

Anoop Balachandran[1], Duane B. Corbett[1], Amal A. Wanigatunga[2], Boya Lin[1]. [1]University of Florida, Gainesville, FL. [2]Johns Hopkins University, Baltimore, MD. (Sponsor: Todd M. Manini, FACSM)
(No relevant relationships reported)

PURPOSE: The metabolic cost of walking increases with age, but the effect of functional status that accompanies aging remains unknown. The purpose of the study was to compare the metabolic cost of walking between low functioning (LF) and high functioning (HF) older adults.
METHODS: Ten HF and ten LF older adults (70+ years), pair matched by age (±3 Yrs) and gender, were categorized using the Short Physical Performance Battery (SPPB) that ranks participants from 0 (worst performance) to 12 (best performance) based on balance, walk speed, and chair stand tests. High functioning participants scored >10 (11.5 ± 0.7) and low functioning participants scored <8 (6.06 ± 1.4). Participants walked over ground at self-selected usual and rapid paces. Participants also walked at a standard pace on the treadmill at 0.76 m/s. Expiratory gases were measured using a portable indirect calorimeter. Gross metabolic rate was defined as W·L/kg/min. Metabolic cost was expressed as gross metabolic rate by walking speed (W·L·s/kg/min/m). Peak energy expenditure was measured during a graded exercise treadmill test to normalize walking metabolic rate (e.g. walking metabolic rate as a percent of peak metabolic rate).
RESULTS: HF participants walked faster than LF participants: usual (1.14 vs. 0.81 m/s, p < .001) and rapid (1.41 vs. 1.13 m/s, p = .006) pace. Gross metabolic rate was 21% higher in HF adults compared to LF adults for usual paced walking (3.3 ±.67 vs. 4.2 ± 0.83, respectively) and 27% higher for rapid-based walking (3.9 ± 0.84 vs. 5.3 ± 0.79, respectively). However, no group differences were noted for walking at usual (-0.46, 95% CI: 0.54, -1.46), rapid (0.31, 95% CI: 0.44, -1.07), or standard pace (0.11, 95%, CI: 0.75, -.51). There was a strong trend for LF participants to walk at a higher percent of VO2 peak on usual (71% vs. 55%, p =.12), rapid (85% vs. 75%, p =.31) and standard pace walk tests (89% vs. 71%, p =.01).
CONCLUSIONS: In comparison to HF older adults, LF older adults had lower gross metabolic rate due to their slower walking speed. Despite their slower pace, LF older adults walk at a higher percentage of their peak energy expenditure. Collectively, these

results support the notion that LF older adults favor a walking speed that optimizes metabolic cost, but are susceptible to higher relative energy expenditure due to their lower peak capacity.

B-73   Exercise is Medicine®/Poster - **EIM: Exercise and the Older Adult**

Comparative Th1 Th2 of Elderly Women Engaged in a Program of Resistance or Aerobic Exercise

Otavio Machado[1], Maria Elizabeth Pereira Passos[1], Heloisa Helena de Oliveira[1], Vinícius Leonardo Diniz[1], Laiane Cristina dos Santos[1], Mariana Mendes de Almeida[1], Eliane Borges da Silva[1], Cesar Miguel Momesso[1], José Paulo de Moraes Junior[1], Evandro Diniz Corvino[2], Luiz Francisco Killian[2], Renata Gorjao[1]. *[1]UNICSUL, SAO PAULO, Brazil. [2]FEFISO, SOROCABA, Brazil.*
(No relevant relationships reported)

It is well-known the alterations that occur in the immune response with aging that can generate an imbalance of the immune response leading to a low-grade chronic inflammation. Some studies have described the decrease in proliferative capacity of Th1 cells in elderly. The imbalance between Th1 and Th2 cells seems to play a role in the development of autoimmune and inflammatory diseases. **PURPOSE:** Therefore, the aim of this study was to evaluate Th1 and Th2 responses and verify Th1/ Th2 ratio in elderly women engaged in different exercise programs. **METHODS:** Initially, 27 elderly women (65± 3.2 years old) were selected and distributed into four groups accordingly to exercise program that they practiced: 1. sedentary (SED); 2. resistance training practitioners (RE); 3. aerobic exercise practitioners (AE); 4. resistance and aerobic exercise practitioners (REAE). Th1 and Th2 cell populations were assessed by flow cytometry. **RESULTS:** Th1 response was higher in RE groups (RE, 16.7± 5.8% ; REAE 15.7± 4.7%) when compared with AE (12.5± 2.9%), and SED (12.9± 4.4%). Inversely, Th2 had a trend to decrease in exercise programs (SED, 10.4± 5.3; REAE, 9.2± 4.9; AE, 7.6± 3; RE, 4.9± 2.4 %) Finally, the Th1/ Th2 ratio was higher in RE (3.2± 1.4) versus REAE (2.2± 1.4), AE (1.9± 0.9) and SED (1.3± 0.3). **CONCLUSIONS:** Increased Th1/Th2 ratio was due to a higher response of Th1 cells and lower response of Th2 cells. These findings suggest an improvement in Th1 response in elderly women engaged in exercise program, mainly in resistance exercise groups.

The Effects Of Core Muscle Training Combined With Lower Limbs Strengthening On Physical Fitness Of community Elderly

YU-TSAI TU, Hsiang-Ying Hsueh, Feng-Chiao Lo, Mu- Jung Kao. *TAIPEI CITY HOSPITAL, TAIPEI, Taiwan.*
(No relevant relationships reported)

According to the long-term care service planning proposed by the Ministry of Health and Welfare in Taiwan, 80% of the aging population requiring long-term care service would also require community-based or home-base care. The strength of lower limbs and core muscle plays important role in prevention against fall behavior, especially for the community elderly.**PURPOSE**: To evaluate the physical fitness of the elderly in local community care-concern center in Taiwan, a four-month course of regular core muscle training and lower limbs strengthening was conducted.**METHODS:** Four elderly (Age: 66±1.6 years of age; Body height: 156.7±6.6 cm, Body weight: 62.5±13.7 kg) without any severe illness were included in this study. The training of core muscle training and lower limbs strengthening last for four months with 3 sessions per week, 60 min per session, and an intensity of 5-6 on the Ratings of Perceived Exertion scale. Physical fitness was evaluated one week before and after the intervention. Data of multiple variables were collected by using questionnaire and examination on functional fitness including grip, two-min step test, back scratch test, and 8-foot up-and-go test. The ranges of motion and isometric strength of lumbar spine and knee were measured by the microFET3. Descriptive statistics, independent sample t-test, and paired-samples t test were used to evaluate the effects of the intervention. **RESULTS:** The results showed significant improvement after the 4-month course in back scratch test, 2-min step test, chair sit-and reach test, and isometric strength of lumbar spine and knee (p < 0.05). Among the other tests, no significant differences were observed. **CONCLUSION:** Core muscle training combined with lower limbs strengthening for community elderly can improve physical fitness and isometric strength of low back and knee.

Multicomponent Exercise Program Effects On Functional Capacity And Cognition In Frail Hospitalized Patients

Mikel Lopez Saez de Asteasu[1], Nicolás Martínez-Velilla[2], Álvaro Casas-Herrero[2], Fabricio Zambom-Ferraresi[2], Francisco Antonio Amu-Ruiz[1], Javier Alonso-Renedo[2], Mikel Izquierdo[1]. *[1]Public University of Navarre, Pamplona, Spain. [2]Complejo Hospitalario de Navarra, Pamplona, Spain.*
(No relevant relationships reported)

Frail older adults have reduced functional and physiological reserves, rendering them more vulnerable to the effects of hospitalization, which frequently results in failure to recover from functional decline related to the hospitalization and new disability**.** **PURPOSE**: To analyze the effects of a multicomponent exercise program on functional capacity and cognition in frail hospitalized patients. **METHODS**: Randomized clinical trial conducted in 326 patients admitted in an Acute Care Unit were randomly assigned to the intervention (IG) or control group (CG). The intervention consisted of a multicomponent exercise training program, composed of supervised progressive resistance exercise training at low-moderate intensities 30-60%RM (Repetition Maximum), balance training, and walking for 5-7 consecutive days. Evaluations of functional capacity (Short Physical Performance Battery (SPPB), Gait velocity Test (GVT), GVT under dual task conditions, Barthel index), strength assessments; maximal isometric force of handgrip (HG), knee extension and hip flexion, 1RM test in leg press, chest press and knee extension exercises, and cognitive tasks; Mini Mental State Examination (MMSE), Trail Making Test Part A (TMT-A) and verbal fluency test were conducted at admission and previous to discharge in both groups. **RESULTS**: 326 completed pre/post evaluations (IG n= 126, CG n=141). Drop-out rate was 18%. In the IG, significant improvements were observed at discharge in all the functional capacity outcomes (SPPB 4.4 vs. 7.0 points, GVT 14.1 vs. 10.9s., Verbal GVT 17.6 vs. 13.2s., Arithmetic GVT 17.6 vs. 12.9s., p<0.001 and Barthel score 83.8 vs. 85.9 points p<0.05) strength measurements (HG 17.2 vs. 18.8kg., knee extension 97.8 vs. 112.7N., hip flexion 90.8 vs. 104.4N., 1RM leg press 57.7 vs. 76.3kg., 1RM chest press 24.2 vs. 28.4kg., 1RM knee extension 38.5 vs. 47.0kg, p<0.001) and cognitive tasks (MMSE 22.1 vs. 24.3 points, TMT-A 154.6 vs. 121.3s., verbal fluency 6.0 vs. 8.0 words, p<0.001). In contrast, in the CG, no significant improvements were found in those outcomes. **CONCLUSIONS**: A multicomponent exercise program, with special emphasis in progressive resistance training, is an effective therapy to improve functional capacity and cognitive function in frail patients during hospitalization.

