Resistence Exercise for Health

Research shows resistance exercise (RE) may be as effective as aerobic exercise (AE) for improving many facets of health. However, while roughly 50% of people meet AE guidelines, less than one-third meet RE requirements.

RE improves:
• Mental health
• Cardiorespiratory health
• Vascular health
• Muscle oxidative capacity
• Strength and power

RE also lowers the risk of mortality independent of aerobic exercise, improves the prognosis of type 2 diabetes, reduces age-related muscle loss and increases the amount of physical activity older adults perform outside of their exercise routine. Starting with single-set exercises or lifting once per week (i.e., minimal dose programming) helps.

Take-homes:
• Bodyweight exercises can be effective
• Minimal-dose programming is a good way to start
• Keeping track of your progress is beneficial