Correlation between One-leg Standing Time and Trail Making Test in Japanese Older Adults

Yasuo KIMURA[1], Kazuko OHKI[2], Mamoru HISATOMI[1], Mieko SHIMADA[3], Nobuko K. HONGU[4]. *[1]Inst. Fitbess & Health Sciences, Toshima, Tokyo, Japan. [2]Sugiyama Jogakuen University, Nagoya, Japan. [3]Chiba Pref. University of Health Sciences, Chiba, Japan. [4]The University of Arizona, Tucson, AZ.*
(No relevant relationships reported)

PURPOSE: For older adults maintaining the ability to control balance is closely associated with the risk of falling, an independent mobility, including walking, and engagement with active life. The aim of this study was to examine the one-leg standing time with eyes open and its association with physical, cognitive, and psychological functions in community-dwelling older adults residing in Japan. **METHODS**: Sixty-five women aged 65 years and over (mean age 73+7 yrs.) participated in the study. They were being involved in habitual physical activity at least once a week for three months prior to the study. At the first assessment session, participants completed a demographic questionnaire and one-leg standing balance test. The participants were then divided into two groups according to time of one-leg standing time with eyes open: 1) longer than 15 seconds (n=46, high group - HG: 75.4+61.7 sec.) and 2) shorter than 15 seconds (n=19, lower group - LG: 7.8+3.0 sec.). All participants performed hand-grip strength (HGS), chair-stand (CS), timed up-and-go (TUG), 10-m maximal gate speed (MGS), mini-mental state examination (MMSE), and trail making test (TMT). Data were analysed using unpaired t-test and ANCOVA. **RESULTS**: For all participants the mean length of one-leg standing time was 60.2+45.2 sec. (2 - 120 sec.). Significant difference (p<0.05) were observed between two groups: age (HG; 70.3+3.4, LG; 72.3+3.6 yrs.), HGS (HG;24.9+3.8, LG;22.2+5.8 kg), CS (HG;8.0+2.1, LG;9.0+2.2 sec.), TUG (HG;5.2+1.0, LG;5.7+0.8 sec.), MGS (HG;1.82+0.24, LG;1.69+0.28 m/sec.), MMSE (HG;28.4+1.8, LG;26.9+2.2 score). After adjusting for age, the only significant difference (p<0.05) observed between the two groups was for TMT (HG;90.5+23.0, LG;119.8+49.3 sec.).

WEDNESDAY, MAY 30, 2018

CONCLUSIONS: Physical, cognitive, and psychological functions were significantly related to one-leg standing time. The results of this study also identified the balance ability and cognition decline. Future studies need to confirm these observations in larger samples to track balance-cognitive decline over time among older adults.

Effects of Personal Training on Body Composition and Physical Fitness in Older Adults with DLSD

Gae Hwan Park[1], Chae-Hee Park[2]. [1]*FIT Training Center, Seoul, Korea, Republic of.* [2]*Korea National Sport University, Seoul, Korea, Republic of.* (Sponsor: Wojtek Chodzko-Zajko, FACSM)
(No relevant relationships reported)

Exercise treatment is recommended for older patients with lumbar spine diseases that result in degeneration of muscles and the skeletal system and a resultant decline in function. However, it is often difficult for patients to exercise by themselves and assistance from an exercise professional can be valuable to maintain health status and improve quality of life. **PURPOSE**: This study was designed to evaluate the effect of personalized exercise instruction on changes in body composition, physical fitness and pain management in older adults with degenerative lumbar spinal disorders (DLSD). **METHODS**: Three individuals (Range$_{age}$=66-78 yrs), who no prior experience with a personal trainer and who reported chronic low back pains for more than 12 weeks, participated in the study. This study was conducted by a researcher and a professional personal trainer who had more than 10 years' experience in the personal training area. The data was collected by employing a single-subject, ABA repeated measure design. In addition, schematic analysis was utilized to visualize the changes of participants' body composition, physical strength and rating of perceived pain. A paired t-test using SPSS WIN 20.0 was employed to examine before-and-after differences for key outcome measures. **RESULTS**: The results showed that muscle mass was increased and body fat mass and central obesity were decreased at the end of phase B, which coincided with the period of supervision by the personal trainer. Additionally, there were statistically significant changes in strength of upper and lower extremity, cardiovascular endurance, upper and lower body flexibility and the rating of perceived pain. **CONCLUSIONS**: This study resulted in better understanding of the role for individualized instruction by exercise professionals for older adults with degenerative lumbar spinal disorders. Furthermore, the results may have some applicability to the design and implementation of future personal training programs for seniors with similar conditions.

Knowledge And Practices Of Primary Health-care Providers To Counsel About Physical Activity And Fall Prevention

Harry Papadopoulos, Lorena Guerrero, Mara Nery-Hurwit. *Pacific Lutheran University, Tacoma, WA.* (Sponsor: Eli Lankford, FACSM)
(No relevant relationships reported)

The benefits of regular physical activity on health, fall prevention, and quality of life are widely recognized. However, only a small percentage of older adults meet the current recommendations for aerobic exercise and strength. Primary care providers are in a unique position to counsel patients about exercise and provide them with exercise locations and prescription. PURPOSE: The aim of this study was to assess the perceptions of health care providers regarding knowledge and confidence to assess and counsel older adult patients about physical activity and fall prevention. METHODS: One hundred and twenty health care providers in Pierce County, Washington received a link to an online survey. The survey consisted of 35 questions including demographic and general practice questions, and questions that assessed knowledge and counseling practices of primary care providers about physical activity and fall prevention. Chi-square was used to determine if categorical variables differ from one another. Significance was set at p < 0.05. RESULTS: Thirty-four (28.3% response rate) individuals responded to the questionnaire. Most of the respondents were physicians (56%). Fifty-six percent of the respondents (χ^2= 0.25, p = 0.17) indicated that they routinely counsel their patients to participate in exercise programs that promote fall prevention. Only 12.5% (χ^2 = 8.38, p < 0.05) of the primary care providers responded that they refer their clients to an exercise specialist. The majority (93.8%) of the health care providers were not aware of the Exercise is Medicine® website (χ^2 = 12.25, p < 0.01). Eighty-seven percent (χ^2 = 9.0, p < 0.01) of the respondents described their knowledge of fall prevention assessment and management as "not very knowledgeable" to "somewhat knowledgeable." Most of the health care providers (68.8%, χ^2 = 2.25, p = 0.13) indicated that they routinely administer fall risk screening. CONCLUSION: These results show that while half of these primary care providers counsel their patients to participate in exercise programs, only a small percentage of them refer their clients to an exercise specialist. Furthermore, the lack of knowledge of the Exercise is Medicine® initiative and website by health care providers indicates the importance of further education of health care providers.

Golf Intervention Improves Fast but Not Self-selected Gait Speed.

Nicole A. Marcione[1], Andrea M. DuBois[1], Steven Castle, MD[2], George J. Salem, PhD, FACSM[1]. [1]*University of Southern California, Los Angeles, CA.* [2]*Greater Los Angeles Veterans Affairs Hospital, Los Angeles, CA.*
(No relevant relationships reported)

Title: Golf Intervention Improves Fast but Not Self-selected Gait Speed. Gait speed (GS) is an important global indicator of successful aging, and slow gait speeds are associated with poor health outcomes in later life, such as falls, hospitalization and mortality. Slower GS may also limit social interaction, functional capabilities and independence; thus, attenuating the slowing of GS should be a priority for seniors. Using golf as an exercise intervention, we hypothesized that golf may improve GS and walking endurance in older adults. **PURPOSE:** The objective of the preliminary investigation was to examine the influence of a 12-week golf intervention on GS in older adult military veterans. **METHODS:** GS (m/s) was measured pre-and post a 12-week golf intervention in 4 older, male military veterans (65-79 years). The 12-week golf training was conducted at a 9-hole, Par-3 course. The training consisted of warmup exercises, swing practice at the net, and progressive golf play culminating in playing all 9 holes during weeks 11 and 12. Participants completed 3 gait trials (10m) of each condition: self-selected (SSGS) / habitual walking and walking "as fast and as safe as possible" (FGS) in a motion analysis laboratory. A 6-minute walk test (6MWT) was completed outside on an even, concrete walking path. Participants were instructed to "walk as fast and safe as possible, covering as much distance as possible in the 6-minute time limit." **RESULTS:** SSGS did not change. FGS improved by 6.08% (ES 0.76) and GMWT distance increased by 4.1% (ES: 0.78). **CONCLUSION:** Following the 12-week golf intervention, participants improved their FGS and their 6MWT distance; however, SSGS did not change. This demonstrates that fast gait may be an important outcome measure to consider when investigating older adult activity interventions. The ability to walk faster and for longer distances can have salient effects on overall wellbeing and safety. In everyday life, habitual GS may **not** be sufficient when challenges in the environment emerge, such as the need to cross a street quickly or get out of the way of a moving vehicle. Results from this study suggest that a 12-week golf training intervention changed the walking ability in older military veterans. Our study also demonstrates the utility of including other measures of walking performance in addition to SSGS.

Correlations Among Subjective vs. Objective Physical Activity, Diet, and Medication Use in Older Adults

Victoria E. Warren, Kelsey D. Loss, Kyle L. Timmerman. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)
(No relevant relationships reported)

Due to the increased burden of chronic disease, prescription medication use in older adults is high. This rise in the use of multiple medications (polypharmacy) is concerning due to its relationship with adverse drug related events (ADEs), drug-drug interactions, and increasing healthcare costs. Level of physical activity (PA) and habitual dietary nutrient intake are lifestyle factors that may influence prescription medication use and associated complications. The **PURPOSE:** of this study was to identify correlates among PA level measured subjectively and objectively, habitual nutrient intake, and prescription medication use in older adults. **METHODS**: In 96 older adults (58F, 38M, 77±7.7 years) prescription medication use (Rx), subjective PA level (Community Healthy Activities Model Program for Seniors, CHAMPS), and objective PA level (Accelerometer, Actical, Phillips Respironics) were measured. In a subset of 73 subjects, habitual dietary intake of nutrients was assessed (3-Day Diet Log). Partial correlations were run between variables while controlling for age, sex, and body mass index (BMI). Significance was set to p <0.05. **RESULTS**: Mean values±SE for the variables include: moderate-to-vigorous subjective PA (MVPA-S): 1353±120 kcal·wk^{-1}, moderate-to-vigorous objective PA (MVPA-O): 51.2±5.1 min·day^{-1}; Rx number: 3.4±0.3; total caloric intake: 2107±64 kcal·d^{-1}; and percent polyunsaturated fatty acid (PUFA) intake: 10.4±7.0 g·kcal·d^{-1}. Rx was inversely correlated with MVPA-S (r= -0.24, p< 0.05) and with MVPA-O (r= -0.31, p< 0.05). MVPA-S and MVPA-O were positively correlated (r= 0.64, p< 0.01). Rx number was inversely correlated with percent dietary intake of PUFA (r= -0.31, p< 0.01). There were no significant correlations between Rx and other nutrients. **CONCLUSION**: Preliminary data show that Rx use in older adults is inversely associated with subjectively and objectively measured PA level. These data also show a strong correlation between the subjective and objective measures of PA, which could be important when looking at measurement possibilities in clinical settings and for future studies. Additionally, these data show an inverse correlation with Rx number and PUFA. These preliminary data suggest that lifestyle factors may significantly influence Rx use and associated complications.

1014   Board #275   May 30 3:30 PM - 5:00 PM

Standing Balance,Muscle Strength And Proprioception of Each Lower Limb Joint- Which Are Significant Predictors For Mobility In Community-dwelling Older Adults?

Yejun Wang[1], Jia Han[1], Judith Anson[2], Gordon Waddington[2], Roger Adams[2]. *[1]Shanghai University of Sport, Shanghai, China. [2]Unicversity of Canberra, Canberra, Australia.*
(No relevant relationships reported)

Lower limb proprioception, muscle strength and standing balance are all proposed as important factors in relation to mobility of the elderly. However, it is not clear what the relative contributions are for hip, knee and ankle proprioception, and strength and postural sway.
PURPOSE: To determine the relative contributions of proprioception at each lower limb joint, muscle strength and standing balance, to mobility in community-dwelling older adults.
strength.
METHODS: A group of 102 community-dwelling adults, with mean age of 68.4 years, volunteered. Hip, ankle and knee joint proprioception were measured in standing using joint-specific versions of the active movement extent discrimination apparatus (AMEDA). Muscle strength was determined by grip strength with a hand dynamometer as a proxy variable, and bipedal postural sway was assessed via the Biodex Balance System, tested in anterior-posterior and medio-lateral directions, with eyes open and with eyes closed. Mobility was measured using the timed-up-and-go test (TUG).
RESULTS: TUG scores for the group were significantly worse with low ankle proprioception ($r = -0.29$, $p<0.01$) and low hand grip strength ($r = -0.25$, $p = 0.01$), and across age in years, TUG scores showed an inverted-U shaped function ($p < 0.001$) with the greatest decline after 75 years of age. From multiple regression, ankle proprioception was shown to be the most important factor in predicting TUG performance (Adj $R^2 = .13$, $p < 0.001$).
CONCLUSIONS: Results here add a specific proprioceptive component, ankle proprioception in standing, to the known association of strength with mobility in the elderly. Further, these results suggest that to effectively improve mobility in the elderly, and reduce falls risk, intervention methods should focus on improving ankle proprioception ability as well as increasing strength.

Exercise Prescription Intervention Plan for Pre-frail and Frail Elderly in New Taipei City

Hui-Ping Lin, Yu-Ting Tseng, Chi-Hung Lin. *Department of Health, New Taipei City Government, New Taipei City, Taiwan.*
(No relevant relationships reported)

In response to the aim of active aging promoted by the World Health Organization, a plan for intervention in elderly frailty through exercise is in urgent need. In 2016, New Taipei City's elderly health check-up program introduced frailty assessments and exercise intervention. However, 10-57% of frail elderly showed no immediate improvement after exercise intervention.
PURPOSE: The establishment of "Exercise is Medicine"(EIM) Taiwan personnel training and standardized training modules through EIM Taiwan, in the hope of enhancing exercise intervention effectiveness for individuals assessed as pre-frailty or frailty in New Taipei City's elderly frailty assessments.
METHODS:1. Planning of exercise intervention options and training courses: Training content included assessment before exercise and exercise recommendation principles, and exercise prescriptions and recommendations for various chronic diseases. 2. EIM training for physicians and allied health professionals: The EIM Taiwan training included 16-hour courses for physicians and allied health professionals, respectively. Through the training of EIM Taiwan professional personnel, the provision of individualized exercise plans for pre-frail and frail elderly can be implemented.
RESULTS: On March 14, 2017, Eric Liluan Chu, the mayor of New Taipei City cosigned a Memorandum of Cooperation (MOU) with EIM Global. After signing the MOU, a total of 195 physicians and 344 allied health professionals were trained as the EIM-certified professional personnel in Taiwan. Through these EIM-certified physicians, individualized exercise prescriptions were given to elderly assessed as pre-frailty or frailty, with exercise plans then implemented through the guidance of allied health professionals. In 2017, a total of 24,778 people have taken elderly frailty assessments and 23.8% of above elderly received the implementation of exercise plans.
CONCLUSIONS: In addition to continuing to implement exercise intervention for pre-frail and frail elderly, our program aims to establish an EIM Taiwan training guidance handbook. Through these actions, it is expected to enhance exercise intervention effectiveness and reverse frailty in New Taipei City.

The Effect Of Two Low-dose Strength/Balance Programs On The Physical Function Of Mobility-limited Older Adults

Michael P. Corcoran, Ian Sotnek, Jonathan Lashyn, Jordan Vetter, Domenic DiSisto. *Merrimack College, North Andover, MA.* (Sponsor: Kevin Finn, FACSM)
(No relevant relationships reported)

Background: Strength and balance training are critical to maintaining physical function and delaying the onset of major mobility disability in older adults (OAs). The minimum amount of this training required to yield clinically meaningful improvements in physical function is not clear. **Purpose**: To evaluate the effect of two low dose strength/balance programs on physical function in mobility-limited OAs. **Methods**: Twenty community-dwelling OAs with mobility limitations were randomized to one of two strength/balance doses (n=10/dose), held 3x/week at a local YMCA for 10 wks. Eligible participants were ≥ 65 yrs of age, exhibited mild to moderate mobility impairment (short physical performance battery (SPPB) score of 3-9 out of 12), sedentary (<125 minutes/week of any kind of physical activity, determined by 7-day pre-baseline accelerometry), and had no major medical issues that would preclude exercise. Exercise doses were as follows: Low dose (L): 1 set each of chair stands, hip abduction, step-up and back with head turns, toe raises, and a balance stand). Higher dose (H): 2 sets of the previous mentioned exercises were performed. Each exercise had three variations of difficulty to accommodate different participant abilities and the number of reps were based on an RPE of 7 out of 10. Participants were assessed on SPPB score and 400m walk speed before and after the intervention by individuals blinded to which dose that participant was randomized to. Clinically meaningful improvements were defined as an SPPB improvement of 0.5 points and a 400m walk speed improvement of 0.05 m/sec. Data was analyzed using a t-paired test. Results are expressed as means ($\pm$ std deviation). **Results**: SPPB score improved by 2.5 ($\pm$ 1.1) points among the entire cohort (p<0.001). Improvement was significant for each dose alone (L: 1.5 ($\pm$ 0.6), p<0.05), (H: 3.0 ($\pm$ 0.82), p<0.001). The improvement in SPPB score in the higher dose was significantly different from that observed with the lower dose (p<0.05). There was no significant effect of either dose on 400m walk speed.
Conclusion: A 10 wk strength/balance program performed 3x/week and consisting of a single set each of select strength/balance exercises was sufficient to elicit clinically meaningful improvements in physical function for OAs with mild to moderate mobility limitations.

Associations Between Grip Strength And Generalized Anxiety Disorder: Results From Tilda

Brett R. Gordon, Cillian P. McDowell, Matthew P. Herring. *University of Limerick, Limerick, Ireland.*
(No relevant relationships reported)

There is a need to identify risk factors for anxiety in older adults that can be targeted for prevention. Associations between grip strength and Generalized Anxiety Disorder (GAD) in older adults are not established.
Purpose: To investigate associations between grip strength and both concurrent probable GAD and the development of GAD during two-year follow-up**.**
Methods: The Irish Longitudinal Study on Ageing (TILDA) is a large prospective cohort study that assesses the social, economic, and health circumstances of community dwelling adults aged ≥50 years and their partners of any age in Ireland. Participants completed a hand grip strength assessment with a Baseline hydraulic hand dynamometer. A score of ≥23 on an abbreviated version of the Penn State Worry Questionnaire defined caseness of probable GAD at baseline. At follow-up, GAD was assessed with the Composite International Diagnostic Interview – Short Form. Participants were divided into sex-specific tertiles based on strength. Data were analysed with linear and logistic regression in September 2017.
Results: Adjusting for age, sex, waist circumference, social class, smoking status, and physical activity, the middle and high strength tertiles were associated with 27.3% ($p\leq0.002$) and 23.1% ($p\leq0.017$) lower odds of prevalent GAD, respectively. A one-standard-deviation increase in strength was associated with 12.1% ($p\leq0.004$) lower odds. The incidence of GAD was 2.0% (n=84). The middle and high strength tertiles were associated with 31.4% ($p>0.38$) and 66.5% ($p\leq0.05$) reduced odds of incident GAD, and a one-standard-deviation increase in strength associated with 24.2% ($p>0.18$) lower odds. There was no significant interaction between strength tertiles and sex in predicting Wave 1 worry symptoms, and no significant interaction between sex and strength tertiles or continuous strength in cross-sectional or longitudinal logistic regression models (all $p>0.20$)
Conclusion: The current findings provide initial support for the protective effect of grip strength on GAD among older adults. Increased hand grip strength may protect against GAD in older adults, although further research with larger samples is needed. Additionally, experimental research is needed to establish causal and mechanistic relationships between strength and worry in older adults.

Abstracts were prepared by the authors and printed as submitted.

Thermoregulation, Strokes, And Dementia: A Healthy Heart Begets A Healthy Brain.

Saejel G. Mohan[1], J. Mark VanNess[1], Jonathan M. Saxe[2], Greg Roberts[2], Lewis E. Jacobson[2], Courtney D. Jensen[1]. *University of the Pacific, Stockton, CA. [2]St. Vincent Hospital, Indianapolis, IN.*

(No relevant relationships reported)

More than 5 million Americans live with dementia; it affects 10% of the population over age 65. There is no cure, but recognition of risk factors could be helpful for prevention. Identifying demographic, genetic, and behavioral risk factors can improve the prescription of lifestyle choices, such as exercise training, to minimize risk. **PURPOSE**: To evaluate predictors of dementia in a patient population. **METHODS**: We obtained the patient registry of a hospital in the Midwestern United States. Demographic data, vital signs, health history, and current diagnoses were recorded. There were 2,244 consecutive patients admitted over a 3-year period who met inclusionary criteria; 105 of these patients had a diagnosis of dementia. Logistic regression tested the effects of age, sex, vital signs, and diagnostic history on incidence of dementia in this sample. **RESULTS**: Significant predictors of dementia were age ($p<0.001$), diastolic blood pressure ($p=0.048$), core temperature ($p=0.040$), presence of a bleeding disorder ($p=0.028$), and diagnosis of a previous stroke ($p<0.001$). For each degree F that core temperature increased, the odds of dementia were elevated by 44% (95% CI: 1.02 to 2.05). A history of stroke was the most pronounced predictor of dementia (95% CI: 1.89 to 7.57). When history of stroke was analyzed as the dependent variable, core temperature continued to be a significant predictor ($p=0.025$); holding all other variables constant, each additional degree F associated with a 48% elevation in the odds of a stroke (95% CI: 1.05 to 2.10). **CONCLUSION**: Age and cardiovascular function are known risk factors for strokes, and strokes are a known risk factor for dementia. In this sample, core temperature emerged as a significant predictor of both stroke and dementia. While poor thermoregulation may be a consequence, rather than a cause, of dementia, a possible consideration is the relationship between heat in the brain, cerebral oxygen demand, and blood brain barrier permeability. The brain's energy demand is several orders of magnitude greater than other body cells, and thus temperature dissipation for the brain is vitally important. Because exercise training improves thermoregulatory capacity, it is possible that this capacity could benefit the brain in previously unidentified ways.

1019   Board #280   May 30 3:30 PM - 5:00 PM

Changes in Cardiovascular Health Following Exercise in Older Men and Women at Risk for Dementia

Andrea F.M. Petrella, Narlon C. Boa Sorte Silva, Dawn P. Gill, Robert J. Petrella, FACSM. *Western University, London, ON, Canada.* (Sponsor: Robert J. Petrella, FACSM)

(No relevant relationships reported)

Purpose: To investigate the effects of a 24-week multiple-modality exercise intervention with additional mind-motor training on cardiovascular health and fitness. The secondary objective was to investigate whether the intervention had gender-specific effects on the study outcomes. **Methods:** Community-dwelling older adults (n = 127, age = 67.5 [7.3] yr, 71% women) were randomized to a 45-min multiple-modality exercise intervention with additional 15 minutes of either mind-motor training (M4 group) or an active control intervention (15 minutes of balance, range of motion and breathing exercises, [M2 group]). Assessment occurred at: baseline, 24 weeks (intervention endpoint), and 52 weeks (after a 28-week no-contact follow-up). The study outcomes were: predicted maximal oxygen consumption (pVO2max), automated office blood pressure (BP), carotid atrial compliance (cAC), intima-media thickness (cIMT), as well as body weight. Mixed between-within ANOVA was used to examine: i) main effects of time (baseline vs 24 weeks), intervention group (M4 vs M2) and gender (men vs women); ii) interactions of time x intervention group, and time x gender. **Results:** Results at 24 weeks: both M4 and M2 demonstrated improvements in pVO2max (*p<.001*), with no interaction effects for group or gender (all *p>.05*). For BP measures, both groups showed reduction in systolic (*p<.001*) and diastolic (*p=.001*) BP, with no interaction effect for intervention group; however, women showed greater reduction in diastolic BP compared to men (*p=.02*). No significant changes were observed in cIMT, cAC, or body weight. Results at 52 weeks: improvements in pVO2max were retained (*p<.001*), however, the M4 group showed higher pVO2max when compared to M2 (*p=.005*), with no interaction effects for gender. Significant reduction in systolic BP (*p<.001*) was observed for both M4 and M2, with no interaction effects for group or gender. For diastolic BP, M4 showed significant reduction compared to M2 (*p=.04*); women also demonstrated greater reduction compared to men (*p=.02*). There was no significant change in cIMT, cAC or body weight. **Conclusion:** Our results suggest that women may be more likely to benefit from group-based, multiple-modality exercise programs in measures of cardiovascular health.

The Effect of Two Training Protocols on Post Exercise Lactate Clearance in Heart Failure Patients

Yair Blumberg[1], Eyal Amon[2], Basem Hijazi[1], Offir Ertracht[3], Ilan Goldenberg[2], Robert Klempfner[2], Shaul Atar[1]. *[1]Bar Ilan, Zefat, Israel. [2]Sheba Medical Center, Ramat Gan, Israel. [3]Galilee Medical Center, Nahariya, Israel.*

(No relevant relationships reported)

Introduction: Heart failure (HF) patients suffer from functional aerobic impairment due to reduced cardiac output and O_2 delivery. This condition leads to metabolic and physiological changes, such as longer recovery time from physical activity. It was shown that aerobic exercise confers a beneficial effect on quality of life (QOL) and physiological parameters in HF. High intensity interval training (HIT) has been argued by some studies to have a superior rehabilitative effect compared to moderate aerobic training (MAT). We hypothesized that HIT has a superior effect on lactate clearance and, by extension, on recovery from exercise. **Methods:** Twenty-nine HF patients were randomized into two exercise groups: MAT or HIT, and trained twice a week for 12 weeks. Before and after completion of the exercise program patients were assessed for QOL, six-minute walk test (6MWT) and a cardiopulmonary exercise test (CPET). Blood lactate concentration was measured after the CPET and lactate clearance kinetics were fit to each patient by a bi-exponential time function. **Results:** HIT group showed a significant improvement compared to baseline in QOL and aerobic capacity (VO2 max 21.4±7 *vs.* 17.5±3 ml/min/kg, 6MWT 461±71 *vs.* 355±58 m). Both exercise groups improved lactate clearance, as represented by the γ2 constant. While the MAT group showed a trend towards significance (0.061±0.020 units) (p=0.07), the HIT group improved lactate clearance significantly (0.074±0.020 units) (p<0.01). **Conclusions**: HIT improves lactate clearance kinetics; thereby can partly explain the improved QOL attributed to exercise training

Effects Of 12 Weeks Of Yoga Program in Middle Aged Women With Frozen Shoulder

Ilsu Kwon, Jae-keun Oh, Taeyeon Kim. *Korea National Sport University, Seoul, Korea, Republic of.*

(No relevant relationships reported)

PURPOSE: The aim of this study is to identify the effects of yoga exercise program on muscle function and pain of shoulder in middle aged women with frozen shoulder. **METHODS:** Subjects were divided into 2 groups; yoga group (n=8) and control group(n=8).They participated in yoga exercise program 3days per week, 50minutes every day during 12 weeks and were measured Visual Analogue Scale, Shoulder Pain and Disability Index, Range of Motion, Strength, Pressure threshold to develop rehabilitation program for frozen shoulder. Data of the results was analyzed by using the SPSS/PC Window version 21.0 statistics program. To verify interaction between the groups, Two-Way ANOVA was conducted. All the statistical significance level was set at p<05. **RESULTS**: In VAS, there was a significant interaction between the groups and time(p=.002). In SPADI(Shoulder Pain and Disability Index), Yoga group showed significantly decreased score after exercise with interaction in times and groups(p=.020). In shoulder Pressure threshold, Yoga group showed a significant increase at subscapula (p=.024) and teres minor of affected shoulder with interaction in times and groups(p=.012). **CONCLUSION:** As a result, yoga exercise program is considered as helpful for middle aged women with frozen shoulder to relieve pain. However, correlation of shoulder muscle strength and range of motion were not clearly identified in this study. In future study, experiments for change of range of motion and muscle strength during yoga exercise and various groups of subjects might be required to establish theoretical basis.

VO$_2$ Peak, Energy Cost and Stress Biomarkers Responses to High Intensity Interval Protocol (HIIT)

Franz H. Burini, Rafael Rezende, Pedro Rodstein, Thalles Messora, Julio Mariano, Roberto C. Burini, FACSM. *UNESP Medical School, Botucatu, Brazil.* (Sponsor: Roberto C Burini, FACSM)

(No relevant relationships reported)

High Intensity Interval Training (HIIT) Protocols are well stabilised in the literature as a beneficial health inducing strategy to improve health, fitness levels and metabolic biomarkers. Risks management of participation of HIIT programs is challeging despite benefits. Cardiovascular, Musculoskeletal and Metabolic issues, such as dehydration status may play an important role on pre-participation screening of participants. **Purpose:** The purpose of this study was to evaluate energy cost and metabolic stress biomarkers due a HIIT protocol. **Methods:** 8 males (23±6years) were evaluated during a HIIT protocol (30 minutes of CrossFit based multitask pattern) using a Portable Metabolic Analyzer (K4b^2 - Cosmed®) for VO$_2$, energy expenditure and substrate oxidation. Blood samples were taken before and after protocol for Creatine-Kinase (CK), Creatine-Kinase Myocardial Band (CK-MB), Lactate Dehydrogenase (DHL), and Cortisol levels analysis. **Results:** VO$_2$ peak during HIIT protocol were 53.1mL/kg.min^{-1}±6.2mL/kg.min^{-1}; with peak energy cost of 17.3±4.1kcal.min^{-1}; being the fat oxidation less than 10% during the role protocol. Pre *vs* Post levels for CK, CK-MB, DHL and Cortisol were 1129,6±213.6U/L *vs* 1300,8±341.2U/L; 57,1±3.2U/L *vs* 68.0±3.7U/L; 646,1±27.1mg/dL *vs* 720,8±32.7mg/dL and 12,1±1.1µg/dL *vs* 17,2±1.8µg/dL respectively. **Conclusions:** Energy cost of the HIIT protocol evidences some of the benefits, thus leading to weight-loss strategy. Stress biomarkers CK, CK-MB, DHL and Cortisol responses to HIIt protocol suggests metabolic overload on systemic and local: skeletal muscle and myocardial tissue, despite clinical outcomes (pain or claims). Risk *versus* Benefit analysis of HIIT protocols should be focused on general populations and specific patients, wich may lead to detrimental health outcomes.

Patterns of Physical Activity and Muscle Strengthening Exercise in U.S. Undergraduates

Adrienne Wald. *The College of New Rochelle, New Rochelle, NY.* (Sponsor: Carol Ewing Garber, FACSM)

(No relevant relationships reported)

BACKGROUND: Universities and colleges are target settings for the *Exercise is Medicine*® (EIM) on Campus initiative, aiming to make physical activity a part of campus culture and to foster collaboration between campus organizations for physical activity assessment and promotion.**PURPOSE**: To describe the prevalence of meeting targets for aerobic (PA) or muscle strengthening (MS) exercise of U.S. undergraduates, by gender, and across various university and college types, sizes, and settings.**METHODS**: Data from undergraduate respondents to the 2011 American College Health Association-National College Health Assessment II (ACHA-NCHA-II) were classified by meeting or not meeting target PA and MS recommendations. Data were analyzed by cross tabulation analysis (X^2) by PA and MS status by gender, and across university designation (public vs. private), region of the country (Northeast, South, West, or Midwest), campus size (by student enrollment) and by 4-year or 2-year community college (type).**RESULTS**: The sample of undergraduates, aged 18-24 years (n=75,511), included 33.5% men 46.3% women and (0.2%) transgender (TG) students. Among these, there were significant differences (p< 0.001) across genders and meeting PA and meeting MS: 55.2% men, 48.4% women, and 35.9% TG students met PA, and 47.7% men, 32.6% women, and 25% TG met MS. Meeting PA was significantly different by campus size (p<0.001) and type (p<0 .05), but not by region (p= 018) or designation (p= 0.775). Significant differences for meeting MS were found across regions (p< 0001), campus size (p< 001), type (p =0.49), and university designation (p<0 .001). **CONCLUSIONS**: PA and MS exercise participation in college students is modest at best, and it varies across geographic locations and differing campus characteristics. These results suggest that targeting college students with *EIM on Campus* is indicated, particularly sub-populations where PA and MS participation is low.

Multiple Strength Assessments to Evaluate Adaptations to High-Load and Low-Load Blood Flow Restricted Exercise

Summer B. Cook, FACSM[1], Dain P. LaRoche, FACSM[1], Todd M. Manini, FACSM[2]. [1]*University of New Hampshire, Durham, NH.* [2]*University of Florida, Gainesville, FL.*

(No relevant relationships reported)

Differences in muscle strength adaptations between high-load (HL) and low-load blood flow restricted (BFR) resistance training protocols may be due to the type of strength test performed (e.g isotonic, isokinetic and isometric). **PURPOSE:** To assess differences in isotonic, isometric and isokinetic strength adaptations in older adults following HL and BFR resistance training. **METHODS:** Thirty-six males and females (mean: 75.6±7.6 years, 1.67±.09 m, 74.3±13.2 kg) classified as being at risk of mobility limitations were randomly assigned to HL (70% 1-RM) or low-load BFR (30% 1-RM coupled with a vascular restriction) exercise for the knee extensors twice per week for 6 weeks. A control group performed light upper body resistance and flexibility training. Knee extension 10-RM to predict 1-RM strength, isometric maximum voluntary contraction (MVC) and isokinetic strength at 60·s^{-1}, 180·s^{-1}, and 300·s^{-1}were measured before and after 6-weeks of training. **RESULTS:** HL and BFR training increased predicted 1-RM strength 34% (P<.001) and 24% (P<.001) respectively, from baseline to 6-weeks of training. HL training produced a 16% increase in MVC (P=.002) while BFR training did not change (P=.91). No interventions, included the control, resulted in changes in isokinetic strength at the various speeds (P>.20). **CONCLUSION:** Strength improvements from HL resistance training carried over to other strength tests. This favorable adaptation did not occur following BFR exercise which may limit the effectiveness of this training program. Isotonic training does not carry over to isokinetic strength adaptations and therefore may be a drawback when implementing resistance training programs for older adults. Supported by NIH grant 1R15 A6040700-01A1.

1025   Board #286   May 30 3:30 PM - 5:00 PM

Oral Creatine Hydrochloride Supplementation: Acute Effects on Intermittent, Submaximal Bouts of Resistance Exercise

Daniel McDonough, Shawn Simonson, Yong Gao, Scott Conger. *Boise State University, Boise, ID.* (Sponsor: Dr. Zan Gao, FACSM)

(No relevant relationships reported)

PURPOSE: Creatine hydrochloride (CrHCl) supplementation and its effects on muscular performance and body composition remains largely unexplored. The purpose of this study was to examine the acute effects of oral CrHCl supplementation on three intermittent, submaximal bouts of bench press and repeated vertical jump exercises (maximal repetitions) and body composition measures (body weight [BW], fat-free mass, and fat mass).
METHODS: Fifteen resistance trained males ($\bar{X}_{age}$ = 22.8 ± 2.0 years; $\bar{X}_{wt}$ = 81.6 ± 9.9 kg) completed 3 sets of the barbell bench press (70% 1RM) and 3 sets of the repeated counter-movement vertical jump (CMJ; 85% maximal CMJ height), with 2 min rest between sets, before and after a 7 d CrHCl intervention (4 g·d^{-1}). Participants continued their normal resistance training and nutrition routines. A two-factor repeated measures ANOVA was used to determine significant main effects (time and set) and interaction effects (time x set) for bench press and CMJ performances from pre- to post-intervention. A one-factor repeated measures ANOVA was used to assess pre- to post-intervention differences in body composition.
RESULTS: Significant main and interaction effects for time and set were found in the bench press from pre- to post-intervention, $F (2, 28) = 4.2\text{-}268.3$, $p < 0.005$; $n^2 = 0.2\text{-}0.9$, with post-hoc analysis indicating increased performance on later sets (eg, Set 3 > Set 2 > Set 1). Significant main effects for time and set were found in the CMJ test from pre- to post-intervention, $F (2, 28) = 27.5\text{-}55.6$, $p < 0.005$; $n^2 = 0.7\text{-}0.8$, but no interaction effect was found ($p > 0.05$). Post-hoc analysis indicated increased performance on later sets (eg, Set 3 > Set 2 > Set 1). BW was the only body composition measure to reach significance ($p < 0.005$).
DISCUSSION: Findings suggest 7 d of CrHCl supplementation (4 g·d^{-1}) to increase repetitions completed on three sets of the intermittent, submaximal bench press and CMJ exercises and BW. The non-significance in the time x set interaction for CMJ performance may due to small sample size, and thus future research with larger samples is warranted.

A Comparison of Two Tai Chi Interventions Tailored for Different Health Outcomes

Yin Wu[1], Beth Taylor, FACSM[1], Patrick Coll[2], Susan Glenney[1], Crystal Park[1], Richard Fortinsky[2], Cindy Senk[3], Kirsten Benson[3], Matt McGowan[3], Slyvia DiBiasi[3], Ken Zaborowski[1], Ming-Hui Chen[1], Holly Lewis[4], Jacqueline Wolff[1], Shiqi Chen[1], Linda S. Pescatello, FACSM[1]. [1]University of Connecticut, Storrs, CT. [2]University of Connecticut Health Center, Farmington, CT. [3]Seabury Continuous Care Community, Bloomfield, CT. [4]University of Pittsburgh, Pittsburgh, PA. (Sponsor: Linda S. Pescatello, FACSM)

(No relevant relationships reported)

Tai Chi can be tailored based on five major styles, over 108 forms, and three fundamental elements that include breathing techniques, mental relaxation, and movement principles. However, it is not clear if Tai Chi interventions tailored for specific health outcomes will result in different health benefits. **Purpose**: To compare the health benefits of two different Tai Chi interventions targeted for improvements in blood pressure (BP) (PRESSURE) or balance (BALANCE). **Methods**: We tailored PRESSURE to emphasize breathing techniques and mental relaxation; and BALANCE to emphasize movement principles that challenge balance. Participants were randomized based upon baseline values to PRESSURE (n=12), BALANCE (n=13), or CONTROL (n=10). Tai Chi was practiced 3 sessions/week, 60 minutes/session, for 12 weeks. CONTROL (n=10) performed normal daily activities. We measured a variety of cardiovascular, balance, and functional fitness health outcomes pre-and post-intervention. Differences among groups were tested with analyses of covariance with age, body mass index, heart rate, and baseline BP as covariates. **Results**: Participants were older (78.9±5.7 yr), overweight (25.9±4.3 Kg/m^2) adults, with pre-hypertension (systolic BP[SBP]/diastolic BP, 126.5±14.4/69.3±8.4 mmHg), and mostly women (82.9%) and naive to Tai Chi (97.1%). PRESSURE improved Chair Sit-to-Stand Test (CSTS) by 1.0±1.8 times/30s versus CONTROL (p=0.029); and BALANCE improved Single Leg Stance Test by 5.4±18.0 s (p=0.049) and CSTS by 1.0±1.7 times/30s (p=0.027), and tended to lower SBP by 4.2±16.0 mmHg (p=0.052) versus CONTROL. However, there were no differences between PRESSURE and BALANCE versus CONTROL for any health outcome (p>0.05) **Conclusion:** Contrary to our hypothesis, Tai Chi interventions tailored for specific health outcomes did not result in different health benefits. Yet, our results suggest that older adults who are naive to Tai Chi achieve a variety of health benefits from different types of Tai Chi practice within the first few months of participation.

1027 Board #288 May 30 3:30 PM - 5:00 PM

ICT Use and Physical Activity & Implication for Musculoskeletal Pains among Tertiary Institution Students in Kwara State Nigeria

Seidina Yakubu Iliasu[1], Olufunmilola Leah Dominic[1], Faatihah Adeyinka Niyi-Odumosu[2], Talabi Ebun Adetayo[1]. [1]University of Ilorin, Ilorin, Nigeria. [2]Loughborough University, Loughborough, United Kingdom.

(No relevant relationships reported)

PURPOSE: Recent studies show that prolonged ICT use is associated with increased sedentariness and postural imbalances. This has implication for the prevalence of musculoskeletal pains among ICT users. To investigate the implications of ICT use for physical activity level and musculoskeletal pains among tertiary institution students in Kwara state. **METHODS**: The research design was ex-post facto. Multistage sampling comprising stratified, purposive and simple random sampling was used to select 2,442 students with average age of 22.8 years from three tertiary institutions in Kwara state. The institutions consisted of federal, state and private. Validated (Rho = .71) ICT Use, Physical Activity and Musculoskeletal Pain Questionnaire (IUPAMP-Q) was used for data collection. ICT referred to mobile phones, tablets/i-pads, computers and television sets. Percentage and Mean were adopted for demographic descriptions, physical activity level and ICT use while hypotheses were tested with t-test and Multiple Regression at a 0.05 alpha level. **RESULTS**: The study revealed that only 56.4% (1,377) of the students performed the recommended physical activity. Mean physical activity level (PAL) of moderate ICT users was higher than excessive ICT users by 178.9METs/wk, which was statistically significant (N = 2426; t (2424) 6.227; p = .001). Majority reported musculoskeletal pain after continuous ICT use for at least 1hour; neck pain = 75.7% (1,836), shoulder pain = 59.9% (1,137) and back pain = 74.4% (1,805). ICT use positively correlated with musculoskeletal pains; it predicted 27% shoulder pain, 30% neck pain and 16% back pain (F(2,2421), 16.769; 18.475, 9.886; p = .001) respectively. **CONCLUSIONS**: use of ICT is a risk factor for musculoskeletal pain and mobile phone was the highest predicting factor. A collaborative effort within tertiary institution communities to inculcate physically active lifestyle and individualised structured ICT use is recommended.

1028 Board #289 May 30 3:30 PM - 5:00 PM

Bedside Exercise Device for Heart or Liver Transplantation Recipients in Early Postoperative Period

Ssu-Yuan Chen[1], Shoei-Shen Wang[1], Ray-Heng Hu[2], Yih-Sharng Chen[2], Ching Lan[2], Andrew K. Dorsch[3], Bruce H. Dobkin[3]. [1]Fu Jen Catholic University Hospital and Fu Jen Catholic University, New Taipei City, Taiwan. [2]National Taiwan University Hospital and National Taiwan University, Taipei, Taiwan. [3]University of California, Los Angeles, CA.

(No relevant relationships reported)

PURPOSE: The aims of this randomized, assessor-blinded clinical trial are to investigate the effect of exercise 25 min or more per day on the bedside exercise device in heart or liver transplantation recipients who are at-risk for functional deterioration during a long inpatient stay after transplantations. **METHODS**: Adult patients who received a heart or liver transplantation were randomized to either UCFit exercise group or usual care group. UCFit exercise group will exercise on the bedside exercise device which uses foot pedals that record exerted forces against adjustable resistances, measure repetitions of upper and lower extremity cycling movements, and give feedback about performance via a wireless internet connection. Usual care group was only encouraged to increase the amount of physical activities. The outcome measure was level of independence for walking, walking speed, 6-minute walking distance, Short-Form 36 health-related quality of life, heart rate variability, knee strength, and cardiorespiratory fitness. **RESULTS**: Thirty-five patients who received a heart (n=13) or liver (n=22) transplantation participated at a median of 8 days after surgery. No adverse events were reported during the median study period of 15 days. The UCFit exercise group (n=15) showed increased standard deviation of all NN intervals (SDNN) from 16.5±13.0 ms to 26.3±18.7 ms, compared to the usual care group (n=20) from 18.4±18.9 ms to 16.6±17.9 ms (p= 0.01 during interaction analysis); and increased the square root of the mean of the sum of the squares of differences between adjacent NN intervals (RMSSD) from 8.8±7.6 ms to 22.3±24.9 ms, compared to the usual care group from 18.4±32.8 ms to 16.5±30.4 ms (p= 0.03). The UCFit exercise group achieved a trend toward greater 6-minute walking distance and higher knee strength at discharge compared to the usual care group. No significant between-group differences were detected in the other outcomes of interest. **CONCLUSIONS**: In this ongoing trial of bedside exercise with remote monitoring for inpatient organ transplantation rehabilitation, exercise 25 min or more per day showed increased heart rate variability of the study subjects in the early postoperative period. Supported by Grant MOST 104-2314-B-002 -221 -MY3 from Ministry of Science and Technology, Taiwan.

Improving College Students' Health-Related Fitness Through Physical Activity Classes

Wenhao Liu, FACSM, Ethan E. Hull, Istvan Kovacs. *Slippery Rock University, Slippery Rock, PA.*

(No relevant relationships reported)

PURPOSE: College period is usually associated with weight gain and physical fitness decline among population of college students. This study investigated whether and to what extent physical activity (PA) classes could reverse this tendency.
METHODS: Participants were 124 college students (mean age: 20.76±1.03, 73 males and 51 females) who enrolled in 16-week PA classes in a university in the US. The PA classes met two or three times a week with a total of 150 minutes/weekly, focusing on different activities addressing health-related physical fitness. Body mass index (BMI), 20-meter Progressive Aerobic Cardiovascular Endurance Run (PACER), curl-ups, push-ups, trunk lift (in inches), and sit and reach (in inches) tests were administered to the participants at the beginning (pretest) and the end (posttest) of the semester. Performances of each measure at the two test points were compared with paired-samples t test. All data analyses were conducted by sex, and cases were excluded pairwise. The numbers of students who participated in each paired assessment (i.e., having a measure at both test points) ranged from 59 to 71 for males and 42 to 51 for females.
RESULTS: For males, significant improvement (p < .001) occurred in PACER (Pretest 59.41±21.78 vs. posttest 64.58±22.39), curl-ups (55.40±20.73 vs. 62.10±19.04), push-ups (23.56±6.62 vs. 27.21±7.79), and trunk lift (10.21±2.20 vs. 12.54±2.08). Sit and reach showed a non-significant improvement (17.27±2.99 vs. 17.52±3.01, p < .10). BMI was the only measure remaining unchanged (25.83±4.65 vs. 25.80±4.50, p = .38). As for females, significant improvement (p < .005) was observed in PACER (35.31±11.74 vs. 40.67±12.68), curl-ups (43.59±21.78 vs. 50.39±20.40), push-ups (18.76±6.64 vs. 21.06±8.05), trunk lift (11.82±2.48 vs. 13.04±1.72), and sit and reach (18.56±3.57 vs. 19.31±3.86). The only measure remaining unchanged was BMI (23.62±3.10 vs. 23.60±2.99, p = .73).

CONCLUSIONS: While there is a tendency of weight gain and fitness decline among university students, PA classes addressing health-related physical fitness are effective in maintaining body weight and improving other health-related physical fitness components for college students.

1030   Board #291   May 30 3:30 PM - 5:00 PM

Retrospective Analysis Of A Supervised Exercise Program Offered To Post-hematopoietic Stem Cell Transplant Patients

Kate M. Edwards[1], Adelle Bottrell[1], Steven R. Larsen[2], Michael Marthick[3]. *[1]University of Sydney, Sydney, Australia. [2]Royal Prince Alfred Hospital, Sydney, Australia. [3]Chris O'Brien Lifehouse, Sydney, Australia.* (Sponsor: Ollie Jay, FACSM)
(No relevant relationships reported)

A growing number of cancer patients receive hematopoietic stem cell transplants (HSCT), a potentially curative treatment, but engenders adverse symptoms of fatigue, reduced physical function and decreased quality of life. Maintaining physical fitness for functional independence and the ability to perform activities of daily living is a high priority for patients. Exercise programs have been found to be effective in improving physical fitness and quality of life and reducing fatigue level in haematological cancer patients, and recently supervised programs have been offered to patients as part of Wellness treatment. **PURPOSE:** To evaluate adherence, safety and physiological effects of an eight-week supervised exercise program in post HSCT patients. **METHODS:** A retrospective study including 55 patients (N=22 female) referred to the optional exercise program after undergoing HSCT for a haematological malignancy. Safety and adherence information was collected throughout the program. Physiological outcomes were measured at baseline and post program (fatigue, quality of life, strength, 6 minute walk test (6MWT), balance and body composition). **RESULTS:** No adverse events were reported during the program and patients demonstrated a high (86.1%) adherence to supervised sessions. Fatigue decreased (4.6±1.9 to 3.4±2.1, p=.003) and Quality of Life increased (105.9±17.8 to 113±17.8, p=.040) from baseline to post intervention. Physical function increased in all measures (6MWT, 413.8±97.2m to 497.4±82.5m, p<.001; 1RM leg press 56.3±34.7kg to 68.0±36.6kg, p=.011; 1RM seated row, 32.7±15.0kg to 40.0±17.5kg, p=.001; Chair stand, 12.0±3.7 to 15.0±3.0, p<.001). Reported weekly physical activity also increased (114.2±132.7min to 205.7±137.8min, p<.001). Body mass, fat free mass and body fat percentage did not change. **CONCLUSIONS:** In line with prior findings, this supervised exercise program was an effective treatment for comorbidities associated with HSCT. Importantly, these results include participants who self-enrolled in the program, and paid a contribution to the cost. The high adherence and significant improvements confirm the efficacy of an exercise program and support the continued offerings of such Wellness treatment as part of usual care.

1031   Board #292   May 30 3:30 PM - 5:00 PM

Shriners Hospitals For Children® At Galveston Exercise Prescription Guidelines For Children With Severe Burn Injury

Eric Rivas[1], David N. Herndon[2], Janos Cambiaso-Daniel[3], Victoria G. Rontoyanni[2], Shauna Glover[2], Craig Porter[2], Oscar E. Suman, FACSM[2]. *[1]Shriners Hospitals for Children and The University of Texas Medical Branch, Galveston TX, and Texas Tech University, Lubbock, TX. [2]Shriners Hospitals for Children and The University of Texas Medical Branch, Galveston, TX. [3]Medical University of Graz, Austria, Shriners Hospitals for Children and The University of Texas Medical Branch, Galveston, TX.* (Sponsor: Oscar E. Suman, FACSM)
(No relevant relationships reported)

PURPOSE: Burn trauma is associated with metabolic abnormalities coupled with prolonged immobilization and deconditioning, where burned patients have markedly reduced strength and aerobic exercise capacity. Over the last 20 years, Shriners Hospitals for Children®—Galveston has endeavored to improve the rehabilitation of burned children. A key contribution from this work has been identifying the benefits of rehabilitation exercise training (RET) in restoring function in burned children. Currently, there are no clear guidelines for the implementation of RET in burned individuals. Therefore, we quantified the training logs for exercise intensity, frequency, and duration of 6 weeks of this program in order to develop a basic framework for outpatient RET in patients recovering from severe burns. **METHODS**: Thirty-three children (mean±SD, 11 female, 12±3 yrs, 145±18 cm, 40±11 kg) with severe burns (49±15% body surface area burned, with 35±22% third-degree burn) completed a 6-week resistance and aerobic exercise training program. Cardiorespiratory function (peak VO_2), strength and power, and lean body mass (LBM) were measured pre- and post-RET. Outcome measures were analyzed as a relative percentage of the age-sex matched non-burned counterpart (n=33, 11 females, 12±3 yrs, 154±20 cm, 49±22 kg).

RESULTS: At discharge, LBM was attenuated by 77% [of non-burned values], peak torque by 53%, power by 62%, and cardiorespiratory fitness by 56%. After 6 weeks of training, LBM increased from pre-training values by 5% (82% of non-burned values), peak torque by 18% (71%), power by 20% (81%), and cardiorespiratory fitness by 18% (74%; P<0.0001 for all). The quantification of exercise logs found that physical capacity can be improved by aerobic exercise training at 5 metabolic equivalents (74% of peakVO_2) performed at least 3 days per week and 150 min per week and by resistance training performed at volume loads [reps × sets × weight] of 280 (19% of total body mass, TBM) for the upper body and 590 (42% TBM) for the lower body at least 2 days per week. **CONCLUSIONS**: For the first time, we quantify our RET program and provide exercise prescription guidelines specific to burn populations. Future research should build upon this work and individualize exercise prescription to optimize rehabilitation benefits in severely burned children.

Post-menarcheal Trabecular Bone Score as a Function of Organized Physical Activity

Jodi N. Dowthwaite[1], Renaud Winzenrieth[2], Tamara A. Scerpella[3]. *[1]SUNY Upstate Medical University; Binghamton University, Syracuse, NY. [2]Medimaps Group, Merignac, France. [3]University of Wisconsin, Madison, Madison, WI.* (Sponsor: Jill Kanaley, FACSM)
(No relevant relationships reported)

PURPOSE: Trabecular bone score (TBS) grades lumbar spine trabecular texture based on DXA scan gray level variation. In adults, TBS correlates with trabecular density indices and predicts fracture risk, independent of areal bone mineral density (BMD). However, few pediatric studies have evaluated TBS, with none demonstrating significant exercise loading associations. Bone accrual accelerates circum-menarche; thus, we hypothesized that circum-menarcheal organized physical activity (OPA, h/wk) would correlate with post-menarcheal TBS, suggesting potential for improvement of baseline adult trabecular texture via circum-menarcheal exercise.
METHODS: Annual DXA scans and semi-annual OPA records were collected via a prospective, longitudinal study of exercise and bone accrual. Analysis inclusion criteria were: 1) a postero-anterior lumbar spine DXA scan (Hologic, Waltham MA) from 0-1 year post-menarche; 2) prior year OPA records. Raw TBS data were generated using proprietary TBS iN-sight software (v2.2, Medimaps, France), adjusted for pediatric-specific soft-tissue effects. Multiple regression evaluated linear and quadratic associations between prior year OPA and TBS, accounting for gynecological age; β and significance are reported for each predictor. To reduce variance inflation, the quadratic function was mean-centered.
RESULTS: Data were included for 111 girls, with means as follows: age 13.4 yrs (10.0 to 15.6, sd 1.1), age at menarche 12.9 yrs (sd 1.1), gynecological age 0.5 yrs (sd 0.3), OPA 8.0 h/wk (sd 5.8) and TBS 1.38 (1.15 to 1.58, sd 0.08). In a regression model entering OPA, OPA^2 and gynecological age, a significant non-linear association was observed with OPA (respective β= 0.003, -0.001, 0.043, p=0.08, 0.003, 0.12).
CONCLUSIONS: Our data suggest a target circum-menarcheal OPA range of 5 to 15 h/wk. Further research is needed to confirm that TBS is modifiable via pediatric exercise to optimize baseline adult trabecular texture.

TBS as a Function of Organized Physical Activity: Raw Scatter Graph and Modeled Accounting for Gynecological Age

Postprandial Lipemic Responses After A High-fat Meal And Low- Or High-intensity Interval Exercise

Racine R. Emmons, Michael A. Figueroa, Toni T. LaSala. *William Paterson University, Wayne, NJ.* (Sponsor: Gordon Schmidt, FACSM)

(No relevant relationships reported)

Evidence suggests that high-intensity interval training can be as beneficial, or superior to traditional low to moderate intensity, long duration exercise in clearing postprandial triglycerides (TG).**PURPOSE**: To compare the effect of exercise intensity on postprandial lipemic responses after a high fat meal. **METHODS**: Maximal oxygen consumption (VO2) was measured in 13 participants (9 male, 4 female). There were no differences between males and females among age (males: 24±2 years; females 23±2 years), height (1.74 ± 0.04 meters vs. 1.69 ± 0.09 meters, respectively), or VO2max (41.42 ± 3.87 mL/kg/min vs. 36.97 ± 1.39 mL/kg/min, respectively.) Males weighed heavier than females (78.9 ± 11.2 kg vs. 65.3 ± 2.1 kg, $p = 0.04$). In a randomized crossover design, participants returned on two separate occasions where they arrived fasting and consumed a high-fat milkshake made from premium chocolate ice cream and heavy whipping cream, delivering 1.3 g/kg bodyweight of fat. Participants performed either low intensity exercise (LE) on a treadmill at a self-selected pace to elicit a heart rate (HR) of 40-60% of heart rate reserve (HRR) for 30 minutes or perform high-intensity interval exercise (HE) of 8 repetitions of 30 second sprints on a treadmill with 90 second active rest. Participants returned on a non-consecutive test day to perform the opposite test. Blood was sampled via fingerstick for TG at baseline (T0), 1 hour (1H), 3 hours (3H), and 5 hours (5H) postprandially. Area under the curve (AUC) determined the postprandial TG response via the trapezoid method. Comparisons among TG at each time point and AUC were determined via paired samples t-tests. Significance was set at $p<0.05$. **RESULTS**: No differences were found among baseline, 1H, or 3H TG values between the exercise conditions (p >0.05). 5H TG and AUC were lower in LE compared to HE (5H: 149.54 ± 113.18 mg/dL vs. 195.85 ± 117.14 mg/dL, respectively, t(13)= -3.384, $p=0.005$, $d=0.402$; AUC: 430.39 ± 269.64 mg/dL vs. 508.12 ± 256.97 mg/dL, respectively, t(13)=-2.212, $p=0.04$,$d=0.295$). Normalized peak TG values were not significantly different across groups. **CONCLUSIONS**: LE resulted in lower postprandial lipemic responses and lower peak compared to HE. The relatively short HE session may have not been sufficient in duration to clear postprandial TG.

1070   Board #2   May 31 8:00 AM - 10:00 AM
Similar Substrate Use During Prolonged Cycling in Men and Women

Beth W. Glace, Ian J. Kremenic, Malachy P. McHugh, FACSM. *Lenox Hill Hospital, New York, NY.* (Sponsor: Malachy McHugh, FACSM)

(No relevant relationships reported)

PURPOSE: It is generally accepted that, compared to men, women rely more upon lipids as a substrate during moderate intensity exercise. However, most studies were conducted in a fasting condition, which is not how prolonged exercise is typically performed. The purpose of this study was to compare substrate use between sexes in well-trained cyclists during prolonged exercise after a standardized breakfast. **METHODS**: Well-trained cyclists [18 women, 16 men] were recruited. Subjects reported to our lab twice. On the first day they performed a VO_{2max} test. At 7:30 a.m. on a subsequent day, they drank a standardized breakfast of a liquid meal replacement which provided 6 kcals/kg. At 9 a.m. they pedaled on their own bikes for 2 hours at their ventilatory threshold [~65% VO_{2max}] with 5,1-min sprints interspersed throughout. Water was provided at a rate of 1% body mass/h. Ventilatory gas exchange was measured every 20 min to calculate RER. Descriptive data were compared using independent t-tests, ventilatory data were compared using repeated measures ANOVA. **RESULTS**: Men and women were of similar age [38 yrs, p=0.92] and VO_{2max} was typical of well-trained, recreational cyclists: 56 ml/kg/min for men, and 47 ml/kg/min for women. Body mass declined by 1% and did not differ between sexes [p=0.98]. RER declined during exercise [p<0.001] but there was no difference between sexes [p=0.38] and no time x sex interaction [p=0.78], indicating that substrate usage was

similar between men and women. Perception of effort and heart rate increased over time, but did not differ between men and women [time x sex p≥0.26, effect of sex, p≥0.62].
CONCLUSIONS: The notion that women rely more upon lipids during exercise was not supported by our data in fed subjects. Men and women who perform prolonged exercise after a light meal, as is typical, are likely to use similar amounts of fats and carbohydrates. This underscores the importance of nutritional status in studies comparing men and women.

No Lipolytic Suppression With Pre Exercise Carbohydrate Regardless of its Glycemic Index

Daniel A. Baur[1], Brandon D. Willingham[2], Smith M. Kyle[2], Kisiolek N. Jacob[2], Morrissey C. Margaret[2], Ragland J. Tristan[2], Saracino Patrick[2], Ormsbee J. Michael, FACSM[2]. *[1]Elon University, Elon, NC. [2]Florida State University, Tallahassee, FL.* (Sponsor: Michael Ormsbee, FACSM)

(No relevant relationships reported)

INTRODUCTION: It is well-documented that ingesting carbohydrate prior to exercise reduces fat oxidation, and that this effect is attenuated with low glycemic index carbohydrates. However, it is yet to be established whether these metabolic effects are primarily the result of alterations in the mobilization of free fatty acids (FFA) from adipose tissue (i.e. lipolysis) or whether these effects impact exercise performance. PURPOSE: To determine the impact of pre-exercise carbohydrate of different glycemic indices on subcutaneous abdominal adipose tissue (SCAAT) metabolism and running performance. METHODS: Ten trained male runners completed three experimental trials consisting of 30 min at 60% VO_{2max}, 30 min at 75% VO_{2max}, and a 5-km time trial (TT). Thirty min prior to exercise, participants consumed one of three beverages: 1) 75 g low glycemic index modified starch supplement (UCAN), 2) 75 g high glycemic index glucose-based supplement (G), or 3) a non-caloric placebo (PL). SCAAT lipolysis was assessed via microdialysis. RESULTS: Prior to exercise, blood glucose and insulin were elevated with G vs. PL ($+53.0 \pm 21.3$ mg·dL⁻¹ [SD]; $p = 0.000$; $+33.9 \pm 11.0$ μU·mL⁻¹; $p = 0.000$) and G vs. UCAN ($+36.6 \pm 24.9$ mg·dL⁻¹; $p = 0.00007$; $+25.2 \pm 11.0$ μU·mL⁻¹; $p = 0.000$), respectively. Fat oxidation was attenuated, and carbohydrate oxidation increased prior to exercise with G vs. PL (-0.06 ± 0.06 g·min⁻¹; $p = 0.005$; $+0.18 \pm 0.07$ g·min⁻¹; $p < 0.0001$) and G vs. UCAN (-0.06 ± 0.05 g·min⁻¹; $p = 0.004$; $+0.18 \pm 0.14$ g·min⁻¹; $p < 0.0001$). There were no differences in SCAAT lipolysis or running performance. CONCLUSIONS: Pre-exercise carbohydrate results in metabolic effects favoring carbohydrate utilization, and these effects are attenuated with low glycemic index carbohydrate. However, these effects are not the result of alterations in SCAAT lipolysis, nor do they affect exercise performance.

Overload Alters Skeletal Muscle Glucose Utilization but not Glucose Uptake or Hypertrophy in Insulin-Resistant Mice

Luke Weyrauch[1], Shawna McMillin[1], Kristen Turner[2], Carol Witczak[1]. *[1]East Carolina University, Greenville, NC. [2]University of Iowa, Iowa City, IA.*

(No relevant relationships reported)

Resistance exercise training/chronic muscle loading induces skeletal muscle hypertrophy and improves systemic glucose homeostasis in individuals with type 2 diabetes. Surprisingly, it is presently unknown if the improvement in glycemic control is due to an increase in muscle glucose uptake. **PURPOSE:** To determine if chronic muscle loading (overload)-induced muscle glucose uptake is impaired by insulin resistance. **METHODS & RESULTS:** Male C57BL/6J mice (6 wks old) were fed

a low fat diet (LFD) or a 60%kcal high fat diet (HFD) for 12 wks to induce insulin resistance. Plantaris muscle overload was elicited by unilateral ablation of the distal 2/3 of the gastrocnemius and soleus. The contralateral leg was sham-operated. Muscles were weighed 5 days later. Overload increased muscle mass ~40% in both LFD and HFD mice. To assess glucose uptake, muscles were incubated in [^{3}H]-2-deoxyglucose. Overload increased muscle glucose uptake ~80% in both LFD [Sham: 0.52±0.02; Overload: 0.91±0.04 (μmol/g muscle/h)] and HFD mice [Sham: 0.49±0.04; Overload: 0.86±0.09 (μmol/g muscle/h)], showing that overload stimulates glucose uptake independent of insulin resistance. To determine if this effect is due to increased glucose transporter (GLUT) or hexokinase levels, immunoblots were performed. Overload did not alter GLUT4 or hexokinase. In contrast, overload increased GLUT1 ~70%, but only in insulin resistant muscles. Decreased glycogen enhances glucose uptake. To determine if overload lowered glycogen levels, glycogen content was measured using a hexokinase-based reagent. Overload increased muscle glycogen ~26% in LFD (Sham: 29.0±1.6; Overload: 36.1±1.5 nmol/mg muscle), and ~40% in HFD mice (Sham: 31.2 ±2.1; Overload: 42.3±1.7 nmol/mg muscle). To determine if overload-induced glucose uptake is dependent on glucose utilization, muscles were incubated in [5-^{3}H]-glucose to assess glycolytic flux, and immunoblots performed to assess the rate limiting enzyme of the pentose phosphate pathway, glucose-6-phosphate dehydrogenase (G6PD). Overload did not alter muscle glycolytic flux. In contrast overload increased muscle G6PD ~140% in LFD, and ~82% in HFD mice. **CONCLUSION:** Insulin resistance does not impair overload-induced muscle hypertrophy or glucose uptake, but does alter glucose utilization. **SUPPORT:** NIH R01 DK103562

Post-Exercise Fructose-Maltodextrin Ingestion Enhances Subsequent Endurance Capacity

Gareth A. Wallis, Tim Podlogar, Ed Maunder. *University of Birmingham, Birmingham, United Kingdom.* (Sponsor: Professor Janice Thompson, FACSM)

(No relevant relationships reported)

PURPOSE: Restoring muscle and liver glycogen content during short-term (<6 h) recovery from prolonged exercise is pertinent for athletes seeking to maximize performance in repeated exercise bouts. Previous research suggests co-ingestion of fructose-glucose carbohydrate sources augments liver and has equivalent effects on muscle glycogen storage during short-term recovery from prolonged exercise compared to isoenergetic glucose ingestion. The aim of the present investigation was to determine if this has a discernible effect on subsequent exercise capacity.
METHODS: Eight trained endurance runners and triathletes performed two experimental trials in a single-blind, randomised, and counterbalanced cross-over design. Trials involved treadmill running to exhaustion at 70 %VO$_{2max}$, a four-hour recovery with 90 g.h^{-1} of glucose-maltodextrin (GLU) or fructose-maltodextrin (FRU) ingestion (1:1.5 ratio), and a second bout of treadmill running to exhaustion at 70 %VO$_{2max}$. Indirect calorimetry and stable isotope methods were employed to estimate substrate oxidation and ingested carbohydrate oxidation.
RESULTS: Endurance capacity in the second exercise bout was significantly greater with FRU (81.4 ± 22.3 vs. 61.4 ± 9.6 min, P = 0.02), a *large* magnitude effect (ES = 1.84 ± 1.12, 32.4 ± 19.9 %). Total carbohydrate oxidation rates were not significantly different between-trials at given time-points, although the total amount of carbohydrate oxidised in the second exercise bout was significantly greater with FRU (223 ± 66 vs. 157 ± 26 g, P = 0.02). Ingested carbohydrate oxidation rates, representing carbohydrate stored during recovery and/or that derived from ongoing absorption, were greater during bout two with FRU (P = 0.001). Plasma glucose and non-esterified fatty acid concentrations were not significantly different between-trials. Plasma lactate concentrations were significantly greater during recovery with FRU (P = 0.001). Self-reported nausea and stomach fullness during bout two were marginally in favour of FRU.
CONCLUSION: Short-term recovery of endurance capacity was significantly enhanced with fructose-maltodextrin vs. glucose-maltodextrin ingestion during recovery.

Prolonged Low-moderate Intensity Exercise On Physiological Markers Of Metabolic And Oxidative Stress

Dominique Gagnon[1], Sandra Dorman[1], Stephen Ritchie[1], Shivaprakash Jagalur Mutt[2], Ville Stenbäck[2], Jarek Walkowiak[3], Karl-Heinz Herzig[2]. *[1]Laurentian University, Sudbury, ON, Canada. [2]University of Oulu, Oulu, Finland. [3]Poznan University, Poznan, Poland.*

(No relevant relationships reported)

Oxidative stress results in lipid, protein and DNA oxidation as well as metabolic dysfunctions. This may result in chromosomal damage, telomere erosion, and accelerated cellular ageing. Long-term physical activity promotes healthy metabolic and oxidative profiles. The effects of prolonged physical activity however, are unknown.
Purpose
This study investigated the effects of prolonged physical activity on oxidative and metabolic stress in healthy adults participating in a 260-km wilderness canoeing expedition.
Methods
Twenty-seven participants took part in the study. Sixteen went on a 14-day wilderness canoeing expedition (EXP) (24 ± 7 yrs, 72 ± 6 kg, 178 ± 8.0 cm, 18.4 ± 8.4 %BF, 47.5 ± 9.3 mlO$_2$·kg^{-1}·min^{-1}), covering a distance of 260 km, requiring 6-9 hrs of low to moderate exercise daily, and eleven were used as controls (CON) (31 ± 11 yrs, 72 ± 15 kg, 174 ± 10 cm, 22.8 ± 10.0 %BF, 47.1 ± 9.0 mlO$_2$·kg^{-1}·min^{-1}). Blood sample collection was completed before and after the expedition. ANCOVA analyses were performed on metabolic and oxidative variables as well as telomere length from isolated blood mononuclear cells.
Results
For metabolic results, no statistical differences were observed in total cholesterol, high- and low-density lipoprotein, testosterone and insulin concentration. Triglycerides were lower following the expedition (EXP 69 ± 18 *vs.* CON 106 ± 45 mg·dL^{-1}; p = 0.002). Malondialdehyde was unaffected (EXP 4.2 ± 1.3 *vs.* CON 4.1 ± 0.7 μM; p > 0.05) but superoxidase dismutase activity, representative of antioxidant activity, was greater in the expedition group (EXP 3.1 ± 0.4 *vs.* CON 0.8 ± 0.5 U·ml^{-1}; p < 0.001). Finally, telomere length was unchanged (EXP 1.00± 0.48 *vs.* CON 0.89 ± 0.28 TS ratio; p > 0.05).
Conclusion
The present results suggest that there is a stronger cellular protective response from antioxidants to counteract the exercise-associated production of pro-oxidant free radical and reactive oxygen species during prolonged low-moderate physical loading. This shift in cellular oxidative balance, however, did not seem to be sufficient to induce a notable change in telomere length.

In Vivo Knockdown of Hepatocellular eNOS Reduces Cellular Anti-Oxidant Defense and Mitochondria Biogenesis/Function

Grace Meers, Rory Cunningham, Matthew Panasevich, R. Scott Rector, FACSM. *Harry S Truman Memorial VA Hospital and University of Missouri, Columbia, MO.*

(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the effects of long-term knockdown of endothelial nitric oxide synthase (eNOS) in hepatocytes in vivo to establish a potential regulatory role in liver mitochondrial health. METHODS: C57Bl6 mice (6 months of age) were tail vein injected with either an adeno-associated virus with a hepatocyte specific promoter for the shRNA induced silencing of eNOS (AAV8-Ttr-shRNA-eNOS; 1x10^11 GC; N=8) or a scramble control (AAV8-Ttr-shRNA-Scr, N=8). The mice were maintained on a low fat control diet and terminal studies performed 12 weeks post AAV-shRNA injection. RESULTS: Body mass and percent body fat did not differ between treatment groups. Hepatocellular knockdown of eNOS significantly (p<0.05) lowered hepatic gene expression of anti-oxidant defense, including glutathione peroxidase (GPX-1, ~30%), superoxide dismutase 2 (SOD2, ~30%), and NAD(P)H quinone dehydrogenase 1 (Nqo1, ~40%) compared to Scr control. These are all known targets of the anti-oxidant response element transcription factor, nuclear factor-E2-related factor-2 (Nrf2). In addition to apparent downregulation in anti-oxidant defense mechanisms, AAV-shRNA-eNOS also significantly reduced mitochondrial biogenesis marker peroxisome proliferator-activated receptor gamma coactivator 1α (PGC-1α mRNA) by ~30% (p<0.05) and LC3II protein content in isolated mitochondria (a marker of mitophagy) by ~40% (p=0.16) compared to Scr control. This was coupled with significant reductions in both basal and state 3 hepatic mitochondrial respiration with AAV-shRNA-eNOS compared with Scr control. CONCLUSION: These findings represent the first observations that long-term in vivo knockdown of eNOS specifically in hepatocytes with AAV-shRNA results in suppression of hepatic anti-oxidant defense, impaired hepatic mitochondrial biogenesis and mitophagy, and reduced hepatic mitochondrial function. Funding: This work was supported by VA-Merit Grant I01BX003271-01 (R.S.R.).

Acute Exercise by Insulin Resistant Rats Induces Muscle Fiber Type-selective Improvement in Insulin-stimulated Glucose Uptake

Mark W. Pataky, Carmen S. Yu, Yilin Nie, Edward Arias, Manak Singh, Robert Ploutz-Snyder, Christopher Mendias, Gregory Cartee, FACSM. *University of Michigan, Ann Arbor, MI.* (Sponsor: Gregory Cartee, FACSM)

(No relevant relationships reported)

PURPOSE: To determine if acute exercise induces muscle fiber type-selective changes in glucose uptake (GU), glycogen content or GLUT4 protein abundance in insulin resistant rats.
METHODS: Rats were fed a high-fat diet (HFD; 60% fat) or a low-fat diet (LFD; 13% fat) ad libitum for two weeks. On the experimental day, HFD rats were sedentary (SED) or exercised (2h swim exercise). All LFD rats remained SED, serving as controls. Exercised rats were studied immediately-post exercise (IPEX) or 3.5h post-exercise (3.5hPEX). Isolated epitrochlearis muscles were incubated with [^{3}H]-2-deoxyglucose (2DG). Muscles from IPEX and SED controls were incubated without insulin. Muscles from 3.5hPEX and SED controls were incubated ±100µU/ml insulin. Muscles were incubated with collagenase to isolate single fibers. Fiber type (myosin heavy chain expression: type I, IIA, IIB, IIX, IIAX, or IIBX) was determined by SDS-PAGE. In the same single fibers, GU was measured by [^{3}H]-2DG accumulation. Fiber type-specific glycogen was measured by histochemical periodic-acid Schiff staining. GLUT4 abundance was determined by immunoblotting. Data were analyzed by one-way ANOVA.
